## 1. Vector-Valued Functions and Motion in Space

### Lecture 1: Vector Functions and Space Curves

#### Definition of a Vector Function

A vector function  $\mathbf{r}(t)$  is typically expressed in terms of its components:

$$\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$$

- $x(t), y(t), z(t)$ : Scalar functions of  $t$  (coordinate components).
- $\mathbf{i}, \mathbf{j}, \mathbf{k}$ : Unit vectors in the directions of the  $x$ -,  $y$ -, and  $z$ -axes, respectively.

For instance,  $\mathbf{r}(t) = t^2\mathbf{i} + \sin(t)\mathbf{j} + e^t\mathbf{k}$  represents a vector function in 3D space, where the component functions  $t^2$ ,  $\sin(t)$ , and  $e^t$  govern the motion along the respective axes.

#### Definition of Domain

If a vector function is defined as:  $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$

The domain of  $\mathbf{r}(t)$  is the intersection of the domains of its components,  $x(t)$ ,  $y(t)$ , and  $z(t)$ .

#### Example of Domain

Find the domain of the vector function:

$$\mathbf{r}(t) = \ln(t)\mathbf{i} + \sqrt{t}\mathbf{j} + \left(\frac{1}{t}\right)\mathbf{k}$$

Solution:

1. The term  $\ln(t)$  is defined only when  $t > 0$ .
2. The term  $\sqrt{t}$  is defined only when  $t \geq 0$ .
3. The term  $1/t$  is defined only when  $t \neq 0$ .

The domain of  $\mathbf{r}(t)$  is the intersection of these constraints:

$t > 0$  (as it satisfies all three conditions)

Thus, the domain of  $\mathbf{r}(t)$  is the interval  $(0, \infty)$ .

## Limits of Vector Functions

If a vector function is defined as:

$$\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$$

Then the limit as  $t$  approaches  $c$  is given by:

$$\lim_{t \rightarrow c} \mathbf{r}(t) = \lim_{t \rightarrow c} x(t)\mathbf{i} + \lim_{t \rightarrow c} y(t)\mathbf{j} + \lim_{t \rightarrow c} z(t)\mathbf{k}$$

The limit exists if and only if the limits of all its components,  $x(t)$ ,  $y(t)$ , and  $z(t)$ , exist and are finite.

## Examples of Limits

1. Evaluate  $\lim_{t \rightarrow 2} \mathbf{r}(t)$ , where  $\mathbf{r}(t) = t^2\mathbf{i} + \sin(t)\mathbf{j} + e^t\mathbf{k}$ :

$$\lim_{t \rightarrow 2} \mathbf{r}(t) = 4\mathbf{i} + \sin(2)\mathbf{j} + e^2\mathbf{k}$$

2. Determine  $\lim_{t \rightarrow \infty} \mathbf{r}(t)$ , where  $\mathbf{r}(t) = (1/t)\mathbf{i} + (1/t^2)\mathbf{j} + (1/e^t)\mathbf{k}$ :

$$\lim_{t \rightarrow \infty} \mathbf{r}(t) = 0\mathbf{i} + 0\mathbf{j} + 0\mathbf{k}$$

## Continuity of Vector Functions

A vector function  $\mathbf{r}(t)$  is continuous at a point  $t = c$  if:

1.  $\mathbf{r}(c)$  is defined.
2.  $\lim_{t \rightarrow c} \mathbf{r}(t)$  exists.
3.  $\lim_{t \rightarrow c} \mathbf{r}(t) = \mathbf{r}(c)$ .

**Example:**

$$\mathbf{r}(t) = \begin{cases} t^2\mathbf{i} + \sin(t)\mathbf{j} + e^t\mathbf{k} & t \leq 1 \\ 2t\mathbf{i} + t^2\mathbf{j} + \ln(t+1)\mathbf{k} & t > 1 \end{cases}$$

To check continuity at  $t = 1$ :

$$\text{Left-hand limit: } \lim_{t \rightarrow 1^-} \mathbf{r}(t) = 1^2\mathbf{i} + \sin(1)\mathbf{j} + e^1\mathbf{k}.$$

$$\text{Right-hand limit: } \lim_{t \rightarrow 1^+} \mathbf{r}(t) = 2(1)\mathbf{i} + 1^2\mathbf{j} + \ln(2)\mathbf{k}.$$

Since the left-hand and right-hand limits are not equal,  $\mathbf{r}(t)$  is not continuous at  $t = 1$ .

## Derivatives of Vector Functions

The derivative of a vector function  $\mathbf{r}(t)$  is defined as:

$$r'(t) = \lim_{h \rightarrow 0} \frac{r(t+h) - r(t)}{h}$$

This derivative describes the instantaneous rate of change of  $r(t)$  with respect to  $t$ . The derivative measures how the vector  $r(t)$  changes direction and magnitude as  $t$  varies.

In component form:

$$r'(t) = x'(t)i + y'(t)j + z'(t)k$$

The derivative of a vector function is also a vector function, describing how each component changes with respect to the parameter  $t$ .

### Example of Derivative

Find the derivative of the vector function:

$$r(t) = t^2 i + \sin(t) j + e^t k$$

Solution:

Differentiate each component with respect to  $t$ :

$$1. dx(t)/dt = 2t$$

$$2. dy(t)/dt = \cos(t)$$

$$3. dz(t)/dt = e^t$$

Thus, the derivative is:  $r'(t) = 2t i + \cos(t) j + e^t k$

H.W. (1)

### Exercises

1. Find the domain of  $r(t) = (t^2)i + \ln(t)j + (\frac{1}{t})k$ .
2. Determine the domain of  $r(t) = \sqrt{t+1}i + (\frac{1}{t-2})j + e^t k$ .
3. Verify the domain of  $r(t) = t^3 i + (\ln(t-3))j + \sqrt{(t-4)}k$ .

### Exercises

1. Evaluate  $\lim_{t \rightarrow 0} r(t)$ , where  $r(t) = \ln(t+1)i + t^2 j + \sqrt{t} k$ .
2. Determine if  $r(t) = (1/t)i + tj + e^t k$  is continuous at  $t = 1$ .
3. Sketch the curve described by  $r(t) = \cos(t)i + \sin(t)j + tk$ .
4. Verify if  $r(t) = t^3 i + t^2 j + tk$  is continuous for all values of  $t$ .

## Exercises

1. Find  $r'(t)$  for  $r(t) = t^3 \mathbf{i} + t^2 \mathbf{j} + t \mathbf{k}$ .
2. Determine  $r'(t)$  for  $r(t) = \ln(t)\mathbf{i} + \sqrt{t}\mathbf{j} + e^{(2t)}\mathbf{k}$ .
3. Compute  $r'(t)$  for  $r(t) = \sin(t)\mathbf{i} + \cos(t)\mathbf{j} + t^4\mathbf{k}$ .

## Definition of Velocity Vector, Speed and acceleration vector

If  $r(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$  is the position vector of the particle moving along a smooth curve in space, then

Then the velocity vector is the derivative of  $r(t)$ :  $v(t) = r'(t) = dx(t)/dt \mathbf{i} + dy(t)/dt \mathbf{j} + dz(t)/dt \mathbf{k}$

At any time  $t$ , the direction of  $\mathbf{v}$  is the **direction of motion**, the magnitude of  $\mathbf{v}$  is the particle's **speed**, and the derivative  $\mathbf{a} = dv/dt$ , when it exists, is the particle's acceleration vector. In summary:

1. Velocity is the derivative of position:  $\mathbf{v} = \frac{d\mathbf{r}}{dt}$ .
2. Speed is the magnitude of velocity:  $\text{Speed} = |\mathbf{v}|$ .
3. Acceleration is the derivative of velocity:  $\mathbf{a} = \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2}$ .
4. The unit vector  $\mathbf{v}/|\mathbf{v}|$  is the direction of motion at time  $t$ .

## Example 1: Straight-Line Motion

Given the position function:  $r(t) = 5t^2\mathbf{i}$  Find the velocity, speed, and acceleration

Solution:

1. **Velocity:**  $v(t) = dr(t)/dt = 10t \mathbf{i}$
2. **Speed:**  $||v(t)|| = |10t| = 10|t|$
3. **Acceleration:**  $a(t) = dv(t)/dt = 10 \mathbf{i}$
4. **The direction of motion at time  $t$ :**  $\frac{\mathbf{v}}{|\mathbf{v}|} = \frac{10t\mathbf{i}}{10|t|} = \pm \mathbf{i}$

## Example 2: Circular Motion in 2D

Let the position function be:  $r(t) = \cos(t) \mathbf{i} + \sin(t) \mathbf{j}$  Find the velocity, speed, and acceleration.

Solution:

1. **Velocity:**  $v(t) = dr(t)/dt = -\sin(t) \mathbf{i} + \cos(t) \mathbf{j}$
2. **Speed:**  $||v(t)|| = \sqrt{(-\sin(t))^2 + (\cos(t))^2} = \sqrt{1} = 1$
3. **Acceleration:**  $a(t) = dv(t)/dt = -\cos(t) \mathbf{i} - \sin(t) \mathbf{j}$

## Example 3: Motion in 3D

Given:  $r(t) = t^2 \mathbf{i} + e^t \mathbf{j} + \ln(t) \mathbf{k}$  Find the velocity, speed, and acceleration for  $t > 0$ .

Solution:

- 1. Velocity:**  $\mathbf{v}(t) = d\mathbf{r}(t)/dt = 2t \mathbf{i} + e^t \mathbf{j} + 1/t \mathbf{k}$
- 2. Speed:**  $||\mathbf{v}(t)|| = \sqrt{(2t)^2 + (e^t)^2 + (1/t)^2}$
- 3. Acceleration:**  $\mathbf{a}(t) = d\mathbf{v}(t)/dt = 2 \mathbf{i} + e^t \mathbf{j} - 1/t^2 \mathbf{k}$

#### Example 4: Helical Motion

Given the position:  $\mathbf{r}(t) = \cos(t) \mathbf{i} + \sin(t) \mathbf{j} + t \mathbf{k}$ , Find the velocity, speed, and acceleration.

Solution:

##### 1. Velocity:

$$\mathbf{v}(t) = d\mathbf{r}(t)/dt = -\sin(t) \mathbf{i} + \cos(t) \mathbf{j} + \mathbf{k}$$

$$\mathbf{2. Speed:} \quad ||\mathbf{v}(t)|| = \sqrt{(-\sin(t))^2 + (\cos(t))^2 + 1^2} = \sqrt{2}$$

$$\mathbf{3. Acceleration:} \quad \mathbf{a}(t) = d\mathbf{v}(t)/dt = -\cos(t) \mathbf{i} - \sin(t) \mathbf{j}$$

#### Differentiation Rules for Vector Functions

Let  $\mathbf{u}$  and  $\mathbf{v}$  be differentiable vector functions of  $t$ ,  $\mathbf{C}$  a constant vector,  $c$  any scalar, and  $f$  any differentiable scalar function

- 1. Constant Function Rule:**  $\frac{d}{dt} \mathbf{C} = \mathbf{0}$
- 2. Scalar Multiple Rules:**

$$\frac{d}{dt} [c\mathbf{u}(t)] = c\mathbf{u}'(t)$$

$$\frac{d}{dt} [f(t)\mathbf{u}(t)] = f'(t)\mathbf{u}(t) + f(t)\mathbf{u}'(t)$$
- 3. Sum Rule:**  $\frac{d}{dt} [\mathbf{u}(t) + \mathbf{v}(t)] = \mathbf{u}'(t) + \mathbf{v}'(t)$
- 4. Difference Rule:**  $\frac{d}{dt} [\mathbf{u}(t) - \mathbf{v}(t)] = \mathbf{u}'(t) - \mathbf{v}'(t)$
- 5. Dot Product Rule:**  $\frac{d}{dt} [\mathbf{u}(t) \cdot \mathbf{v}(t)] = \mathbf{u}'(t) \cdot \mathbf{v}(t) + \mathbf{u}(t) \cdot \mathbf{v}'(t)$
- 6. Cross Product Rule:**  $\frac{d}{dt} [\mathbf{u}(t) \times \mathbf{v}(t)] = \mathbf{u}'(t) \times \mathbf{v}(t) + \mathbf{u}(t) \times \mathbf{v}'(t)$
- 7. Chain Rule:**  $\frac{d}{dt} [\mathbf{u}(f(t))] = f'(t)\mathbf{u}'(f(t))$

#### Example 1: Vector Functions of Constant Length

$$\mathbf{r}(t) \cdot \mathbf{r}(t) = c^2$$

$$\frac{d}{dt} [\mathbf{r}(t) \cdot \mathbf{r}(t)] = 0$$

$$\mathbf{r}'(t) \cdot \mathbf{r}(t) + \mathbf{r}(t) \cdot \mathbf{r}'(t) = 0$$

$$2\mathbf{r}'(t) \cdot \mathbf{r}(t) = 0.$$

The vectors  $\mathbf{r}'(t)$  and  $\mathbf{r}(t)$  are orthogonal because their dot product is 0.

#### Example 2: Derivative of a Dot Product

Let  $\mathbf{u}(t) = (t, \sin(t), e^t)$  and  $\mathbf{v}(t) = (\cos(t), t^2, \ln(t+1))$ . We aim to compute the derivative of their dot product:

$$\frac{d}{dt} (\mathbf{u}(t) \cdot \mathbf{v}(t)) = (\cos(t) + \cos(t)t^2 + e^t \ln(t+1)) + (-t \sin(t) + 2t \sin(t) + \frac{e^t}{t+1})$$

### Example 3:

Prove that:  $\frac{d}{dt} \left( \mathbf{v} \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right) \right) = \mathbf{v} \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^3\mathbf{v}}{dt^3} \right)$

$$\frac{d}{dt} \left( \mathbf{v} \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right) \right) = \left( \frac{d\mathbf{v}}{dt} \right) \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right) + \mathbf{v} \cdot \frac{d}{dt} \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right)$$

The first term becomes:

$$\left( \frac{d\mathbf{v}}{dt} \right) \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right) = 0$$

This is because the cross product of any vector with itself is perpendicular to that vector, and the dot product of perpendicular vectors is zero.

$$\frac{d}{dt} \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right) = \left( \frac{d^2\mathbf{v}}{dt^2} \right) \times \left( \frac{d^2\mathbf{v}}{dt^2} \right) + \left( \frac{d\mathbf{v}}{dt} \right) \times \left( \frac{d^3\mathbf{v}}{dt^3} \right)$$

The first term is zero because the cross product of any vector with itself is zero:  $(d^2\mathbf{v}/dt^2) \times (d^2\mathbf{v}/dt^2) = 0$

$$\text{Thus, } \frac{d}{dt} \left( \mathbf{v} \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^2\mathbf{v}}{dt^2} \right) \right) = \mathbf{v} \cdot \left( \frac{d\mathbf{v}}{dt} \times \frac{d^3\mathbf{v}}{dt^3} \right)$$

### Integrals of Vector Functions

For a vector-valued function:  $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$

The integral is computed as:  $\int \mathbf{r}(t) dt = \left( \int x(t) dt \right) \mathbf{i} + \left( \int y(t) dt \right) \mathbf{j} + \left( \int z(t) dt \right) \mathbf{k} + \mathbf{C}$

Here,  $\mathbf{C}$  is the constant vector of integration.

### Example 1: Integration of a Vector Function

To integrate a vector function, we integrate each of its components. Consider the vector function:

$$\int ((\cos t)\mathbf{i} + \mathbf{j} - 2t\mathbf{k}) dt$$

We compute the integral component-wise:

$$\int \cos t dt \mathbf{i} + \int dt \mathbf{j} - \int 2t dt \mathbf{k}$$

Evaluating each component:

$$(\sin t + C_1) \mathbf{i} + (t + C_2) \mathbf{j} - (t^2 + C_3) \mathbf{k}$$

Combining the constants into a single constant vector  $\mathbf{C}$ :

$$\int ((\cos t)\mathbf{i} + \mathbf{j} - 2t\mathbf{k}) dt = (\sin t)\mathbf{i} + t\mathbf{j} - t^2\mathbf{k} + \mathbf{C}$$

### Example 2: Definite Integral of a Vector Function

We compute the definite integral of the same vector function over the interval  $[0, \pi]$ :

$$\int_0^\pi ((\cos t)\mathbf{i} + \mathbf{j} - 2t\mathbf{k}) dt$$

Component-wise integration yields:  $\int_0^\pi \cos t dt \mathbf{i} + \int_0^\pi 1 dt \mathbf{j} - \int_0^\pi 2t dt \mathbf{k}$

Evaluating the integrals:  $([\sin t]_0^\pi) \mathbf{i} + ([t]_0^\pi) \mathbf{j} - ([t^2]_0^\pi) \mathbf{k}$

Substituting the limits:  $(0 - 0) \mathbf{i} + (\pi - 0) \mathbf{j} - (\pi^2 - 0) \mathbf{k} = \pi \mathbf{j} - \pi^2 \mathbf{k}$

### Example 3: Finding the Position Function

Suppose a hang glider has an acceleration vector given by:  $\mathbf{a}(t) = -(3 \cos t)\mathbf{i} - (3 \sin t)\mathbf{j} + 2\mathbf{k}$

The initial velocity are:  $\mathbf{v}(0) = 3\mathbf{j}$  and  $\mathbf{r}(0) = 4\mathbf{i}$ . We aim to find the position function  $\mathbf{r}(t)$ .

Step 1: Find the velocity function by integrating acceleration:

$$\mathbf{v}(t) = \int \mathbf{a}(t) dt = -(3 \sin t)\mathbf{i} + (3 \cos t)\mathbf{j} + 2t\mathbf{k} + \mathbf{C}_1$$

Using the initial condition  $(\mathbf{v}(0) = 3\mathbf{j})$ :  $3\mathbf{j} = -(3 \sin 0)\mathbf{i} + (3 \cos 0)\mathbf{j} + 0\mathbf{k} + \mathbf{C}_1$

Solving for  $\mathbf{C}_1$ , we find  $\mathbf{C}_1 = 0$ .

Step 2: Find the position function by integrating velocity:

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt = (3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + t^2\mathbf{k} + \mathbf{C}_2$$

Using the initial condition  $\mathbf{r}(0) = 4\mathbf{i}$ :  $4\mathbf{i} = (3 \cos 0)\mathbf{i} + (3 \sin 0)\mathbf{j} + (0)\mathbf{k} + \mathbf{C}_2$

Solving for  $\mathbf{C}_2$ , we find  $\mathbf{C}_2 = \mathbf{i}$ .

The position function is:  $\mathbf{r}(t) = (1 + 3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + t^2\mathbf{k}$

### H.W.(2)

1. Let  $\mathbf{F}(t) = [t^2, e^t, \sin(t)]$ . Compute  $\mathbf{F}'(t)$ .

2. Let  $\mathbf{A}(t) = [t, t^2, e^t]$  and  $\mathbf{B}(t) = [\cos(2t), \sin^{-1}(t), t^3]$ . Compute  $\frac{d}{dt}(\mathbf{A}(t) \cdot \mathbf{B}(t))$

3. Let  $\mathbf{A}(t) = [t^2, e^t, t]$  and  $\mathbf{B}(t) = [\sin(t), \cos(t), t^3]$ . Compute  $\frac{d}{dt}(\mathbf{A}(t) \times \mathbf{B}(t))$ .

4. A particle's position is given by  $\mathbf{r}(t) = [t^2, \ln t, \sin(t)]$ . (a) Compute the velocity vector  $\mathbf{v}(t)$ . (b) Compute the speed (d) Compute the acceleration vector  $\mathbf{a}(t)$  and find its magnitude.

5. Compute  $\mathbf{v}(t)$ , speed, and  $\mathbf{a}(t)$  for  $\mathbf{r}(t) = \ln(t)\mathbf{i} + \sqrt{t}\mathbf{j} + e^{2t}\mathbf{k}$ .

## Projectile Motion

Projectile motion describes the motion of an object under the influence of gravity when launched with an initial velocity. It is analyzed in two dimensions: horizontal (x) and vertical (y).

### Equations of Motion

1. Initial Velocity ( $v_0$ ): The initial velocity is split into horizontal ( $v_{0x}$ ) and vertical ( $v_{0y}$ ) components:  $v_{0x} = v_0 \cos(\theta)$ ,  $v_{0y} = v_0 \sin(\theta)$  -----(1)

2. Forces Acting: The only force acting on the object is gravity, which causes a constant vertical acceleration ( $g$ ) downward. There are no horizontal forces (ignoring air resistance)

3. Horizontal motion (x):

- The horizontal acceleration is zero ( $a_x = 0$ ).
- The horizontal velocity is constant ( $v_x = v_{0x}$ ).
- The horizontal position is given by integrate  $v_x$ :  $x(t) = v_{0x} t$   

$$t = \frac{x}{v_{0x}} \text{ --- (2)}$$

4. Vertical motion (y):

- The vertical acceleration is  $a_y = -g$  (downward due to gravity).
- The vertical velocity changes over time:  $v_y(t) = v_{0y} - g t$ .
- The vertical position is given by:  $y(t) = v_{0y} t - \frac{1}{2} g t^2$ . -----(3)

5. Trajectory of the Projectile: The path of the projectile is parabolic and described by the equation:

From the equations (1), (2) and (3) we get  $y = x \tan(\theta) - \frac{1}{2} g \left( \frac{x}{v_{0x}} \right)^2 = x \tan(\theta) - \frac{g x^2}{2 v_{0x}^2}$

6. Height, Flight Time, and Range for Ideal Projectile Motion:

$$\text{Time of Flight: } T = \frac{2v_{0y}}{g} = \frac{2v_0 \sin \theta}{g}$$

Proof: since at maximum height  $v_y(t) = v_{0y} - g t = 0 \Rightarrow t = \frac{v_{0y}}{g} \Rightarrow$  the time is  $2t = \frac{2v_{0y}}{g}$

$$\text{Maximum Height: } H = \frac{v_{0y}^2}{2g} = \frac{(v_0 \sin(\theta))^2}{2g}$$

$$\text{Range: } R = \frac{v_0^2 \sin(2\theta)}{g}$$

### Example

A ball is launched with an initial velocity  $v_0 = 20$  m/s at an angle of  $\theta = 45^\circ$ . Find: 1) the time of flight, 2) the maximum height, and 3) the range.

### Solution

$$1. \text{ Time of Flight: } T = \frac{2v_{0y}}{g} = \frac{2v_0 \sin \theta}{g}$$

Substituting  $v_0 = 20$ ,  $\sin(45^\circ) = \sqrt{2} / 2$ , and  $g = 9.8$ :  $T = (2 (20 \cdot \sqrt{2} / 2)) / 9.8 = (20 \sqrt{2}) / 9.8 \approx 2.89$  seconds

$$\text{Maximum Height: } H = \frac{v_{0y}^2}{2g} = \frac{(v_0 \sin(\theta))^2}{2g}$$

Substituting  $v_0 = 20$ ,  $\sin(45^\circ) = \sqrt{2} / 2$ , and  $g = 9.8$ :  $H = ((20 \cdot \sqrt{2} / 2)^2) / (2 \cdot 9.8) = (100) / 19.6 \approx 5.1$  m

$$3. \text{ Range: } R = \frac{v_0^2 \sin(2\theta)}{g}$$

Using  $\sin(2\theta) = \sin(90^\circ) = 1$ :  $R = (20^2) / 9.8 = 400 / 9.8 \approx 40.8 \text{ m}$

### Example 2:

A projectile is launched with an initial velocity  $v_0 = [10, 20] \text{ m/s}$ . Gravity is  $g = 9.8 \text{ m/s}^2$ . Find the position  $r(t)$  after  $t$  seconds and at  $t=2$ .

Solution:

1. Horizontal motion (x-component):

$$x(t) = v_{0x} t = 10 t.$$

2. Vertical motion (y-component):

$$y(t) = v_{0y} t - (1/2) g t^2 = 20 t - 4.9 t^2.$$

3. Position vector:

$$r(t) = [x(t), y(t)] = [10t, 20t - 4.9t^2].$$

At  $t = 2 \text{ s}$ :

$$x(2) = 10(2) = 20, y(2) = 20(2) - 4.9(2)^2 = 20.4.$$

$$r(2) = [20, 20.4] \text{ m}.$$

### Exercises

1. A projectile is launched with an initial velocity  $v_0 = [15, 25] \text{ m/s}$ . Assuming  $g = 9.8 \text{ m/s}^2$ :

- Write the parametric equations for the horizontal and vertical positions  $x(t)$  and  $y(t)$ .
- Find the maximum height of the projectile.
- Find the time of flight (when the projectile hits the ground).

2. A projectile is launched from the origin with velocity  $v_0 = [10, 30] \text{ m/s}$ .

- Find the equation of the trajectory  $y(x)$ .
- What is the range of the projectile (horizontal distance traveled when it hits the ground)?

3. Find the time of flight and final position:

A ball is thrown from a height of 5 m with an initial velocity  $v_0 = [12, 20] \text{ m/s}$ :

- How long does it take for the ball to hit the ground?
- Where does it land?
