to be 648,000 and it is expected to be increased to 2.71 million corresponded to 15% of entire population of aged in 2050^[3].

Dementia is a serious geriatric disease that is developed chronically and deteriorated, the social activities, work life, interpersonal relationship, etc. are limited by the cognitive disorder, memory impairment, behavior disorder, change of character, etc, and the wandering behavior or psychotic symptoms, problem behavior are shown^[4].

Dementia causes the serious mental, physical and economic burden to the patient with dementia and the family, for which it is reported that 68% of the family caregivers of the patient with dementia feel the high level of care burden^[5] and such care burden is related to the physical symptoms, depression, health perception subjective well-being of the primary caregiver^[6]. In addition, in the results of performing the stepwise regression analysis to verify the factors having influence on the cumulative stress of family with demented elderly, for the variable having influence on the cumulative stress, the anxiety showed the statistically significant difference out of the mental health condition, and the inclination that the higher the anxiety, the more the cumulative stress is increased was shown^[7]. Moreover, the dementia care brings the change in the depression and the stress of the caregiver^[8].

For that, it is reported that 68% of the family caregivers feel high level of care burden^[5]. and such care burden is related to the physical symptoms, depression, health perception and subjective well-being of the primary caregiver^[9].

In addition, the results of performing the stepwise regression analysis to verify the factors having influence on the cumulative stress of family with demented elderly, for the variable having influence on the cumulative stress, the anxiety showed the statistically significant difference out of the mental health condition, and the inclination that the higher the anxiety, the more the cumulative stress is increased was shown^[10]. Paid caregiver family with demented elderly vacation system is being implemented from July, 2014 to support the rest (vacation) of family that cares the demented elderly at home. This system allows the family to leave the demented elderly under the short-term protection service of the long-term care institution, etc. for 6 days a year bearing 15% of the cost regardless of the monthly limit but the stress reduction

program for the family with demented elderly is not sufficient.

Therefore, this study intended to provide the basic data to develop the program for the health promotion and the health education of the family members who are caring the patient with dementia by identifying the influence on the stress of family member.

Method

The subjects of the study were the first analysis of 685,391 people over 45 years old by requesting raw data from the Community Health Survey from 2015, 2016 and 2017. The yearly trend analysis was conducted.

The statistical software R program was used for data analysis, and frequency analysis and chi-square analysis were conducted for the general characteristics, health lifestyle, chronic diseases, depression, and stress according to cohabitation family with dementia patients or not. Performed linear by linear coupling were used for the yearly trend analysis. Logistic regression analysis was performed to analysis the factors related to depression as a dependent variable of cohabitation family with dementia patients.

Result and Discussion

1. General characteristics and trend of cohabitation family with dementia patients by year (2015, 2016 and 2017): As a result of analyzing general characteristics according to whether they live with dementia patients, the rate of family living together was 1.1%, which was very low. In the age group, 34.9% were significantly higher in the family members over 75 years of age ($p < 0.001$).

The level of education was the highest in elementary school (25.8%) ($p < 0.001$). Marital status was significantly higher in the case of spouses (70.7%) ($p < 0.001$). In household income, 3 million won was significant from 1 million won to 3 million won ($p < 0.001$).

In house occupations, housewives and unemployed workers had the most time (47.1%), followed by agriculture, forestry and fisheries (14.4%), simple labor workers, sales service workers, professional administrative workers, office workers, and others ($p < 0.001$).

As a result of analyzing the yearly trends in 2015, 2016 and 2017, the yearly trends in the age group 75

years and older showed a significant increase of 32.2%, 35.3% and 37.0%. On the other hand, 45-64 and 65-74 years of age showed a significant decrease, indicating that no-no-care of the elderly is increasing ($p < 0.05$).

In occupational classification, housewives and unemployment decreased significantly to 48.4%, 47.7%,

and 45.2%, and the second largest occupational group in agriculture, forestry, and fishery was 15.9%, 14.0%, and 13.3%. There was a decreasing trend ($p < 0.001$).

On the other hand, the number of job category showing a yearly increase was professional administrative managers, which increased by 6.1%, 6.4% and 11.7% ($p < 0.001$) [Table 1].

p-value calculated by χ^2 -test and linear to linear coupling., The silent answer was missing.

2. Health behaviors and trend of cohabitation family with dementia patients by year (2015, 2016 and 2017): The person who smoked in the past but currently does not smoke was 55.8% showing significantly higher than the persons who smoke very much or smoke sometimes ($p < 0.001$). For the annual drinking trend of the household cohabiting with the dementia patient, the person who is drinking was 72.8% showing significantly high and the proportion of not drinking was high compared to the group not cohabiting with the dementia patient ($p < 0.001$).

For the severe physical activities, the person who does severe physical activities were 67.7% having significantly high ($p < 0.001$). According to the analysis of health behaviors based on cohabitation status with the dementia patients, the annual drinking and severe physical activities did not show the significant trend change. In the currently smoking, which showed the significant trend change, the person who smoked in the past but current does not smoke was 54.3%, 56.5% and 59.7% showing that the subject who stops smoking is being increased significantly ($p < 0.001$) and the subject who stops smoking shows the increasing trend by year ($p < 0.001$) [Table 2].

Table 2. Health behaviors and trend of cohabitation family with dementia patients by year (2015, 2016 and 2017) Unit: N(%)

Categories	Cohabitation family with dementia patients				Trend by year					
	Yes		No		2015		2016		2017

4. Results of logistic regression analysis taking depression as dependent variable: In the results of logistic regression analysis taking the depression as dependent variable, in case of the 75 years or older, the depression was significantly increased by 6.210 times compared to the age from 45 years to 64 years ($p < 0.05$). For the education level, the depression was increased significantly by 4.765 times in the

elementary school graduates, by 6.293 times in the high school graduates and by 7.848 times in the college graduates or higher compared to the uneducated ($p < 0.05$). The depression was increased significantly by 6.434 times in the agriculture, forestry and fisheries compared to the homemaker or unemployed ($p < 0.05$) [Table 4].

Conclusion

Currently, the diverse programs for the caregiver of demented elderly are implemented by the national responsibility system for dementia but the customized regional program to relieve the depression of the family cohabiting with the patient with dementia during the busy time of the farm village, mountain village and the fishing village besides the subjects of low income of 75 years old is not sufficient.

Therefore, the systematic free counselling program for the management of depression and stress in the male elderly of 75 years or older who have low income and cares the patients with dementia is needed desperately.

A Study on the Adjustment to the College Life: Focusing on Mediated Effect of Self-Differentiation

Weon-Hee Moon¹, Jeong-Yeon Kim²

¹Professor, Department of Nursing Science, Pai Chai University, South Korea, ²Professor,
Department of Medical Administration & Information, Health Institute of Technology, South Korea

Abstract

Background/Objectives: To find relationships among stress, self-differentiation, and adjustment to college life in the college students and verify the mediated effect of self-differentiation between stress and adjustment to the college life.

Method/Statistical Analysis: Data were collected from 1,192 attending college students and analysed using SPSS Statistics 22. T-test and ANOVA were used to confirm the level of stress by the adjustment level to the college life, differences of self-differentiation, adjustment level to the college life by the levels of stress and self-differentiation.

Findings: Even with the same level of stress, there were differences in the adjustment to the college life by degree of self-differentiation. The stress and self-differentiation of the college students were significant predictors for the adjustment to the college life by 15.8%, which showed higher level of the adjustment to the college life as the stress was lower and self-differentiation was higher, demonstrating partial mediated effect of self-differentiation between the stress and adjustment to the college life.

Improvements/Applications: Based on these study results, controlling stress by enhancing self-differentiation is considered to be helpful for the adjustment to the college life.

Keywords: *Adjustment, College life, Stress, Self-differentiation, College students, Mediation effect.*

Introduction

Most of the Korean college students experience the life historical process of entrance examination until they enter the colleges. This is the transitional period from the late adolescent to the adult, facing the developmental tasks to have to adapt the new environment of college such as relieving from dependency in the adolescent period and playing a role of adult. Most of the Korean students live

together with their families rather than separating and they are in the situations not to be free from the contexts of families on the multiple issues of adjustments that can occur in the college life such as career development, interpersonal relationship, personality, values, and so on^[1]. Therefore, well adjustment to the college environment primarily will be the major prerequisite to achieve a variety of developmental tasks which should be acquired by the college life. Multiple experiences in the family environment would work as the variables to adjust to the new environment. For the adjustment to the college life of the students, it is necessary to study the interactions and relationships with various variables in the family environment.

In Korea, Je^[2] developed the index of self-differentiation in Bowen's theory, demonstrating less interpersonal conflicts as the level of self-differentiation

e-mail: jykim@hit.ac.kr

was higher, and more interpersonal conflicts and less development of adjustment mechanism as the level of self-differentiation was lower in a study to investigate the relationship between self-differentiation and dysfunctional behaviors. Studies were published on the relationships among the level of self-differentiation, mental health and symptoms of maladjustment, and problematic behaviors in the subjects mainly with adolescents, college students and married men and women. You^[3] reported that dysfunctional behaviors were generated when family projection was significant, they experienced the emotional disconnection a lot, and family return was severe in a study on the adjustment to the college life and career preparation behaviors by the level of self-differentiation. Park and Jo^[4] showed in their study on the adjustment to the college life by the level of self-differentiation that well adjustment to the college life as the level of self-differentiation was higher, especially when their ego was integrated, family return was less, they belonged to the nuclear families with well differentiation. Park^[5] reported relatively higher explanatory power with 30% in the children's self-differentiation for their adjustment to the school lives, demonstrating the influential predictors with differentiation between cognitive and emotional functions, emotional disconnection, and family return.

In summary of the prior studies, the level of self-differentiation could be closely related to the adjustment to the college life. Family functions have been described variously with multiple concepts to explain and evaluate the family dynamics in view of family system.

Kerr and Bowen^[6] considered the concept to show the degree of individualization in the family system as self-differentiation. Self-differentiation means not only the individual thinking capability upon separating thinking from emotion but also the emotional maturation and degree of individualization from the family in which he or she was born^[7]. That means, self-differentiation is the course to establish the identity upon individualization from the mass of undifferentiated ego and to acquire freedom in the self-impulsive and emotional thinking and behaviors^[8]. Kang et al^[9] reported that the most essential concept in Bowen's family therapy theory was self-differentiation which was related to the control of emotion. Bowen^[7] suggested that self-differentiated people lived goal-oriented lives since they could respond the stress efficiently upon thinking independently to relieve from the emotional integration.

Considering adjustment as a series of processes that individuals control themselves and change the environment so as to lower the imbalance or discomfort factors between them and environment and to live their lives with balanced ones upon accepting a variety of desires in the society, the individuals can solve the conflicts by themselves being independence from their parents emotionally in any difficult situations if their egos are differentiated as healthy and matured personalities. Being independence itself means to transit into the actionable state as the independent individual. Balanced adjustment to the environment is possible only in case that emotional support from the families and individualization are performed together since the most active independence enables when it is performed based on the emotional stability.

Self-differentiation which will be discussed in this study implicates the directly opposed concept as well as those to facilitate complementarily, therefore, it is necessary to review the issues of development how they are related with the psychosocial adjustment in view of family system including the family relationship. In this respect, this study is to investigate whether the level of self-differentiation perceived by the college students mediates the stress and adjustment to the college life. The objective of this study is to provide with the fundamental data to prepare the alternatives for effective adjustment to the college life considering the level of self-differentiation in the college education and counseling.

Method

The survey was conducted with structured questionnaires in the subjects with 1,192 college students who understood its purposes and consented the participation in the study. A total of 1,104 survey sheets was used as the final analysis excluding the data with insincere responses and abnormal standardized residual values over ± 3 .

In the analyses of the Research, an index of college life adjustment modified by Kim^[10] with existing indexes^[11-13] was used including three sub-domains (adjustment to the study; adjustment to the society; and college environment and general adjustment) and its Cronbach α was .85. An index of college life stress developed by Chon and Kim^[14] was used including eight sub-domains (economic problems, relationships with the opposite sex, relationships with professors,

relationships with friends, career problems, values, and study). It contained 50 questionnaires of 3-point-scale meaning higher experience of college life stress as the score was higher, and the reliability on the sub-domains of stress was .82-.89 in this study. Self-differentiation index developed by Je^[2] based on Bowen’s family system theory was used to measure the level of self-differentiation, including 5 sub-domains (cognitive versus emotional function, ego-integration, family projection process, emotional disconnection, and family return). It contained 36 questionnaires of 4-point-scale meaning higher level of self-differentiation as the score was higher. Its Cronbach α on sub-domains of self-differentiation index was .56-.82 in this study (overall .87).

Data were analyzed using SPSS Statistics 22. T-test and ANOVA were used to confirm the level of stress by the adjustment level to the college life, differences of self-differentiation, and adjustment level to the college life by the levels of stress and self-differentiation. With respect to the mediated effect of self-differentiation in the relationships with the stress and adjustment, Sobel test was performed to find out the statistical significance on the mediated effect after performing regression analysis according to the analysis process of mediated effect suggested by Baron & Kenny^[15] (1st step, effects of independent variables to mediated variables; 2nd step,

effects of independent variables to dependent variables; and 3rd step, effects of independent variables with mediated variables to dependent variables).

Result

- 1. Adjustment to the college life by levels of stress and self-differentiation:** The group with lower level of the stress and higher level of self-differentiation showed higher level of adjustment to the college life and the group with higher level of the stress and lower level of self-differentiation did lower level of adjustment, demonstrating statistically significant differences [Table 1].

Table 1. Adjustment by level of stress and self-differentiation

Stress	Self-differentiation	n	Adjustment	F
Low	Low	179	3.14±0.40	62.47*
	High	372	3.40±0.45	
High	Low	377	2.99±0.38	
	High	176	3.15±0.40	

*: p<0.01

- 2. Mediated effect of self-differentiation:** [Table 2] shows the results whether self-differentiation was mediated to the relationship between the stress of college students and their adjustment level to the college life.

Table 2. Mediation effect of self-differentiation

Step	Predictors	Variable	B	SE	β	t	Adj.R ²	F
1	Stress	S-differentiation	-0.46	0.02	-0.49	-18.64*	0.24	347.51*
2	Stress	Adjustment	-0.30	0.03	-0.33	-11.41*	0.11	130.27*
3	Stress	Adjustment	-0.18	0.03	-6.15	-6.15*	0.16	104.55*
	S-differentiation		0.26	0.03	0.27	8.40*		

*: p<0.01

In the 1st step, the stress was shown as the statistically significant predictor for self-differentiation ($\beta = -.490$, $t = -18.642$, $p < .001$) and its explanatory power of regression model was 23.9%. In the 2nd step, the stress was shown to predict the adjustment significantly ($\beta = -.325$, $t = -11.413$, $p < .001$) and its explanatory power of regression model was 10.5%. In the 3rd step, the stress ($\beta = -.266$, $t = -6.1473$, $p < .001$) and self-differentiation ($\beta = .266$, $t = 8.403$, $p < .001$) were shown to predict the adjustment significantly in the regression model predicting both

simultaneously, and its explanatory power of regression model was 15.8%. That means, self-differentiation predicted the adjustment even in the controlled state on the adjustment with the influences of the stress, demonstrating the stress with negative prediction of adjustment apart from the mediated effect. Therefore, self-differentiation can be considered as the partial mediated variable between the stress and adjustment to the college life. Lastly, upon Sobel test results, the statistically significant mediated effects were found

with 7.648 [Figure 1]. In conclusion, self-differentiation can be considered with partial mediated effect in the relationship between the stress and adjustment.

* p < .001, Sobel test z=7.648, p=.000

Figure 1. Mediated effect of Self-differentiation in the relationship between Stress and Adjustment

Discussion

First, upon the results of the stress by the adjustment level of college life and the differences of self-differentiation, the group with lower level of adjustment to the college life showed higher levels in overall stress level and its sub-domains and lower levels in overall self-differentiation and its sub-domains. This is consistent with the previous reports that the level of adjustment to the college life was lower as the level of stress was higher^[4], and the level of self-differentiation was lower^[16]. Geun^[17] reported in his study on the relationship among self-differentiation, symptoms of maladjustment, and problematic behaviors in the adolescents that symptoms of maladjustment were occurred such as psychosomatic symptom, obsession, interpersonal sensitivity, depression, anxiety, hostility, paranoia, phobic anxiety, psychosis, and so on when the level of self-differentiation was low, and the level of self-differentiation could predict the maladjustment symptoms and problematic behaviors, which supports the results of this study.

Second, upon the results of the adjustment level of college life by the level of self-differentiation when the students experienced the same level of the stress, the level of the adjustment of college life was different by the level of self-differentiation even with the same level of the stress. It would be all right for the adjustment to the college life if the levels of stress and self-differentiation were low, however, in case of the high level of stress,

the level of the adjustment to the college life was enhanced by lowering the level of stress if the level of self-differentiation was high while the adjustment level was lowered without controlling the stress if the level of self-differentiation was low.

Third, the stress and self-differentiation of the college students were significant predictors with 15.8% of explanatory power on the adjustment to the college life. As the level of the stress was lower and the level of self-differentiation was higher, the level of the adjustment to the college life was higher, and self-differentiation showed the partial mediated effect in the relationship between the stress and the adjustment to the college life. As the level of self-differentiation was higher, the experiences of living stress were lower without considering the stress seriously^[18]. Self-differentiation may play a role to enhance the level of the adjustment to the college life by controlling stress in a way to maintain harmonious interpersonal relationship upon proper responses to the stressful situations by active reactions such as problem-centric ones or pursuing social support^[19], and upon expressing their feelings in the proper time and places with well socialized adjustment way.

Being the college students from the high school ones, they develop a variety of relationships and experience multiple problems such as competitions for job seeking, financial problems like tuition fee, pocket money and so on, and the stress from the anxiety on the future. From the results of this study, it is considered that enhancing self-differentiation is important since those with high level of self-differentiation perceive the stress low and cope with it properly to enhance the level of the adjustment to the college life. In the previous studies, the level of self-differentiation was determined by the results of family interactions^[20], the positive correlation was found in the communication between parents and children^[18] and the level of self-differentiation was higher as the communication was more open^[21].

Conclusion

From the results of this study, it is considered that enhancing self-differentiation is important since those with high level of self-differentiation perceive the stress low and cope with the stress properly to enhance the level of the adjustment to the college life. Hence, it is necessary to prepare multiple programs that can enhance the interaction between children and parents and acquire

the open communication skill. In addition, there were many studies on the effects of self-differentiation as the independent variable to the dependent variables, however, few studies on the effects of self-differentiation as the dependent variable, which requires further studies. This study had the meaning to find out the mediated effect of self-differentiation in the relationship between the stress and the adjustment to the college life although it has the limitation to generalize the results since the random sampling was performed among the college students in a region in Korea. Further studies are anticipated to be able to review the effective supports on the adjustment to the college life by understanding in multidimensional aspects upon development of structural equation model to verify the causality among major variables that can explain the adjustment to the college life.

Study on the Oral Health Attitude and Behaviour and the Changes in Dental Plaque According to the Use of Qraycam

Hyun-Kyung Kang

Associate Professor, Department of Dental Hygiene, Silla University, 46958, South Korea

Abstract

Background/Objectives: The study aimed to identify changes in dental plaque after intraoral application of a disclosing agent in two Qraycam groups and to investigate changes in oral health attitudes and behaviours.

Method/Statistical Analysis: The study population consisted of 80 people who participated in the study between May and August 2019. The equipment used was Qraycam and a plaque control records (O'Leary index); oral health attitudes and behaviours were investigated. Differences in participant characteristics according to Qraycam use were analysed by χ^2 test, while changes in the PCR(O'Leary index) by area for Qraycam use and non-use groups were analysed by pre-post paired-samples t-test. The influence on the oral health attitudes of the Qraycam use group was analysed by multiple linear regression analysis. All analyses were performed using IBM SPSS ver. 25.0 (IBM Co., Armonk, NY, USA) and the significance level for statistical testing was set to 0.05.

Findings: In the Qraycam use group, a decrease in the PCR in the left and right sides showed statistically significant differences ($p < 0.05$), while a change in the total PCR also showed a statistically significant difference ($p < 0.05$), with the right side showing a greater change in dental plaque. In the Qraycam non-use group, there were no statistically significant differences in the decrease in the left, right, and total PCR. In the Qraycam-use group, the biggest influencing factor on oral health attitudes was oral health behaviour ($p < 0.05$).

Improvements/Applications: PCR(O'Leary index) decreased significantly in the Qraycam use group, influencing oral health education, attitudes, and behaviours. The active use of Qraycam for community-based oral health activities and clinical dentistry would assist oral health promotion.

Keywords: O'Leary index, Oral health attitude, Oral health behaviour, Plaque control record(PCR), Qraycam.

Introduction

The most basic care method for maintaining healthy oral conditions and enjoying better quality of life is dental plaque management through proper tooth brushing^[1]. If dental plaque is not removed physically

or chemically, the types and amount of microorganisms can increase. Dental plaque is a non-calcified bacterial mass, which can typically be removed sufficiently by the physical force used when brushing teeth with a toothbrush^[2]. Since dental plaque has a yellow or milky white colour, similar to teeth, people sometimes have difficulty in distinguishing dental plaque from natural teeth with the naked eye. As dental plaque becomes worse, periodontal disease may occur. With periodontal disease, subjective symptoms caused by incipient lesions do not appear until the disease has progressed to a considerable extent and is left untreated in most cases since there is no discomfort. Therefore, such periodontal diseases can be viewed as a chronic disease since they

Corresponding Author:

Hyun-Kyung Kang

Associate Professor, Department of Dental Hygiene,
Silla University, 46958, South Korea
e-mail: kanghk75@gmail.com

are often treated in the advanced stage^[3]. Periodontal disease is preventable by dental plaque control, and up to now, the method of using a disclosing agent to test the effect of dental plaque control has helped increase the effectiveness of oral health education. It has been reported that oral health education method for motivating patients and the maximization of the visual effect by using a disclosing agent are effective in improving oral hygiene^[4]. To achieve behavioural changes in patients, it is necessary to induce motivation. In particular, for oral health education, continuous and long-term behavioural changes are very important. Proper oral health education and the use of oral care products can build reasonable oral care habits. Oral health education through a disclosing agent for dental plaque examination is very effective, but using a disclosing agent is time consuming in that the surface of each tooth must be coloured and the examination must be performed after rinsing the mouth. Moreover, it requires effort from both the patient and examiner and there is discomfort when cleaning the coloured tooth surface upon completion of the examination^[1].

To resolve such discomfort, new technology has been developed which would allow dental plaque to be detected without colouring. Recently, the latest diagnostic equipment using fluorescence have been introduced in dentistry, a prime example of which is quantitative light-induced fluorescence (QLF) used for detecting incipient caries lesions^[5-6]. QLF is an equipment that detects the red fluorescence emitted by a metabolite called porphyrin, which is secreted by intraoral bacteria^[7]. It has been reported that dental examinations using Qraycam can produce results similar to directly observing the teeth of study participants and it has the excellent ability of visual inspection in distinguishing between dental caries and restorations^[8]. The advantages of this equipment include the fact that it does not use a disclosing agent for dental plaque assessment and that older dental plaques show redder fluorescence^[7], which could be very helpful visually when educating patients. A study by Lee^[9] investigated and reported on the oral hygiene status of adolescents who smoke by addressing the disadvantage of observing dental plaque by using a disclosing agent to overcome the problem of different results being found according to the subjective perspective and skill level of the examiner.

The present study aimed to apply a disclosing agent inside the oral cavity to check whether any change in dental plaque is actually observed in both Qraycam use

and non-use groups. The study also aimed to investigate changes in oral health attitudes and oral health care behaviour. Oral care education and motivation through the use of a disclosing agent is an appropriate and excellent method, but Qraycam is very beneficial for motivating patients and can help the effectiveness of education in addition to being more convenient to patients. For dental hygienists, it helps examine the overall health status of patients and the quantification of the results, while also being helpful in providing such information to patients to promote behavioural changes.

Accordingly, the objective of the present study was to investigate the effectiveness of oral health education and changes in attitude and behaviour based on changes in PCR(O'Leary index) in groups that used or did not use Qraycam.

Method

The study population consisted of 80 people who visited the 00 university for clinical dental hygiene practical training between May and August 2019. The appropriate sample size needed for the χ^2 test, paired t-test, and multiple linear regression analysis was calculated via priori power analysis using the G*power 3.1 program. The present study was conducted with approval from the Institutional Review Board (IRB) of Silla University (1041449-201904-HR-002).

Qraycam is a dental diagnostic equipment developed by AIOBIO (Seoul, South Korea). The students who participated in the present study have experience from repeated training in treating patients, and thus were familiar with the items that appeared in the questionnaire. During practical training, a dental hygiene assessment was performed according to normal lessons and the items were surveyed using a preliminary questionnaire and records. Upon completion of all preliminary surveys, the investigation was conducted by dividing participants into those who received oral health education by Qraycam images and those who did not.

A plaque control record (O'Leary index) is used to assess the ability of patients to perform dental plaque control. It indicates the location or amount of dental plaque and measurement is possible with just the dental mirror and a probe. Generally, since it can accurately investigate the areas with dental plaque build-up, the areas where a toothbrush and dental floss should be used can easily be identified, while the surfaces of the teeth are coloured with a disclosing agent and each

tooth is divided into four surfaces for the assessment of any remaining dental plaque in the tooth margins^[10]. In the present study, the PCR(O’Leary index) of all participants were investigated to determine the changes in dental plaque.

The study used thirteen oral health attitude items that Lee^[11] applied to workers aged 18 to 65. Each item was graded on a five-Likert scale with 1 point for “not at all” and 5 points for “very much so”. The maximum possible score was 65 points, with higher scores indicating higher oral health attitudes.

This is the contents extracted from the chart records in clinical dental hygiene practice^[12]. Oral health care behaviour consisted of eight items regarding the frequency of tooth brushing, duration of tooth brushing, tooth brushing intensity, tooth brushing time, tooth brushing method, the use of fluoride toothpaste, interdental cleaning, and tongue cleaning. The maximum possible score was sixteen points, with higher scores indicating better oral health care behaviour.

To analyse the differences in the general characteristics of the participants according to the use of Qraycam, a χ^2 test was performed. Changes in PCR by area in the Qraycam use group were investigated by a pre-post paired-samples t-test. Changes in PCR by area in the Qraycam non-use group were also investigated by a pre-post paired-samples t-test. The influence on the oral health attitudes of the Qraycam use group was analysed by multiple linear regression analysis. All analyses were performed using IBM SPSS ver. 25.0

(IBM Co., Armonk, NY, USA) and the significance level for statistical testing was set to 0.05.

Result and Discussion

Typical oral diseases, such as dental caries and periodontal disease, are caused by bacterial dental plaque; thus, dental plaque control is the simplest and most efficient method for preventing oral disease. Therefore, sound dental plaque control practices can be very helpful in preventing oral disease. There is a variety of oral health education method for achieving dental plaque removal. The present study investigated whether using Qraycam can be helpful for dental plaque removal by dividing the participants into Qraycam use and non-use groups.

[Table 1] shows general characteristics of participants, the Qraycam usage rate in males and females was 59.4 percent and 47.9 percent, respectively; the Qraycam usage rate was relatively higher due to the participants being involved in practical training in school. When the participants brushed their teeth, they usually used their right hands. The Qraycam usage rate in the groups with and without negative experiences during previous treatments was 50.0 percent and 52.9 percent, with and without regular visits to the dental clinic was 50.0 percent and 53.4 percent, with and without scaling experience was 54.5 percent and 48.0 percent, and with and without oral health care education experience was 51.6 percent and 53.1 percent, respectively. The Qraycam use and non-groups according to general characteristics of participants showed no statistically significant differences.

Table 1. General characteristics of participants

		A	B	Total	χ^2	p
1	Men	19(59.4)	13(40.6)	32(100.0)	1.011	0.219
	Women	23(47.9)	25(52.1)	48(100.0)		
2	Right	41(53.2)	36(46.8)	77(100.0)	0.459	0.602
	Left	1(33.3)	2(66.7)	3(100.0)		
3	NO	36(52.9)	32(47.1)	68(100.0)	0.035	0.548
	Yes	6(50.0)	6(50.0)	12(100.0)		
4	NO	31(53.4)	27(46.6)	58(100.0)	0.076	0.489
	Yes	11(50.0)	11(50.0)	22(100.0)		
5	NO	12(48.0)	13(52.0)	25(100.0)	0.295	0.381
	Yes	30(54.5)	25(45.5)	55(100.0)		
6	NO	26(53.1)	23(46.9)	49(100.0)	0.016	0.541
	Yes	16(51.6)	15(48.4)	31(100.0)		

1:Gender, 2:Use of hands, 3:Negative experience during previous treatment, 4: Regular visits to the dental clinic, 5: Scaling experience, 6:Oral health care education experience, A: Use group of Qraycam, N(%), B: Non-use group of Qraycam, N(%), *p<0.05 by χ^2 test

[Table 2] shows the changes in plaque control record by area in the Qraycam use group. A decrease in the right PCR showed a statistically significant difference ($p = 0.002$) and a decrease in the left PCR also showed a statistically significant difference ($p = 0.002$). Changes in the total PCR also showed a statistically significant difference ($p = 0.001$), with the right side showing greater change in dental plaque (diff. 9.01). As shown in Table 2, dental plaque was removed better on the left side than on the right side. Most of the participants were right-handed and right-handed people typically have difficulty cleaning the right side of their mouths, as compared to the left side. This is because there may be difficulties with the appropriateness of the direction or approach of the toothbrush, as compared to the left side. Generally, when oral health education is conducted, instructions are given on how to clean the right teeth, left teeth, and anterior teeth. Since oral health education was conducted in many cases after showing images in the Qraycam use group, the decrease in dental plaque may have shown significant change.

Table 2: Changes in plaque control record by area in the Qraycam use group (N = 42)

PCR	Before	After	Mean diff	p
Right side	45.91	36.90	9.01	.002
Left side	42.65	34.81	7.84	.002
Total	46.28	37.73	8.55	.001

* $p < 0.05$ by paired t-test

[Table 3] shows the changes in plaque control record by area in the Qraycam non-use group. A decrease in right, left, and total PCR did not show statistically significant differences. However, as shown in Table 3, dental plaque was removed better on the left side than on the right side. The PCR of the right teeth appeared relatively higher in the Qraycam non-use group, while the PCR of the left teeth was very similar to that of the Qraycam use group. However, the difference between the before and after was not high.

Table 3: Changes in plaque control record by area in the Qraycam non-use group (N = 38)

PCR	Before	After	Mean diff	p
Right side	49.68	47.65	2.03	0.471
Left side	42.65	43.38	4.30	0.102
Total	46.90	42.17	4.72	0.138

* $p < 0.05$ by paired t-test

As shown in [Table 4], oral health attitudes in the Qraycam use group appeared significantly higher in the order of oral health behaviour ($\beta = 1.715$) and total plaque control record (before) ($\beta = 0.134$), while the explanatory power was approximately 33.2 percent with adjusted R square = 0.332.

Table 4: Influence on oral health attitude in the Qraycam use group (N = 42)

	β	Std. Error	t	p
(Constant)	22.092	9.668	2.285	0.028*
1	3.344	1.936	1.727	0.093
2	-0.063	0.102	-0.618	0.541
3	0.134	0.065	2.050	0.048*
4	-0.036	0.083	-0.433	0.668

1: Gender, 2: Age, 3: Total Plaque Control Record Before, 4: Total Plaque Control Record After, 5: Use of hands, 6: Oral Health Behaviour, Dependent Variable: Oral Health Attitude, R Square = 0.430, Adjusted R Square = 0.332, * $p < 0.05$ by Multiple linear regression analysis

The limitations of the present study include the following: First, the participants were selected by convenience sampling and the study used questionnaires and practical lesson records of clinical hygiene students. Therefore, there are difficulties in generalising the findings. Second, although the results were derived by a single-group pretest-posttest design using before and after comparisons during visits and re-visits by the participants, there were difficulties in testing the effect of Qraycam due to the absence of a control group, despite efforts to control the exogenous variables. If future studies can identify the interventional effect of Qraycam through a study design using experimental and control groups, then such differences could be presented more clearly. Studies to date have often focused on the validity and reliability of dental plaque and dental examinations using Qraycam. However, the present study is valuable in that it demonstrated the interventional effect of oral health education through Qraycam.

Conclusion

The objective of the present study was to identify the influence on the oral health education effect, attitudes, and behaviours through changes in PCR of the Qraycam use and non-use group. The study was conducted on 80 people who visited the 00 university for clinical dental hygiene practical training between May and August

2019. The participants understood the objectives and method of the study, had no systemic problems and were otherwise healthy, and consented to participate in the study. The findings were as follows:

1. In the Qraycam use group, a decrease in the left and right PCR showed statistically significant differences ($p < 0.05$). The total PCR also showed statistically significant differences ($p < 0.05$), with the right side showing greater changes in dental plaque.
2. In the Qraycam non-use group, a decrease in the left, right, and total PCR showed no statistically significant differences.
3. In the Qraycam use group, the biggest influencing factor on oral health attitude was oral health behaviour ($p < 0.05$).

Through the present study, PCR decreased significantly in the Qraycam use group and appeared to influence the effect of oral health education, attitude, and behaviour. Accordingly, it is believed that the active use of Qraycam of community-based oral health activities and clinical dental hygiene would be helpful for oral health promotion.

Differences of Passive Ankle Stiffness in Post-Stroke Hemiplegia by Varying Angular Velocity between the Paretic and Non-Paretic Side

Dae-Yeon Lee¹, Wan-Young Yoon²

¹Professor, Kangnam University, Faculty of Liberal Arts, South Korea,

²Professor, Seowon University, Clinical Exercise Physiology, South Korea

Abstract

Background/Objectives: The purpose of this study was to investigate the effect of passive stiffness on joint function by analyzing the in the passive stiffness of the PS and NPS ankle joint at various angular velocity.

Method/Statistical Analysis: The differences of the stiffness of ankle according to different angular velocity in both sides were compared and analyzed in 11 hemiplegic patients. Analyses on the difference of stiffness of ankle joint at each angular velocity between the P and NP side were performed using a paired t-test. The ANOVA with repeated measure was performed to analyze the differences of the stiffness. Statistical significance was defined as $P < .05$.

Findings: In the comparison on the passive stiffness of ankle joint, the paretic side was turned out to be higher in the passive stiffness than the non-paretic side at all angular velocity (20, 40, 60 deg/sec, $P < .05$). In addition, the analysis on the differences of the stiffness according to the changes in angular velocity showed that the stiffness was found to be the largest at 60 deg/sec and the smallest at 20 deg/sec in both paretic and non-paretic side indicating that the stiffness increases in the higher velocity ($P < .05$). These results indicate that the range of movement of paralyzed muscles caused by stroke is limited due to the increased passive ankle stiffness and that the velocity of movement is related to the joint function.

Improvements/Applications: This study can be exploited as a basis to evaluate the passive ankle stiffness of paretic muscles of stroke patients affecting joint function and as a data for rehabilitation program.

Keywords: Stroke, Hemiplegia, Muscle, Passive Stiffness, Angular Velocity, Rehabilitation.

Introduction

Spasticity shows velocity-dependent characteristics in addition to abnormal increase of muscle tension. Since spasticity causes some serious problems, such as footdrop in plantarflexion of the ankle joint, which hinders basic functional behavior such as walking, it is an important part of rehabilitation [1]. The spasticity and hypertonia of muscles due to stroke are known to be

induced by a wide variety of causes, the major causative factors, nevertheless, are yet to be clearly understood. Changes in muscle tension are caused by changes in the reflex and non-reflex factors, leading to an increase in the passive stiffness of joint and muscles [2]. Changes in muscle fascicle length, thickness, and pennation angle, in addition to the neurological factors, are known to cause the changes in passive ankle stiffness [3]. The passive stiffness is also induced by an increase in plantarflexion moment with changes in muscle viscoelasticity properties. As such, movement disorder such as paralysis after brain injury occur with changes in muscle architecture and in the passive characteristics of muscles as well, hence leading to serious influence on daily life in a negative manner. Previous studies have

Professor, Seowon University, Clinical Exercise Physiology, South Korea

e-mail: wanyoung72@gmail.com

shown that the passive spasticity of the paretic muscle is 43% higher than that of the non-paretic muscle^[4]. Hence, understanding the stiffness that increases in the ankle joint after stroke and analyzing the changes in stiffness in respect to the velocity of motion can be an important part of the evaluation of function. In particular, since the ankle joint is an important joint that is directly related to natural ability of human, walking, it is a clinically crucial joint for returning to daily living activity after stroke and it is a body segment that is deeply affected by paralysis and spasticity compared to other joints^[5]. In addition, the typical walking pattern of stroke patients is caused by plantarflexion of the ankle joint, and the recovery is slower than other joints^[6]. It has been studied by many researchers since it is important to understand the factors listed above for functional recovery of the ankle joint^[7].

Joints move the skeleton by generating torque, a muscle-generated force of rotating characteristics. Force is used as a moment in biomechanical analysis, the moment, which changes as the angle changes while the joint is moving, can be described as a function of stiffness, i.e., the stiffness is the moment divided by the angle (Nm/deg)^[8]. The spasticity of ankle joint and an increase of muscle tension is a major causative factor and have been intensively studied thus far. It has been suggested that the degree of non-reflective factors may influence more than reflective factors and some studies have suggested that the degree of spasticity can lead to a change in the passive characteristics of the ankle joint, limiting the amount of torque generated internally^[9]. The spasticity of paralyzed muscle is closely related to the velocity of joint motion since the spasticity

shows a velocity-dependent feature due to excessive exaggeration of stretch reflexes. Hence, it is essential to understand the velocity of joint angle and the change pattern of spasticity since the velocity of joint motion in functional movement such as walking affects the rigid muscles^[10,11].

In this study, the passive stiffness of the ankle joint after stroke was analyzed by measuring the difference of the joint angle and the angular velocity of the paretic and non-paretic side using the torque-angle relationship curve and slopes which indicate the relation between the torque generated from the ankle joint and the angle at a specific point in time. In addition, we aimed to analyze the velocity of motion and the trend of passive stiffness increase by means of measuring the motion of different velocities in different conditions to analyze the characteristics of the velocity-dependent rigid muscles.

Method

- 1. Participants:** The participants voluntarily agreed to participate and signed on the consent form for the experiment after hearing the explanation of the contents and purpose of the study, the experimental procedure, human rights protection of the subject, and the safety of the study. The participants were selected for patients who were able to walk independently at a chronic stage 6 months after onset and had ankle stiffness graded as less than 2 on Modified Ashworth Scale (MAS). The physical characteristics and medical history of the subjects are shown in Table 1.

Table 1. Medical history and physical characteristics of each subject.

2. **Experimental Procedures:** Torque was measured by dynamometer (cybex, lumex, USA) to calculate the passive stiffness of the ankle joint according to the velocity of movement. For the measurement, participants sat comfortably in the dynamometer chair, straightened the knees, set the ankle joint to anatomical 0 degree, and secured it with a strap to the footrest. The range of ankle joint motion was measured within the range from 10 degrees of dorsiflexion to 30 degrees of plantarflexion. The motion was repeatedly performed for 10 times for each velocity and the data were collected for 6 intermediate excluding the beginning and ending two times. A 5 minute break was set between the measurements to rule out the interference effect between the velocities and the velocity condition was scheduled in a random basis.
3. **Data Analysis:** The raw data were collected on a personal computer using Lab View 8.0 (National Instrument, USA). The dynamometer received the synchronization signal of torque and angle and converted each analog signal into digital one and stored them in a personal computer. The voltage value gained from the dynamometer was recalibrated, converted to actual Nm value and subjected for analysis. The remaining signals were derived from real data using Chart 5 for Window (AD Instrument, USA) program. Passive stiffness was analyzed by determining slopes ranging from 10 degrees of plantarflexion to 10 degrees of dorsiflexion of the torque-angle curve during the operation at each velocity [8].

Result and Discussion

As shown in Table 2, the passive stiffness of the ankle joint, which was determined by measuring the slope between 10 degrees of plantarflexion and 10 degrees of dorsiflexion, was measured at an angular velocity of 20 deg/sec as 2.61±1.25 of non-paretic side and 4.46±2.11 paretic side, indicating that the stiffness of paretic side was larger than that of non-paretic side with statistical significance. The passive stiffness at angular velocity of 40 deg/sec was measured as 3.40±1.57 in non-paretic side and 6.93±2.63 in paretic side indicating consistent patterns as in the 20 deg/sec as paretic side showed higher value with statistical significance. In case of 60 deg/sec, it was measured as 3.94±1.88 in non-paretic side and 8.69±3.85 in paretic side also resulting in the consistent pattern as the paretic side showed higher value with statistical significance. The

passive stiffness of paretic side turned out to be higher in all angular velocity tested and all the differences were statistically significant ($P < .05$). The degree of stiffness increase according to the velocity tended to increase as the angular velocity increases.

Table 2. Passive ankle stiffness of post stroke hemiplegia in different angular velocity

Side \ Velocity	Nom-Paretic side	Paretic side
20 deg/sec	2.61±1.25	4.46±2.11*
40 deg/sec	3.40±1.57	6.93±2.63*
60 deg/sec	3.91±1.88	8.69±3.85*

The result above was consistent with the results of previous studies that the stiffness increased during passive movement of the joints [10-12]. This means that neurological changes after cerebral infraction and changes in the material and biomechanical properties of the muscles and tendons cause negative consequences on joint movement, and velocity-dependent properties greatly influence on adaptation to external environmental changes and on controlling the proper velocity of joint movement. Biomechanical changes in the ankle joint correlate with decreased joint range and increased ankle resistance and stiffness together with spasticity after stroke [15].

Figure 1 shows the difference in ankle joint stiffness between the paretic side and non-paretic side at ankle joint angular velocity of 60 deg/sec. As shown in the figure, the torque increases as the ankle joint flexes to the dorsal side and as the slope increases. The slope is higher in paretic side than in non-paretic side, so the hardness is higher indicating the stiffness is higher in paretic side.

Figure 1. Torque-angle relationship slope of paretic and non-paretic side in 60 deg/sec ankle movement. NP: non-paretic, P: paretic

The torque-angle curve in the whole range of joint motion given in Figure 2 shows the overall pattern. The paretic side increases slowly in the plantarflexion compared to the non-paretic side, and the torque increases rapidly toward the dorsiflexion. This means the intrinsic muscle ability to stretch is deteriorated as resistance due to spasticity and contracture largely increased when the plantarflexion muscle becomes longer. These results mean that the resisting torque of the ankle joint generated during dorsiflexion is relatively greater than the resisting torque during plantarflexion, thus, the heel strike of the stance phase and the toe off, which is the beginning of the swing phase, are prevented during walk [16]. The stiffness increase with the elevating velocity of the joint movements indicates that the resistance of rigid muscle increases according to the joint movement [17]. Although the increase in exaggeration of stretch reflex, which is intrinsic characteristics of spasticity, cannot be directly observed with the velocity suggested in this study, the increasing passive stiffness will also affect active movement and muscle traits and will interfere with various movements given that voluntary movements are not smooth due to the nature of stroke [18].

Figure 2. The torque-angle curve in the full range of ankle joint

Changes in the material properties of muscles are secondary to nerve damage. The stiffness of the paralyzed muscles is associated with changes in the reflex mechanisms and passive mechanical properties of the muscles at rest, resulting in contractures and reduced joint range. Many current clinical tests cannot clearly distinguish the contributions between the two, but the abnormal increase in torque occurs equally. Furthermore, as stiffness increases, the range of motion decreases and the motor function of the limbs decreases [6].

Passive stiffness may be related with increased amount of collagen in muscle, however the evident

for long term accumulation in connective tissue has not been elucidated [19]. After stroke, the paralyzed muscles are immobilized for a long while, thus reducing the longitudinal load on the muscles. This reduction is reportedly known to cause muscle atrophy, shorten sarcomere and accumulate fat in connective tissue. A long-term study with immobilization of rats has revealed an increase in collagen fibers in the endo/epimysium of connective tissue, and a change in the ratio of muscle fibers and collagen related to gene expression has been observed [20]. When the muscle loses its intrinsic stretch ability in the process of the force generated by the muscles acting on the skeleton via the muscle, the magnitude of the force is proportional to the size of the cross sectional area that is the thickness of the muscle, and is determined by various factors such as the pennation angle and muscle fiber length. Debilitation of muscles results in a decrease in thickness and the pennation angle and this phenomenon frequently occurs in paralyzed muscles after stroke. Eventually, all changes in biomechanical properties from muscle fibers to joint levels can cause functional impairment; it is hence thought to be important to analyze the complex correlations among the variables and the contribution of each factor to the malfunction in the studies of paralyzed muscles due to stroke.

Conclusion

As a result, the paretic side showed resistance in joint toward movement than the non-paretic side. The difference in stiffness appeared to be generally larger in higher velocity of movement than in lower velocity. Spasticity, a representative symptom of paralyzed muscles, directly affects joint movement, and the resistance is increased by shortened muscles due to changes in its material properties, thus increasing joint stiffness. In addition, the changes of the degree of change in stiffness dependent according to the velocity of movement means that it is difficult to adapt to various changes between the inside the body and external environment. Hence, it will be important to resolve these problems through various interventional method.

Factors Affecting Subjective Health Status in Adult Male Workers with Metabolic Syndrome Using Seventh Korean National Health and Nutrition Examination Survey (KNHANES, 2016-2018)

Lee Kyongeun

Assistant Professor, Department of Nursing, Tongmyong University, Republic of Korea

Abstract

Background/Objectives: Metabolic syndrome has been increasing for the last 10 years in South Korea, and the rate of increase in the prevalence rate of male workers is especially fast. Metabolic syndrome is a disease for which continuous care is important. Motivation for health behavior that induces health promoting behavior is affected by subjective health status. Accordingly, subjective health status of adult male workers with metabolic syndrome in South Korea and factors influencing subjective health status will be examined in this study.

Method/Statistical Analysis: This study performed secondary data analysis using the Seventh Korean National Health and Nutrition Examination Survey. The number of participants of the Seventh Korean National Health and Nutrition Examination Survey was 29,321. There were 469 adult male workers with metabolic syndrome. Subjective health status was measured using a 5-point scale for subjective judgment of one's health status. In this study, subjective health status of the subjects according to general characteristics, health-related characteristics and health-related behavioral characteristics were verified by t-test and ANOVA. Multiple regression was used to analyse the factors causing significant differences in subjective health status.

Findings: The results showed body discomfort, perceived stress, comorbidity, muscle strengthening and walking exercise, restriction of activity were significantly associated with subjective health status.

Improvements/Applications: The results of this study show that the developed interventions are needed to improve health of adult male workers with metabolic syndrome in Korea.

Keywords: *Metabolic syndrome, adulthood, subjective health status, national survey, secondary analysis*

Introduction

Metabolic syndrome is defined as a comprehensive disease that is clinically classified as to have three or more symptoms among abdominal obesity, blood

pressure, diabetes, HDL cholesterol and neutral fat^[1]. In South Korea, the prevalence rate of metabolic syndrome is very high that 32.1% of adults in their 30s and older have metabolic syndrome. In adults aged up to 50s, metabolic syndrome is 2~3 times more often in men than women^[2]. The risk and incidence rate of metabolic syndrome in Korean male workers are high because stress from work intensity, overtime work and get-togethers and lack of exercise lead to an increase of neutral fat and fasting blood sugar, decrease of HDL cholesterol, and increase of blood pressure and waist size. This is shown in the results of a previous study, which reports that sex,

Corresponding Author:

Lee Kyongeun

Assistant Professor, Department of Nursing,
Tongmyong University, Republic of Korea
e-mail: leekyongeun@gmail.com

age and occupational class are associated with metabolic syndrome^[3].

These previous study proposed to intervene the factors influencing metabolic syndrome^[4]. In other words, since the prevalence rate of metabolic syndrome is high in adult men in South Korea, it is regarded as important to verify the factors related to metabolic syndrome and providing interventions to lower the risk of metabolic syndrome. Various previous studies made the effects to verify and intervene the factors related to metabolic syndrome^[5-6].

In terms of nursing, it is important not only to examine the risk factors of metabolic syndrome but also to examine perceived subjective health status related to metabolic syndrome. By paying attention to subjective health status that affects health behavior of metabolic syndrome patients and verifying the factors influencing subjective health status, method of improving subjective health status can be prepared. Subjective health status is self-perceived health status, and accurate perception of health status is known to have significant impact on health promoting activities^[7-8]. Improved perception of subjective health status can lead to an increase of health promoting activities, which would then create a virtuous circle of managing metabolic syndrome as patients can positively perceive their own health status.

Previous studies on metabolic syndrome patients of diverse ages propose various method of improving health promoting activities to take care of metabolic syndrome. Body weight, drinking, smoking, sleep, rest, stress, health examination and exercise were presented as the factors influencing metabolic syndrome, and efforts were made to intervene these factors^[9]. Such efforts can directly affect health-related behavior of metabolic syndrome, but they cannot examine changes in subjective health status perceived by the patient group. Since subjective health status determines subjective status of one's health, positive perception can be turned into a more comfortable and long-term habit of metabolic syndrome management. However, domestic studies on subjective health status of metabolic syndrome patients only compared subjective health status between normal group and metabolic syndrome group. None of them investigated the factors influencing health promoting activities.

This study was carried out only on adult male workers aged 20 years or above who are exposed to a

high risk of metabolic syndrome to analyze subjective health status and propose a health-related intervention that can improve subjective health status.

Method

- 1. Study Design:** This study involves secondary data analysis. Data used in this study were constructed based on the Seventh Korean National Health and Nutrition Examination Survey, and weighted values were considered to increase representativeness and accuracy of data. Accordingly, this study was designed to calculate the analytical results by considering complex sampling factors according to the data structure and analysis method presented in the Korean National Health and Nutrition Examination Survey Analysis Guideline.
- 2. Sample:** The Seventh Korean National Health and Nutrition Examination Survey was not a complete enumeration survey but a sample survey conducted on 29,321 respondents. Based on the criteria for Adults Treatment Panel □ of the National Cholesterol Education Program, along with the criteria for men suggested by Korean Society for the Study of Obesity in the case of waist size, 469 final subjects of this study were selected by classifying adult workers who satisfy three or more of the following criteria^[10] [Table 1].

Table 1. Clinical identification of the metabolic syndrome in men – Any 3 of the following

Risk Factor	Defining Level
Abdominal obesity	Waist circumference >90cm
Triglycerides	≥150mg/dL
HDL cholesterol	<40mg/dL
Blood pressure	sbp≥130mmHg/dbp≥85mmHg
Fasting glucose	≥110mg/dL

- 3. Ethical Considerations:** This study obtained prior approval of the Institutional Review Board at T University (201905-HR-004). Data used in this study were provided by Korea Centers for Disease Control and Prevention after removing personal identification information in accordance with the Personal Information Protection Act.
- 4. Measures:**
 - 1. General characteristics and health-related characteristics:** Items of the Korean National Health and Nutrition Examination Survey such

as education, occupation status, living state, home ownership, income, unmet healthcare needs, weight change, perceived body shape, body discomfort, restriction of activity, comorbidity, perceived stress and depressive mood were analyzed as general characteristics and health-related characteristics. Health-related characteristics included unmet healthcare needs, weight change, perceived body shape, body discomfort, restriction of activity, comorbidity, perceived stress and depressive mood as items that can influence metabolic syndrome.

2. Health-related behavioral characteristics: Current smoking status, current alcohol drinking status, frequency of binge drinking, participatory rate of aerobic exercise, muscle strengthening exercise, walking exercise were analyzed as health-related behavioral characteristics. Drinking, smoking and exercise are known as primary risk factors of metabolic syndrome, and they were included as health-related behavioral characteristics.

5. Data Analysis: The study results were derived using SPSS 23.0 and STATA 13.0 programs. Subjective health status of adult male workers with metabolic syndrome according to general characteristics, health-related characteristics and health-related behavioral characteristics were analyzed using t-test, ANOVA and multiple regression.

Result

In the Korean National Health and Nutrition Examination Survey, subjective health status was measured on a 5-point Likert scale ranging from ‘1 point: Extremely poor’ to ‘5 points: Extremely good.’ Responses with a score closer to 5 points were continuous variables meaning ‘poor’ subjective health status.

The differences in subjective health status of adult male workers with metabolic syndrome in South Korea according to general characteristics and health-related characteristics are as presented in [Table 2]. There were statistically significant differences in subjective health status according to income, unmet healthcare needs, weight change, body discomfort, restriction of activity, comorbidity, perceived stress and depressive mood.

The factors influencing subjective health status of adult male workers with metabolic syndrome in South Korea are as shown in [Table 4]. The regression model for subjective health status of the subjects was significant ($F = 6.960, p < .001$), and explanatory power

of the overall model was 12.3% (adjusted $R^2 = .123$). The factors influencing subjective health status were found to be recent body discomfort, perceived stress, comorbidity, restriction of activity, walking exercise and muscle strengthening exercise.

Discussion

This study is secondary data analysis using data from the Seventh Korean National Health and Nutrition Examination Survey, carried out to examine the factors influencing subjective health status of adult male workers aged 20 years or above among metabolic syndrome patients through multiple regression analysis.

In this study, perceived subjective health status was examined as an indicator that reflects actual health status by checking subjective health status of adult male workers with metabolic syndrome in South Korea. Since subjective health status is a universal tool to self-evaluate one's health status, it is included in the Korean National Health and Nutrition Examination Survey. Therefore, examining the factors influencing subjective health status measured using this tool can be presented as the grounds for policy suggestions to improve health status of the subjects.

Mean age of the adult male workers with metabolic syndrome was 48.06 years. As they need to work for more than 10 years based on the retirement age of 60

years in South Korea, male workers with metabolic syndrome can be regarded as the primary targets of health care. The results related to medical services that were not suggested in previous studies on metabolic syndrome were found in this study. It was found that the subjects who cannot receive medical services when they want have poor subjective health status. In addition, low income of workers was associated with poor subjective health status, which agrees with previous study^[11]. Also, reduction of body weight was found to have an adverse effect on subjective health status in this study. Weight loss had an adverse effect in this study because the subjects of this study are men. As for health-related characteristics, body discomfort during the past 2 weeks and restriction of activity were related to poor subjective health status. Perception of subjective health status was found to have direct impact on the judgment of one's actual health status^[8].

The subjects of this study who have one or more comorbidities such as hypertension, diabetes mellitus and dyslipidemia showed poor subjective health status. This is probably because patients who have to manage

more than one disease have low subjective perception of health status. The subjects with high perceived stress showed poor subjective health status compared to low perceived stress. Poor subjective health status was also shown with depressive mood that continued for more than 2 weeks. Since subjective health status is health status perceived by oneself, both physical and mental health status seem to affect the results. In terms of health care, it would be necessary to pay attention to the intervention of negative mental health status of adult male workers with metabolic syndrome^[12].

For health-related behavioral characteristics, subjective health status of adult male workers with metabolic syndrome was not affected by drinking. The subjects who smoke on a daily basis showed poor subjective health status compared to other subjects. Continuous smoking can be habitual or caused by mental stress. Therefore, patients with metabolic syndrome are recommended to manage health by planning interventions based on the reason for smoking. For exercise, subjective health status was improved with increasing consistency of muscle exercise and walking exercise. This was similar to the results of a previous study reporting that physical activities can become interventions to reduce the risk of metabolic syndrome^[4]. It is suggested to create exercise interventions for Korean male workers with metabolic syndrome.

Looking at previous overseas studies on subjective health status, comparison was difficult due to the lack of research papers about metabolic syndrome patients. The results of this study derived from the analysis of national data were helpful in examining subjective health status of Korean adult male workers with metabolic syndrome, verifying their general characteristics, health-related characteristics and health-related behavioral characteristics, and proposing directions for health care.

Conclusion

In this study, physical factors such as exercise performed to improve health, body discomfort and restriction of activity were found to be the factors influencing subjective health status. Accordingly, various interventions need to be developed and applied to enhance health and improve subjective health status of adult male workers with metabolic syndrome in South Korea. Although health care interventions should be provided on the national level for adult male workers with metabolic syndrome, there are realistic

limitations. A possible method is to make each company manage metabolic syndrome of workers through policy suggestion, but it needs to be preceded by an additional study that verifies the grounds for intervention of metabolic syndrome.

Factors Influencing Self-rated Health Status in Middle-aged Women with Osteoporosis: Based on the 7th Korea National Health and Nutrition Examination Survey

Kyongeun Lee

Assistant Professor, Department of Nursing, Tongmyong University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to examine factors influencing self-rated health status in middle-aged women with osteoporosis in Korea.

Method/Statistical Analysis: This study carried out secondary analysis using the available data of the 7th Korea National Health and Nutrition Examination Survey (2016-2018). Total subjects are 462 middle-aged women with osteoporosis. The data were analyzed by using descriptive statistics, multiple regression.

Findings: Health-related quality of life ($p = .045$), comorbidity (hypertension, diabetes mellitus, dyslipidemia) ($p = .001$), body discomfort ($p = .038$), current alcohol drinking status ($p < .001$), perceived stress ($p < .001$), occupation ($p < .001$) were significantly associated with self-rated health status in middle-aged women with osteoporosis. The regression model for self-rated health status of the subjects was significant ($F = 15.622$, $p < .001$), and explanatory power of the overall model was 34.7%. (Adjusted $R^2 = .347$). Based on the results of this study, factors influencing self-rated health status of middle-aged women with osteoporosis in Korea included occupation ($p = .011$), current alcohol drinking status ($p = .024$), body discomfort during the past 2 weeks ($p = .001$), comorbidity (hypertension, diabetes mellitus, dyslipidemia) ($p = .030$), perceived stress ($p = .004$), and health-related quality of life ($p < .001$).

Improvements/Applications: The results of this study will be helpful in developing interventions to improve health management and can ultimately improve self-rated health status.

Keywords: *Osteoporosis, middle-aged women, self-rated health status, national survey, secondary analysis.*

Introduction

Osteoporosis is a disease characterized by high risk of bone fracture caused by the weakening of bones from reduced mass^[1-2]. In general, osteoporosis is known to be more prevalent in women than men and with increasing age^[1-2]. A study reports that over one-third of the entire middle-aged female population of Korea experiences bone fracture caused by poor bone health^[3]. As such,

health risk of osteoporosis occurs more frequently in women. There are various causes of high prevalence rate of osteoporosis in women including the reduction of hormones after the menopause and poor exercise habit and nutrition intake compared to men^[4]. The reason why osteoporosis draws attention is because it not only arouses serious secondary risks such as fracture but also has negative influence on health status by limiting activities of daily living with pain and disability^[5]. Therefore, osteoporosis of women is an important disease that needs to be managed carefully.

Self-rated health status refers to subjective awareness of one's own health status^[6]. Self-rated health status is a comprehensive and inclusive measure of evaluating one's own health, and the method is

very easy^[7]. Accordingly, Korea National Health and Nutrition Examination Survey include self-rated health status, which identifies health status affected by various domains of everyday life such as diseases and medical service status, as a survey item. The dominant view is that subjective health status is a valid tool to determine actual health status^[8]. Accurate subjective awareness of health status can lead to health care behavior. Therefore, it is important to pay attention to self-rated health status in order to enhance health^[9]. Examining the factors that affect subjective health status can be an important process to prepare for an effective health care strategy.

A study that examined self-rated health status of osteoporosis patients showed that patients who are aware of having osteoporosis have worse self-rated health status, but this study did not analyze the factors influencing subjective health status^[10]. In a previous study on the factors influencing health promoting behavior related to osteoporosis, subjective health status was found to affect health promoting behavior to prevent osteoporosis. Patients with better self-rated health status showed better health promoting behavior^[11].

Studies on self-rated health status were carried out on a variety of disease groups, and the results showed that self-rated health status is associated with quality of life, physical and mental health, and practice of health behavior^[12-14]. Verifying the factors influencing self-rated health status would be meaningful in verifying the factors that need educational interventions to promote health of patients. As it is difficult to find studies on the factors influencing self-rated health status of middle-aged women with osteoporosis, this study aims to provide the basic data for understanding the factors influencing self-rated health status of female osteoporosis patients aged 40 years or above and seeking the method of improving their health. This study intends to examine the characteristic factors that influence self-rated health status in all middle-aged women with osteoporosis of Korea using the Korea National Health and Nutrition Examination Survey.

Method

- 1. Study Design:** A secondary analysis was conducted using the available data of the 7th Korea National Health and Nutrition Examination Survey (2016-2018). The Korea National Health and Nutrition Examination Survey applies the multistage stratified clustered sampling method, which is a complex sampling design that represents the entire population.
- 2. Sample:** From 8,127 respondents of the 7th Korea National Health and Nutrition Examination Survey, 508 persons who clearly responded to the question asking about osteoporosis as 'Yes' or 'No' were extracted. Among them, 462 women aged 40 years or above were selected as the final subjects of this study, and their responses were used for the analysis.
- 3. Measures:** In this study, age, education, occupation, duration of osteoporosis, satisfaction of dietary patterns, weight change, body discomfort during the past 2 weeks, restriction of activity, comorbidity (hypertension, diabetes mellitus, dyslipidemia), perceived stress, depressive mood more than 2 weeks, and health-related quality of life were analyzed as general characteristics and health related characteristics. And current smoking status, current alcohol drinking status, participatory rate of aerobic exercise within 1 week, muscle strengthening exercise within 1 week, walking exercise within 1 week were analyzed as health related behavioral characteristics.
- 4. Data Analysis:** The data for this study were analyzed using the SPSS 23.0 and STATA 13.0 programs as follows. Based on secondary data analysis, general characteristics, health-related characteristics and health-related behavioral characteristics were analyzed using frequency, percentage, mean and standard error. Self-rated health status of osteoporosis patients according to general characteristics, health-related characteristics and health-related behavioral characteristics was analyzed using t-test, ANOVA and multiple regression. The significance level (α) was defined as 0.05 or below for all analyses. In this study, the score is based on a 5-point scale ranging from 1 to 5 points. A score closer to 5 points indicates poor self-rated health status.

Result

As for self-rated health status according to sub-items of general characteristics and health-related characteristics, there were statistically significant differences in self-rated health status with occupation ($p < .001$), duration of osteoporosis ($p < .001$), satisfaction of dietary patterns ($p = .004$), body discomfort during the past 2 weeks ($p < .001$), restriction of activity ($p < .001$), comorbidity such as hypertension, diabetes mellitus and dyslipidemia ($p < .001$), perceived stress ($p < .001$), and depressive mood perceived for more than 2 weeks ($p < .001$) [Table 1].

Discussion

This study used raw data from the 7th Korea National Health and Nutrition Examination Survey to verify that factors influencing self-rated health status of women with osteoporosis aged 40 years or above in Korea. Out of 8,127 respondents, 462 women aged 40 years or above who have osteoporosis were selected

as the subjects to examine the differences in self-rated health status according to general characteristics, health-related characteristics and health-related behavioral characteristics.

This study verified significant differences in self-rated health status according to general characteristics, health-related characteristics and health-related

behavioral characteristics of middle-aged women with osteoporosis. And also the factors influencing subjective health status were identified. The factors influencing self-rated health status were found to be body discomfort during the past 2 weeks, comorbidity (hypertension, diabetes mellitus, dyslipidemia), perceived stress, and health-related quality of life level. In other words, osteoporosis patients showed poor subjective health status when they have body discomfort and comorbidity. They also showed poor subjective health stress if they perceive stress. Health-related quality of life was found to affect self-rated health status. Poor health-related quality of life resulted in poor subjective health status. To clarify the correlation between subjective health status and influencing factors, additional analysis must be performed in a future study.

High subjective health status was shown in patients who have occupation, high satisfaction of dietary patterns, no body discomfort experienced during the past 2 weeks, no restriction of activity, low degree of perceived stress, no depressive mood perceived for more than 2 weeks, and no comorbidity such as hypertension, diabetes mellitus and dyslipidemia. This was similar to a study conducted on obese adults^[15] and studies that examined subjective health status of elders^[15-16]. In addition, high subjective health status was shown with short duration of osteoporosis, indicating that time passage after diagnosis of osteoporosis has an negative influence on self-rated health status. Therefore, it would be necessary to check difficulties in management of osteoporosis at different times and come up with appropriate educational approaches for intervention.

In the case of health behavior, patients who currently drink alcohol showed higher subjective health status than patients who do not drink. This is probably because drinking relieves stress and has a positive impact on self-rated health status, but additional analysis is required to identify the cause of this result. In addition, it is necessary to verify that patients do not neglect management of osteoporosis because of drinking. Participatory rate of aerobic exercise within 1 week and walking exercise within 1 week caused positively significant differences in self-rated health status. Therefore, this study proposes a method of positively changing self-rated health status by adding physical activities, namely light aerobic exercise and walking exercise, to manage osteoporosis.

Since previous studies suggest that self-rated health status is related to quality of life, physical and

mental health, and practice of health behavior^[12-14], it is important to verify the factors influencing self-rated health status to find an effective strategy to improve subjective health status. In this study, the factors influencing subjective health status were analyzed. The results showed that educational interventions can be applied to body discomfort during the past 2 weeks, comorbidity (hypertension, diabetes mellitus, dyslipidemia), perceived stress, and health-related quality of life level. Body discomfort is thought to be recognized from restriction of activities to reduce chronic pain, back pain and risk of bone fracture in osteoporosis patients. Interventions to resolve various situations that lead to pain and activity restriction would be necessary to reduce body discomfort experienced by osteoporosis patients. Comorbidities were found to have an adverse effect on subjective health status. Accordingly, an additional study is required to identify the factors related to the effects of comorbidity on subjective health status. Furthermore an intervention program to verify and reduce the cause of body discomfort and an integrated education program to manage osteoporosis and comorbidity would be necessary. Also, various interventions must be developed to remove the causes of stress and change awareness of stress situations to improve subjective health status according to perceived stress.

Conclusion

The meaning of this study is in verifying self-rated health status of middle-aged women with osteoporosis and deriving the factors influencing self-rated health status using data from the Korea National Health and Nutrition Examination Survey, a survey conducted to examine health status of Korean citizens.

A Study on Factors Affecting Communication Ability of Korean Nursing Students

Young Hee Jeong¹, Mi Jin Kim²

¹Professor, Dept. of Nursing Science, Woosong College, Korea, ²Professor, Dept. of Nursing Science, Daejeon Institute of Science and Technology, Korea

Abstract

Background/Objectives: This study was attempted to identify factors affecting the communication ability of nursing students. The study subjects were 210 nursing students.

Method/Statistical Analysis: This study was statistically processed using SPSS. 19 program and correlation analysis and hierarchical regression analysis were used to confirm the relationship between the main variables.

Findings: As a result, the communication ability of nursing students showed a positive correlation with self-awareness, empathy, self-esteem. Regression analysis was found to have a significant effect on self-awareness, empathy, and self-esteem. Among them, empathy was the most influential and the explanatory power of the main variables was 53.4%. That is, the higher the empathy ability, the higher self-awareness, and the higher self-esteem of nursing college students, the higher the communication ability ($F = 80.871$, $p < .000$). That is, the higher the empathy ability, the higher self-awareness, and the higher self-esteem of nursing college students, the higher the communication ability.

Improvements/Applications: Therefore, universities should provide continuous education to improve empathy, self-esteem, and self-awareness in order to improve communication skills of student nurses, and develop specific education method and operational strategies through follow-up studies.

Keywords: *Self-awareness, empathy, self-esteem, communication ability, nursing students.*

Introduction

Nurses need to fulfill the roles of communicating and cooperating continuously with professional manpower in other areas with the aim of solving practical or potential problems of patients in the hospital environment^[1]. The effective communication ability necessary to perform such a professional and dynamic nursing job efficiently is required as an important qualification to be a nurse^[2]. Nurses' therapeutic communication ability in clinical

practice contributes to patients' relief in symptoms, improvement in physiological functions, and emotional stability^[3]. Nurses need to form a therapeutic relationship with patients and explore and solve their health problems positively through a diversity of verbal and nonverbal communication skills. For this reason, therapeutic communication skills are emphasized as one of the core competences essential to nurses and have been used effectively within the therapeutic relationships in clinical practice^[2]. In South Korea, nursing education institutions are aware of the importance of communication training and presents it as important learning outcome of education^[3]. Colleges develop education programs to help students improve their communicative competence in curriculums, build structural and systematic education systems, taking stages, association, and integration into account, and provide various types of education^[4].

While the educational contents include conceptual learning related to knowledge about communication and clinical training performance evaluation, they may reportedly have limitations in allowing students to develop communication skills fully^[3-4].

It is reported, also, that even nurses getting relevant education can have their therapeutic communicative competence easily affected by diverse variables, including unpredictable emergencies and their own stress at busy clinical sites, and have difficulty in sustaining consistent communication^[1]. For nursing education, therefore, it is necessary to cultivate nursing equipped with consistent and sustainable communication ability against a diversity of situational variables in clinical practice and to help develop communication skills by covering the internal factors involved in communication, instead of delivering knowledge simply.

The literature review regarding nurses in South Korea found that nurses who were more confident in their job, were more responsible, had better self-esteem, and were more autonomous were more self-assertive and better at coping with the conflicts in interpersonal relationships^[5]. As can be seen in the finding that self-assertive communication was effective in coping actively with stressors in a clinical situation^[6], education related to individuals' internal factors involved in communication is more effective in developing communication ability than education simply based on knowledge acquisition.

The literature review regarding the factors for communication ability of nursing students in South Korea found that self-awareness and self-esteem were

repetitively covered as important variables^[3,7]. Greater emphasis is placed on the variable of self-awareness, which is to understand and pay attention to one's own inner world, improve the understanding of others and empathy, and, ultimately, contribute to effective communication ability^[1,3]. In other words, knowledge education and practical training simply based on concepts have limitations in improving practical communication ability and it is possible to develop sustainable communication ability only by changing inner contributors of human beings that take the fundamental lead in communication.

From this perspective, attention should be paid to the associations among the variables of self-awareness, self-esteem, and empathy in the literature review regarding

communication ability. Self-awareness is to pay attention to one's own inner thinking or emotions and nurses' self-awareness capabilities are concerned with the efforts to understand and empathize with patients as they are and serve as crucial resources in forming relationships with them^[8]. Self-esteem means a type of attitude by which individuals respect and regard themselves as desirable and valuable; it was reported that people with higher self-esteem were better at interpersonal relationships^[9] and had better communicative competence^[7].

While a few studies on the effects on communication ability of nursing students were identified by variables, no integrative research has been conducted on which of self-awareness, empathy, and self-esteem is more influential and it was difficult to determine the relative impact of these variables. However, it is important to determine which of these variables makes greater contributions to the improvement in communication ability if the ground for effective nursing education is secured, taking the efficiency of the educational contents into account.

On the basis of the literature review regarding communication ability of nursing students in South Korea, this study aimed to analyze the associations among self-awareness, self-esteem, empathy, and communication ability and determine the contribution of the influential variables.

Method

Data collection was performed among 210 graduates-to-be as nursing students in South Korea. It was performed using structured questionnaires from November to December 2017. It was performed among those students who were given explanation by the researcher and gave their consent; the notice was given that all the data related to the research were anonymous and that the refusal to participate in the research might cause no disadvantage.

For the purpose of exploring the factors affecting communication ability in nursing students, an SPSS.19 program was used to determine the effects of self-awareness, empathy, and self-esteem on communication ability. To determine the findings suitable to the goal of the research, such statistical techniques as frequency analysis, correlation analysis, and hierarchical regression analysis were used.

1. Survey Tools: Self-awareness of nursing students

was measured using the self-awareness inventory which had been developed by Fenigstein, Scheier, and Buss^[10] and adapted by Eun^[11]. This tool is in the five-point scale with a total of 20 items in such sub-areas as private self-awareness, public self-awareness, and social anxiety. The scores ranged from 1 *totally disagree* to 5 *totally agree*, with a higher score meaning better self-awareness. For its reliability, Cronbach $\alpha = .74$ in Eun^[11] and Cronbach $\alpha = .65$ in this study.

Empathy of the nursing students was measured using the tool which had been developed by Davis^[12] and Bryant^[13] and applied by Kim et al.^[14]. This tool is in the five-point scale with a total of 30 items whose scores ranged from 1 *totally disagree* to 5 *totally agree*, with a higher score meaning a higher level of empathy. For its reliability, Cronbach $\alpha = .85$ in Kim et al. ^[14] and Cronbach $\alpha = .86$ in this study.

Self-esteem was measured using the tool which had been developed by Rosenberg^[15] and translated by Jeon^[16]. It has total of 10 items; the higher score, the higher level of self-esteem. For its reliability, Cronbach $\alpha = .82$ in this study.

Communication ability was measured using the communication ability inventory developed by Lee et al.^[17]. This tool is in the five-point likert scale with a total of 49 items whose scores ranged from 1 *very rarely* to 5 *very often*, with a higher score meaning a higher level of communication ability. It is composed of five elements of competence—interpretation, role performance, self-presentation, goal-setting, and message transition—and 13 negative items for preventing any bias in responses were recoded. For its reliability, Cronbach $\alpha = .70$ at the time of its development by Lee et al.^[17] and Cronbach $\alpha = .90$ in this study.

Result

1. General characteristics of subject: The general characteristics of the participants are as presented in [Table 1]. Among the 210 participants, there were more female students (190; 90.5%) than male ones (20; 9.5%). As for academic achievement, 1 student (0.5%) was *very satisfied*, 53 (25.2%) were *satisfied*, and 113 (53.8%) were at the *average* level. More than 50% of the students were satisfied with their major: 9 students (4.3%) were *very satisfied*, 98 (46.7%)

were *satisfied*, and 87 (41.4%) were at the *average* level. As for peer relationships, 19 students (9.0%) were *very satisfied*, 137 (65.2%) were *satisfied*, and 48 (22.9%) were at the *average* level. As for communication ability, 4 students (1.9%) were *very satisfied*, 86 (41.0%) were *satisfied*, and 99 (47.1%) were at the *average* level; thus, more than 50% of the students were at the *average* or higher levels of satisfaction with the peer relationships, major, academic achievement, and communication ability.

Table 1. General Characteristics of Study Participants

Characteristics	Categories	n(%)	M±SD
Gender	male	20(9.5)	23.10±.29
	female	190(90.5)	
Academic achievement	very satisfied	1(0.5)	3.03±.75
	satisfied	53(25.2)	
	moderate	113(53.8)	
	unsatisfied	37(17.6)	
	very unsatisfied	6(2.9)	
Satisfaction in major	very satisfied	9(4.3)	3.47±.72
	satisfied	98(46.7)	
	moderate	87(41.4)	
	unsatisfied	14(6.7)	
	very unsatisfied	2(1.0)	
Satisfaction in friendship	very satisfied	19(9.0)	3.80±.66
	satisfied	137(65.2)	
	moderate	48(22.9)	
	unsatisfied	4(1.9)	
	very unsatisfied	2(1.0)	
Satisfaction in communication ability	very satisfied	4(1.9)	3.33±.72
	satisfied	86(41.0)	
	moderate	99(47.1)	
	unsatisfied	18(8.6)	
	very unsatisfied	3(1.4)	

2. Participants’ self-awareness, empathy, self-esteem, and communication ability: The principal variables, such as self-awareness, self-esteem, empathy, and communication ability, were analyzed as shown in [Table 2]. They scored an average of 3.32 out of 5 for self-awareness, 2.83 out of 10 for self-esteem, 3.51 out of 5 for empathy, and 3.47 out of 5 for communication ability self-esteem, empathy, and communication ability.

Table 2. The Degree of General Characteristic, Self-awareness, Self-esteem, Empathy, Communication ability

Variable	Item	Item	Total
		M±SD	M±SD
Self-awareness	20	3.32±.29	66.5±5.89
Self-esteem	10	2.83±.40	28.39±4.02
Empathy	30	3.51±.35	105.37±10.69
Communication ability	49	3.47±.32	170.07±15.92

3. Correlation analysis among self-awareness: The correlation analysis found that there were significant correlations among the principal variables, such as self-awareness, self-esteem, empathy, and communication ability, as presented in [Table 3].

Table 3. Correlations between Communication ability and major variables

Variables	Pearson Correlation (p)			
	a)	b)	c)	d)
a) Self-awareness	1			
b) Self-esteem	.346 (<.000)	1		
c) Empathy	.551 (<.000)	.182 (.004)	1	
d) Communication ability	.640 (<.000)	.345 (<.000)	.633 (<.000)	1

4. Effects of self-awareness, self-esteem, and empathy on communication ability: The regression analysis found that self-awareness ($\beta = .368$), self-esteem ($\beta = .144$), and empathy ($\beta = .404$) had a significant impact on communication ability ($F = 80.871, p < .000$) and that the impact was very likely to account for communication ability (53.4%). Among the principal variables, empathy had the strongest impact, followed by self-awareness and self-esteem. That is, the better empathy, the better self-awareness, and the higher self-esteem, the higher level of communication ability in nursing students [Table 4].

Table 4. Influencing factors on Communication ability

Independent Variables	Model				
	B	SE	β	t (p)	VIF
Constant	24.28	9.48		2.560(.011)	
Self-awareness	.995	.160	.368	6.206(<.000)	1.577
Empathy	.602	.084	.404	7.141(<.000)	1.436
Self-esteem	.570	.199	.144	2.864(.005)	1.136
Statistic results	$R^2 = .541, \text{Adjusted } R^2 = .534, F = 80.871, p < .000, \text{Durbin-Watson} = 1.892$				

Discussion

On the basis of the literature review regarding communication ability in nursing students, this study aimed to analyze the associations among such principal variables as self-awareness, self-esteem, empathy, and communication ability and determine the relative impact of the relevant variables on communication ability.

For self-awareness, they scored higher than 2.82 ± 0.74 in Kang^[18] and slightly lower than 3.40 ± 0.32 in Oh et al.^[2]. They scored similar to 3.31 for secondary school students in Eun^[11]; self-awareness was generally at the similar level to the findings from literature review.

For self-esteem, the nursing students scored 2.83, which was lower than 2.94 in Lee et al.^[7] applying the same tool; however, there was no significant gap but similarity between the two studies. For empathy, the nursing students scored an average of 3.51, which was lower than 3.54 in Jeong^[1], 3.58 in Kim et al.^[14], and 3.67 in Kang^[18]. This is because of the variation in grade and personal factors among the respondents by study design although each of them was conducted in nursing students. For communication ability, they scored 3.47, which was similar to 3.43 in Oh^[2] applying the same tool. The correlation analysis found that such principal variables as self-awareness, self-esteem, and empathy were all positively correlated with communication ability in nursing students. Self-awareness and empathy had a high level of positive correlation with communication ability; self-esteem had a medium level of positive correlation with communication ability, as shown in literature review^[1,7,18].

On the basis of the correlation analysis, all of such independent variables as self-awareness, self-esteem, and empathy significantly affected communication ability, with the total explanatory power estimated at 53.4%. As for the relative impact of the independent variables, empathy, followed by self-awareness and self-esteem, had the strongest impact on communication ability. The literature review found that empathy was strongly correlated with self-awareness^[14]; therefore, it was included in this study as a predictor and its relevance was confirmed in the results. In other words, it was statistically confirmed that empathy was a factor significantly affecting communication ability of nursing students. Empathy refers to an emotional bond by which individuals feel the other's feeling and thinking as their own. People convey their heart through empathy and the empathetic responses between a patient and a nurse

can promote therapeutic relationships, increase trust, induce changes in the patient's health, and improve the therapeutic effects. On the basis of this result, it has been confirmed that very empathetic nursing students are very sensitive to patients' emotions, use their own emotions to empathize, express the emotions both verbally and nonverbally, and improve their communication ability.

In conclusion, all of such factors as empathy, self-awareness, and self-esteem affected communication ability in nursing students and the impact of these variables had great explanatory power; therefore, it is necessary to provide education that can help nursing students improve their empathy, self-awareness, and self-esteem in pursuit of better communication ability. The education stimulating the internal factors of students is expected to overcome the limitations in the effectiveness of the conventional education for acquiring simple knowledge about communication and contribute to the development of communication ability that can be sustained consistently even in an unpredictable nursing situation. Such areas as empathy, self-esteem, and self-awareness are nursing students' internal factors that can be improved through steady educational stimuli and individual students' efforts rather than through fragmentary stimuli; therefore, further research should be conducted to develop specific method and teaching strategies to improve them

Conclusion

In conclusion, nursing education institutions in South Korea need to be aware of the need to combine sustainable educational stimuli for empathy, self-esteem, and self-awareness with the curriculums to improve communication ability; further research should be conducted to develop specific teaching method and management strategies with the aim of developing effective teaching strategies.

The Effects of ICT-based Public Health Center Mobile Health Care Project on Adult Health Risk Factors

Young Ju Lee

Professor, Dept. of Nursing, Gimcheon University, Gyeongbuk, Korea

Abstract

Background/Objectives: This study uses a single group pretest-posttest design to identify the effects of ICT-based public health center mobile health care project on adult health risk factors.

Method/Statistical Analysis: The subjects of this study were 100 adults, over 19 years of age residing in the jurisdiction of the public health center of G city, who are not yet diagnosed with metabolic syndromes but have at least one kind of risk factors. The general characteristics of the subjects were analyzed by using the frequency and percentages, and the comparison and analysis before and after the program were analyzed by using t-tests.

Findings: Blood pressure decreased significantly, as the systolic blood pressure decreased from 141mmHg to 136mmHg and the diastolic blood pressure decreased from 87mmHg ($p < .001$) to 83mmHg ($p < .001$). Fasting blood sugar decreased significantly from 111mg/dL to 104mg/dL ($p < .001$). The waist circumference decreased significantly from 93.4cm to 92.4cm ($p < .001$). Although triglyceride decreased from 222.4mg/dL ($t = 18.2, p < .001$) to 193.6mg/dL ($t = 23.7, p < .001$), the difference was not significant ($p = .051$). HDL-cholesterol increased from 42.1mg/dL to 44.4mg/dL which showed significant differences ($p = .003$). As there were also significant results on the HDL-cholesterol, it was proved that the ICT-based public health center mobile health care project is highly effective on the adult health risk factors (blood pressure, fasting blood sugar, waist circumference and HDL-cholesterol).

Improvements/Applications: There should be improvements in health management habits through management in physical activities and nutrition for metabolic syndromes of adults that can lead to chronic diseases, and expand health promotion projects that use ICT as a prevention health care service.

Keywords: Mobilehealth careproject, Metabolic syndromes, Healthrisk factor, ICT, Publichealthcenter.

Introduction

The present society is consistently on the search for a solution to the increase of the national health care costs and the socioeconomic burden due to the aging population and the increase of chronic diseases^[1].

Due to the fourth Industrial Revolution and a rapid advancement of technology, the number of mobile service subscribers rapidly increased, and mobile health which integrates the mobile services is being focused as the new alternative to health management^[2-3]. Recently, there has been an increase in the focus for mobile health due to wide distribution of wireless connection and wearable smart devices and development of biosensor technology, leading to an active integration of ICT and medical instruments^[4]. 'Mobile Healthcare' or 'Mobile Health (mHealth)' refers to medical and public health work supported by mobile devices^[5]. Mobile healthcare has been receiving even more attention as there are active integration of ICT and medical devices with the

Professor, Dept. of Nursing, Gimcheon University,
Gyeongbuk, Korea

e-mail: sonamu0815@gmail.com

development of wireless connection and wearable smart devices, and the miniaturization and high density integration of biosensors^[6]. According to a report from the EC (European Commission), the major implementation factor of mobile healthcare is reducing medical costs for developed countries and increase accessibility to basic healthcare for developing countries^[7-8].

According to a recent study on the rate of metabolic syndromes of Korean adults, it was shown that 20.3% of the adults, or one out of five adults, had metabolic syndromes, which resulted in a need to prevent the metabolic syndromes^[9]. Metabolic syndromes are groups of physiological, biochemical, clinical and metabolic factors that are mutually related that increase the direct risks of all death factors such as Type 2 Diabetes and cardiovascular diseases^[10]. There should be intervention programs or studies to improve the risk factors of metabolic syndromes that can lead to chronic diseases for adults and for the adults to have healthy diets, physical activities, quit smoking and reduce drinking^[11-13]. Lee and Kim^[14] studied the effects of an intelligent VR exercise-appropriate protocol on the biological health factors of chronic stroke patients, and Park et al^[15] studied the possible benefits of a comprehensive support on obesity management of elementary school students using mobile phones as a qualitative study on the aspect of program providers. In addition, in the study by Lee and Park^[16] that identified the effects of an increase in physical activities with mobile healthcare on the body composition and risk factors of metabolic syndromes of the office worker men, it was shown that there is a positive effect of the increase of physical activities with mobile healthcare on the change of the body composition and risk factors of metabolic syndromes of the office worker men. However, after systematically studying literature on the health behavior intervention and the theoretical inter-correlation, there were little cases of developing mobile intervention programs based on the behaviour theory^[17]. In addition, there needs to be various kinds of studies that identify the effects of the ICT-based public health center mobile health care projects on adult health risk factors.

Therefore this study aimed to identify the effects of the ICT-based public health center mobile health care projects on adult health risk factors.

Method

This study uses a single group pretest-posttest

design to identify the effects of ICT-based public health center mobile health care project on adult health risk factors [Figure 1].

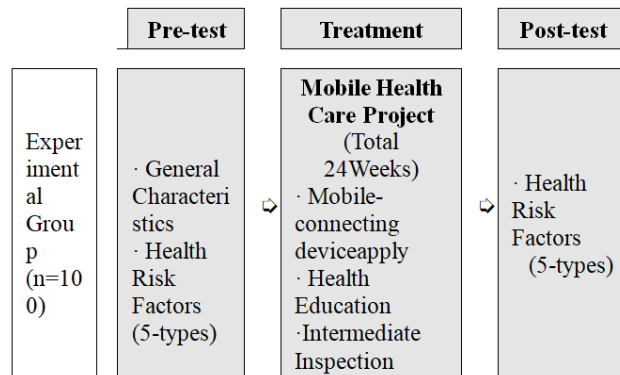

Figure 1. Design of Research

The subjects of this study were among the adults over 19 years of age residing in the jurisdiction of the public health center of G city, who are not yet diagnosed with metabolic syndromes but have at least one kind of risk factors out of the five health risk factors of the standards of metabolic syndromes according to the national health screening examinations^[18] who agreed to participate in this study. The adults who did not have prior experiences in participating in mobile health care projects were prioritized in selection; those who have developed into chronic diseases were excluded, and if there are too much new participants, those with higher numbers of health risk factors were selected in priority^[19-20]. The exclusion criteria were if data such as activity measurements were not transmitted during two weeks of the study, if the subjects lost the devices due to carelessness, if the risk factors have developed into chronic diseases during the course of the study and if the subjects were transferred to another jurisdiction, and a total of 100 subjects that match all criteria were selected for this study. The study started in February 2018 with selecting appropriate subjects to the selection criteria, and progressed on from May to October 2018 with the pre-test of the measured variables, the mobile health care project for 24 weeks (6 months) and the post-test after the project.

Starting from May 2018, the subjects were connected to a mobile application via Bluetooth and a mobile-connecting device such as activity measuring tools on their smart phones (at least Android 4.3, IOS 7.0), and for the 24 weeks (6 months) until October 2018, the subjects measured the number of walks, the walking time, walking distance, consumed calories, and real-time

heart rates which were sent to the mobile application and to the health center staff on the web. During the period, according to the results of health behaviors such as self-managing service, health information providing services, reciprocal health counseling services and continuous practice supporting services for the subjects based on a mobile application, it was possible to set health goals through counseling services such as quitting smoking and reducing drinking from nurses, nutrition counseling from nutritionists according to diet evaluation, physical activity counseling from physical activity instructors to induce sustainable customized health behaviors. Before and after (24 weeks) the mobile health care project, the study used surveys through the web to analyze the risk factors according to the subjects out of the five health risk factors (blood pressure, fasting blood sugar, waist circumference, triglyceride, HDL-cholesterol).

This study used SPSS Win 23.0 Program for the statistical analysis. The general characteristics of the subjects were analyzed by using the frequency and percentages, and the surveys through the web before and after the mobile health care projects (24 weeks) and the change and the analysis of the five health risk factors (blood pressure, fasting blood sugar, waist circumference, triglyceride, HDL-cholesterol) were analyzed by using t-tests.

Result and Discussion

1. General characteristics of the subjects: Out of the subjects of this study, 24% were aged between 30 and 39 (24 subjects), 33% were aged between 40 and 49 (33 subjects) and 36 were aged between

50 and 59. In terms of gender, 38 were males and 62 were females. In terms of the number of health risk factors, 24% of the subjects had one risk factor (24 subjects), 33% had 2 risk factors (33 subjects) and 43% (43 subjects) of the subjects had more than three, which was the highest proportion [Table 1].

Table 1. General characteristics of the subjects (N = 100)

Variables/Categories		n(%)
Years	20 years ~ 29 years	1(1.0)
	30 years ~ 39 years	24(24.0)
	40 years ~ 49 years	33(24.0)
	50 years ~ 59 years	36(36.0)
	60 years ~ 69 years	3(3.0)
	70 years <	3(3.0)
Gender	Male	38(38.0)
	Female	62(62.0)
Health risk factor	One	24(24.0)
	Two	33(33.0)
	Three≤	43(43.0)

2. Change and comparison in retention rate by Blood Pressure and Fasting Blood Sugar: [Table 2] After comparing the blood pressure before and after the mobile health care projects, both types of blood pressure decreased significantly, as the systolic blood pressure decreased from 141mmHg to 136mmHg and the diastolic blood pressure decreased from 87mmHg ($p<.001$) to 83mmHg ($p<.001$). Fasting blood sugar decreased significantly from 111mg/dL to 104mg/dL ($p<.001$).

Table 2. Change and comparison in retention rate by Blood Pressure (N = 100)

Variables	Group	Pre M±SD	Post M±SD	Difference M±SD	t	p
Blood Pressure (Systolic/ Diastolic) (mmHg)	Exp.(n = 100)	141/87±8.71	136/83±9.62	-5.03/-4.23 ±8.66/7.45	-4.56/-4.74	<.001
	t	135.58	118.40			
	p	<.001	<.001

	t	41.82	41.20			
	p	<.001	<.001			

Exp.: Experimental group

Discussion

This study was attempted to find out how the ICT-based mobile healthcare project affects health risk factors in adults with health risk factors according to the metabolic syndrome criteria in the national health examination results.

In this study, the subjects who participated in the mobile health care project were effective with blood pressure and fasting glucose. Similar to the results of this study, Kim et al.^[21] conducted a trial intervention to verify the short-term effects of the mobile application ‘NICE Health Ten’ on 68 adults in their 20s for 8 weeks, and fasting blood sugar, which had the highest screening rate, decreased from 16.2% to 4.4%.

In particular, as blood pressure and blood sugar are important health risk factors that can lead to chronic diseases, the subjects should focus on improving these factors with physical activities, managing nutrition and health and receiving counseling from experts. Although this study did not analyze the correlation of blood pressure and blood sugar with managing nutrition and health, there should be future studies to analyze the correlation. As well, the individuals with such risk factors should be continuously educated on self-managing the blood

pressure and blood sugar and should make sure that they do not lead to chronic diseases with additional education on quitting smoking and reducing drinking.

In addition, the subjects who participated in the mobile health project showed effective results in waist circumference and HDL-cholesterol. However, triglycerides did not show significant results. In a study by Kim^[21] to verify the short-term effects of the mobile application ‘NICE Health Ten’, triglyceride and HDL-cholesterol each decreased from 13.2% and 11.8% to 2.9%. Also, Chen et al.^[21] verified that the Internet-based health intervention program of eHealth for adults was effective for adults with one or more unnatural factors of the diagnosis standards of metabolic syndromes after providing individual feedback. Although this study did not show a significant result for triglyceride, as triglyceride is a major health risk factor that can lead to chronic diseases, those with problems in triglyceride should improve their levels with physical activities, managing nutrition and health and receiving counseling from experts.

Due to the rapid development of the mobile healthcare industry in Korea, there has been an increased interest in using mobile technology in the health promotion field

which is also rapidly developing. Although there are many studies that add mobile technology to the health management and intervention programs, there are still little studies that are based on theories or models. Therefore based on the results of this study, there should be future studies based on theories and models on the various mobile healthcare projects and intervention programs to prevent the metabolic syndromes of adults.

Conclusion

The purpose of this study was to identify the effects of ICT-based public health center mobile health care projects on the health risk factors of the adults. Through this study, it was proved that the ICT-based public health center mobile health care projects are highly effective on the adult health risk factors (blood pressure, fasting blood sugar, waist circumference and HD-cholesterol). Although there was no significant difference in the health risk factor of triglyceride, there should be future studies on the changes of health risk factors according to the changes in counseling to quit smoking and reduce drinking for nurses, practice rate of health behaviors and diet. In addition, there is a need of ICT-based health promotion projects as a preventive health care service through managing nutrition and physical activities for those with metabolic syndromes who are at risk for chronic diseases.

A Study on the Subjectivity of Organ Donation for Adults

Hye-Won Jeon¹, Dong-Hee Seo²

¹Professor, Kkottongnae University, Department of Nursing, South Korea, ²Professor, Kkottongnae University, Division of Social Welfare and Counseling Psychology, South Korea

Abstract

Background/Objectives: The purpose of this study is to understand subjective structures of subjectivity on organ donation by using of Q method, draw up plans to promote positive perceptions by each type and utilize a basic material to provide authentic ways for activating organ donation.

Method/Statistical Analysis: To collect non-structured statements, a population was extracted by use of materials such as literatures and news articles and interviews, then finalized 32 Q samples. These were distributed final 33 p samples via Q sorting procedures and analysed the results throughout Q factors analysis.

Findings: Subjectivity of organ donation was finally verified 4 types and explained 59.2% of total variables. The power of explanation by type was 40.3% for the 1st type, 10.6% for the 2nd type, 4.8% for the 3rd type and 3.5% for the 4th type. Among 33 participants, 18 for 1st type, 6 for the 2nd type, 6 for the 3rd type and 3 for the 4th type was distributed. Each type was shown as a type for social public interest-oriented donors, a reluctant type for donating their conviction, a passive type for donating organs and a type for donating organs after their death recognition.

Improvements/Applications: This study will be helpful and useful in drawing up plans for promoting positive perceptions depending upon individual subjectivity of organ donation and utilizing basic materials to provide realistic ways for activating organ donation.

Keywords: Organ, donation, subjectivity, adult, Q-methodology.

Introduction

With the development of medical technology, we are trying to prolong lifespan as well as keep our life healthy, however organ transplantation is only effective and only solution for the patients who are terminally ill^[1-2]. The success rate for organ transplantation is increasing and the number of patients who need to transplant organs is also rapidly increasing^[3]. The Brain-death organ donors were 515 in Korea in 2017, it was significantly lower than in other countries compared to number of

donors per million people^[4]. Organ donation not only enables the patients who wait for being transplanted to prolong their life but has a great effect on people nearby the patients. It is the matter for patients, their family and society^[5]. It might therefore be the matter which is ultimately meant to pursue the public interest of all members of our society and is also seems crucial to ensure more organ donors and applicants registered to settle problems occurred by order imbalance of organ donation. However, negative effects such as organ trade caused by an extreme imbalance that supply of organ donation falls short of demand pose social issues.

In addition, a lot of ethical and procedural arguments were raised. To settle this, Korean government has made lots of efforts to create systematic transplantation procedures like prohibition of organ trade and legalization of organ harvesting of brain death by foundation of KONOS responsible for organ transplantation making

Corresponding Author:

Dong-Hee Seo

Professor, Kkottongnae University, Division of Social Welfare and Counseling Psychology, South Korea
e-mail: dseokr@kkot.ac.kr

law on organ transplant and amending it several times. However, it is reported that the number of organ donors is getting decreased because of the influence of cultural Confucian tradition not to embarrass own body, reduced prevalence of brain death and manpower shortage needed for brain death management^[6]. It is also reported that prolonged life expectancy made supply of organs lower by low death rate, and that legal issues like consent with family members, issues of organ donation information, and issues on management are factors that impede activation of organ to donation^[3,7]. There is still a lack of awareness of organ donation, if any, it is very rare to pledge to donate organs, and even though organ donation pledges were made, there are few cases that lead to actual organ donation. It is therefore needed to make effort to revitalize organ donation^[7,8].

Therefore, it is important to establish social atmosphere where citizens and medical staffs naturally accept organ donation and advertisement and educational activities at national level should be preceded through cultural diffusion of organ donation to inspire recognition on organ donation^[5]. Approaches for increasing individual organ donation pledges, for eliciting family's consent and for establishing social atmosphere should be driven.

There were lots of precedent descriptive studies on the perception, knowledge and attitudes of organ donation based on certain groups such as medical personnel, medical university students, nursing university students, nurses, etc^[1-2,9-10]. However attitudes on organ donation are difficult to define as positive or negative recognition and an action to register as an organ donor is required for grasping subjective structures of individual value, belief, attitude, etc. Therefore, this study was to understand subjective structures on organ donation by applying Q methodology which provides individual insight on humans' subjectivity. Additionally, the study was performed to draw up plans for promoting positive perceptions depending upon individual subjectivity of organ donation and utilize basic materials to provide realistic ways for activating organ donation.

Method

Q methodology is based on the assumption of intraindividual difference in significance, and scores difference among samples represents meaning difference to the researcher who sorted it^[11].

1. Q Sample: To collect non-structured statements

which enable to express subjectivity of participants, materials such as literatures and news articles and interviews were utilized. Except duplicated statements through interviews, two researchers selected 50 statements and rearranged 35 statements were finally determined to 32 statements by two researchers a enabling to include various opinions.

- 2. P Sample:** Q methodology, a research method that conceptualize contents rather than people, should be taken into account the characteristics that different opinions can occur more than random method and the number of samples is not as large as random method^[12]. After explaining the purposes of the study and it will not be used in any other purpose, 33 subjects who understood the purposed of the study and agreed to participate in the study were finally selected and written consent from in writing
- 3. Q Sorting:** Each subject was given 32 Q cards written each statement on it and forced to arrange in important order according to personal perspective. Q cards were classified into most strongly agreed statement (+4) and most strongly disagreed statement (-4). Starting from the 1st week of March, 2019 for four weeks, researchers met respondents in person, explained and classified. The statements placed both extremes were forced to write the reason why they chose.
- 4. Data Processing:** Upon completion of P sample investigation, score was given as following; +1 point was given to the most strongly disagreed and +9 was given to the most strongly agreed. After each score had been coded, major factor analysis method was carried out by using PC QUANL Program. Various numbers of factors were input on the base of Eigen value more than 1.0 then 4 types which enabled to depict its unique property were classified among results.

Result

Subjectivity on organ donation was eventually identified in 4 types accounting for 59.2% of total variances. The power of explanation by type was [Table 1]. Among 33 respondents, 18 for the 1st type, 6 for the 2nd type, 6 for the 3rd type and 3 for the 4th type was divided and correlation which shows degree of similarity is as shown in [Table 2]. To grasp subjective characteristics and the differences by type on organ donation, the most strongly agreed statements and the most strongly disagreed statements in each type were

primarily interpreted among 32 statements. In each type, the respondents who have weight factor more than 1.00 represent its type as a typical person, showing 12 for the 1st type, 4 for the 3rd type, 1 for the 2nd and 4th respectively.

Table 1. Eigen value and variances, cumulative variance

	Type 1	Type 2	Type 3	Type 4
Eigen value	13.287	3.493	1.586	1.161
Variance	.403	.106	.048	.035
Cumulative variance	.403	.509	.557	.592

Table 2. Correlations between types

Type	1	2	3
2	.429		
3	.519	.657	
4	.598	.548	.655

To analyze subjectivity on organ donation, types were described for focusing on the most strongly agreed statement (+4) and most strongly disagreed statement ($Z \leq -1.0$) among 32 statements.

1st Type: Social public interest-oriented type:

The people who belonged to the 1st type thought the purpose of organ donation is to prolong life and to save several people, therefore they thought active promotion is very important. They also thought that more people would participate in organ donation if they knew more about it, and that more patient would be saved through organ donation. On the other hand, they opposed the fact that why they do not donate their organs because of religious belief, values, and thinking of rising from the dead and that it is hard to accept their bodies are transplanted into others. Unlike other three types, they would let the people around them know their intention for organ donation. The people who represented the 1st type intended to donate their organs in the future, and thought education is absolutely necessary, even though they have never been educated about organ donation. The people in the 1st type were named social public interest-oriented donors because they thought organ donation as a crucial act which enables to save several lives.

2nd Type: Reluctant type:

The people who belonged to the 2nd type had in common on organ donation in that organ donation is valuable in prolonging others' lives, however they did not have any intention for organ donation to help others. They regarded organ

donation as either donating least organs such as corneas or donating only to the extent that body is intact. A respondent in his 50s worried about postmortem mutilation and never admitted being destruction of a body. 5 out of 6 belonging to in this type did not have intention for organ donation, and most of them had no blood donation experience compared to other types. They thought it valuable to donate organs, they however did not perceive organ donation as an act to help others, but a separate matter from them. Given that they were very reluctant to join organ donation, they were called a reluctant type for donating one's conviction.

3rd Type: Passive type: The people who belonged to the 3rd type felt the necessity for organ donation, they, however did not want their death and thought organ donation was made consent with their parents or family members. They also thought if their parents had known their children's organ donation, they would strongly have opposed or expressed sad on it. This type had more educational experience on organ donation, but the effect on it was minimal. Since they thought decision making on organ donation had not been changed, they did not agree on the opinion of active promotion or education on organ donation. On the other hand, it will be valuable if organ donation enables to prolong someone else's life. They had no active intention for organ donation, however they thought donated organs were used to save lives through appropriate procedures. They were named passive type for donating organs mainly because they did not want to think anything related to death.

4th Type: Type for donating organs after their death:

The people who belonged to the 4th type thought to donate organs connects directly the death, as not knowing anything, they could donate organs after death. So this type is considered as type for donating organs after the death recognition. They thought on one side they admit upcoming death if they are told about organ donation by medical team and on the other side they worried about whether organ is sold or not. In addition, they did not think religious belief or values as obstacles for organ donation. Since they were reluctant to donate their organs, they could not accept their family's donation yet. To them organ donation is the recognition of their death. They however thought 'I can give a good impression to others around me by donating organs.' The people in this type were named organ donors after their death recognition because they are the type, who cannot donate their organs now, but can donate organs after their death.

Discussion

The study was conducted to study subjective structures on organ donation according to personal characteristics and subjectivity in Korea where there are a lot of patients who need organ donation but actual organ donors were very low. The analyzed 4 types had each characteristic however, they had 8 statements in common. While in [8] study on organ donation and organ transplantation, the more position an individual has, the higher intention for organ donation the person has, in this study the people in the 1st type had more positive perception on organ donation, therefore they had higher intention for organ donation. [9] reported that knowledge on organ donation had been significantly affected on attitude and subjective norm. With this, continuous education and governmental level promotion will be required to increase organ donation. The fact that the people belonged to the 1st type had a lot of blood donation experiences backed up the argument that they had higher responsibility for the society [13].

The 2nd type admitted the value for organ donation at the same time they were reluctant to donate their organs due to a sense of rejection on postmortem mutilation. According to [14], the need for respect for organ donors responded positively accounting for 77.3% of total respondents, and the ways for respect were presented 'support service for funeral (63.4%)', and 'Support program for the bereaved at social level (40.6%)' in order. This can be seen the same that the respondents in the 2nd type stated that they need after death support for those who had brain death after organ donation. For 2nd type respondents, provision of accurate information on organ transplantation and postmortem mutilation will be a top priority. They recognized the value of organ donation, but they were reluctant to donate organs.

The 3rd type had educational experience on organ donation and participated in the real organ transplant surgery, rather they did not have positive intention on organ donation. They tended to distrust effects of education, but they thought they need organ donation. To them, emotional support and education is needed, emphasizing them positive value that organ donation can enable others to live a new life.

The 4th type is the type that organ donation is connected to death and they thought their family dislike to donate their organs. In this respect, they need to be interested in organ donation and education to change their wrong awareness on organ donation is required.

The understanding for organ donation should be aimed through death education, information for making them look back on value of life should be given and chances for selection should be provided for them.

It is suggested that programs to encourage positive attitude on organ donation and put it into practice should be developed depending on each type through appropriate education.

Conclusion

This study was designed to understand subjective structures on organ donation by using Q method which provides unique insight of humans' subjectivity. The subjectivity on organ donation by adults was revealed 4 types. This study will be utilized as basic materials in preparing for ways to promote positive awareness and realistic ways to activate organ donation depending on individual subjective type on organ donation. Along with, information related to organ donation should be provided to make meaningful death through death preparation education and chances to select organ donation should also be generated. The development of educational or promoting program for activating organ donation registration is suggested by understanding characteristics of each type.

Attitude about Advanced Directives among Middle-aged Using Q Methodology

Mi-Young Chon¹, Hye-Won Jeon²

¹Professor, Konkuk University, Department of Nursing, South Korea, ²Professor, Kkottongnae University, Department of Nursing, South Korea

Abstract

Background/Objectives: The purpose of this study was to identify type of attitude about advanced directives among the middle-aged using Q methodology.

Method/Statistical Analysis: For the Q population, an in-depth interview and literature review were used to select 34 Q samples for Q-sort. P-sample was made with 37 middle-aged and Q-sort was performed on a 9-point scale according to their subjective agreement. The analysis by PC-QUNAL program resulted in three types.

Findings: The result of this study showed 48.1% of total variance, with 20 people (38.2%) of Type 1, 12(5.7%) of Type 2, and 5(4.2%) of Type 3. The 1st type named “yes, in principle” agreed to sign up advanced directives and disagreed life-long treatment. The people belonged to the 2nd type absolutely agreed to sign up advanced directives and thought its decision should be made on their own. This type can be called “Yes, absolutely type.” The 3rd type is “Probably I will, But” type. It means that they will be responsible for everything that might happen by family deciding to stop life-long treatment. They are unlikely to stop life-long treatment from a parent or a child position.

Improvements/Applications: As the result of this study suggests, based on classification of attitude about advanced directives among the middle-aged, intervention program for the middle-aged will need to be developed and different, individualized intervention strategies provided.

Keywords: *Attitude, Advanced directives, the Middle-aged, Q methodology, subjectivity.*

Introduction

The advancement of medicine has been enabled patients who were critically serious or unconscious to prolong their life span. Depending on life support systems, doubts were raised whether the patients themselves really wanted such life or not, prolonged their painful life meaninglessly and received life-saving treatment helplessly^[1]. In addition, even ethical dilemmas such as

disagreements were brought between medical staffs and patients' cares without expressing patients' opinions^[2]. In Korea, a special committee for life-long treatment was composed, issuing cases of Boramae and Grandma Kim. Since February, 2018, patients who were judged medically impossible have enabled to make decisions on life-long treatment themselves and executed life-time medical decision method, respecting patients' self-decision and ensuring the best interests^[3]. This means setting up standards and procedures not to be received life-long treatment enabling to end up patients' life with dignity.

What advanced directives means that a person over 19 years old must visit one of registry offices for advanced directives designated by the Ministry of Health and Welfare hear full explanation and compose intention

e-mail: hwjeon@kkot.ac.kr

forms in writing not to be treated or suspend life-long medical treatment^[4].

Advanced Directives regard human beings' dignity that all the people's life is noble to the last minute as a top priority. They can give an opportunity for patients to enhance their life in the final stage and prepare for a dignified death by discussing and deciding treatment plan along with their families and medical staffs^[1]. Middle age, proceeding for old age is a period of preparing and introspecting own death as well as experiencing indirect death of their parents and close acquaintances. Therefore, the study to understand attitudes on advanced directives is needed targeting middle age. So far, studies conducted about advanced directives were about knowledge, attitudes, educational needs, intention, etc. involved by nursing students, the elderly and health workers^[3, 5].

Since the attitudes on advanced directives were subjective and varied depending on personal experiences, sociocultural background and values, a study showing subjective recognition of middle age and considering sociocultural context was tried presenting intervention. Q method for analysing systematically and grasping its category was used in the study to know exactly what advanced directives meant. Through this study, we should know there is no meaningless life and want to use it as a fundamental material of educational program development which able to understand that life is valuable to the last minute.

Method

1. **Research Design:** Since Q method designed to measure the subjective self, latent acts of individual had each type's feature understood according to subjective structure of humans ^[6], Q method was employed to investigate attitudes type of middle age on advanced directives in this study.
2. **Concourse and Q sample:** In this study, literature review related to advanced directives was conducted and in-depth interview targeted middle aged male and female was performed to the point of saturation of the statement's material. Through this process, 90 Q populations were extracted in total. Using Q method, after altering and modifying the statements by experienced nursing professionals, 34 Q statements were finally decided.
3. **P sample:** Q method does not treat interindividual difference but intraindividual difference in significance, it is therefore enough that the number

of P sample generates factors and compare among factors. P sample for this study was aimed at 37 middle aged subjects.

4. **Q sorting:** P sample subjects were presented 34 cards written statements selected by Q samples then forced to distribute them on a nine-point scale from strongly disagree (-4), neutral (0), to strongly agree (+4) according to the degree to which they have made. The subjects should write the reasons why they chose the extremes (+4, -4) among statements. These will be utilized as useful information in interpreting each Q factor.
5. **Data analysis:** Collected data was analyzed as Q factors with PC QUANL program. For deciding ideal number of factors, the number of factors was entered variously based on the Eigen value over 1.0 then three types judged ideally were finally selected through calculated result.

Result

1. **Formation of the types:** The attitudes on advanced directives through Q factors analysis were shown as three types. After analysing weighing factors and variable quantities, three types explained approximately 48.1% of total variables; explanations per each type were 38.2% for the 1st type, 5.7% for the 2nd type and 4.2% for the 3rd type [Table 1].

Table 1. Eigen Value, Variance, and Cumulative Percentage

Variables	Type 1	Type 2	Type 3
Eigen value	14.115	2.109	1.564
Variance (%)	.382	.057	.042
Cumulative variance	.382	.439	.481

Among 37 subjects, 20 for the 1st type, 12 for the 2nd type and 5 for the 3rd type was divided, and correlation between types was as shown in [Table 2].

Table 2. Correlation Matrix between Types

Variables	Type 1	Type 2	Type 3
Type 1	1.000		
Type 2	.725	1.000	
Type 3	.672	.563	1.000

The higher factor weights a subject has within each type, the more typical characteristic the subject shows. This means that such a person represented the corresponding type.

2. Characteristics by types: To analyse characteristics by types on advanced directives, characteristics by types were described for focusing on the most positive statement ($Z \geq +1.0$) and the most negative statement ($Z \leq -1.0$) among 34 statements

Type 1: Yes, in Principle: In the 1st type, the most strongly agreed statements were ‘It is much more meaningful to spend the rest of life with one’s loved family than to receive the lifespan treatment to prolong own life. ($Z = 1.74$)’ and ‘It is right to follow the patient’s will in case of patient’s intention to stop the lifespan treatment ($Z = 1.39$).’ While the most disagreed statements in the 1st type were ‘I will not compose advanced directives because I want to receive all the available treatment until I take my last breath ($Z = -1.77$).’, ‘Tendency of neglecting life can be prevailed in societies if discontinuing life-long treatment allows ($Z = -1.44$)’. Also, the strongly agreed statements compared to other types were ‘It is most appropriate for patient’s family to decide to discontinue life-long treatment.’, ‘Educational programs at national level will be helpful and useful when making decisions on death or life-long treatment.’ in order and the most strongly disagreed statements were ‘I will encourage others like friends or colleagues to compose advanced directives.’, ‘From a parent or a child position, I feel like I have not done my duty to stop life-long treatment.’ in order.

20 subjects out of 37 in total belonged to the 1st type, and they agreed to compose advanced directives and objected to life-long treatment. They also think it is better to organize the rest of their life according to their will and meaningful to spend the rest of time with their family. Plus, they think educational programs at national level are needed. They, however, think it is most appropriate for patient’s family to decide to discontinue life-long treatment, at the same time they do not encourage others to compose advanced directives. So this type can be called “Yes, in principle”

Type 2: Yes, absolutely: In the 2nd type, the most agreed statements were ‘I will compose advanced directives because I do not think receiving life-long treatment is worth ($Z = 1.60$)’, ‘I will compose advanced directives because I think living with no consciousness is to live like a dead person in case of treating life-long treatment ($Z = 1.48$)’. The most disagreed statements in the 2nd type, on the other hand, were ‘Even though I lie without consciousness or neither control bowel nor move, I must carry on my life to the end because

human dignity is still existed ($Z = -1.90$)’, ‘Since it is not up to me to decide whether I live or die, life should be kept to the end of my life ($Z = -1.70$)’, ‘I will not compose advanced directives because I want to receive all the available treatment until I take my last breath ($Z = -1.64$)’. Also, the strongly agreed statements compared to other types were ‘I will compose advanced directives because I think living with no consciousness is to live like a dead person in case of treating life-long treatment’, ‘People should live with their own will. It is meaningless to live with the help of machines’ in order. The most strongly disagreed statements were ‘Since it is not up to me to decide whether I live or die, life should be kept to the end of my life’, ‘Educational programs at national level will be helpful and useful when making decisions on death or life-long treatment’ in order.

12 subjects out of 37 in total belonged to the 2nd type, and they objected to meaningless life-long treatment in that live unconsciously with the help of machines at the same time they strongly agreed to compose advanced directives. They think it will be painful for the family to see the process of life-long treatment and to discontinue life-long treatment keeps the dignity of human beings in situations where medical treatment is impossible. So, this type can be called “Yes, absolutely”

Type 3: Probably I will, but: In the 3rd type, the most agreed statements were ‘It is right to follow the patient’s will in case of patient’s intention to discontinue life-long treatment ($Z = 1.70$)’, ‘Advanced directives should be composed in advance as it is important to state that I have an intention to discontinue life-long treatment ($Z = 1.50$)’ in order. The most disagreed statements in the 3rd type, on the other hand, were ‘I will not compose advanced directives because I want to receive all the available treatment until I take my last breath ($Z = -2.05$)’, ‘I think medical staffs will not be likely to cure sincerely if I compose advanced directives ($Z = -1.66$)’ in order. The strongly agreed statements compared to other types were ‘Even though a member of family is in a state where recovery is impossible, I want to do all the available medical treatment I can as a family’, ‘Since it is not up to me to decide whether I live or die, life should be kept to the end of my life’ in order, and they were not revealed in other types. The most strongly disagreed statements were ‘I will compose advanced directives because I think living with no consciousness is to live like a dead person in case of treating life-long treatment’, ‘People should live with their own will. It is meaningless to live with the help of machines’ in order.

5 subjects out of 37 in total belonged to the 3rd type, and they will compose advanced directives by themselves, however they basically objected to discontinuing life-long treatment. They think life is meaningful even with the help of machine unconsciously and human life should be maintained until the end of life that God has given. In other words, they think life exists in heaven. They will compose advanced directives for themselves; it means that they will be responsible for everything that might happen by family deciding to stop life-long treatment. So, this type can be called “Probably I will, But”

The common perspectives between types were ‘I will compose advanced directives because I do not think receiving life-long treatment is worth ($Z = 1.18$)’, ‘I will compose advanced directives in advance because it will be painful for the family to see the process of life-long treatment ($Z = 1.07$)’, ‘I cannot compose advanced directives because I have little medical knowledge or experience ($Z = -1.26$)’, ‘I will not compose advanced directives because I want to receive all the available treatment until I take my last breath ($Z = -1.82$)’, etc.

Discussion

The study was carried out to divide types for attitude on advanced directives targeting middle aged by using of Q methodology. The 1st type named ‘yes, in principle’ agreed to sign up advanced directives and disagreed life-long treatment. As just shown in the study [7] for middle aged adults 82.3% of the respondents agreed to draw up advanced directives, middle aged showed interest in them. In the study [7] 80.5% of the subjects would not have life-long treatment, showing that a lot of middle aged had the same thought like the 1st type. The respondents belonged to the 1st type reported that they need education programs at national level for decision making on life-long treatment. This was proved by the study [8] that after getting an education on advanced directives for seniors at the local community, efficacy score on the understanding of advanced directives and decision making has significantly improved. It is therefore considered drawing up advanced directives through educational programs making us end life, prepare death, and reflect on life.

The people belonged to the 2nd type absolutely agreed to sign up advanced directives and thought its decision should be made on their own. It needs to be distinguished the recognition of a patient’s right to die

from death as a result of exercising the right to self-determination on medical practice [9]. They also said they would sign up advanced directives for their family, which is the same as the study found that advanced directives reduce stress, anxiety, depression of the family after the patient dies [10]. This implies that we need to be more active in signing up advanced directives.

Respondents in the 3rd reported that while they would sign up for advanced directives for themselves, they would do the entire available medical cure for their family members even though they are in a state where recovery is impossible. This is the same result shown as in the study [11] saying they stop meaningless life-long treatment for themselves, but they cannot give up their parents’ treatment. They said they would compose advanced directive for themselves, not to feeling regret or guilty if their family decides to stop treatment. After all, it is the same context as the argument that it is common for guardians to make all decisions [12]. Therefore, it is necessary to provide a chance to prepare his or her death naturally by discussing and deciding with family members about his or her life-long treatment when in healthy.

Conclusion

As a consequent of this study, since adults have intentions for composing advanced directives commonly educational strategies suitable for life cycle and program development are required for right understanding on advanced directives. To have an education with the contents of keeping human dignity at the last period of life, requiring proper treatment and cure, hospice palliative care, the reflection of life and death will instill a positive consciousness on advanced directives. It also requires a change in understanding of death and accepting it in a natural way in making decision in advance. Therefore, it is desirable to have an education on preparing for death.

Effects of Smartphone Addiction on Radiology Students' Interpersonal Satisfaction

Yuxin Huang¹, Hong-Ryang Jung², Cheong-Hwan Lim²

¹Doctor, ²Professor, Dept. of Health Care, Hanseo University,
46 Hanseo 1-ro Haemimyeon Seosansi Chungcheongnamdo, 31962, Republic of Korea

Abstract

Background/Objectives: Although smart phone is known for its convenient functions and portability, it is also causing smart phone addiction which is becoming a serious social issue. The objective of this study was to determine the degree of smartphone dependence in university students majoring in radiology and analyze the influence of smartphone addition on their interpersonal relationships.

Method/Statistical Analysis: : A questionnaire was used to survey 431 university students about the use of smartphone. The questionnaire had 26 questions. Each question was evaluated with a 5-point Likert scale. Its Cronbach's α value was 0.893. Students' satisfaction for interpersonal relationship was determined according to their situation. Three additional socio-demographic characteristics (economic level, addiction, and gender) were also determined. Questions and answers were provided face-to-face.

Findings: Overreliance on smartphones was the highest in living standards with income at the "middle" level with 240 (55.64%) and female students at 184 (42.6%) in gender, higher than 247 (57.3%) for male students. In terms of interpersonal satisfaction, 247 (57.3%) male students showed high levels of satisfaction with each other's relationships, while in terms of smartphone overreliance, the group of people who are not satisfied (3.545 ± 0.34) showed high levels. Correlation analysis showed a static correlation between sex and smartphone over-dependence ($r = .217, p < .001$), and there was a negative correlation between smartphone and interpersonal satisfaction ($r = -.236, p < .001$).

Improvements/Applications: Based on results of this study, a program should be developed to prevent smartphone dependence of students and raise interpersonal satisfaction. Results of this study could be used as basic data necessary for education on smartphone dependence prevention in university students.

Keywords: *Smartphone, Smartphone addiction, Smartphone dependence, Radiology university student, Interpersonal satisfaction.*

Introduction

Smartphones not only have communication and internet functions due to rapid development of IT

technology and communication systems, but also make it easy and convenient to transcend time and space. They are revolutionizing life.

Unlike mobile phones, smartphones combine the functions of digital devices as well as texts and phones, allowing users to use various convenient functions such as information search, music, media, games, and learning. In addition, it is possible to have convenient access to information and networks without being influenced by time and place, but the convenient function and portability of such smartphones can cause negative phenomena such as addictive use of smartphones. Excessive use

e-mail: hrjung@hanseo.ac.kr

of smartphones by university students can be expected to cause significant obstacles in daily life as well as psychosocial problems^[1]. Smartphone overreliance can be considered an act addiction and there are no official diagnostic criteria for smartphone overreliance, so there is a mix of definition and classification.

Considering the trend in the spread and usage of smartphones, it is urgent to recognize and prevent dependence of smartphones^[2]. Smartphone dependence rate in university students has been reported to be 18.1%, more than three times higher than the rate (5%) in age groups of 40s and 50s^[3]. Recently, studies have been mainly focused on teenagers. There is a need to perform research on smartphone dependency in university students^[4].

Currently, smartphones are commonly used by university students in the information society. Smartphone is used as a tool for obtaining communication media and information in daily life. Unconsciously relying on smartphones while acquiring mutual information and information through smartphones can be said to be a trend of over-dependence symptoms and individualism.

Over-dependent use of smartphones can lead to interpersonal problems. Interpersonal relationship refers to the ability to interact effectively with others, including the formation and initiation of relationships with others, the assertion of one’s rights or displeasure, the opening of personal information, emotional support of others, and conflict management^[5]. Failure to form a smooth interpersonal relationship results in emotional isolation and reported correlation between smartphone over dependence and interpersonal satisfaction in order to understand the relationship between loneliness, anxiety and depression, which are side effects of smartphone overreliance caused by interpersonal related factors^[6].

In recent years, smartphone dependence in university students has been increasing. Various studies have been conducted on smartphone dependence of university students. However, researches on the identification of related factors of relationship satisfaction are insufficient. In previous studies, university students are stressed by personal characteristics, interpersonal relationships, study, and careers. They feel anxiety and confusion at the same time as they worry about employment, causing psychological problems^[7]. Most psychological problems are reported to arise from interpersonal satisfaction^[8]. Therefore, the objective of

this study was to determine the degree of smartphone dependence in university students majoring in radiology and analyze the influence of smartphone addition on their interpersonal relationships.

Method

- 1. Subject:** A questionnaire survey was performed to determine factors affecting interpersonal satisfaction on internet relations among Korean radiologists from March to July 2018. A total of 500 questionnaires were distributed and 431 (86.2%) copies were collected. Thus, the total number of subjects was 431 including 247 (57.3%) males and 184 (42.6%) females.
- 2. Method:** The questionnaire used in this study had 15 questions (Cronbach’s α value 0.899). It was developed by the Korea Information Technology Agency^[9]. Interpersonal satisfaction level was measured using the scale developed by Eun hyuk Ki (1999). The test of interpersonal relationship satisfaction was reconstructed according to university students’ condition. It had 26 items of “interpersonal satisfaction” (Cronbach’s α value of 0.893) evaluated with a 5-point Likert scale^[10]. The questionnaire was composed of three additional socio-demographic characteristics (economic level, addiction, and gender). Questions and answers were given face-to-face. For data analysis, frequency analysis and correlation analysis were performed using IBM SPSS Statistics version 23. Statistical significance level was set at $p < 0.05$.

Result

- 1. Smartphone Dependence and Interpersonal Relationship Satisfaction Level:** [Table 1] As a result of technical statistics to find out the level of dependency on smartphones and the level of interpersonal satisfaction, the level of interdependence on smartphones was 2.64 out of 5 points, and the level of interpersonal satisfaction was 3.56 out of 5 point.

Table 1. Smartphone Dependence Level and Interpersonal Relationship Satisfaction Level (N = 431)

Division	Average±SD
Addiction level	2.64±0.61
Interpersonal Satisfaction	3.56±0.53

2. Interpersonal Satisfaction According to Personal Characteristics, Dependence on Smartphone: [Table 2] According to personal characteristics, average difference analysis was performed to identify difference between Smartphone over dependence and interpersonal satisfaction. The

difference in smartphone over dependence was found to be 2.54 for males and 2.78 for females ($p < .001$), according to living standards, “Upper” is 2.78, “middle” is 2.56, “Lower” is 2.71, and there are statistically significant differences ($p < .001$).

Table 2. Difference in smartphone addiction according to personal characteristics (N = 431)

Personal Characteristics		Smartphone Addiction		t/F value	p-value
		N	M±SD		
Gender	Male Student	247	2.54±0.62	-4.16**	0.000
	Female Student	184	2.78±0.58		
Level of Living	Lower	97	2.71±0.66	4.99**	0.007
	Middle	240	2.56±0.57		
	Upper	94	2.78±0.65		

* $p < .05$, ** $p < .001$

[Table 3] Regarding the level of interpersonal satisfaction, it was 3.61 for male students and 3.50 for female students, showing statistically significant difference between the two ($p < .05$).

Table 3. Regarding the level of interpersonal satisfaction (N = 431)

Personal characteristics		Smartphone addiction		t/F value	p-value
		N	M±SD		
Gender	Male student	247	3.61±0.57	2.03*	0.043
	Female student	184	3.50±0.47		
Level of living	Lower	97	3.59±0.54	2.17	0.115
	Middle	240	3.59±0.53		
	Upper	94	3.46±0.50		

* $p < .05$

3. Interpersonal Satisfaction Differences Depending on Smartphone Dependence: [Table 4] The t-test was performed to find out the difference in the interpersonal satisfaction level according to the dependency on the smartphone. Smartphone over dependence was 225, interpersonal satisfaction was 3.323, aesthetic dependence was 206, interpersonal satisfaction was 3.545, aesthetic dependence was high, and there was a statistically significant difference between the two groups ($p < .001$).

Table 4. Difference in self-control according to whether or not a smartphone is addictive (N = 431)

Division		Smartphone addiction		t/F value	p-value
		N	M±SD		
Addiction	Addiction	225	3.323±0.31	46.06***	0.001
	Non-addiction	206	3.545±0.34		

*** $p < .001$

4. Relationship between smartphone dependency and interpersonal satisfaction: [Table 5] A correlation analysis was conducted to examine the relationship between gender, economic level, smartphone dependence, and interpersonal satisfaction. There was a positive correlation between gender and smartphone dependence ($r = .217$, $p < .001$). Correlation was shown.

Table 5. Relationship between smartphone addiction and self-control (N = 431)

	Gender	Level of living	Smartphone addiction	Self-control
Gender	1			
Level of living	.007	1		
Smartphone addiction	.217***	-.027	1	
Self-control	-.083	-.018	-.236***	1

***p<.001

Discussion

Each country of the Organization for Economic Cooperation and Development stresses the role of the middle course that leads to a job after graduating from a university. In these days, smartphone over dependence and interpersonal relationships are the most important period as university students are developed into later adolescence as there is a growing interest and policy regarding smartphone overreliance on university students.

Existing literatures on smartphones have focused on university students, adolescents, and adults. Many studies have been conducted in Korea. This study examined smartphone dependency and interpersonal relationship satisfaction among university students majoring in radiology. Korean students are using SNS, UCC, Kakao Talk, and BAND applications without using face-to-face interactions. Griffiths (1995) has suggested that interpersonal satisfaction is a variable that has a significant effect on smartphone dependence. Therefore, the purpose of this study was to investigate the importance of interpersonal relations in university life and society by grasping the relationship between satisfaction of interpersonal relations and dependence of smartphones of university students majoring in radiology.

Kim Choon-kyung (1991) reported the result of her research that her relationship is weak because she spends a lot of time playing games using her smartphone and lacks time to hang out with her friends. Kang Yeon-dal (2010) has shown that the higher the level of smartphone game addiction, the higher the anxiety of interpersonal relations. Park Ji-hyun (2017) has shown that the relationship between university students' anxiety and smartphone dependence is the same as the result between smartphone dependency and interpersonal satisfaction.

In the study of Kim Nam-sun (2012), female university students showed higher scores for smartphone dependence than male university students^[11]. Syu (2010) has also compared men and women in smartphone use and found that females use smartphones and download applications more often than men. In the present study, female students also had higher smartphone dependence than male students, consistent with results of previous studies.

University students are stressed by their new life after completing high school, such as completing credits, learning majors, relationships, careers, and employment (Baek, Hye-young et al., 2016). It has been shown to act dependently^[12]. This interdependent behavior is related to interpersonal ability and smartphone dependence. It has been shown that interpersonal ability and smartphone dependence have a negative correlation^[13].

In the relationship between smartphone over dependence and interpersonal satisfaction, Kim Sa-ri (2002) has shown a significant correlation between interpersonal satisfaction and smartphone dependence^[14,15]. Results of the present study showed that interpersonal satisfaction was low in university students, consistent with results of previous studies. In addition, the higher the smartphone dependency, the lower the interpersonal satisfaction, resulting in inadequate correlation.

When university students become radiographers and come into contact with many people, they should always be wary that they can become addicted by adjusting their use of smartphones on their own to ensure proper interpersonal relationships.

Conclusion

This study analyzed the factors affecting the interpersonal satisfaction level according to the dependency of smartphones.

First, the level of dependency on smartphones was 2.64, and interpersonal satisfaction was 3.56. The female students showed high dependence on smartphones, and the level of living was high in the “medium”.

Second, interpersonal satisfaction was found to be high among male students, and high degree of dependency on smartphone aesthetics.

Third, the correlation analysis showed a positive correlation between gender and smartphone dependence, and there was a negative correlation between smartphone and interpersonal satisfaction.

This study grasped the degree of dependence on smartphones among university students in radiology, analyzed the effect of smartphone dependence on interpersonal satisfaction, and suggested ways to satisfy interpersonal relationship in smartphone use of all university students in the future. Results of this study could be used as basic data for education on smartphone dependence prevention in university students.

Effects of Cognitive Exercise Therapy on Tactile Sensations of the Hands and Activities of Daily Living in Stroke Patients

Jong-Hoon Moon¹, Jin-Hwa Jung², Hwi-Young Cho³

¹Professor, Department of Occupational Therapy, Kyungdong University, ²Professor, Department of Occupational Therapy, Semyung University, ³Professor, Department of Physical Therapy, Gachon University, Republic of Korea

Abstract

Background/Objectives: The aim of present study was to evaluate the effects of cognitive exercise therapy (CET) on tactile sensations of the hands and activities of daily living in stroke patients.

Method/Statistical Analysis: A total of 14 stroke patients with impaired hand sensations were participated and were randomly assigned to the CET group or the traditional occupational therapy (TOT) group. Patients in the CET group performed cognitive tasks using their spatial and tactile senses, whereas those in the TOT group received traditional occupational therapy. The intervention periods of the two groups were 30 min per day, five-times per week for four weeks. All participations were assessed before and after intervention with light touch sensation using the Mono-Filament, two-point discrimination sensation using the Disk-Criminator (static and dynamic tactile sensations), and the modified Barthel index (MBI) for activities of daily living ability.

Findings: The CET group appeared significant improvements in static and dynamic two-point discrimination, and the MBI before and after the intervention. Also, the TOT group showed a significant improvement in MBI after intervention. At post-test, the CET group showed significant improvements in two-point discrimination and light touch compared to the TOT group.

Improvements/Applications: These findings suggest that CET can induce improvement of the tactile sensations of the hands in stroke patients. Thus, we suggest that CET can be used for tactile-sensory rehabilitation of patients with stroke in clinic.

Keywords: *Cognitive exercise therapy, Hand, Activities of daily living, Stroke, Tactile sensation.*

Introduction

Stroke is the most common central nervous system disorder in the Republic of Korea as well as the world, and it causes neurological problems in the sensory, motor, mental, perceptual, and speech functions^[1]. More

than 85% of patients with stroke experience hemiplegia, and over 69% have upper extremity motor function impairment^[2]. Post-stroke dysfunctions of the upper extremities cause significant problems with functional movement in performing the independent activities of the daily life, such as feeding and self-care^[3]. The incidence of decreased sensory function after stroke is up to 65%^[4]. As patients with stroke with sensory deficits show limitations in movement and performance of functional tasks, treatments for motor and sensory functions of the upper extremities are important in rehabilitation^[5].

In the past, using simple objects such as cups, cones,

and a pegboard, therapeutic exercise was performed to enhance motor and sensory functions. Recently, however, more diverse therapeutic intervention methods have been used to improve the upper limb function of stroke patients in clinics. According to previous researches, the treatment of constraint-induced movement therapy (CIMT)^[6], virtual reality^[7], and robot-assisted therapy have a positive effect in the upper extremity functions in stroke patients^[8]. However, constraint-induced movement therapy requires 5 hours of intense training per day^[6], while virtual reality and robot-assisted therapy are expensive and have space constraints^[7-8]. Therefore, these limitations make it difficult to conduct the interventions in the clinics, and an effective intervention that overcomes these limitations is required.

Cognitive exercise therapy (CET) was designed by Carlo Perfetti in Italy at 1979. It is closely associated with the reorganization of the central nervous system and is a remedial approach based on learning theory^[9]. In other words, the treatment is based on learning theory and restores body damage through cognitive processes (perception, attention, memory, judgment, and language). This cognitive process can induce a change in the brain neuronal plasticity^[10]. Thus, CET has been used for disorders with emotional and/or psychiatric problems in the clinic and the researches.

CET has been actively studied in the Republic of Korea but mostly in case studies and not through sufficient experimental research. Recently, Lee et al.^[11] examined the effect of CET and task-oriented training on the upper limb functions in stroke patients, and reported a larger improvement in the upper extremity functions with CET compared to that with task-oriented training. However, this study as well as other studies did not identify the effect of CET on sensory functions especially the hands, in stroke patients.

The aim of this study investigated the effects of CET on tactile sensations of the hands and activities of daily living (ADL) in patients with stroke.

Method

Present study was performed on 14 individuals with chronic stroke who were admitted in a rehabilitation unit located in Seoul, Korea. The inclusion criteria were: 1) clinically diagnosed stroke; 2) more than 6 months of stroke onset; 3) a manual muscle testing (MMT) sensitivity of 6.65 mm (monofilament) or less; and 5)

a Mini-Mental State Examination (MMSE) score of 24 or more. The exclusion criteria were: 1) visual spatial neglect or visual impairment; and 2) severe spasticity. The subjects participating in the study provided written informed consent. The study was approved by the Gachon University Institutional Review Board (approval number: 1044396-201708-HR-137-01). Also, present study is in accordance with the Declaration of Helsinki.

Sensory tests were performed to evaluate the tactile sensations in the hands of the subjects, and the modified Barthel index (MBI) was used to assess an activities of daily living. All outcome tests were performed under blinded condition by one occupational therapist with minimum 3 years of clinical experience. To conduct accurate measurements, the measurer was trained and checked on the measurement method used in this study one week before the test.

We used the Semmes-Weinstein monofilament (Baseline, USA) to measure the minimum threshold at which the subject felt light touch of the hand^[12]. This monofilament consists of different diameters and degree of stiffness. Stimulus was applied to the hands with the perpendicular to skin until the filament was slightly bent. The threshold was measured by repeating the stimulation of the index finger of the paretic hand thrice, until the filament bent at the site for 1.5 seconds^[13].

To measure the two-point discrimination sense, the Dellon 2-Pint Disk-Criminator (Baseline, USA) was used^[14]. Static and dynamic tests were performed. The dynamic test provided stimulation to the proximal part of the distal side of the index finger of the paretic hand, and the static test was performed by taking a point^[15].

MBI was used to assess the level of the activities of daily living for stroke patients or other patients with neurological problems. This method has 10 categories, and was measured as 0 at complete dependence and 100 at independence of activities of daily living. The intra-rater reliability of the MBI is $r = .89$ and the inter-rater reliability is $r = .95$ ^[16].

The 14 subjects were randomly assigned to the CET group or traditional occupational therapy (TOT) group after they met the inclusion criteria. Tests were performed in both groups for 30 min/day, 5 times a week, for 4 weeks.

Patients in the CET group performed cognitive tasks using their spatial sense and tactile sense based on the

protocol used in a previous study^[11]. In the cognitive tasks using spatial senses, an occupational therapist covered the subject’s eye and subsequently moved the subject’s arm passively along the circle drawn on the task board. The size of the circle was identified. The subjects verbally expressed their feelings toward recognizing the differences. Cognitive tasks using tactile senses were performed by the subjects using their hands. Subsequently, an occupational therapist pressed various sponges of varying hardness on the subject’s hands. Subjects were masked and made aware of the hardness of the sponge. Further, subjects identified the hardness of the sponge being pressed on their hands. Subjects were asked to express their feelings verbally while recognizing differences in the sense of pressure. Occupational therapist performed therapeutic intervention without knowing which group the subject belong to. Patients in the TOT group performed a passive or an active range of motion exercises of the upper extremity, using an incline board, stacking cone, ring, pegboard, and putty for improvement in their fine motor and upper extremity functions after stroke.

The Statistical Package of the Social Sciences (SPSS) version 23.0 was used for the statistical analyses. The Wilcoxon signed-rank test was performed to compare the dependent variables within each group before and after intervention. The Mann–Whitney U test used to compare differences in the dependent variables between the groups. A p-value < .05 was considered statistically significant.

Result and Discussion

1. General Characteristics: The general characteristics did not differ between the groups (p>.05) [Table 1]. Also, there were no significant differences between the groups in light touch, static or dynamic two-point discrimination, and MBI before intervention (p>.05) [Table 2].

Table 1. General characteristics

	CET group (n = 7)	TOTgroup (n = 7)	P
Age (Year), mean±SD	57.57±5.83	59.43±8.72	.665
Gender, n(%)			.593
Male	3 (42.9)	4 (57.1)	
Female	4 (57.1)	3 (42.9)

Table 2. Comparison of tactile sensory and activities of daily living before intervention

	CET group (n = 7)	TOT group (n = 7)	P
	Mean±SD	Mean±SD	
LT (g)	3.50±0.57	3.66±0.62	.646
TPDs (g)	10.43±3.15	10.00±2.83	.747
TPDd (g)	11.29±3.04	11.00±2.31	.897
MBI (score)	85.71±5.50	86.57±5.86	.699

Footnotes. CET: cognitive exercise therapy, TOT:traditional occupational therapy, LT: light touch, TPDs: two point discrimination (static), TPDd: two point discrimination (dynamic), MBI: modified Barthel index, SD: standard deviation.

- 2. Comparison of tactile sensations and activities of daily living:** The CET group showed significant improvements in static and dynamic two-point discriminations and MBI before and after intervention (p<.05), but no significant improvement in light touch (p>.05). The TOT group showed significant improvement in MBI before and after intervention (p<.05), but no significant improvement in light touch or static or dynamic two-point discrimination (p>.05) [Table 3].
- 3. Change score for tactile sensory and activities of daily living between two groups:** After intervention, the CET group had a significantly greater improvement in light touch and dynamic two-point discrimination than the TOT group based on the change in scores (p<.05). Static two-point discrimination and MBI showed no significant differences between the groups (p<.05) [Table 4].

Discussion

Previous CET studies were conducted mainly in the Republic of Korea. To date, the research on CET or its effect on sensory functions was not insufficient. In

addition, since most previous studies were conducted as the case studies or not as the randomized controlled trial (RCT), there are limitations that make it difficult to clearly demonstrate the effects of CET.

Results of this study showed that the CET group had significantly improved static and dynamic two-point discrimination sensation and MBI before and after intervention, while the TOT group showed significant improvement only in MBI. After intervention, the CET group had significantly greater improvement in light touch and dynamic two-point discrimination than the TOT group.

The CET group showed significant improvement in light touch and dynamic two-point discrimination

of hands than the TOT group. In Van de Winckel et al.'s functional magnetic resonance imaging study, cognitive tasks using spatial and tactile senses applied in CET activated the premotor cortex areas closely associated with hand functions^[10]. This result supports the improvement in sensory functions of the hand in this study. The recovery of upper extremity and hand functions is the slowest recovery after stroke, and control of hand movement must include grasp and prehensile activity for the activities of daily living^[17]. Lee et al. found that CET had a greater effect on the improvement of upper extremity function compared to TOT^[11]. However, our study did not assess upper extremity or hand function.

TPDs (g)	-1.00±0.82	-0.29±0.49	.080
TPDd (g)	-0.71±0.49	-0.14±0.38	.037*
MBI (score)	2.00±0.58	2.29±1.50	.632

Footnotes. *p<0.05 CET: cognitive exercise therapy, TOT:traditional occupational therapy, LT: light touch, TPDs: two point discrimination (static), TPDd: two point discrimination (dynamic), MBI: modified Barthel index, SD: standard deviation.

There was no significant difference between the two groups. The interpretation of these results can be explained in three ways. First, there is a possibility that the results are not clear because the sample size is

small. Second, there is a possibility that CET will not be effective in improvement of activities of daily living. Third, we measured the evaluation of activities of daily living using MBI. The subcategories of MBI have more evaluation items for the lower extremity functions, such as gait, than for the upper extremity functions. Therefore, there is a possibility that it was difficult to confirm the improvement of the upper extremity functions.

The limitations of this study are as follows. First, the sample size was small. Therefore, it may be difficult to generalize the findings to population with stroke. Second, we performed only a relatively short period of intervention with four weeks of treatment. Third, we did not confirm the sustained effect of treatment. Finally, we did not evaluate proprioception or motions of the hands. In order to verify the effect of CET, one should check whether there is an improvement in motion or proprioception.

Conclusion

In conclusion, these findings suggest that CET can induce improvements in the tactile sensations of the hands in patients with stroke better than TOT. However, further studies with more subjects. In addition, it is necessary to study whether it is effective in improving the upper limb functions as well as sensory functions. In further studies, more patients should be included for long-term effects, and randomized controlled trial is required.

Effects of Voice Quality Improvement Program for Professional Voice Users with Functional Voice Disorders

Jingren Wang¹, Hyunju Park²

¹Adjunct Professor, Hansei University, Department of Performing-Art, ²Assistant Professor, Gachon University, Department of Language Pathology, South-Korea

Abstract

Background/Objectives: One of the most emphasized aspects in voice therapy is voice quality. We investigated the effect of our intervention program on improving voice quality and reducing vocal fatigue.

Method/Statistical Analysis: 10 musical actors/actresses with functional voice disorders were given eight training sessions once a week, and both subjective and objective evaluations of their voices were conducted before and after the training. K-SVHI and VFI were used to measure voice handicap index and voice fatigue index. Praat was used to measure the objective acoustic indices. To examine the statistical significance, a paired sample *t*-test was performed.

Findings: The result of subjective voice quality evaluation showed that both scores of voice handicap index and voice fatigue index were decreased. The objective voice evaluation results showed that the jitter (%) and shimmer(%) scores decreased while the harmonics to noise ratio (HNR) and the speaking fundamental frequency (SF0) scores increased. The lower the jitter and shimmer, the better the quality of voice, while the higher the HNR, the better the quality of voice. The difference between pretest and posttest scores was statistically significant except for the SF0. The reason for small changes in the SF0 seems to be that all participants of musical actor/actresses who skillfully use the voice were able to control their voice to maintain the frequency at a certain level.

Improvements/Applications: Our findings indicate that patients with functional voice disorders have problems ways to use their voice and showed that their voice quality and vocal fatigue can be improved by modifying and training four stages of voice production.

Keywords: *Functional Voice Disorders, Professional Voice Users, Voice Quality, Vocal Fatigue Index (VFI).*

Introduction

Professional voice users are a group of people who use a voice to maintain their jobs, including singers, actors, teachers, and salesmen etc.^[1]. They are interested in ways to preserve voice quality at high risk of being exposed to voice disorders. Musical actors/actresses among professional voice users are highly advanced

artists because they have to digest both theatrical and musical elements, produce short-term intensive voice and imitate the voices of various characters. In the process of playing their role, they are accompanied by muscle tension dysphonia due to incorrect posture, inefficient respiration, excessive muscle tension, and incomplete obstruction of the vocal folds and frequently exposed to functional voice disorders such as vocal nodule, Reinke's edema, and vocal polyp, as well as experiencing voice fatigue^[2]. Functional voice disorders are caused by the misuse and abuse of voice, not by organic or neurological reasons, and are a type of voice disorders that clinicians can easily recognize because they can visualize the larynx structure and function^[3].

In order to properly assess voice disorders, objective measurements using voice analysis devices are necessary. However, according to the previous research, there may be less correlation between the expert’s objective evaluation of the voice quality and the voice user who perceives it when the voice quality is degraded^[4]. This is supported by the fact that there are many patients who seek an otolaryngologist with a complaint of globus sensation even in the absence of specific voice disorders^[6]. In order to properly evaluate voice disorders and to grasp treatment outcomes, not only objective evaluation but also subjective evaluation of voice users should be considered^[5,7,8]. Functional voice disorders aim primarily at correcting improper use of voice, not surgeries or medical interventions to restore normal phonation function, and direct treatment is known to be more effective in improving voice quality than indirect treatment^[9].

This study was to look at the results of subjective evaluation and objective examination after providing intervention through a series of voice quality improvement program designed by the researchers for professional voice users with functional voice disorders. To this end, we set up the following research questions. First, are there any significant differences in the voice disorder index and the vocal fatigue index before and after applying the voice quality improvement program? Second, are there any significant differences in the acoustic indices (SF0, jitter, shimmer, HNR) before and after applying the voice quality improvement program?

Method

The participants of this study were 10 musical actors/actresses living in Seoul and Gyeonggi area. They were all diagnosed with functional voice disorders by an otolaryngologist, and the specific types of voice disorders can be found in [Table 1]. The age ranged from 19 to 29 years with an average of 24, and the musical actors/actresses’ careers ranged from five months to seven years and six months variously.

Table 1. Information of participants

Sex	Age (Year)	Career (Year)	Type of Voice Disorders
Male	29	1.5	Muscle tension dysphonia
	19	2.5	Vocal nodule
	20	0.5	Chronic edema
	26	2.0	Chronic edema
	23	4.7	Vocal nodule

Sex	Age (Year)	Career (Year)	Type of Voice Disorders
Female	25	7.6	Irregular vocal cords mucous membrane
	25	4.8	Vocal nodule
	24	1.0	Vocal nodule
	24	6.5	Vocal nodule
	24	5.5	Vocal nodule

The data collection took about three months from June 11 to September 13, 2018. The orientation and the pre evaluation were conducted for all participants prior to proceeding with the intervention program. The program was implemented a total of 8 sessions for 60 minutes once a week. One week after the end of the program, the post evaluation for all of them was conducted. The specific research progress is as follows.

1. Developing and implementing the program: In

order to improve the voice quality of the participants, it was necessary to correct erroneous voice production ways and train vocalization according to the voice production principle. Only by approaching the fundamental problem of the interaction and movement of highly complex vocal organs can solve the inveterate problem of voice quality properly. Therefore, we divided into four steps such as posture, respiration, vocal folds contact, and voice quality based on the order of voice production, and then in order to improve the function of each step, a five-step voice quality improvement program was developed and applied to all participants as follows.

Step 1: Since the posture of the singer necessarily affects the respiratory function, the posture correction was performed during singing. Leaning against the wall, the head, shoulders and hips were attached to the wall, and the ears, shoulders and pelvis were aligned in a straight line when viewed from the side, and the jaws was pulled in the direction of the body so that the head was not bowed down.

Step 2: The degree of improvement of respiratory function was identified by implementing the respiratory measurements using simple instruments for measuring inspiratory capacity such as Medline’s Incentive Spirometer – 4,000ml Capacity and One-Way Valve so that the subject was able to recognize the respiratory function and participate actively in the training.

Step 3: If the respiratory function was judged to be degraded, Ultrabreathe (Tangent Healthcare, Ltd.) was

used to train the muscles involved in respiration. After the abdominal was inflated for effective movement of the diaphragm, it was directed to show the movement of the thorax.

Step 4: Hypofunctional voice disorders is characterized by disappearing vibration or stiffness of the vocal folds and by widening glottis chink. Therefore, vocal folds contact training such as vocalization was performed using a wooden tongue depressor to induce smooth and proper vocal folds contact and respiratory support. The vowels were induced to phonate correctly by snapping the wood tongue depressor with the teeth.

Step 5: As a way to improve acoustic characteristics and induce the right singing which is an important factor in voice quality, five steps were trained in sequence, such as Semi-Occluded Vocal Tract Exercises, SOVTEs to descend the larynx position and the opening of the throat which increased the voice quality by adjusting the length and width of the resonance cavity^[10]. SOVTEs used voiced consonant [v], [z], nasal consonant [m], [n], [ŋ], rounded vowel [o], [u], lip trill and tongue trill to close a part of the vocal tract, while the rest was relaxed by using physiological phenomenon such as yawn/sigh and was done by expanding the cross-sectional area of the resonance cavity. At this time, it was required to parallel to vocal folds contact training.

Figure 1. An Example of SOVTEs

2. Evaluation of voice quality

1. Subjective voice quality evaluation:

Subjective voice evaluation used two tools. First, The Korean Version of the Singing Voice

Handicap Index (K-SVHI)^[11] is a subjective evaluation that measures the effects of voice disorders on the quality of life in people such as singers who using voice. This tool has a total of 36 questions and is intended to assess the degree of effects on physical, emotional, economic and social areas with a five-point scale. Next the Vocal Fatigue Index (VFI)^[12] is used to assess the degree of vocal fatigue of participants felt. This tool has a total of 19 questions and consists of three parts. That is, it is divided into 11 questions related to the degree of vocal fatigue and avoidance of voice use, 5 questions related to physical discomfort due to vocal fatigue, and 3 questions related to improvement of symptom due to rest after voice use. VFI is also on a five-point scale.

Subjective voice evaluation allowed the participants to rate after reading the questions themselves. The reliability of the pre evaluation was measured by re-evaluating all participants two times before the intervention program. Although the tools had the same 5-point scale from 0 to 4, the total number of questions was different. So the first author summed these scores and converted them into percentages to measure the reliability of the pre evaluation as the difference between the two evaluations. As a result of it, the percentage error value of the total score of K-SVHI was 3.337% and the percentage error value of the VFI was 5.657%, indicating that the reliability of the pre evaluation data was high. Therefore, the first test data were used to compare with the post test data, in order to exclude the familiarity due to retest.

2. Objective voice quality evaluation: In this study, computer-based Praat (v.6.0.33) was used as the objective voice evaluation tool. The acoustic indices of interest to the authors were jitter(%), shimmer(%), harmonic to noise ratio(HNR, dB), and speaking fundamental frequency (SF0) which are commonly used in the objective voice evaluation^[4]. Jitter and shimmer are acoustic indexes mainly examining the stability of voice. Jitter shows the pitch, that is, irregularity in the frequency of voice production, and shimmer shows the loudness, that is, irregularity in the intensity of

voice production^[13]. It is used to objectively measure the periodicity of vocal folds vibration and to observe the presence or absence of voice disorders, severity, voice quality, and voice change of patients^[4,13]. HNR is an index of how much noise is mixed in a voice and is especially important when evaluating hoarse voices. To obtain these quantitative data, the first author recorded it by allowing the participants to phonate three times a/vowel for at least five seconds and analyzed the length of 1.5 seconds of it. In addition, since SF0 needs to get the mean value of the speaking frequency, the researcher made the subjects read the extracts from the first part of the ‘A Fall Admiration’ paragraph which is often used in voice evaluation and recorded the best results to analyze it^[14]. The microphone used was Supe Uni-Directional Condenser Microphone (320E) and the subjects were examined at a 45-degree angle while keeping the distance between the subjects and the microphone at 30cm in a closed room without noise.

- 3. Statistical processing:** To examine whether our program was effective for the participants, the improvement of the subjective voice quality or not was compared by pre-post K-SVHI score and VFI score and the improvement of the objective voice quality or not was compared with pre and post values for jitter, shimmer, HNR, and SF0. Statistical verification was implemented by paired sample *t*-test using Statistical Package for Social Sciences (SPSS, version 25), the mean and standard deviation (SD) of each result were compared and the significance level was set to 1%.

Results and Discussion

The result of the subjective evaluation after applying the intervention program showed that both K-SVHI score and VFI score were decreased. Both evaluations mean higher score is that the degree feeling the problem about their voice is worse and lower score is that the degree feeling the problem about their voice is less. As shown in [Table 2], the two evaluation scores were significantly lower than before applying the program and the difference between the pre and post scores was also statistically significant[K-SVHI ($t = 4.05, p < .01$), VFI ($t = 3.99, p < .01$)]. This means that the program has improved the voice problems and vocal fatigue of participants

Table 2. T-test results for subject evaluation score differences (N = 10)

Index	Pre/ post-	Score	Mean	SD	<i>t</i>
K-SVHI	Pre-	70.20	39.20	30.59	4.05 **
	Post-	31.00			
VFI	Pre-	35.60	16.20	12.86	3.99**
	Post-	19.40			

** $p < .01$

The objective evaluation results after applying the program showed that SF0 and HNR were higher than before applying the intervention program, and the jitter and the shimmer were lower than before applying the intervention program [Table 3]. The higher the HNR, the better the quality of voice, while the lower the jitter and shimmer, the better the quality of voice. As a result of statistically verifying the difference of pre and post test scores, SF0 did not show statistically significant difference, but jitter, shimmer and HNR showed statistically significant difference[sF0($t = -1.39, p > .01$), jitter ($t = 4.06, p < .01$), shimmer ($t = 4.26, p < .01$), HNR ($t = -4.96, p < .01$)]. This means that the voice quality of the participants has been objectively improved. However, it seems that there was no significant difference in SF0 to be due to intentionally maintaining a constant speaking fundamental frequency in the test before and after intervention because the participants were musical actors with relatively good voice control ability.

Table 3. T-test results for objective evaluation score differences (N = 10)

Index	Pre/ post-	Total score	Mean	SD	<i>t</i>
SF0	Pre-	165.48	-3.17	7.25	-1.39
	Post-	168.65			
Jitter (%)	Pre-	0.45	0.02	0.02	4.06**
	Post-	0.22			
Shimmer (%)	Pre-	4.06	2.14	1.59	4.26**
	Post-	1.92			
HNR (dB)	Pre-	17.91	- 5.88	3.75	-4.96**
	Post-	23.79			

** $p < .01$

Conclusion

The results of this study show that voice quality can be improved by modifying and training the existing inappropriate voice production method at each stage such as respiration, phonation, resonance, and articulation. In

particular, our program was designed to be easily used by anyone. K-SVHI and VFI as subjective evaluation tools and Praat as objective evaluation tools, are easy to download and use online and directions are also simple. Just as you adjust and train your lifestyle according to specific and efficient programs for your physical beauty or strength, naturally repeating the procedure presented in this study to daily life will be an appropriate training method to improve or maintain quality of voice.

Our study involved patients with various medical diagnoses, and our program has been shown to be effective for all of them, regardless of their cause or type. However, further research is needed since the difference in effects by the type of medical diagnosis was not identified due to the small number of participants. This study is meaningful to show that the voice quality of functional voice disorder patients can be improved by training the control ability of vocal organs through the program combined with classical vocal music phonation.

The Study of the Correlation between Cognition Function and Quality of Sleep in the Elderly

Ju-Young Park¹, Yeong-Ae Yang²

¹Professor, Department of Occupational Therapy, Dong-Ju College, Korea, ²Dept of Occupational Therapy, College of Biomedical Engineering, Inje University; Institute of Aged Life Redesign, Inje University, Korea

Abstract

Background/Objectives: Sleep function affects human health, Recently, studies on various variables affecting mental health management and cognitive function of elderly people are being actively conducted due to the increase of elderly population. The purpose of this study was to investigate the correlation between cognitive function and quality of sleep in the elderly.

Method/Statistical Analysis: The participation was 33 normal elders over 65-year-old. Cognition function was evaluated with the Montreal Cognitive Assessment (MoCA), and quality of sleep was evaluated with sleep Scale A. The data were then analyzed for frequency and correlation by using statistical software (SPSS 21.0).

Findings: The average age of the study subjects was 82.4 years. The average MoCA score was 17.1 ± 3.8 and sleep scale A score was 29.6 ± 8.9 . The results of MoCA and sleep scale A showed a positive correlation ($r = .417, p < .05$).

Improvements/Applications: The results of the study show that the lower the quality of sleep in the elderly, the lower the cognitive function. The results of this study will discuss whether sleep quality can be used to predict mental health in older adults.

Keywords: MoCA, Sleep Scale A, Elderly, Cognition, Correlation.

Introduction

Sleep affects various factors in human health. Sleeping an average of 7 hours a night, average sleep quality was better related to health, affect balance, satisfaction with life, and feelings of tension, depression, anger, fatigue, and confusion than average sleep quantity^[1]. Sleep disorders in the elderly are a common problem, show various symptoms such as difficulty sleeping and maintaining sleep, frequent arousal,

frequent use of sleeping drug, and excessive daytime sleepiness^[2].

In the study of factors affecting the quality of sleep of the elderly in the community, there were significant differences in sleep quality between income, exercise time, and subjective health and higher the depression, the lower the quality of sleep^[3]. As the elderly population increases, studies on various variables affecting mental health management and cognitive function of the elderly are being actively conducted. The analysis of factors related to mental health of the elderly showed that the higher quality of life, the less stress, depression, and suicidal thoughts^[4].

Changes in cognitive function in old age vary from person to person, but Changes in cognitive function according to the normal aging process and disease of dementia are important social issues. Recently, studies

Corresponding Author:

Professor, Department of Occupational Therapy,
College of Biomedical Science and Engineering, Inje
University, Korea

e-mail: yya6853@hanmail.net

on the correlation between cognitive decline and sleep in the elderly have been actively conducted. However, the majority of studies have been conducted on subjects that show decreased cognitive function, such as dementia^[5-7].

We recognized the need for the study of the correlation between cognitive function and sleep quality in normal elderly people. The purpose of this study was to evaluate MOCA and sleep scale A of normal elderly, to measure cognitive function and sleep quality, and to investigate the relationship between cognitive function and sleep quality.

Method

This study is correlation study. The purpose of this study is to investigate the cognitive function and sleep quality of the elderly, to identify the correlation between cognitive function and sleep quality.

This study surveyed 40 elderly people over 65 years old. The subjects is normal elderly who performed independent activity of daily living (ADL), not have impaired hand function due to past medical history. The subjects of this study are as follows. Those who understand the purpose of this study, agree to participate, and respond appropriately to the evaluation items. We visited the senior welfare center, explained the evaluation tool and the purpose of the study to the facility manager, and received permission and cooperation to proceed with the research.

The Montreal Cognitive Assessment (MoCA) is an assessment tool developed to screen patients with mild cognitive impairment (MCI). The assessment takes 10 minutes and is a 30-point cognitive screening test. Evaluation items are as follows; Visuospatial/executive, naming, memory, attention, language, abstraction, delayed recall, orientation. MoCA is a screening tool useful for detecting mild dementia or MCI in subjects with a score of 25 or higher on the Mini-Mental State Examination (MMSE).The use of this assessment tool can identify older people at risk of developing dementia in older people who have been diagnosed with MCI^[8-9].

The Sleep Scale A is a questionnaire consisting of 15 questions to measure the quality of sleep. Available for all age groups, each question describes symptoms of sleep quality. The details of the question are whether it takes long to fall asleep or sleepy after waking up in the morning. The response consists of a Likert 4 point

scale, ranging from 1 point is ‘almost always’ to 4 point is ‘almost never’. The score is a minimum of 15 and a maximum of 60, which means that the higher the score, the higher the quality of sleep. Cronbach’s α is 0.75^[10].

In this study, 7 of the 40 responses were excluded from insufficient data and 33 data were analyzed. SPSS 21.0 Version program was used, and the general characteristics of the subjects, MoCA, and the quality of sleep were used descriptive statistics. The correlation between MoCA and sleep quality was analyzed by Pearson’s Correlation Coefficients.

Result and Discussion

- 1. General characteristics of the subjects:** The general characteristics of the study subjects are as follows. 45.5% were male and 54.5% were female. The most common age group was 80 years of age and older (60.6%). In the past year, 66.7% of patients visited the hospital, 27.9% of the subjects had arthritis. 84.8% subjects did not smoke and 75.8% did not drink alcohol[Table 1].
- 2. MoCA and sleep scale A score of participants:** The MoCA and sleep scale A scores of the participant were as follows. The average score of cognitive function was 17.1±3.8, and the quality of sleep was 29.6±8.9[Table 2].

Table 1. General characteristics of participants (N = 33)

Characteristic	Categories	N(%)
Gender	Male	15(45.5)
	Female	18(54.5)
Age	70-74	6(18.2)
	75-79	7(21.2)
	More than 80	20(60.6)
Diseases	No	12(36.4)
	Arthritis	9(27.3)
	HTN	3(9.1)
	Diabetes	2(6.0)
	Heart disease etc	1(3.0) 6(18.2)
Smoking	No	28(84.8)
	yes	5(15.2)
Drinking	No	25(75.8)
	yes	8(24.2)

Table 2. MoCA and sleep scale A score of participants (N = 33)

Categories	M±SD
MoCA	17.1±3.8
Sleep scale A	29.6±8.9

The differences of cognitive function and sleep quality according to smoking and drinking were examined. First, the difference of cognitive function and sleep quality according to smoking status was checked. The non-smoking group had higher sleep quality score than the smoking group, but there was no significant difference. On the other hand, the smoking group showed a higher cognitive function score than the non-smoking group, but there was no significant difference. Second, the cognitive function and sleep quality according to drinking status were checked. The drinking group had higher scores of cognitive function and sleep quality than the non-alcohol group[Table 3].

Finally, the correlation between MoCA and sleep scale A scores were as follows and there was a significant positive correlation($r = .417, p < .05$)[Table 4].

Table 3. Differences in cognitive function and sleep quality according to smoking and drinking

Categories	Group	N	MoCA	Sleep scale A
Smoking	Non-smoking	28	16.9±3.9	29.9±9.2
	smoking	5	17.6±3.3	28.0±7.5
Drinking	Non-Drinking	25	16.64±4.0	28.92±9.0
	Drinking	8	18.38±2.8	31.63±8.8

Table 4. Correlation between MoCA and sleep scale A

	MoCA	quality of sleep
MoCA	1	.417*
Sleep scale A	.417*	1

* $P < .05$

Discussion

The results of this study find that there was a positive correlation between cognitive function and sleep quality. Recently, research on the relationship between cognitive function and sleep has been an issue. However, most of the studies were based on subjects with diseases such as chronic respiratory disease or mild cognitive impairment. This study is meaningful because it is a result of the correlation between cognitive function and

sleep quality in normal elderly people.

Review the results of the preceding study. First, the analysis of the relationship between sleep quality, cognitive function, depression and daily activities of the elderly in long-term care facilities showed no correlation between sleep quality, cognitive function, depression and daily activities, but depression and cognitive function^[11].

The second study confirmed the nighttime sleep polymorphism test and cognitive function in normal elderly and MCI group. As a result, there was no significant difference in nighttime sleep characteristics between the two groups, but it was confirmed that working memory was decreased in the normal elderly who had difficulty maintaining nighttime sleep. In this study, the majority of the problems of subjects with low scores on sleep quality are nighttime sleep difficulties^[12].

The third study examined the correlation between sleep quality and cognitive function in patients with chronic respiratory disease and found a significant correlation between sleep patterns and cognitive function^[13].

Next we will discuss the qualitative data of this study. Sleep disorders of the subjects with low scores in sleep scale A include: Sleep apnea, insomnia, often wake up at night. Two people who had low scores on sleep quality were taking sleeping pills for insomnia. Others said they could not sleep unless they consume alcohol. In a study that investigated the quality of sleep in older adults, The items with the lowest score were ‘get up often’ and ‘it’s hard to fall asleep’ after waking up^[3]. This is similar to the results of this study.

The suggestions of this study are as follows. First in this study, there was no statistically significant difference, but further research is needed to investigate the cognitive function and quality of life according to alcohol consumption and smoking. Second, it is necessary to study the detailed correlation between s factors of cognitive function and sleep quality. Third, based on the results of this study, we hope that future sleep quality can be used as an index for predicting mental health of the elderly.

Conclusion

The purpose of this study was to investigate the relationship between cognitive function and sleep quality in normal elderly people. MoCA was used to check

cognitive function, and Sleep Scale A was evaluated to check sleep quality.

As a result of measuring the cognitive function and sleep quality of the normal elderly, it was confirmed that there is a correlation between the cognitive function of the elderly and the amount of sleep.

The previous study also confirmed that there is a correlation between cognitive function and sleep quality. This study is meaningful in that it prepared basic data for utilizing the sleep quality of the elderly as an index for predicting mental health..

Further research is needed to determine the relationship between component of cognitive function and sleep quality. And It will need to expand the number of study subjects.

Effects of Acute Exercise Intensities on Blood Lipid and Growth Factors in Middle School Students with Intellectual Disabilities

Hong-Young Jang¹, Mihyun Lee²

¹Research Professor, Dept. of Medical Sciences Convergence research Center for Medical Science, Jeonju University, Republic of Korea, ²Adjunct Professor, Dept. of Physical Education, Sungkyul University, Republic of Korea

Abstract

Objectives: The purpose of this study was to examine the effects of acute exercise intensities on changes in blood lipids and growth factors in middle school students with intellectual disabilities.

Method: The study participants were randomly assigned into low intensity (n = 8), moderate intensity (n = 9) and high intensity (n = 9) groups. Acute exercise intensities was classified into low intensity (40~54% HRR), moderate intensity (55~69% HRR) and high intensity (70~85% HRR) using heart rate reserve (HRR). Blood lipids (total cholesterol, Triglyceride, high-density lipoprotein cholesterol, Low-density lipoprotein cholesterol) and growth factors (insulin-like growth factor-1, growth hormone, thyroxine, thyroid stimulating hormone) were measured before and after executing the physical activity program.

Findings: According to the results for blood lipids, high-density lipoprotein cholesterol (HDL) was significantly increased in the high-intensity group compared to the low-intensity group. For growth related hormones, insulin-like growth factor-1 (IGF-1) was significantly increased after exercise in the high-intensity group compared to the moderate-intensity group.

Applications: When the same amount of acute exercise was given to middle school students with intellectual disabilities, HDL was found to increase by the largest amount in the high-intensity group. IGF-1 was also found to be most effective in the high-intensity group. Future studies need to comprehensively account for sex and level of obesity.

Keywords: *Acute Exercise, Exercise Intensity, Intellectual Disabilities, Blood Lipid, Growth Factors.*

Introduction

People with intellectual disabilities have higher levels of C-reactive protein (CRP), which is a factor in inflammation and muscle atrophy, than non-disabled people and, coupled with their poor physical activity participation and inadequate diet, results in low exercise performance and high exercise fatigue^[1]. In addition, their below-average intellectual ability and

lack of adaptive behaviour make it difficult to acquire information on the nervous system and acquire new information and technologies^[2]. Their low physical fitness levels, and high obesity rates leads to a decline in motor function as their age increases, high mortality, which requires effective weight management^[3, 4].

Lack of exercise in adolescence is closely associated with obesity and cardiovascular risk factors^[5, 6]. It is also an important factor that affects adult health as well as adult disease^[7]. Nevertheless, there are many studies related to the health benefits of regular exercise for adolescents without disabilities, but there are only a few studies on physical activity whose subjects are adolescents with intellectual disabilities^[7, 8].

Table 1. Demographic characteristic of the participants

Characteristics	Low intensity group (n = 8)	Moderate intensity group (n = 9)	High intensity group (n = 9)
Female, n(%)	2(25%)	3(33%)	3(33%)
Age (year)	15.75±0.46	15.78±0.44	16.00±0.00
Height (cm)	165.01±7.66	161.10±7.34	164.32±6.05
Weight (kg)	60.88±19.65	58.14±16.50	60.21±10.57
Body mass index (kg/m ²)	24.56±14.27	27.10±13.47	25.19±11.76
VO ₂ max (Ml/kg/min)	59.04±8.50	54.90±14.99	55.44±10.12

Long-term regular exercise is reported to have a positive effect on blood lipids and reduce body fat and abdominal fat, reducing the risk of cardiovascular disease^[9]. It has been shown to directly stimulate adolescent growth-related hormones and contribute to tissue growth and development^[10]. This exercise effect can be considered an adaptation phenomenon due to acute exercise performed at an appropriate amount and intensity. However, most of the studies on blood lipids and growth-related hormones according to acute exercise intensity have been conducted on non-disabled subjects. The results showed a decrease in triglyceride (TG) after moderate intensity exercise, but there was only either no change in high-density lipoprotein cholesterol (HDL-C) or increased HDL-C after high intensity exercise^[11, 12]. Since each researcher has a difference in the exercise intensity and exercise amount used with the subjects, there is a lack of information on which exercise intensity is effective for adolescents with intellectual disabilities. In addition, growth-related factors are expected to be affected by exercise intensity, but the basis for this has not yet been identified.

Therefore, this study conducted simple acute exercise according to three exercise intensity groups for middle school students with growing intellectual disabilities. The purpose of this study is to examine its effects on changes in blood lipids (total cholesterol: TC, TG, HDL-C, Low-density lipoprotein cholesterol: LDL-C) and growth factors (insulin-like growth factor-1: IGF-1, growth hormone: GH, thyroxine: T4, thyroid stimulating hormone: TSH).

Method

1. Participants: This study conducted a convenience sampling of 26 middle school students with mild intellectual disabilities attending special classes in the city of A. Random sampling was performed for the 26 selected participants, dividing them into

groups as follows: nine in the high intensity group (HIG), nine in the moderate intensity group (MIG) and eight in the low intensity group (LIG). The physical characteristics of the study subjects are shown in [Table 1]. Approval for the study was obtained from the Institutional Review Board at The Y University Research Ethics Committee

2. Procedure: The maximum oxygen intake and maximum heart rate were measured using Balke-Ware protocol to set the individual exercise intensity of each participant^[13]. Participants wore portable wireless breathing gas analyzers (K4b², Cosmed, Italy) and wireless heart rate monitors (RS-400, POLAR, Finland).

After a maximal graded exercise testing (GXT), a week was given for resting and this study was conducted. Acute physical exercise intensity was divided into low intensity (40-54% HRR), moderate intensity (55-69% HRR), and high intensity (70-85% HRR) exercise groups using heart rate reserve (HRR)^[14]. Blood samples were collected before and after training to compare changes in blood variables and growth-related factors according to exercise intensity in acute physical activity programs.

3. Measures: The acute exercise program consisted of an aerobic training, and a fitness training exercise program using one's body. The wireless heart rate monitor RS400 was used to set and maintain exercise intensity for each group. The heart rate and exercise time for each set exercise intensity were entered into the heart rate monitor, and an alarm was set when the lower and upper values were measured so that they could be checked during the exercise.

In order to equalize the amount of exercise, the daily exercise amount was calculated to be 10%^[15] of the basic metabolic rate, and the exercise time was calculated as equivalent to 200kcal consumption for

each subject and applied individually.

The blood lipids of TC, TG, HDL-C, and LDL-C were analyzed using a blood analyzer (VITROS DT 60 II, Johnson & Hohnson Co. USA). Analysis of growth-related factors of IGF-1, GH, T4, and TSH was performed using radioimmuno assay (RIA). The analysis of all measurement data was performed by S clinical pathology center.

4. Data Analysis: All data collected in this study was analyzed via the SPSS ver. 22.0 program. To verify the difference of blood lipids and growth-related factors according to acute exercise intensity groups (LIG, MIG, HIG), premeasured values were set as covariates and an analysis of covariance (ANCOVA) was performed. Bonferroni was used for post hoc testing by group. Effect Size (ES) was presented as η^2 (eta). In terms of behavioural science, the effect size was interpreted by η^2 standard (Large: .14,

Medium: .06, Small: .01) as proposed by Cohen [15]. The significance level of all data was set to $\alpha = .05$.

Result

1. Blood Lipids: In order to verify the difference in blood lipid changes by acute exercise intensity (low, moderate, high intensity), the results of ANCOVA with the premeasured values set as covariates are shown in [Table 2]. TC (F = .536), TG (F = 1.895) and LDL-C (F = .305) did not show significant differences by exercise intensity. On the other hand, HDL-C (F = 4.108) showed significant difference according to acute exercise intensity. Post hoc test results showed that HIG was significantly lower than LIG ($p < .05$).

In terms of effect of blood lipid by intensity of acute exercise program, triglycerides (η^2 (eta) = 0.141) and HDL-C (η^2 (eta) = 0.263) showed large effects size.

Table 2. Covariance of blood lipids by acute exercise intensity group

		Pre-test Mean±SD	Post-test Mean±SD	Adjust post-test Mean±SE	F-value	η^2
TC	LIG (n = 8)	141.56±27.72	147.89±28.44	150.83±3.24	.536	0.045
	MIG (n = 9)	143.11±18.48	154.00±29.61	155.32±3.23

2. Growth Factors: In order to verify the difference of growth-related factor change by acute exercise intensity, the pre measured values were set as covariates. The results of ANCOVA are shown in [Table 3]. GH (F = 1.700), T4 (F = 1.023) and TSH (F = 3.111) did not show statistically significant difference. On the other hand, IGF-1 (F = 3.991)

showed significant difference by acute exercise intensity. Post hoc test results showed that HIG was significantly higher than MIG ($p < .05$).

In terms of effect of blood lipid by intensity of acute exercise program, it showed large effect size on IGF-1 (η^2 (eta) = 0.258) and TSH (η^2 (eta) = 0.213).

according to groups in order to compare/analyze changes in blood lipids and growth related factors under conditions that consume the same calories for middle school students with intellectual disabilities.

Discussion

In this study, three acute exercise intensities (low, moderate, and high) were performed differently

According to the results, blood lipids in HDL-C were significantly higher in HIG than in LIG as shown in [Figure 1].

Figure 1. Changes in high density cholesterol with acute exercise intensity

LIG: Low intensity group, HIG: high intensity group:

According to a study comparing blood lipids by acute exercise intensity among university students, triglycerides decreased by more than 10%, from 80%~90% of the individual's lactate threshold (LT), 90 minutes after exercise. For HDL-C, the increase in concentration was greater in LT 90%~100% than during other intensity [16]. Another study examined changes in HDL-C with 70% LT and LT for healthy elderly and reported a significant increase in 24-hour HDL-C in LT [17]. Regarding exercise intensity and blood lipids, Wood et al. [18] reported that low intensity exercise would

not significantly change blood lipoprotein levels, but that high intensity exercise can increase blood HDL-C levels and decrease TG and a reduction in HDL-C could promote the development of atherosclerosis. It is thought that the repetitive increase in HDL-C at high intensity exercise can further stimulate the increase of HDL-C, which is manifested by long-term exercise adaptation.

In growth-related factors, IGF-1 was significantly increased more in HIG than MIG after exercise as shown in [Figure 2].

Figure 2. Changes in insulin-like growth factor-1 with acute exercise intensity

MIG: moderate intensity group, HIG: high intensity group

Previous studies confirmed that IGF-1 concentrations were highest at 65%~70% HRmax, suggesting that further studies are needed to examine the response of IGF-1 after exercise at specific exercise intensities [19]. In this study, IGF-1 showed a significant increase during high intensity exercise, but not during moderate intensity, and that there was no significant difference in GH. This result is consistent with the result that GH is increased more in low intensity exercise [20], and that the increase of GH production is independent of each other regardless of an increase in IGF-1 concentration [21, 22].

According to the recently updated 2018 Physical Activity Guidelines for Americans [23], acute physical

activity alone can lower blood pressure, improve sleep, and strengthen the body's ability to convert blood sugar into energy. In this study, targeting adolescents with intellectual disabilities, high intensity exercise in acute exercise increased HDL-C and increasing the synthesis of IGF-1. Based on these findings, more attention and follow-up studies are needed for the physical activity or exercise of adolescents with intellectual disabilities.

Conclusion

When middle school students with intellectual disabilities were given the same amount of exercise by acute exercise intensity, it was confirmed that high

intensity exercise increased HDL-C and had a significant effect on IGF-1. If middle school students with intellectual disabilities continue to perform high intensity exercises in the future, positively changed factors may be further stimulated to prevent cardiovascular disease and to have a positive impact on growth. As this study did not consider the sex and obesity level of people with intellectual disability, further study is necessary considering other factors such these.

Comparison of Blue Light Blocking Effects of Tips and Tinted Lenses for Dental Light Curing Machines

Sook-Jeong Lee

*Department of Dental Hygiene, Professor of Silla University, 140 Baegyang-daero (Blvd),
700beon-gil (Rd.), Sasang-Gu, Busan, 46958, Republic of Korea*

Abstract

Background/Objectives: This study aimed to examine the blue-light blocking effect according to the curing light tip and the color of the protective eyeglass lens for the operator's eye protection.

Method/Statistical Analysis: The transmittance of light with a wavelength between 200 and 900 nm was measured three times at 1.8 nm intervals using a UV-vis spectrophotometer (LAMBDA 265, Perkinelmer, Inc.). Then the average values obtained were compared for analysis. The visible- and blue-light transmittances of all the tips and tinted lenses were examined, and the ratios of blue light in the transmitted visible light were analyzed to compare the blue-light blocking effects.

Findings: The transmittance of visible light with a wavelength between 380 and 750 nm was highest in the yellow lens (60.58%), followed by company B's tip (55.23%), company A's tip (51.46%), the orange lens (47.48%), company C's tip (41.53%), and the red lens (41.00%). The blue-light transmittance was 0.14% in company A's tip for the curing light gun, 0.75% in company B's tip, and 0.12% in company C's tip, which were all very low. Among the tinted lenses, the orange lens had the lowest blue-light transmittance (0.20%), the red lens had a blue-light transmittance of 6.59%, and the yellow lens had the highest blue-light transmittance (12.53%). For the analysis results of the ratio of blue light in the transmitted visible light, it was 0.27% for company A's tip, the best blue-light blocking rate, and 20.68% for the yellow lens, the worst blue-light blocking rate. The ratios of blue light in the transmitted visible light for companies B and C's tips were 1.35 and 0.29%, respectively, showing that they have a good blue-light blocking effect.

Improvements/Applications: The curing light tips and orange lens used for the analyses in this study showed a blue-light blocking effect. In the case of blue-light blocking by tinted lenses, further studies are required because the blocking rate may vary depending on the lens tint concentration.

Introduction

Humans need light to identify the natures, shapes, directions, and locations of objects as well as the distances between them, and to perceive space and the objects they

want to know. Light is divided into two types: natural light obtained from the sun, including that from visible light that can be perceived by the human eye as well as infrared to ultraviolet light; and artificial light made for convenient use according to human needs^[1,2]. In the case of natural light obtained from the sun, the available time for human use is limited to daytime, the bright time of day. The artificial light made to address this limitation can help people perform activities in places where things are invisible due to darkness, or at various time zones, which greatly helps expand the range of human activities and the convenience of life.¹

Artificial light not only provides convenience in daily life but also utilizes a different wavelength of light. As it has various transmittances to and interactions with materials according to its wavelength, it is used for the diagnosis and treatment of various diseases, such as gamma rays applied to cancer cells, X-ray used to diagnose and treat diseases by checking the inside of the human body, and treatment using infrared rays. Its effects were confirmed by the results of various studies^[3-7].

In the field of dentistry, X-ray, which is artificial light necessary for panoramic, standard, bitewing, and occlusal imaging, is used to accurately determine the conditions of the patient's periodontal tissue, dental components, and jaw bone, where the teeth are situated. In addition to X-ray, light is also utilized for the composite resins used to repair the teeth during dental treatment. The use of a light curing gun that irradiates blue light to cure plastic composite resins is also a therapeutic process using light^[8-10].

As such, the utilization of artificial light in various medical fields has spurred the development of many technologies, but to see the therapeutic effect of the light irradiated for treatment, a large amount of light should be irradiated for a short time. It also causes side effects as well as the action for treatment^[7,11].

In particular, during the light irradiation process, the practitioners and assistants who have to treat patients while checking the treatment site are exposed to a large amount of light irradiated by the light curing gun for a short time. The risk exposure is even likely to be higher when there are many patients who need to be treated using the light curing gun. Wearing appropriate safety glasses to block the light during the treatment process will minimize the exposure to the side effects, although the light is not completely blocked^[12,13]. This study aimed to investigate the color and transmittance of the most effective lens that maximizes light blocking and minimizes the risk of exposure to light while using the light curing gun among the various lights used in dentistry.

Method

For curing the plastic composite resins used for tooth restoration, artificial blue light is irradiated using a light curing gun. The light is irradiated for a short time, but a large amount of light is irradiated, directly or indirectly stimulating the operator's eyes. To minimize

this stimulation of the light curing gun operator's eyes by the blue light, the manufacturers of light curing guns sell these with tips. This study intended to find an efficient method of blocking light by measuring the light transmittances of these tips and of eyeglass lenses tinted with red, yellow, and orange dyes that are expected to block blue light.

The transmittances of light with a wavelength between 200 and 900 nm were measured at 1.8 nm intervals using a UV-vis spectrophotometer (LAMBDA 265, PerkinElmer, Inc.) [Figure 1]. The transmittances of the curing light tips and eyeglass lenses were measured three times, respectively, and then the average values were compared for analysis.

The transmittances of the visible and blue light of all the curing light tips and tinted eyeglass lenses were examined [Figure 2,3], and the ratios of blue light in the transmitted visible light were analyzed to compare the blue-light blocking effects. Based on the regulations of ANSI Z80.3 1986, visible light was classified as light between 380 and 750 nm, and blue light as light between 380 and 500 nm.

Figure 1. UV-vis spectrophotometer (LAMBDA 265, PerkinElmer, Inc.)

Figure 2. Curing light tips and eyeglass lenses tinted with red, yellow, and orange dyes.

Result and Discussion

Using a UV-vis spectrophotometer, the light transmittances of three companies' curing light tips and eyeglass lenses tinted with red, yellow, and orange dyes within the 200-900 nm wavelength range were measured [Figure 4]. In the visible-light region (380-750 nm), the curing light tips and tinted eyeglass lenses showed different light transmittance spectra according to the wavelength, which indicates that the light transmittance is different depending on the curing light tip and eyeglass lens color concentration.

Figure 3. Light transmission process after mounting the UV-vis spectrophotometer (LAMBDA 265, Perkinelmer, Inc.) and lens.

Figure 4. Spectral transmittance curves of dental curing light tips for blue-light blocking and tinted eyeglass lenses.

Figure 5. Spectral transmittance curves of dental curing light tips and tinted eyeglass lenses in the blue-light (380-500nm) region

The spectral distribution of only the blue-light region within the 380-500 nm wavelength range is shown in Figure 5. Among the three companies' curing light tips, those of companies A and C showed almost similar spectra, and there was no difference in the distribution of the spectrum. Only company B's curing light tip showed a slight difference near the 500 nm wavelength. Among the tinted eyeglass lenses, the red lens showed a nearly constant transmittance spectral curve in the blue-light region while the yellow lens showed increased light transmittance near the 450 nm wavelength. The orange lens showed a spectral distribution with almost no blue-light transmission, like companies A and C's curing light tips.

Among the light transmittances within the 380-750 nm wavelength measured using a UV-vis spectrophotometer (LAMBDA 265, Perkinelmer, Inc.) [Table 1], the visible-light transmittance was highest (60.58%) for the yellow lens, followed by 55.23% for company B's curing light tip, 51.46% for company A's curing light tip, 47.48% for the orange lens, 41.53% for

company C's curing light tip, and 41.00% for the red lens. The blue-light transmittance within the 380-500 nm wavelength region was 0.14% for company A's curing light tip, 0.75% for company B's curing light tip, and 0.12% for company C's curing light tip, which were all very low (less than 1%). Among the tinted eyeglass lenses, the orange lens had the lowest blue-light transmittance (0.20%), the red lens had 6.59% blue-light transmittance, and the yellow lens had the highest blue-light transmittance (12.53%). For the analysis results of the ratio of blue light in the transmitted visible light, it was 0.27% for company A's curing light tip, the lowest, indicating that such curing light tip has the best blue-light blocking rate. The ratio of blue light was 20.68% for the yellow lens, showing that such lens has the worst blue-light blocking rate. Companies B and C's curing light tips both had a good blue-light blocking effect, with the ratios of blue light out of the visible light being 1.35 and 0.29%, respectively. On the other hand, the red lens had a low blue-light blocking effect, similar to the yellow lens (16.07%).

Table 1. Light transmittances of dental curing light tips for blue-light blocking and tinted eyeglass lenses

Wavelength (nm)	Light Transmittance (%)					
	Company A (Tip A)	Company B (Tip B)	Company C (Tip C)	Yellow Lens	Red Lens	Orange Lens
380-750 (Visible light)	51.46	55.23	41.53	60.58	41.00	47.48
200-380 (Blue-light)	0.14	0.75	0.12	12.53	6.59	0.20
Blue-light/Visible light	0.27	1.36	0.29	20.68	16.07	0.42

Conclusion

All the curing light tips that were used in the analysis in this study showed an excellent blue-light blocking effect, and the orange lens showed a similar blue-light blocking effect by the curing light tips. In the case of the yellow and red lenses, the blue-light blocking effect was low. Further experiments are needed to determine whether the yellow and red lenses can produce as much blue-light transmittance as the orange lenses. For this purpose, further research is needed to compare the blue-light transmittances by tint concentration.

Difference of Health Consciousness According to Living Environment and Economic Level of the Elderly in the Urban-Rural Complex Area

Do-Jin Kim¹, Jong-Hyuck Kim², Il-Young Cho³

¹Professor, Dept. of Rehabilitation Sports, Bucheon University, 25 Sinheung-ro 56beon-gil Wonmi-gu, Bucheon-si Gyeonggi-do, 14632, Republic of Korea, ²Professor, Dept. of Medical Beauty Care, Jungwon University, 85 Munmu-ro, Goesan-eup, Goesan-gun, Chungbuk, 28024, Republic of Korea, ³Professor, Dept. of Exercise Prescription, JeonJu University, 303, Chonjam-ro, Wansan-gu, Jeonju, Cheonbuk, 55069, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to provide the basic data to develop suitable health and welfare services for the elderly living in urban-rural complex area, by investigating their living environment, economic level and health consciousness.

Method/Statistical Analysis: This study was conducted on the elderly living in K city, Gyeonggi-do. The data was collected by using survey method, which was designed to find out the living environment, economic level, and health consciousness of the elderly in the urban-rural complex area. The data were analyzed by using PASW 18.0 statistical program, descriptive statistics analysis was conducted to analyze the frequency and ratio of each item, and chi-square analysis(χ^2) was conducted to find out the difference in health consciousness between living environment and economic level.

Findings: The more they had economic difficulties, the higher they watched TV and listened to radio. and the higher the desire for health and exercise programs. Especially, the elderly living alone had poor living environment and economic level, plus high restriction on health and exercise.

Improvements/Applications: It appears that elderly living alone in urban-rural complex area have a high desire to participate in health and exercise programs, which is thought to require attention and research to remove restrictions on physical activity programs for elderly living alone.

Introduction

The health condition of residents of urban area worldwide is much better than that of residents of rural areas. Many positive aspects of urban life, such as

high employment rate, high income, better educational opportunities and access to health care, encourage migration from rural to urban. However, recent studies show that the benefits of urban life and health condition can be eroded by the adverse effects of the urban environment - for example - the increase in fat on the diet, and the sedentary lifestyle can be them^[1]. Risk factors for cities with health risks include substandard housing, congested living conditions, contaminated food, unclean water, inadequate sanitation, poor solid waste treatment services, air pollution and congested traffic^[2].

As the society continuously changes to aging society, more and more elderly will be willing to live

in urban-rural complex area where the urban areas and rural areas coexist. Further, in order to satisfy their leisure and needs, and the migration to urban-rural complex area will increase, and it will lead to a continuous increase in interest in living environment, economic level and health consciousness in urban-rural complex area. Therefore, the purpose of this study is to present basic data for the provision of health and welfare services suitable for urban-rural complex area by identifying living environment, economic level and health awareness among the urban-rural complex area.

Method

1. Research Subject: This study was conducted to the elderly living in K-city, in Gyeonggi-do, and a survey on living environment, economic level and

health awareness was conducted - by distributing 220 questionnaires, consisting of nominal scale. The response to the questionnaire was carried out in a one-on-one manner by the researchers and the auxiliary researchers, and if the study subjects did not respond during the response process, the question was re-asked after explaining the whole process that this survey will be used for statistical purposes. The questionnaire was retrieved through this procedure, but the survey response in Part 11 was excluded as it was not considered appropriate for the analysis by the researchers and the ancillary researchers. In addition, if the answer is avoided again, ‘no answer’ exists as a blank. The questionnaire used in the study is part 209, with the general characteristics of the study subjects as shown in Table 1.

Table1: Physical Characteristic (M±SD)

Variables	Classification	Frequency	Percentage (%)
Gender	Male	61	29.3
	Female	147	70.7
Age	Under 60	5	2.8
	Under 65	4	2.2
	Under 70	14	7.7
	Under 75	62	34.3
	Under 80	42	23.2
	80 years old or older	54	29.8
Education	Not educated	55	27.1
	Elementary School (School dropout)	65	32.0
	Middle School (School dropout)	37	18.2
	High School (School dropout)	29	14.3

	Shamanism	66	31.6
Marital Status	Unmarried	16	7.7
	Married	133	63.6
	Divorce	22	10.5
	Remarriage	2	1.0
	Died after marriage	36	17.2

*Sum total can not 209

- 2. Research Tool:** This study was to find out how the living environment and economic level of the elderly in urban-rural complex area affect the difference in health consciousness among the elderly in the region. In this regard, it was reorganized around the questionnaires of the Seoul Senior Welfare Center and the W General Social Welfare Center, which were consisted of a nominal scale among the survey questionnaire for the needs of local residents. The first content adequacy test was conducted by researchers, ancillary researchers and social workers, and questions that were not suitable for the purpose of this study were excluded. The secondary content adequacy level was constructed based on the advice of a group of experts (the director of the senior welfare center, the professor of physical education and economics). The factors in the response questionnaire consist of total 28 questions, with 11 questions for living conditions, 7 questions for economic level, and 10 questions for health awareness.
- 3. Data Processing Method:** All data processing was analyzed using the PASW 18.0 Statistical Program. A technical statistical analysis was conducted to analyze the frequency and percentage of each question, and a chi-square analysis(χ^2) was conducted to find out the differences between living conditions and economic standards in terms of health consciousness. The significance level was set to $\alpha = 0.5$.

Result and Discussion

- 1. Living Environment:** The results of the analysis of living conditions in this study are summarized as follows. The living conditions of senior citizens in urban-rural complex area are as shown in Table 2. 46.6% of them were living in a monthly renting places, and only 36.1% of them were actually living in the house of their own or their spouses. As for economic conditions, 92.8% of the respondents were beneficiaries of national basic livelihood. As for the current residence period, 74.6% for living there for less than 10 years, 14.4 percent for less than 20 years and 4.8% for more than 40 years. As for cohabitation, the ratio of elderly living alone was significantly higher- 63.2% were living by themselves, and 26.8% were living with their spouses. When seeing the aspect 'The frequency of contact with children', 42.3% contacted with their children more than 1-2 times a month, and

29.1% only met their children during holidays/family events. As for heating in winter, 63.2% used urban gas, and 19.1% just used electric pads. 43.4% of them used less than 100,000 won, and 28.5% answered that administrating cost and housing cost were way too expensive, and 26.4% answered that their house rental fees were high. 33.8% replied that they cleaned their toilet 1-3 times a week, and the satisfaction level of residence was high with 7-8 out of 10 points, 36.4%.

In order to improve the living environment of the elderly, it is necessary to prepare various activation plans and infrastructure to improve the living environment for the elderly in order to design the future of old age, not to be satisfied with the present.

- 2. Health consciousness according to living environment and economic level:** The results of the analysis on health consciousness according to living environment and economic level of this study are as follows. Table 2 shows the result of a chi-square analysis of health consciousness according to the living conditions and economic standards of the elderly in the urban-rural complex area. 21.6% answered that they are 'not quite healthy', and 'paying monthly rent for their house', 15.7% answered 'in a bad physical condition', and 'paying monthly rent for their house', and their χ^2 was $p = .889$. 83.9% of the respondents said that they were 'receiving basic living allowances' and 'taking treatment and medication', and χ^2 was $p = .576$. 40.5% answered that they were alone, and had neurological disorder, and 15.0% replied 'living alone' and 'had internal diseases'. 6.5% of people answered that they were 'receiving less than 500,000 won a month', and 'not that healthy' - χ^2 was found out to be $p = .060$. Regarding the way making their living and serious health problems, 56.8% answered that they were living basic living allowances from government, and had neurological disorders. Then 24.6% followed that they were having internal diseases. Their participants answered and their χ^2 was $p = .001$. Regarding the living expenses and activity of daily living, 22.0% answered that 'mainly pays for administrative fees' and 'managing daily living in a fairly good way' ($p = .051$). 27.0% of the respondents said that they were having economic difficulties and health activity difficulties, and the main reason of that was their economic burden. ($\chi^2 p = .001$) In response to health and leisure

activities, TV/radio watching and listening was the highest(24.0%),and the main reason was also their economic difficulties.(p = .152). In addition, the respondents who answered that they were very difficult in economic condition were the highest, with 17.6% of respondents saying that they needed health and leisure programs such as health classes (p = .147). It is shown that the more economically difficult it is, the higher people had the desire for a health class. However, it is believed that they were replacing leisure time with TV and radio listening due to economic difficulties. The frequency of meeting with children and their ability to perform daily activities were very good at meetings at family or family gatherings, which was 10.6%, and others showed the same frequency(p = .071). TV/Radio watching and listening was 34.1%, using city gas for winter heating method, health and leisure activities, and TV/radio watching and listening were relatively high at 8.7% using electric blanket(P = .716). In terms of residential satisfaction and difficulties in health activities, the ratio of residential satisfaction

of 7-8 points and economic burden to health life was 19.4% and χ^2 was p = .078. In addition, if the residential satisfaction level is 7-8, 16.0% was required for the health class(yoga, dan jeon breathing, Qigong exercise) and χ^2 was p = .078. The minimum wage and the degree of health were 6.5%, except for other opinions, when the minimum wage was less than 500,000 won and not healthy, it was high, and χ^2 was p = .060. In terms of monthly income, treatment and medication, imports of less than 600,000 won, treatment and medication were 48.3% and χ^2 was p = .016.

According to the elderly statistics^[3], more than half of the average daily leisure time of people aged 65 or older was spent on watching TV or other media in 2014, and was reported to be spending leisure time outside of media viewing(i.e. social activities, religious, cultural and sports activities). It is also known that demographic characteristics such as age, gender, marital status, education level, economic level, residential area and employment status affect the quality of health-related life for the elderly.

Table 2: Health consciousness statistics

Variables		Classification Frequency (%)					χ^2
		Not very healthy	Not healthy	Normal	Healthy	Very healthy	
Home Ownership/ Health level	Self Spouse	19(9.3)	31(15.2)	13(6.4)	11(5.4)	0(0)	.889

Conclusion

The purpose of this study was to examine the living environment, economic level, and health consciousness of the elderly in urban-rural complex area. The 220 questionnaires for senior citizens in K City, Gyeonggi Province, were interviewed in a one-on-one manner and 11 questions were excluded due to lack of response during the interview. In the case of the answer questionnaire, non-response questions were included. The retrieved questionnaire presented the results through technical statistics and a chi-square analysis. Through this process, the following conclusions were reached.

First, the percentage of ‘monthly rent in housing’ was high among living conditions, and the proportion of people who were provided with basic living allowance was high. In particular, the percentage of elderly people living alone was relatively high, and the frequency of meetings with their children was only being made during holiday seasons and family event days. Regarding residence heating during winter season, the number of elderly people who spend the winter with electric blankets was found to be relatively high, and excessive housing management costs and high rents were found to be the difficulties of living environment.

Second, they were not having good ‘health consciousness’ considering living environment and economic level. The ratio of the elderly living on a monthly rent was the highest, and especially the recipients of the National Basic Livelihood Security showed more disease and medication. Also, the elderly living alone had more diseases. The higher the economic difficulties, the more restricted the health activities, while the desire

for health-related programs was high.

Urban-rural complex area are being developed from rural areas to urban areas, and elderly people often do not respond to the changing environment rapidly. In addition, the elderly living alone are exposed to many social problems, and in this study, the elderly living alone have relatively higher rate of economic and environmental difficulties. Especially, the more economic difficulties, the higher the desire to participate in health and exercise programs, which is considered to be more highlighted in health and physical education field for future development and solution making. Through this study, it is necessary to focus on the elderly living alone and to take care of the field that eliminates the constraints participating in the exercise program related to health and follow-up research is necessary.

Effects of 8-Week High Intensity Combined Exercise on Body Composition, Blood Lipid and CRP in Obese Middle Aged Men

Do-JinKim¹, Jong-Hyuck Kim², Gyu-Ri Kim³

¹Professor, Dept. of Rehabilitation Sports, Bucheon University, 25 Sinheung-ro 56beon-gil Wonmi-gu, Bucheon-si Gyeonggi-do, 14632, Republic of Korea, ²Professor, Dept. of Medical Beauty Care, Jungwon University, 85 Munmu-ro, Goesan-eup, Goesan-gun Chungbuk, 28024, Republic of Korea, ³Professor, Dept. of Beauty and Cosmetic Science, Eulji University, 553 Sanseong-Daero, Sujeong-Gu, Seongnam-Si, Gyeonggi-Do 1313585, Republic of Korea

Abstract

Background/Objectives: This study was built up to delve into the effects of high-intensity combined exercise on body composition, blood lipid and CRP for 8 weeks obese men living in Korea. For this purpose, treatment effects were divided into 8 weeks high intensity complex exercise group and control group.

Method/Statistical Analysis: The purpose of this research was to study obesity men in their 50s. The study selected subjects who did not participate in periodic physical activity program in the last year. A total of 16 subjects were divided into 8 high-intensity combined exercise group and 8 control group. Basic statistical analysis was performed on high intensity combined exercise group and control group. 2-way ANOVA was performed to investigate the effects of 8 weeks high intensity compound exercise.

Findings: 8 weeks of high-intensity combined exercise among obese middle-aged men in their 50s showed significant differences in body weight, muscle mass, body fat (%) and WHR, and significant differences in TG, TC, HDL-C, and LDL-C in blood lipids. The CRP showed significant interaction effects in the high intensity combined exercise group and the control group.

Improvements/Applications: High intensity combined exercise showed positive changes in body composition, blood lipid and CRP in middle-aged men. This suggests that high-intensity exercise may have effect to men in their 50s with extended life.

Keywords: High Intensity Combined Exercise, Body Composition, Blood Lipid, CRP, Obese Middle Aged Men.

Introduction

The World Health Organization announced that 1.9 billion adults are now overweight and 600 million of them are now suffering from obesity worldwide. In

addition, obesity has now become a global epidemic^[1-2]. In Korea, 17.8% of the 11,467 billion won of socioeconomic costs are caused by obesity problem accounted for over a year, and 52.9% of the total losses are concentrated in the 30s to 50s, which is so-called as a productive population. Therefore, it has become a more crucial problem, and it is urgent to prepare for the obesity measures of Korean men in their 50s who are being hit by obesity^[3]. As such, obesity is now being considered as a major risk factor for heart disease, high blood pressure, diabetes and stroke, and is closely associated with decreased life expectancy, cognitive dysfunction and poor quality of life^[4]. Obesity is a major cause of various non-communicable diseases (NCDs), including

e-mail: jhkim4170@naver.com

life-threatening and non-fatal diseases. Obesity is also leads one of the factors which leads to premature death and physical disability in adulthood [5].

In middle age, they experience physical aging and experience significant physiological changes, such as changes in appearance, weak physical function, vitality and metabolism, and memory and intelligence decline due to cognitive decline. In addition, a decrease in immune function along with cell aging reduces the resistance to disease or external stress, increasing the likelihood of developing chronic diseases[6].

In this period, not only physical strength rapidly declines, but various physiological functions shows declining aspect, which increases the risk of adult disease. Gradually obesity, hypertension, cardiovascular disease, diabetes, etc. may occur[7]. In particular, middle-aged men having white-collar jobs have a sedentary lifestyle and are prone to obesity due to lack of physical activity and sedentary life style and negative changes in body composition[8]. Likewise, increased sedentary activity is accompanied by decreased energy consumption, energy imbalance, and fat accumulation- and ultimately brings fat tissue enlargement, a major feature of obesity caused by calorie intake and consumption imbalance, leads

to negative changes in each organ in the body. It also negatively affects individual psychological factors and finally leads to a deterioration in overall quality of life[9]. Appropriate physical activity improves dyslipidemia, weight and BMI[11],and resistance exercise reduces the risk of developing cardiovascular disease by increasing insulin sensitivity and lowering LDL-C levels[10].

Therefore, this study is an effective exercise prescription program for obesity middle-aged men’s obesity management and cardiovascular disease by comparing and analyzing the effects on high blood lipid, CRP and body composition after 8 weeks of high-intensity combined exercise for obese men in their middle age. The purpose of this study is to present the basic data.

Method

1. Subject of Study: This study was conducted to study was to study obesity men in their 50s. The study selected subjects who did not participate in periodic physical activity program in the last year. A total of 16 subjects were divided into 8 high-intensity combined exercise group (HCG) and 8 control group (CG). The physical characteristics of the study subjects are shown in Table 1.

Table 1: Physical Characteristic of Subjects (M±SD)

Group	N	Age (yr)	Height (cm)	Weight (kg)	Muscle (kg)	Fat (%)
CG	8	54.22±1.27	172.68±3.01	85.95±5.62	59.63±2.36	30.37±3.71
HCG	8	53.29±1.01	173.08±3.24	84.03±4.94	57.73±4.33	31.28±3.61

2. Exercise Program: In this study, the exercise method was 4 days a week for 8 weeks. The high-intensity combined exercise group had undergone a program which included 10 minutes of warm-up, 20 minutes of resistance, 20 minutes of aerobic exercise, and 10 minutes of cool down. The control group was required to maintain daily life as usual for 8 weeks.

In the high-intensity combined exercise group, the warm-up exercise was performed by stretching the upper body and the lower body. The resistance exercise and the aerobic exercise, which were the main exercise, reset the exercise intensity every week. Resistance exercise was performed at 80% level based on 1RM, and aerobic exercise was set

at 80% target heart rate through Polar Heart Rate Analyzer (Polar Electro, Finland). High-intensity combined exercise programs are explained in details at <Table 2>.

Table 2: Exercise Program

Division	Intensity	Combined Exercise
Periods (8week)	Resistance exercise (1RM 80% each 1week/10 repetition 2set/20min)	Squat, Press (bench, leg, shoulder), Leg curl, Barbell curl, Lat pull down, Lunge
	Aerobic exercise (target heart rate 80% each 1week, 20min)	Treadmillrun and walking

3. Measurement method and equipment: The body composition was performed using Inbody

770 Bio Space (Korea). Blood lipid and CRP test was performed before and after 8 weeks of high-intensity combined exercise. The blood was taken to maintain an empty stomach for 12 hours and stable for 30 minutes before the blood was drawn. Blood was collected from the brachial vein by using a disposable syringe. The collected blood was centrifuged at 3000 RPM using a centrifuge and commissioned to a nuclear medical institution for analysis.

4. Data Analysis: Basic statistical analysis was performed on high intensity combined exercise group and control group. 2-way ANOVA was

performed to find out the effects of 8 weeks high intensity compound exercise. The significance level was conducted at .05.

Result and Discussion

1. Body COmposition: According to <Table 3>, there was an interaction effect on body weight (p = .001), body fat(p = .001), WHR (p = .012) and muscle mass (p = .001) in the 8-week high-intensity combined exercise group (HCG) and the control group (CG). This suggests that high-intensity combined exercise has a meaningful effect on body composition change.

Table 3: Body Composition ANOVA

Factor	Group	Pre	Post	P
Weight (kg)	CG	85.95±5.62	86.61±5.52	Group*period: .001 Group: .040 Period: .001
	HCG	84.03±4.94	77.41±3.47	
Fat (%)	CG	30.37±3.71	30.52±3.79	Group*period: .001 Group: .399 Period: .001
	HCG	31.28±3.61	26.18±4.68	
WHR (waist-hip ratio)	CG	.90±.01	.90±.01	Group*period: .012 Group: .575 Period: 1.00
	HCG	.90±.018	.89±.01	
Muscle (kg)	CG	59.63±2.36	59.51±2.66	Group*period: .001 Group: .642 Period: .001
	HCG	57.73±4.33	59.78±3.92	

2. Blood Lipid: According to <Table 4>, there was an interaction effect on TG(p = .006), TC(p = .001), HDL-C(p = .005) and LDL-C(p = .001) in the 8-week high-intensity combined exercise group (HCG) and the

control group (CG). This suggests that high-intensity combined exercise has a significant effect on blood lipid change.

Table 4: Blood Lipid ANOVA

Factor	Group	Pre	Post	P
TG (mg/dl)	CG	109.50±47.07	107.87±46.80	Group*period: .006 Group: .882 Period: .004
	HCG	133.62±58.49	90.37±23.96	
TC (mg/dl)	CG	170.50±29.17	172.50±38.18	Group*period: .001 Group: .297 Period: .001
	HCG	174.00±28.56	138.00±16.81	
HDL-C (mg/dl)	CG	56.12±8.23	56.87±9.10	Group*period: .005 Group: .082 Period: .001
	HCG	46.12±5.22	54.00±5.45	
LDL-C (mg/dl)	CG	105.37±27.30	109.25±29.22	Group*period: .001 Group: .685 Period: .002
	HCG	113.37±22.40	91.62±12.16	

3. CRP (C-reactive protein): According to <Table 5>, there was an interaction effect in CRP in the 8-week high-intensity combined exercise group (HCG) compared to the control group (CG). This suggests that high-intensity combined exercise has a significant effect on CRP.

Table 5: CRP ANOVA

Factor	Group	Pre	Post	P
CRP (mg/dl)	CG	.115±.05	.112±.05	Group*period: .014 Group: .626 Period: .011
	HCG	.146±.10	.055±.01	

Discussion

This study was conducted to compare the differences in blood lipids, CRP, and body composition of 8-week high-intensity complex exercise for obese middle-aged men. For the purpose of presentation, the following is a comparative analysis based on the results of this study and previous studies.

Looking at previous studies on changes in body composition through combined exercise in middle-aged men, Mateus et al^[11] reported that aerobic(50–85% of VO² peak) and resistance (6–10 RM) target obese middle-aged men. Sixty minutes of training, three times per week, and 24 weeks of training showed positive effects on body composition. Donges et al^[12] reported significant improvement in body weight and body fat percentage of body composition after 12 weeks of muscle strength, aerobic exercise and combined training in sedentary middle-aged men. Mohammadi, Khoshnam & Khoshnam^[13] reported significant improvements in body composition in three groups of 12 weeks of aerobic, strength and combined exercise in middle-aged men. Changes in body composition are age-related and have a strong genetic predisposition. It is also affected by environmental factors such as nutrition, disease and physical activity and changes with age, especially in men. Changes in body composition depend on the type, intensity and duration of exercise program^[14].

These results indicate that intense activity can be an effective stimulus to body composition changes, especially high intensity activity, which greatly reduces body weight, BMI, body fat percentage, body fat and waist. This is consistent with the findings presented in the study^[15] that vigorous exercise can be the target of total energy intake and that energy consumption during exercise may be more effective than moderate activity.

Therefore, high-intensity combined exercise performed in this study may play an important role in maintaining health by improving the body composition of obese middle-aged men through the direct metabolism of body fat due to the direct burning of body fat and the increase of muscle mass.

Looking at previous studies on changes in blood lipids through complex exercise in middle-aged men, Seo^[16] reported positive changes in blood lipid after 12 weeks of complex exercise for middle-aged men. The study of Nam & An^[17] reported the effect of blood lipids after a combined exercise for 8 weeks in middle-aged obese men. Atashak, Stannard & Azizbeigi^[18] reported that eight weeks of combined exercise program intervention in overweight middle-aged men was effective in reducing blood lipid LDL-C and TG and increasing HDL-C.

In addition, a study by Byun & Woo^[19] found that 8 weeks of combined exercise in obese men was effective in significantly reducing blood lipid TC, LDL-C, and TG. In this study, a 8-weeks High intensity combined exercise program was conducted to the obese male participants who were in their middle ages, and the program showed significant differences in high-density lipoprotein cholesterol (HDL-C), triglyceride (TG), low-density lipoprotein cholesterol (LDL-C) and total cholesterol (TC) among blood lipids.

These results happen since exercise brings 1) the increase of lipid utilization activity in mitochondria through exercise, 2) the enhancement of glycogen synthase function, 3) the influx of active muscles of free fatty acids in blood and 4) activates the use of lipoprotein and phosphorlipid as energy sources^[20]. Therefore, the high-intensity combined exercise performed in this study is effective in improving the blood lipid of obese middle-aged men and is considered a suitable exercise program to prevent health promotion and cardiovascular disease.

Several previous studies were conducted on the change of C-reactive protein (CRP) through complex exercise in middle-aged men and Libardi et al^[14] conducted a study concentrating on strength, endurance and complex training of middle-aged men. However, as a result of examining the effect on the level, there was no statistically significant difference before and after exercise training. Another group of researchers, Mohammadi, Khoshnam & Khoshnam^[13] reported a

significant improvement in CRP in three groups after 12 weeks of aerobic, strength and combined exercise in middle-aged men. In addition, Jung & Lim^[21] reported that 12 weeks of combined exercise for middle-aged obese men significantly reduced their CRP levels.

In this study, a 8-weeks High intensity combined exercise program was conducted to the obese male participants who were in their middle ages, and the program showed significant differences in CRP. Results of the studies suggest that CRP was reduced by inhibition of inflammation due to the decrease of fat cells - which was all due to high-intensity combined exercise programs^[22]. Therefore, the high-intensity combined exercise performed in this study is thought to help improve the circulatory system by reducing CRP levels and suppressing cardiovascular inflammation in obese middle-aged men.

Conclusion

It is associated with blood-related atherosclerosis as the leading cause of death and deterioration of health in middle-aged men. This study was conducted for 8 weeks of high-intensity combined exercise in obese men in their 50s. High intensity combined exercise showed positive changes in body composition, blood lipid and CRP in middle-aged men. This suggests that high-intensity exercise will have effects to men in their 50s with extended life.

Abstract

Background/Objectives: The purpose of this study was to investigate the effect of lower body center strength exercise on blood lipid and homocysteine in middle-aged men. For this purpose, 20 middle-aged men in their 40s were divided into 10 lower body muscle exercise group and 10 control group. The subjects were selected for those who have not participated in regular exercise and weight loss programs in recent years.

Method/Statistical Analysis: The LBMG's treatment program was followed by muscle exercise around the lower body for 60 minutes, 3 times a week for 12 weeks. CG was to maintain a normal life without any treatment during the 12 weeks of the experiment. Mean and standard deviation of each group and treatment time were calculated and 2-way ANOVA was performed to analyze the treatment effect. The significance level was verified at .05 level

Findings: 12 weeks of lower body muscle exercise showed significant differences in blood lipid variables such as triglyceride, high density lipoprotein, low density lipoprotein, total cholesterol and homocysteine.

Improvements/Applications: The purpose of this study was to investigate the effect of 12 weeks of lower body muscle exercise on blood lipid and homocysteine change. Lipoprotein, total cholesterol, and homocysteine showed positive improvement. In this respect, strength training of the large muscle center of the lower body is considered to be effective in improving blood lipid.

Keywords: Lower Body Muscle Exercise, Blood Lipid, Homocysteine, Middle Aged Men.

Introduction

Korea has already entered the aging society in August 2018, with 12.95 million people (24.5%) in 2030 and 18.85 million people (41%) are expected in 2060^[1]. This implies that people living in this society now will have to live their long middle age than any other

previous generation. In order to live a long middle age, economic ability must be followed even after retirement. However, career and jobs, which are the basis of people's economic ability - are now in such an instable state due to low lifelong employment rate, collapses of the social structure and de-hiring^[2]. In particular, Korean men, now in their 40s, have experienced the rise and fall of the Korean economy since entering the job market during the 1997-1998 financial crisis. Moreover, middle-aged men are known to be vulnerable in various health conditions^[3].

Inactive and sedentary lifestyle is the primary risk factor for coronary artery disease. However, middle-aged men had shown that they have higher risk factors than women, including sedentary life style, smoking,

hypertension, and hyperlipidemia. Middle-aged men could increase the incidence of type 2 diabetes, hyperlipidemia, hypertension, and atherosclerotic cardiovascular disease with complication of obesity- and they were four times more likely to develop cardiovascular disease than men in their 20s-30s, and also the mortality rates have been reported to be three times higher^[4].

Several risk factors for coronary heart disease (CHD) have been found out by studies examining various properties such as genetic markers, lifestyle and health status^[5-6]. In addition, most chronic diseases are associated with a number of unhealthy lifestyle factors, including smoking, unhealthy foods, sedentary activities and excessive alcohol consumption^[7]. The long-term health effects of several different unhealthy lifestyle patterns tend to interact to each other rather than simply being added, and changing life styles have been considered as effective intervention strategies for the management of various chronic diseases^[8].

Physical activity and regular exercise not only can prevent metabolic syndrome and also can lower the occurrence rate of various degenerative diseases, but also can prevent disease, reduce premature mortality and extend lifespan. In addition, higher fitness levels have a positive effect on the prevention and treatment of metabolic diseases such as obesity and diabetes, and the importance of exercise^[9-10].

Muscle strengthening program is one of the exercising method which can effectively improve muscle function. It enables various types of exercise by using various magnetic weight and exercise method using gravity or weight device. It is a representative method of

resistance exercise with excellent activity and relatively easy activity^[11].

It is widely known that muscular strength, cardiovascular endurance, and balancing tend to decrease when people get older^[12-14]. Physical strength reduces cardiovascular risk by up to 50% in the middle age, prevents the development of triglyceride (TG), total cholesterol and low density lipoprotein (LDL) risk factors, and increases high density lipoprotein (HDL) levels^[15-17]. In addition, homocysteine blood concentrations are known as independent cardiovascular risk factors^[18], and the increase of homocysteine is known to be associated with increasing the risk of cardiovascular disease, cognitive disorders, cancer, chronic renal failure and other chronic diseases^[19]. Therefore, this study was conducted to build up the basic data for effective exercise prescription program for prevention of chronic and cardiovascular diseases by comparing and analyzing the effects on blood lipid and homocysteine after 12 weeks of lower body muscle exercise in middle-aged men.

Method

1. Subject of Study: The purpose of this study was to investigate the effect of lower body center strength exercise on blood lipid and homocysteine in middle-aged men. For this purpose, 20 middle-aged men in their 40s were divided into 10 lower body muscle exercise group (LBMG) and 10 control group (CG). The subjects were selected for those who have not participated in regular exercise and weight loss programs in recent years. The physical characteristics of the study subjects are shown in Table 1.

Table1: Physical Characteristic of Subjects (M±SD)

Group	N	Age (Yr)	Height (cm)	Weight (kg)	Fat (%)
LBMG	10	41.35±2.55	175.60±1.24	87.02±5.62	28.56±1.48
CG	10	42.38±2.23	172.82±1.80	85.60±4.94	29.36±2.40

2. Exercise Program: The LBMG’s treatment program was followed by muscle exercise around the lower body for 60 minutes, 3 times a week for 12 weeks. CG was to maintain a normal life without any treatment during the 12 weeks of the experiment. The exercise intensity of the LBMG was set by the researcher by setting the intensity and duration of

the program in consideration of the exercise ability of each subject. Prolonged rest and sugar intake during exercise were limited. The environmental homogeneity of LBMG and CG was secured. The main program of LBMG was 10 minutes each for warm-up and cool-down. Warm-up and cool-down were performed with stretching around the

upper body and lower body. The main exercise was maintained at 65-75% based on 1RM. Exercise events consisted of programs for strengthening lower body muscle exercise. Lower body exercise programs are shown in <Table 2>.

Table 2: Lower body exercise Program

Variable	Treatment program	Time/intensity
Warm-up/cool-down	Upper/lower stretching	Each 10min
Main exercise	Squat, plank, crunch, leg raise, leg press, leg extension, lunge, stiff legged deadlift	40min/1RM<75%, 10times, 2-3set, 2-3min rest

3. Measurement method and equipment: The body composition was performed using Inbody 770 Bio Space (Korea). Blood lipid variables such as triglyceride, high density lipoprotein, low density lipoprotein, total cholesterol and homocysteine were

analyzed before and after 12 weeks of experiment. 24 hours fasting time was maintained before blood test, and blood was collected by nurse and referred to medical center for analysis.

4. Data Analysis: Mean and standard deviation of each group and treatment time were calculated and 2-way ANOVA was performed to analyze the treatment effect. The significance level was verified at .05 levels.

Result and Discussion

1. Blood Lipid: According to <Table 3>, there was an interaction effect on TG (p = .016), TC (p = .001), HDL-C (p = .001) and LDL-C (p = .001) in the lower body muscle exercise group (LBMG) compared to the control group (CG). This suggests that lower body muscle exercise has a significant effect on blood lipid change.

Table 3: Blood Lipid ANOVA

Factor	Group	Pre	Post	P
TG (mg/dl)	LBMG	137.42±26.22	120.21±24.85	Group*period: .016 Group: .563 Period: .012
	CG	120.77±37.68	120.34±33.96	
TC (mg/dl)	LBMG	198.40±27.38	174.49±31.68	Group*period: .001 Group: .590 Period: .001
	CG	176.45±34.89	182.74±44.32	
HDL-C (mg/dl)	LBMG	53.62±9.90	61.32±6.94	Group*period: .001 Group: .038 Period: .004
	CG	51.48±7.63	50.80±7.67	
LDL-C(mg/dl)	LBMG	122.00±20.43	103.04±23.27	Group*period: .001 Group: .156 Period: .005
	CG	116.94±26.91	119.31±28.86	

2. Homocysteine: According to <Table 4>, there was an interaction effect in homocysteine (p = .001) in the lower body muscle exercise group

(LBMG) compared to the control group (CG). This suggests that high-intensity combined exercise has a significant effect on homocysteine.

Table 4: Homocysteine ANOVA

Factor	Group	Pre	Post	P
Homocysteine (umol/L)	LBMG	14.41±2.78	12.56±2.54	Group*period: .001 Group: .005 Period: .001
	CG	13.27±2.35	13.07±1.99	

Discussion

This study was conducted to build up the basic data for effective exercise prescription program to prevent chronic and cardiovascular diseases. 12 weeks exercise program was designed, and the following explains the results by comparing and analyzing the effects on blood lipid and homocysteine after 12 weeks of lower body muscle exercise in middle-aged men.

Physical fitness reduces the cardiovascular risk by up to 50% in middle age, prevents the development of triglyceride (TG), cholesterol (TC), and low density lipoprotein (LDL) risk factors and increases high-density lipoprotein (HDL) levels^[20]. High levels of homocysteine in the blood are also emerging as a new risk factor for health as an independent factor inducing arteriosclerosis along with blood lipids^[21]. In addition, a decrease in homocysteine concentration is associated with a reduced risk of cardiovascular disease, and plasma homocysteine concentration increases with age^[22]. Physical exercise reduced the risk of cardiovascular disease^[23-24] and is now reported that exercise appears to alter blood homocysteine levels^[25].

When delving into previous studies on changes in blood lipids through muscle exercise in middle-aged men, Shim^[26], has shown that the improvement of blood lipids was reported in obese middle-aged men who performed pilates exercise three times a week for 12 weeks (with mid-level intensity) for 65 minutes each time. Additionally, Boo^[27] also reported positive effects of blood lipids through the results of effective resistance exercise to strengthen upper and lower body strength with an exercise program, which was carried out 4 sets per week for 8 weeks, 3 sets (12 times in each set) of using 60~80% intensity of 1~RM. In the study of Eem, Cho & Lee^[28], circuit exercise with 50~60% intensity of HRR for 40 minutes was carried out for 8 weeks, three times a week, 40 minutes each - and did show an improvement in blood lipids. In addition, the study by Shim & Kim^[29] also reported the effect of resistance movements with 50-80% intensity of HRR, twice a week, every 50 minutes, for 15 weeks.

When reviewing the previous studies which dealt with changes in homocysteine through muscle exercise in middle-aged men, Steenge et al^[30] reported that blood homocysteine levels were significantly reduced after 8 weeks of resistance training in adult men. Furthermore, several studies dealt with exercise programs which

had effects on decreasing homocysteine levels^[31]. Previous studies have also suggested that homocysteine concentrations decrease after resistance training^[32], but aerobic exercise training has been shown to be less or no effective in reducing homocysteine levels^[33].

In this study, the lower body muscle exercise of 1RM 65-75% was performed for 12 weeks - three times a week, 60 minutes each for middle-aged men, and the results showed a significant difference in blood lipid and homocysteine. These results suggest that it could reduce the concentration of homocysteine in the blood, because the resistance exercise requires more protein metabolism, increases the protein synthesis for skeletal muscle contractile activity and it also increases protein retention in muscle^[32].

This decrease in homocysteine levels in blood which was demonstrated by resistance training studies seems to be related to exercise, intensity, and exercise performance rather than walking and stair climbing activities^[34]. In addition, one of the mechanisms associated with homocysteine function in cardiovascular disease is due to a decrease in HDL levels. Homocysteine reduces HDL concentration in plasma by inhibiting liver synthesis of apoprotein A, which presents in HDL. Reduced HDL concentrations and increased homocysteine levels may increase the risk of cardiovascular disease^[22].

As described above, the lower body muscle exercise conducted in this study is considered as an effective exercise program, which can prevent cardiovascular diseases by improving blood lipids and homocysteine - by strengthening the thigh muscles of human body. In addition, it is considered that further research is needed to develop realistic and diverse exercise programs and to verify the effects of the results of applying these findings to the field.

Conclusion

The purpose of this study was to investigate the effect of 12 weeks of lower body muscle exercise on blood lipid and homocysteine change. Lipoprotein, total cholesterol, and homocysteine showed positive improvement. In this respect, strength training of the large muscle center of the lower body is considered to be effective in improving blood lipid. Based on this program, various weight loss and metabolic syndrome improvement programs are needed.

Anticariogenic effect of *Sambucus williamsii* var. *Coreana* NAKAI (*S. Williamsii*) Extract on Against *Streptococcus Mutans*

Seoul-Hee Nam

Professor, Dep. of Dental Hygiene, College of Health Sciences, Kangwon National University, Samcheok-si, 25949, Republic of Korea

Abstract

Background/Objectives: The purpose of the present study was to assess the anticariogenic effects of *Sambucus williamsii* var. *coreana* NAKAI (*S. williamsii*) extract against *Streptococcus mutans* (*S. mutans*).

Method/Statistical Analysis: *S. williamsii* purchased from Foodsynergy Co., Ltd. (Seoul, South Korea). Dried *S. williamsii* were then crushed and percolated in 70% ethanol, and concentrated *S. williamsii* extract was applied to *S. mutans* diluted to 5×10^5 CFU/ml at the concentrations of 0, 2.5, 5, 10, 20, and 30 mg/ml. Then the colony-forming units (CFUs) were evaluated at 6 and 24 h.

Findings: The *S. williamsii* extract against *S. mutans* had an minimal inhibitory concentration (MIC) of 20 mg/ml and an minimum bactericidal concentration (MBC) of 30 mg/ml at 6 h, and an MIC of 10 mg/ml and an MBC of 20 mg/ml at 24 h. As the concentration of *S. williamsii* extract increased, the *S. mutans* was more clearly killed over time. The application of *S. williamsii* extract to *S. mutans* has an anti-dental-carries effect.

Improvements/Applications: *S. williamsii* extract promotes oral health promotion by inhibiting the growth of *S. mtans*. It could be used as an effective oral anticariogenic agent.

Keywords: *Sambucus williamsii* var. *coreana* NAKAI (*S. williamsii*), Anticariogenic agent, *Streptococcus mutans*, Anti-dental caries, Oral health.

Introduction

Bacteria stay in the teeth, palates, gingiva, tongue, and buccal mucosa, which have suitable conditions for the bacterial characteristics^[1]. In the world, dental caries (tooth decay) and periodontal (gum) diseases are the most common oral disease, known as cause of tooth loss among adults^[2]. Dental caries is one of the most common and costly diseases. Caries are caused by of the bacteria *Streptococcus mutans* (*S. mutans*). It is most

closely related to dental caries and is mainly found in dental plaque^[3]. *S. mutans* is characterized by high acid resistance compared with other bacteria, and maintains its metabolism continuously even at a low pH^[4].

It is said that oral disease causes difficulty of food intake, pain, discomfort, and dissatisfaction with appearance^[5]. Tooth loss has been reported to reduce the chewing capacity, narrowing the range of foods that one can consume, and to decrease the quantity and quality of meals, making it difficult to maintain one's health and fitness^[6]. Therefore, oral health refers to the state of the oral-related tissues that allow people to eat, speak, and socialize without discomfort, thereby contributing to systemic health^[7]. For this reason, health promotion refers to healthcare that changes the individual's environment or health habits and brings about a higher level of well-being^[8].

Resistant bacteria were found in most antibiotics commonly used in the treatment of infectious diseases, making it difficult to maintain oral health^[9]. Therefore, research on substitutes is underway, and research on natural products to search for new materials with pharmacological activity has been actively conducted worldwide for plants and the like^[10].

Sambucuswilliamsii var. *coreana* NAKAI (*S. williamsii*) is a deciduous shrub belonging to Caprifoliaceaesambucus, which grows in the marshes and valleys of mountains^[11]. *S. williamsii* is a medicinal substance widely used in folk remedies that is known to alleviate swelling and pain and improve blood circulation, and to have anti-inflammatory action^[12]. Therefore, the purpose of this study was to apply *S. williamsii* to the typical dental-caries-inducing bacteria, *S. mutans*, to confirm the possibility of its use as an anti-caries material and to promote oral health.

Method

S. williamsii preparation: The dried *S. williamsii* used in this study was purchased from Foodsynergy Co., Ltd. (Seoul, South Korea). After adding 70% ethanol to crushed *S. williamsii*, an extract was obtained at 60°C for 12 h. The extract was filtered using filter paper (Whatman No. 2, Tokyo, Japan), and the *S. williamsii* extract was concentrated using a rotary vacuum evaporator (N-1300E.V.S. EYELA Co., Tokyo, Japan). The concentrated *S. williamsii* was lyophilized using a freeze dryer (Ilshin Lab Co., South Korea). The sample was stored at -20°C after dilution.

Bacterial Strains: In this experiment, *S. mutans* (KCTC 3065/ATCC 25175) was used after the subculture in brain heart infusion (BHI) broth. *S. mutans* was incubated in BHI at 37°C for 24 h, and was diluted at a 5×10^5 ratio.

Antimicrobial activity by S. williamsii extract concentration: 100 µL of cultured *S. mutans* (5×10^5 colony-forming units; CFUs/ml) was inoculated into a 24-microwell plate containing BHI broth in which *S. williamsii* extract was added at each concentration (0, 2.5, 5, 10, 20, and 30 mg/ml). The total volume of each mixture was 1 ml. The microplate was incubated anaerobically for 6 and 24 h at 37°C, and then the mixture in each well was uniformly smeared in an agar medium and then cultured at 37°C for 24 h to check the number of CFUs.

Statistical Analysis: Student's t-test was conducted to identify the changes that could have occurred after 6 and 24 hours. The difference in each concentration was evaluated through one-way analysis of variance (ANOVA), followed by the Tukey test at $\alpha = 0.05$. Significance analysis of the inhibitory effect was carried out using Ver. 21.0 (SPSS Inc., Chicago, IL, USA)

Result and Discussion

In modern times, the concept of health has evolved into the concept of physical, mental, and social well-being, not merely the absence of physical illness, and as the relationship between quality of life and health has been emphasized, the interest in the impact of oral health on quality of life has also increased^[13]. Due to the increased interest in oral health, the prevention rate of oral diseases is higher than those of other diseases, but people in developed and developing countries still suffer from oral diseases^[14].

Pathogens usually exist as normal bacterial flora, but when the number of specific bacteria increases or decreases in the normal bacterial flora in the oral cavity, it causes diseases like dental caries and periodontal disease, leading to pain and eating disorders, and results in tooth loss. It is also a major cause of bad breath and may cause social problems for the people afflicted with such condition^[15]. Today, there is a comprehensive understanding of the concept of health, and the health behavior with regard to the teeth or oral conditions and their consequences must be considered together. Thus, general bodily health with poor oral health cannot be considered a healthy state^[16].

The widespread use of antibiotics has led to a dramatic decrease in the incidence of bacterial disease, but it has led to an increase in disease due to the bacteria that have become resistant to antibiotics^[17]. For this reason, studies have been actively conducted on the separation and application of natural antimicrobials with superior antimicrobial activity and safety due to the side effects of synthetic antifungal agents, to prevent dental caries and to promote the avoidance of chemical substances^[18]. Therefore, this study was conducted to apply *S. williamsii* extract as a substitute for chemical substances in the treatment and prevention of dental caries induced by *S. mutans*.

The antibacterial effect of *S. williamsii* extract against *S. mutans* was evident with increasing concentration and over time [Figure 1]. Figure 1(a) presents the change

in CFUs according to the application of *S. williamsii* extract after 6 h, and Figure 1(b), after 24 h. As shown in Figure 2, the death rate of *S. mutans* at 6 h depending on the concentration of *S. williamsii* extract was 2.90×10^7 at 0 mg/ml, 1.48×10^5 at 2.5 mg/ml, 4.34×10^4 at 5 mg/ml,

8.73×10^2 at 10 mg/ml, 4.90×10^1 at 20 mg/ml, and 0 at 30 mg/ml. On the other hand, the death rate at 24 h was 1.02×10^{11} at 0 mg/ml, 5.67×10^7 at 2.5 mg/ml, 3.80×10^7 at 5 mg/ml, 4.33×10^6 at 10 mg/ml, 0 at 20 mg/ml, and 0 at 30 mg/ml.

Figure 1. Anticariogenic activity of *S. williamsii* extract against *S. mutans* (A) after 6 h and (B)24 h

Figure 2. The survival rate of *S. mutans* by *S. williamsii* extract

According to statistical test for the significance of the difference between the death rates at 6 and 24 h, respectively, there was no significant difference from 20 mg/ml ($P>0.05$). This means that the time did not affect the killing of the bacteria at 20 mg/ml. In the change

according to the concentration, there was a statistically significant evidence ($P<0.05$), but in between groups, except for *S. mutans* (0 mg/ml), for which *S. williamsii* extract was not treated, there was no difference depending on the concentration [Table 1].

Table 1. The mean±SD number of CFUs and P-value of the antibacterial activity by *S. williamsii* extract

Group	<i>S. mutans</i> (0mg/ml)		2.5mg/ml		5mg/ml		10mg/ml		20mg/ml		30mg/ml		ANOVA P-Value

6h	2.90±0.1 10 ^{7a}	0.000*	1.48±0.4 10 ^{5b}	0.004*	4.34±0.8 10 ^{4b}	0.008*	8.73±0.9 10 ^{2b}	0.004*	4.90±0.1 10 ^{1b}	0.149	0 ^b	-	0.000*
24h	1.02±0.8 10 ^{11a}		5.67±0.3 10 ^{7b}		3.80±0.1 10 ^{7b}		4.33±0.2 10 ^{6b}		0 ^b		0.000*		

*The significant difference for 6h and 24h comparison by student t-test ($P<0.05$)., * Different letters (a and b) by the presented statistically significant result of the one-way ANOVA and post hoc Tukey HSD ($P<0.05$)

The results of this study proved that the application of *S. williamsii* extract to *S. mutans* has an anti-dental-caries effect. As the concentration of *S. williamsii* extract increased, the *S. mutans* was more clearly killed, showing a distinct antimicrobial activity over time. The minimal inhibitory concentration (MIC), which is the minimum concentration of bacteria that cannot be visibly detected, and the minimum bactericidal concentration (MBC), which the concentration at which the bacteria are completely killed, were 20 and 30 mg/ml, respectively, at 6 h. At 24 h, MIC and MBC were 10 and 20 mg/ml, respectively. The concentration at which the antimicrobial activity actively occurred, and at which the bacteria were completely killed, was confirmed to be 20 mg/ml. The statistical analysis showed no significant difference between the changes that occurred at 6 and 24 h at 20 mg/ml, which means that there was a difference in CFUs but there was no statistical difference between the antibacterial effects that occurred at 6 and 24 h.

As for the anti-dental-caries effect of natural extracts, a previous study reported that the MIC and MBC values of *Cyperusrotundus* extract on *S. mutans* in the study was 225 and 450 mg/ml^[19]. When the fact that an antibacterial effect was shown in such study by applying an extract at a higher concentration compared to the present study is considered, the inhibitory effect against *S. mutans* was low compared to *S. williamsii* extract, and *S. williamsii* can be said to have a higher antibacterial effect. According to the study of Antonio et al.^[20], the antibacterial activities of *Coffeacanephora* extract MIC and MBC for *S. mutans* were 7±2 and 160±0

mg/ml. This result showed that *S. williamsii* extract has a higher antimicrobial activity than *Coffeacanephora* extract. Therefore, it can be concluded that *S. williamsii* extract has an excellent effect as an anticariogenic agent against *S. mutans*, and can thus be employed as a natural antibacterial agent in oral care products.

Conclusion

In this study, the application of *S. williamsii* extract to *S. mutans* was shown to be effective in preventing dental caries. The *S. williamsii* extract against *S. mutans* had an MIC of 20 mg/ml and an MBC of 30 mg/ml at 6 h, and an MIC of 10 mg/ml and an MBC of 20 mg/ml at 24 h. In the near future, *S. williamsii* extract may conceivably be used as an effective anti-dental-caries substance for dental caries prevention as for natural medicines.

Development of a Medical Phantom to Evaluate the Function of Low Dose 3D MDCT

Chang- Gyu Kim

Professor, Gimcheon University, Department of Radiological Science, South Korea

Abstract

Background/Objectives: Low dose radiation-based CT imaging is a technology that dramatically improves the information on borders between similar substances but with difference in density. The findings will serve as basic data in developing a CT phantom dedicated for X-ray phase differential imaging.

Method/Statistical Analysis: To evaluate the benefits of a phantom for low dose 3D MDCT, SOMATOM Definition ASH (Siemens, Germany) CT scanner that produces 128 slices of images with one rotation was used. The auto-exposure condition (AEC) was applied as it is frequently used in clinical settings for high dose CT. After the image was acquired, a qualitative analysis was conducted to verify the practical use in a clinical setting.

Findings: In order to evaluate the images acquired from the in-house produced medical phantom and the resolution in the image space, the phantom must be made of substances that have a similar actual atomic number as water. It is practical to produce the phantom for 3D CT by mixing a pure liquid and powder. The absorption, dispersion and phase differential images acquired through the low dose X-ray device were analyzed on a 5 point Likert scale. The absorption image scored 4.3 points for liquid form and 3.50 points for powder form. Both the dispersion image and the phase differential image scored 3.00 points for the liquid form and 4.50 points for the powder form, indicating that the liquid form produces better quality images in the absorption image, while the powder form produces better images in dispersion or phase differential images. The differences were statistically significant ($p < 0.05$).

Improvements/Applications: The findings show that for dispersion and phase differential images, compared to the absorption images, substances in powder form rather than liquid form are conducive to better images. These findings are expected to be of use in the field of medical imaging to produce images with high diagnostic value using low dose radiation.

Keywords: *Low dose CT, image quality, phantom, performance evaluation, radiation.*

Introduction

CT tests have the patient enter a column-shaped machine that generates X-rays to produce a cross-section of the human body. CT, unlike the simple X-ray, has less overlapping of structures and thus allows for more accurate viewing of the lesion^[1, 2].

With the progress made in CT technology, CT can be used for early detection of diseases no matter where the site is, present an approach to invasive tests and facilitate follow-up after treatment. It is thus often used for the diagnosis, treatment and management of any small diseases that cause anatomical changes. With such progress, it is expected that CT will become within several years, an essential part of early radiological tests or initial tests upon admission, just as liver function tests^[3-10].

X-ray is classified as a grade 1 carcinogen by the WHO, along with alcohol and tobacco. As such, when

e-mail: radkcg@hanmail.net

undergoing CT or PET-CT imaging, great care is needed. The total number of CT's taken in Korea increased from 5.25 million cases in 2010 to 7.7 million in 2015. The number of CT equipment, too, increased from 2147 units in 2011 to 2300 units in 2016. This translates into 4.5 units for every 100,000 citizens, which is higher than the OECD average of 2.5 units per same number of people. But during individual check-ups, often CT tests are done unnecessarily. According to a survey by Seoul Medical Center in 2015, the maximum exposure to radiation through optional tests such as CT on the abdomen, lungs or PET CT is on average 14.82mSv. This is four times the radiation exposure Korean citizens are subject to during their daily life over a year (3.6mSv)^[4,11].

The biological effects caused by ionizing radiation in medical setting can be categorized as definitive effects and possible effects. The former is the radiation that goes over the threshold of when the radiation absorbed by the human body triggers a response in the tissue. In most cases, it causes the death of cells and can only occur when a majority of cells exposed to radiation die^[12].

X-ray phase differential imaging technology dramatically improves the information on borders between similar substances but with a difference in density, using data from phase differentials. It is applied to low dose CT imaging. Compared to existing imaging technologies that leverage the difference in the level of X-ray absorbed, low dose radiation can be used to generate high quality images ^[8-12]. However, there is a lack of studies on phase differential CT imaging, and no studies on CT phantoms where phase differential imaging has been applied.

As such, in this study, a CT phantom for the exclusive use of X-ray phase differential imaging was produced to acquire an absorption image and a phase differential image and evaluate the image quality and amount of data from the images. The findings will provide basic data for the development of CT phantoms used in phase differential imaging.

Subjects and Methodology

1. Evaluation of the function of CT using an in-house produced phantom: To evaluate the benefits of a phantom for low dose 3D MDCT, SOMATOM Definition ASH (Siemens, Germany) CT scanner that produces 128 slices of images with one rotation was used [Fig. 1]. The auto-exposure condition

(AEC) was applied as it is frequently used in clinical settings for high dose CT [Table 1].

Table 1. Table title

Parameter	Value
Technique	Adult-Helical
kVp	80
mA	84
Time per rotation (sec)	0.6
mAs _{eff}	35
Scan Field of View	66×66
exposure time(sec)	0.416
Table speed (mm/rot)	26.5
Pitch	0.828
Reconstructed Scan Width (mm)	5

Figure 1.3D MDCT imaging device

2. Production of a phantom for the evaluation of low dose CT: A phantom was produced in the lab to evaluate the function of low dose 3D MDCT. To evaluate images, the phantom was produced in two types – one made with powder materials and another made of liquid materials. The phantom consisting of polyethylene was made into a column with a diameter of 3×1cm and five holes with a diameter of 0.5cm. Phosphor, calcium, calcium from anchovies, aluminum and carbon powder were placed in the holes, To acquire absorption, dispersion and phase differential images, the distance between the focal point and the object was set at 300mm, the fixed grid was placed at 700mm, and the distance between the focal point and the director was set at 1,448mm. The exposure conditions were 22kVp, 20mA and 630msec.

For the liquid phantom, a column with a diameter of 3×1cm and five holes with a diameter of 0.5cm.

Water, sodium chloride, soybean oil, silicone oil and a phosphor solution were placed in an envelope and placed inside the holes. The conditions were set as the same for the powder phantom. The distance between the focal point and the object was set at 300mm, the fixed grid was set at 700mm, and the distance between the focal point and the director was set at 1,448mm to acquire an image under the exposure conditions of 22kVp, 20mA and 630msec.

3. **Image evaluation method:** After the image was acquired, a qualitative analysis was conducted to verify the practical use in a clinical setting. The contrast, detection rate of lesions, and the distinctness of the borders were reviewed for five groups (1: Very low, 2: Low, 3: Average, 4: High, 5: Very high). A team consisting of two medical doctors in radiology and three radiologists with more than 10 years of experience conducted the evaluation.
4. **Statistical Analysis:** For data analysis, SPSSWIN (Ver 13.0) was used. Verification of the significance of the mean value of the radiation exposure measured in the control group and the experiment group was done through a t-test and ANOVA. The significance level of all statistics was set at $p < 0.05$.

Study Results and Review:

1. **Evaluation of the practical benefits of an in-house produced medical phantom for low dose 3D CT:** The phantom consisting of polyethylene was made into a column with a diameter of 3×1cm and five holes with a diameter of 0.5cm. Phosphor, calcium, calcium from anchovies, aluminum and carbon powder were placed in the holes. This phantom was used to evaluate the low dose 3D CT.

The liquid phantom is a column with a diameter of 3×1cm and five holes with a diameter of 0.5cm. Water, sodium chloride, soybean oil, silicone oil and a phosphor solution were placed in an envelope and placed inside the holes. In addition, to evaluate the image spatial resolution, phosphor, calcium, aluminum and barium were placed in holes with a diameter of 0.1 cm, 0.2 cm, and 0.3 of the medical phantom produced.

For the liquid phantom, a column with a diameter of 5×10 cm made of polyethylene and holes with a diameter of 0.5 cm were created. Water, phosphor, calcium,

aluminum and barium in liquid form were injected into the holes for the images to be acquired.

The images acquired from high dose CT using a medical phantom in powder form were as seen in [Fig. 2]. An image of the water, phosphor, calcium, aluminum and carbon substances showed that a distinction of concentration was possible for water and carbon, while for phosphor, calcium and aluminum the high unit density led to images with beam hardening.

The high dose CT imaging test results using a medical phantom in powder form are as seen in [Fig. 2]. Depending on the type of substance, due to beam hardening, evaluation on the image's spatial resolution varied. This shows that to evaluate the spatial resolution in images from CT, substances with a similar actual atomic number to that of water must be used. This finding is expected to be important when producing a medical phantom for CT in the future.

Figure 2. Images acquired from the medical phantom in powder form to evaluate the spatial resolution

To evaluate the practical benefits of a medical phantom made of liquid substances, a 3D CT image was acquired after placing water, phosphor, calcium from anchovies, aluminum and carbon powder inside the phantom. The 3D CT image of a liquid phantom [Fig. 3] shows that for substances with a similar valid atomic number to that of water, three dimensional distinction was difficult. Meanwhile, images acquired when water and powder were mixed, showed a decent three dimensional distinction as seen in [Fig. 3]. This finding indicates that when producing a medical phantom for low dose 3D CT, a mix of liquid and powder is beneficial.

Figure 3. Image acquired for the medical phantom made of a mix of liquid and powder substances

2. Findings from the evaluation of low dose X-ray images: To produce a phantom that would enable evaluation of the function of low dose 3D MDCT, absorption, dispersion and phase differential images were acquired using low dose X-ray. The liquid phantom is a column with a diameter of 5×1cm and five holes with a diameter of 0.5cm. Water, sodium chloride, soybean oil, silicone oil and a phosphor solution were placed in an envelope and placed inside the holes.

Absorption, dispersion and phase differential images were acquired using the in-house produced phantom. The distance between the focal point and the object was set at 300mm, the fixed grid was set at 700mm, and the

distance between the focal point and the director set at 1,448mm. Radiation was applied under the conditions of 22kVp, 20mA and 630msec.

Images acquired from a medical phantom made of liquid substances showed that there was a distinction in contrast for different substances in the absorption image. In the dispersion and phase differential images, more difference was found in the amount of data provided rather than in the contrast [Fig. 4]. In particular, when industrial silicone oil was used, there was a distinct difference in the dispersion and phase differential images compared to in the absorption image. This seems to be due to the difference in the valid atomic number.

Figure 4. Image Absorption, dispersion and phase differential images of the liquid phantom

The powder medical phantom is a column with a diameter of 5×1cm and five holes with a diameter of 0.5cm. Phosphor, calcium, calcium from anchovies, aluminum and carbon powder were placed in the holes. To acquire absorption, dispersion and phase differential

images, the distance between the focal point and the object was set at 300mm, the fixed grid was placed at 700mm, and the distance between the focal point and the director was set at 1,448mm. The exposure conditions were 22kVp, 20mA and 630msec.

While in the absorption image there was a difference in contrast for different substances of the powder phantom, the distinctiveness in contrast between calcium or phosphorus was subtle, making it difficult

to tell them apart. Meanwhile, in the dispersion and phase differential images, there was a relatively greater difference in the amount of data provided in the image, rather than a difference in contrast [Fig. 5].

Figure 5. Image Absorption, dispersion and phase differential images of the liquid phantom

The absorption, dispersion and phase differential images acquired using a low dose X-ray imaging device were analyzed on a 5 point Likert scale. In the absorption image, the score was 4.30 points for the liquid phantom and 3.50 points for the powder phantom. In the dispersion and phase differential images, the score was 3.00 points for the liquid phantom and 4.50 points for the powder phantom. The image quality was higher in the liquid phantom for the absorption image and in the solid phantom for the dispersion and phase differential images. There was also a statistically significant difference ($p < 0.05$).

The findings suggest that compared to the absorption image, in the dispersion image and phase differential image, the powder phantom is more conducive to higher quality images. As such, it is expected to use more widely in acquiring images that offer high diagnostic value through low dose X-ray imaging.

Conclusion

A CT phantom for X-ray phase differential imaging was produced in the lab to analyze its practical benefits in high dose CT. The absorption, dispersion and phase differential images were acquired from low dose X-ray devices to evaluate the image quality and the amount of information provided by the image.

The evaluation showed that in order to evaluate the spatial resolution of images acquired, the medical phantom for the CT must be made of substances with a

similar valid atomic number to that of water, and that it is best that the phantom be made with a mix of liquid and powder substances.

An analysis of the absorption, dispersion and phase differential images acquired from low dose X-ray imaging devices on a 5 point Likert scale showed that the score for the absorption image was 4.30 points for the liquid phantom and 3.50 points for the powder phantom. In the case of dispersion and phase differential images, the score was 3.00 points for the liquid phantom and 4.50 points for the powder phantom, this indicates that the liquid phantom is more beneficial for the absorption image and the powder phantom is more beneficial for dispersion and phase differential images in acquiring high quality images. There was a statistically significant difference in this ($p < 0.05$).

In the above experiments, the dispersion and phase differential images, compared to the absorption image, was better at producing images for substances in powder form rather than in liquid form. This finding is expected to have many applications in the field of imaging technologies to produce images with high diagnostic value using low dose X-ray.

A Study on the Optometrist' Images between Major Students and Non-major Students

Ki-Hun Ye¹, Jung-Eun Ha²

¹Professor, Department of Optometry, ²Professor, Department of Dental Hygiene, Baekseok University, South Korea

Abstract

Background/Objectives: This study was designed to assess the actual state of optometrist' image, to determine their identity, and to provide fundamental feedback to improve their image.

Method/Statistical Analysis: The study involved 303 students, 179 of whom were majoring in optometry, while 124 were not. The subjects were asked to answer an online questionnaire survey in order to analyze optometrist' images. The collected data were compared and analyzed at a significance level of 0.05 using SPSS 18.0.

Findings: In terms of optometrist' general image, optometry major students rated it 3.75, while non-major students gave it 4.02 points ($p < 0.05$). The traditional image scored 4.15 and 4.0, respectively; the social image scored 3.70 and 3.54; the professional image scored 4.18 and 4.02; the social participation image scored 3.66 and 3.48; and the interpersonal relationship image scored 3.92 and 3.70. The scores for all images were statistically significantly different ($p < 0.05$).

Improvements/Applications: The results suggested that optometrist, both as a group and individually, need to make efforts in social voluntary service and social contribution to improve their social participation image, as well as efforts toward social status image improvement to enhance their social image.

Introduction

Health care occupations are meant to serve the disadvantaged. Therefore, persons in these occupations need to serve others, and it is very important that they have aligned personal beliefs and attitudes. Thanks to digital information, consumers today have more medical knowledge, are more interested in health care, and have a higher perception of medical service. As a result, there is a demand for more and better medical

services.^[1-2] Optometrist have been required to not only provide such services as eyesight measurement, making and processing glasses, and selling glasses and lenses, but also to offer a variety of different services to meet customers' needs. In other words, as experts in eye health, they are socially requested to deliver comprehensive information and knowledge about glasses and lenses, eye operations, and ophthalmology (eye diseases).^[3] Fast technological development and innovation have been helping humans to improve their living standards. With the greater acquisition of information, people have been increasingly realizing the importance of the eyes and have become more interested in eye health. In this context, optometrist' social roles have become more significant.

In a situation in which half of the national population wears glasses or lenses, optometrist play a critical role in

e-mail: eyelovebaekseok@bu.ac.kr

eye health and have a responsibility toward the public’s quality of life based on functioning eyes. Optometrist not only measure customers’ eyesight to make and process proper optical glasses and provide some medical services for the eyes, but they also sell glasses and lenses. Therefore, their image is very important^[4]

An image is a sense of one’s feeling received from a person or an object. It represents the belief, sense, or impression of an object exiting one’s mind. The occupational image reflects something general and typical of a particular occupation. The external image of an occupation is formed in consideration of the characters and characteristics of the people with that occupation, their types of jobs, life, pay, work conditions, and welfare, and the impression of the occupation.^[5] The internal image of an occupation is created by the efforts made by the occupational group and each individual. It takes a lot of time and effort to create a positive image, whereas it is very easy for an individual’s incorrect behavior and attitude to give a negative image of the occupation. For this reason, an occupational image is very hard to manage. People of many different occupations make efforts to improve their occupational image. These efforts go in the direction of finding one’s occupational identity and developing it further. It is important to assess the image of optometrist, who take care of the public’s eye health, to enable them to improve it in the future.^[6]

This study analyzed a variety of images of optometrist held by students majoring in optometry (major students) and students not majoring in optometry (non-major students). The study results can be used as fundamental feedback to help establish the true image of optometrist.

Method

In order to compare and analyze optometrist’ images, an online questionnaire survey was conducted on 179 students who were majoring in optometry and 124 who were not (a total of 303 students) from May to June 2019.

The questionnaire consisted of 20 questions (four questions for each of five images). All the questions in the questionnaire were answered on a 5-point Likert scale (5: strongly agree, 4: agree, 3: somewhat agree, 2: somewhat disagree, 1: disagree, 0: strongly disagree). The full score for each image was 20 points, and the mean was based on the four questions. Cronbach’s α ,

which represented the reliability of the questionnaire on optometrist’ images, was 0.95, reflecting very high reliability. The collected data were applied to SPSS 18.0 at a significance level of 0.05 in order to compare and analyze optometrist’ images.

The questionnaire used in this study was created by modifying and supplementing a questionnaire about images of medical occupations to make it applicable to optometrist. For a comparative analysis of optometrist’ images, their images were categorized into five types: their traditional image, which is related to their qualifications (cleanliness and neatness, reliability, frankness and honesty, immediate reaction and response to customers’ requests); their social image, which is related to optometrist’ social roles (high intelligence, high social status, management of eye health, provision of abundant information about the eyes); their professional image as experts in eye health (skillfulness and professionalism, accurate measurement of eyesight and making of glasses, occupational pride, abundance of ophthalmological knowledge); their social participation image, which is related to their social contribution and voluntary service (social recognizability, efforts for the public’s eye health, level of social contribution [voluntary activity], valuableness and effectiveness of job); and their interpersonal relationship image, which is related to their communication with patients and kindness (kindness, cooperativeness and good relationship, non-authoritative communication, comfort and reliability).

Result and Discussion

The general characteristics of the study subjects are presented in Table 1. Regarding the age and name given, major students and non-major students had significantly different images of optometrist ($p < 0.05$). Students in their 20s had somewhat better images of optometrist than those in their teens, and students who called optometrist “Sir” and “Ma’am” or “optician” had better images of optometrist.

Table 1. The general characteristics of the study subjects

Variable	Division	Major Students	Non-Major Students
sex	Male	81	44
	Female	98	80
Age	18-19	78	63
	20-27	101	61

Variable	Division	Major Students	Non-Major Students
Habit of visiting	Existing optical shop	124	86
	New optical shop	55	38
Title	Teacher	94	49
	Optician	32	17
	Sister and uncle	7	13
	Anything else	46	45
Right expression of optical shop	Wrong answers	38	67
	Correct answers	141	57

The correlations in the optometrist' images are presented in Table 2. All the image types (traditional image, social image, professional image, social participation image, and interpersonal relationship image) had statistically significant correlations ($p < 0.05$). Table 3 presents a comparison of optometrist' traditional image and social image between major students and non-major students. Yoo's research on the traditional image of nurses revealed a score of 3.42, which was somewhat lower than the score of 4.09 points for optometrist' traditional image in this study.^[7] In the present study, major students rated optometrist' traditional image 4.15 and non-major students rated it 4.00, whereas in Yoo's study, there was a large difference between major students (3.99) and nonmajorstudents (3.20).^[8] In the question about whether "optometrist are clean and neat, and immediately react and respond to customers' requests",

both student groups gave high marks. In the question about whether "optometrist are frank and honest", major students and non-major students respectively gave 3.89 and 3.78 points, which was relatively low. The image that optometrist, who also manage sales, are not frank and honest can seriously harm customer reliability. Therefore, it is necessary to improve the image of optometrist. In Park et al.'s research on the images of emergency medical technicians, major students and non-major students gave 4.11 and 3.84 points, respectively, to the social image of emergency medical technicians.^[9] In the question about whether "optometrist are highly intelligent", major students gave 4.02 points (the highest score).

In the question about whether "optometrist offer a lot of information on the eyes", non-major students gave 3.86 points (the highest score). In the question about whether "optometrist have a high social status", both major and non-major students gave the lowest scores: 2.86 and 2.84 points, respectively. In Park et al.'s study, in the question about whether "emergency medical technicians have a high social status", both major and non-major students gave the lowest scores: 2.48 and 2.53 points, respectively.^[9] The social status is the position in society and the organizational influence on society. To develop optometrist' social image, it is necessary to improve their image in order to increase their social status.

Table 2. The correlations in the optometrist' images

Variable	Traditional image	Social image	Professional image	Social participation image	Interpersonal relationship image
Traditional image	1				
Social image	.671*	1			
Professional image	.667*	.738*	1		
Social participation image	.608*	.755*	.681*	1	
Interpersonal relationship image	.600*	.598*	.624*	.610*	1

p	.00		.03		.05		.02		.05		.00	

Conclusion

Overall, major students had a more positive image of optometrist than non-major students, and particularly of their professional image, which scored the highest at 4.12 points. Their social participation image scored the lowest, at 3.58. Both major students and non-major students gave the highest scores (4.30 and 4.24, respectively) in answer to the question related to optometrist' traditional image about whether "optometrist are clean and neat". Since optometrist are experts in eye medical service, their hygiene was perceived as the highest. Although optometrist have an occupational mission to serve the public's eye health, their social participation image scored the lowest. In light of this, optometrist need to make efforts toward social contributions and voluntary service in order to improve their social image. Both major students and non-major students gave the lowest scores (2.86 and 2.84) in answer to the question related to optometrist' social image about whether "optometrist have a high social status". Therefore, optometrist, both collectively and individually, need to make efforts to improve their social status.

The Study of Swedish Massage on Anxiety Situation and PPT in Stressed Office Workers

Jae-Gun Seo¹, Su-Hee Choi², Dong-Yeop Lee³

¹Graduate Student,, Dept. of Physical Therapy, Sun Moon University, ²Professor, Dept. of Physical Therapy, Kunjang University College, ³Professor, Dept. of Physical Therapy, Sun Moon University, Korea

Abstract

Background: The purpose of this study was to investigate the effects of Swedish massage on anxiety and pressure pain threshold in office workers with psychological stress.

Method: Sixty office workers with psychological stress were randomly assigned to experimental group 1 and control group. They were assigned into either a Swedish massage group (Experimental group 1, n = 30) or a resting group (Control group, n = 30). A single measurement mediated Swedish massage and rest for 20 minutes and was measured before and after intervention.

Findings: In state trait anxiety inventory (STAI), there were significant differences between before and after the experiment and between the two groups ($p < .05$). The pressure pain threshold (PPT) of the upper trapezius increased in the Swedish massage group ($p < .05$).

Application: These findings indicate that, the Swedish massage applied to stressed office workers showed a significant difference in increase of PPT and decrease of STAI.

Keywords: Swedish massage, STAI, PPT, Stress, Office Workers.

Introduction

At present, there are many studies that indicate chronic stress has a detrimental effect on health. Stress has been shown to be associated with immune function and cardiovascular disease^[1]. According to Bae's study, stress impairs the anti-inflammatory effects of the immune system, leading to chronic infections, chronic immune diseases, or cancer as well as other physiological disorders^[2]. Hawkins's found that about 760 depression, stress or anxiety occurred in 100,000 workers. Moreover, most people would agree that stress can have a negative impact on health, but they don't

know how to prevent or cope with it. Other studies have shown that long-term psychological stress can interfere with psychological and physiological functions and can be more easily infected with diseases that can put more stress on life in addition to causing disease^[3,4,5].

It is very important to find ways to reduce stress that can adversely affect the body. There are a variety of physical therapies that can induce positive emotions through proper stimulation of the skin. Among them, Swedish massage is a treatment that can relieve stress and fatigue by promoting muscle relaxation, and it has been reported to have a significant effect on blood pressure reduction, especially in women^[6]. Massage is a standard treatment used in many countries, whose principle is to apply pressure to muscles in the direction of the blood flow to the heart; it comprises five main techniques that most therapists use in the United States^[7,8,9]. There have been few studies related to treating stressed office workers through Swedish massage, and most of them are applied for the purpose of alleviating muscle spasms and

Corresponding Author:

Professor, Dept. of Physical Therapy, SunMoon University, Korea

e-mail: kan717@hanmail.net

relaxing muscles, although they can help to relieve stress, too. Swedish massage is a method that can effectively apply the five (effleurage, petrissage, friction, tapoment, vibration) according to each situation. Therefore, the purpose of this study is to provide evidence that Swedish massage can be used to relieve stress from the stressed office workers by comparing and analyzing state trait anxiety inventory and pressure pain threshold related to stress when Swedish massage is applied to stressed workers.

Method

1. Subject: The subjects of this study were 60 stressed office workers with 9 points or more on a Psychosocial Well-being Index-short form (PWI-SF) scale, who work at K branch in D city. They were randomly assigned into either a massage group (Experimental group 1, $n = 30$) or a resting group (Control group, $n = 30$). The experiment was conducted in a comfortable light treatment room where the room temperature was maintained between 22 and 24°C. The subject was placed directly on the massage table and a wedge-shaped knee support was placed under the knee at 70° flexion of the hip. Relaxation was allowed. After the experiment began, it blocked conversations, phone sounds, other noises, and electromagnetic waves that could act as variables in the experiment, minimizing the irritation of the surroundings, preventing the subject from sleeping during the experiment, and closing the eyes and taking part in the experiment comfortably. The study consisted of two massage majors, and two massage majors performed massage for 20 minutes. For the massage group, Swedish massage was performed twice on the neck and shoulder for 10 minutes each session, and the resting group rested in the lying position for 20 minutes [Figure 1].

Both groups were provided with the same conditions of time and surroundings. STAI and PPT were measured before and after the experiment. The subjects were fully informed of the purpose of the study, and they gave informed consent prior to entering the study. Only those who have no skin conditions, have no history of thrombosis treatments, do not take prescription medicines related to the cardiovascular system, and agree to perform the same daily activities as usual were included in the study.

Figure 1. Design of experimental procedure

2. Measurement tools:

- 1. State trait anxiety inventory (STAI):** The state trait anxiety inventory (STAI) test before and after the Swedish massage was self-reported and consisted of 20 questions asking how they felt at the very moment in a specific situation, and their levels of feelings were assessed on a 4-point scale^[10].
- 2. Pressure pain threshold (PPT):** Pressure pain threshold (PPT) is measured using an Algometer (Algometer, Sammons Preston, USA, 2010) to assess the pressure pain level at the pain trigger point of the upper trapezius. Subjects sit comfortably in the chair, take an upright position, mark the superior-angle of the shoulder bone, and make it vertical, and as the pressure was gradually increased at a rate of 1lb/sec, they were told to voice “ah” at the point of unbearable pain, and then the pressure gauge reading was measured at that moment in lb/cm². The trigger point of the upper trapezius of the dominant hand was measured and it was used as PPT. After three measurements at the same location, the mean value is used for the analyses. Measurements

before and after massage application were used as comparators^[11] [Figure 2].

Figure 2. Pressure pain threshold measuring method

3. Statistical Analysis: All statistical analyses in this study were conducted using SPSS ver. 21.0 program. One-Way ANOVA test was used to confirm the general characteristics of the subjects. For the normality test between the two groups, Kolmogorov-Smirnov was used, and for the change of dependent variables before and after intervention, the corresponding sample t-test was used, and One-Way ANOVA was used to compare the effects between the two groups. All statistical significance probability (α) of the data were .05.

Result

According to the general characteristics and homogeneity test, although control group with average age of 37.80 years was older than Experimental group 1 with average age of 37.40 years, there were no significant differences between the two groups; although control group with average height of 169.17 cm was taller than Experimental group 1 with average height of 167.07 cm, there were no significant differences between the two groups; although control group was heavier with average weight of 63.97kg than Experimental group 1 with average weight of 61.57kg, there were no significant differences between the two groups; although Experimental group 1 was greater with mean BMI of 22.30 kg/m² than Experimental group 1 with mean Body mass index (BMI) of 22.03 kg/m², there were no significant differences between the two groups. Although in PW, control group was higher with mean value of 23.23 points than Experimental group 1 with mean value of 23.20 points, there were no significant differences between the two groups.

1. STAI: In STAI, there were significant differences between before and after the experiment and between the two groups ($p < .05$). It was judged that Experimental group 1 was lower than control group [table 1].

Table 1: The immediate effects of Exp. 1 group on anxiety (N = 60)

Parameter	Exp. group 1 (n = 30)	Control group (n = 30)	F	p
STAI (before)	36.80±4.67a	36.47±4.83	.074	.78
STAI (after)	30.57±4.65*	36.77±4.28	28.862	.00

Exp : Experimental group 1, STAI: State trait anxiety inventory, a: mean±standard deviation., *: Within-subjects comparison $p < .05$, : Between-subjects comparison $p < .05$

2. PPT: PPT was a variable to determine the level of pain when pressure was applied, which showed significant differences between before and after the

experiment ($p < .05$). But the differences between the two groups were not significant [Table 2].

Table 2: The immediate effects of Exp. 1 group on PPT (N = 60)

Parameter	Exp. Group 1 (n = 30)	Control group (n = 30)	F	p
PPT (lb/cm ²) (before)	11.85±3.83 a	12.19±3.29	.133	.71
PPT (lb/cm ²) (after)	13.87±4.03*	12.40±3.29	2.417	.13

Exp : Experimental group 1, PPT: Pressure pain threshold, a: mean±standard deviation., *: Within-subjects comparison $p < .05$

Discussion

The purpose of this study was to investigate the effects of Swedish massage on the change of STAI and its impact on PPT in stressed office workers. After 20 minutes of massage, there were significant differences in STAI value in Experimental group 1. This suggests that the rhythmic stimulus induces, through a somatosensory area in the skin, increased activity of the vagus nerve, i.e. hyperfunction of parasympathetic nerve, resulting in psychological stability, which leads to differences in STAI between before and after the massage and between the two groups.

Bessel's reported that treatments such as massage are upward treatments enough to restore control of the vagus nerve^[12]. PPT showed significant differences in Experimental group 1 between before and after the treatment, but there were no significant differences between the two groups. Wall's pain theory showed that proper mechanical stimulation on the skin can reduce pain^[13]. Therefore, the rhythmic mechanical stimulation in Experimental group 1 is considered to bring about emotional stability due to the relaxation of muscles and the effects of upregulation. Kim's study of the effects of the experimental group on the activity of the sympathetic nervous system, anxiety, pain, and pressure pain thresholds in the subjects with psychological stress suggested that the scores on the state anxiety scale were relatively lower in the experimental group, which was similar to the outcome of this study^[14]. Farzane's compared the effects of two Swedish massage techniques on vital signs and anxiety in healthy women. Vital signs and anxiety levels were checked for 10 patients who had Swedish massage on their legs, arms, and face, and 10 who had Swedish massage on their back, neck, and chest groups. Vital signs were significantly decreased in both groups and there was no significant difference in anxiety score after massage^[15]. Felipe's study examined the effects of massage on cyclic rhythm, pain, stress index and quality of life in patients with myalgia syndrome. A total of 24 subjects were subjected to a total of 24 Swedish massages twice a week for 3 months and 40 minutes per session. After 3 months, pain was reduced, stress index was decreased, quality of life was improved, but cortisol concentration was not affected by massage treatment^[16]. Najafi's study looked at the effects of massage and music on pain, anxiety and relaxation in burn patients. Of the 240 subjects, 60 were provided with music, 60 were provided with massage, 60 were provided with both music and massage, and the remaining 60

were provided with rest after being treated for general burns; each group had 20-minute intervention per day for a three-day period. In all three groups, the intensity of pain and anxiety decreased and the level of relaxation increased. There were no significant differences between the groups that received intervention, but the effects of the group that received both the massage and music at the same time showed greater effects^[17]. Alsdair's conducted a study on the effects of Thai massage and Swedish massage on fatigue and energy depletion states. Ten subjects received Thai massage and ten subjects received Swedish massage for 45 minutes per session for a period of six weeks. Both types of massage showed improvement in sleep quality, relaxation, stress relief, muscle tone relief and physical and mental well-being^[6]. Therefore, it suggests that appropriate stimulation in Experimental group 1 alleviates state anxiety.

Conclusion

Swedish massage can induce effective relaxation with five different techniques, leading to a decrease in STAI and an increase in PPT. Therefore, it should be considered as an important factor in physical therapy for stressed subjects. The limitation of this study is that it is difficult to generalize the research results because only stressed workers participated in the study. Also, the single measurement design of the intervention does not reveal how long the actual effects will last. In future studies, it is expected that results can be generalized through studies with various types of subjects.

Abstract

Background/Objectives: The purpose of this study is to investigate the effects of interest inducing activities program (IIAP) within three type on attention and self-efficacy in school-aged children.

Method/Statistical Analysis: This study was conducted on 22 children except 3 out of 25 elementary school children registered in the center. In addition, they were classified into craft activities, reading activities, physical activities. To determine the change in the child's attention and self-efficacy, Harris & Harris Grid Test, and self-efficacy questionnaire are used.

Findings: There was no statistically significant difference in attention through IIAP in three groups ($p > 0.05$). In the self-efficacy, there was a statistically significant difference among the groups ($p < 0.05$). And there was no statistically significant difference in attention and self-efficacy among the groups according to IIAP ($p > 0.05$).

Improvements/Applications: We suggest it is important to develop programs for voluntary participation and children's attention and self-efficacy.

Keywords: School-aged children, Interest inducing activities, Attention, Self-efficacy, Motivation.

Introduction

Excessive use of smart phones by elementary school students reduces the need and physical activity of children, which can lead to deterioration of writing ability, attention and learning efficiency by imbalance of physical development and simplification of thinking^[1]. Interest-inducing activities in elementary school age focus on a task and interest in a variety of task activities.^[1] This is an important factor in the learning

process and can help improve attention and self-efficacy by using play, art, music, and fairy tales, which are of interest to low-grade elementary school children with low attention and high aggression, as treatment tools^[2,3]. Attention is the cognitive function required for the information acquisition of school-age children, which is especially important for forming the basis of the learning process. As a factor, the development of elementary school years positively affects children's learning ability and creativity^[4-7]. Therefore, the purpose of this study is to find out how it helps the elementary school children's self-efficacy and attention through the interest inducing activities program (IIAP), which includes handicrafts, reading, and physical activities that can be easily applied to school age children. In addition, this study attempts to identify the differences in children's attention and self-efficacy in three types of interest-inducing activities

Method

In this study, a total of 22 children were selected from 9 male and 13 females, except for three children who did not meet the criteria. Three children were excluded from the selection due to attention deficit hyperactivity disorder (ADHD), disease and dyslexia. The criteria for the study were based on children without orthopedic, neurological, or cognitive problems, who could follow three levels of instruction, read and write, and no other disease. In this method, the Harris & Harris Grid Test (HHGT) was used as attention assessments to investigate the effect on concentration of elementary school students. The test randomly arranged numbers from 1 to 100 in squares of 10×10 , 25 cm wide and 25 cm long, and the participants looked for the numbers indicated by the examiner for 60 seconds and displayed them on the numbers. 1 point was calculated for each number found. In addition, the evaluation of the number plate arranged differently for each test minimized the errors due to the learning effect, and the cases where the participants found different numbers or the same numbers in succession were excluded from the score. In this assessment, the higher the score could mean the higher attention and the Self-Efficacy Questionnaire (SEQ) for self-efficacy evaluation was consisting of 24 items including 7 questions of confidence, 12 items of self-regulating efficacy, and 5 items of preference for task difficulty in self-efficacy component. The higher the score is 120, the higher the self-efficacy. In this study, SEQ was given individually and scored by providing an example for each item that is difficult to understand. HHGT and SEQ was used to evaluate this before and after IIAP. IIAP consisted of three activities: handicraft activity, reading activity physical activity. and before starting the IIAP, Participating children identified the desired program through a questionnaire and classified it into groups. The program was conducted twice

a week for three weeks, for a total of 60 minutes per session. After four weeks, the program was evaluated to be change in children's attention and self-efficacy. The handicraft activity was one of the following: clay work, mosaic, water beads, and corrugated cardboard. Reading activities were performed differently per session, including introducing books, reading books, making books, introducing favorite book scenes, and watching movies based on the books. physical activities included football, simple football, mating, tagging, handkerchief, number racing, simple dodgeball, and badminton according to the difficulty. For the study analysis, data were analyzed using SPSS 21.0. The general characteristics of the subjects were analyzed using descriptive statistics. The differences of HHGT and SEQ between groups before and after IIAP were used by the corresponding paired t-test, and the differences of HHGT and SEQ among the groups before and after IIAP using one-way ANOVA. Statistical significance was $\alpha = 0.05$.

Result and Discussion

1. General characteristics of the subjects: General characteristics of children who participated in this study are shown in [Table 1]. Of the 22 subjects, 10 were male (45.45%), 12 were female (54.55%), and the average age was 9.86 years old, average height 133.52cm, average weight 34.02kg. Handicraft activities group (HAG) consisted of 1 male (12.5%), 7 female (87.5%), average age 8.88 years old, average height 123.50cm, average weight 27.28kg. And reading activities group (RAG) was 2 males (40%), 3 women (60%), mean age 10 years, mean height 131.58cm, mean weight 36.84kg. Lastly, physical activities group (PAG) consisted of 5 males (55.5%), 4 females (44.5%), average age 10.67 years old, average height 140.83cm, average weight 38.44kg.

Table 1. General characteristics of subjects

Variables		TPG (N = 22)	HAG (N = 8)	RAG (N = 5)	PAG (N = 9)
Sex	M	M (10, 45.45%)	M (1, 12.50%)	M (3, 60%)	M (5, 55.50%)
	F	F (12, 54.55%)	F (7, 87.50%)	F (2, 40%)	F (4, 44.50%)

2. Comparison of attention and self-efficacy through IAAP in groups: [Table 2] shows a comparison of attention before and after the IIAP applied to the children. First, HAG changed to 2.40 before and 5.80 after IIAP, RAG group to 3.13 before and 4.13 after IIAP, PAG to 4.22 before and 5.33 after IIAP. There was no statistically significant difference in

both groups ($p > 0.05$). In addition, HAG was 69.13 before and 77.38 after IIAP, and the RAG was 79 before and 89 after IIAP. PAG increased from 80.44 before to 86.78 after IIAP and showed a statistically significant difference in RAG and PAG ($p < 0.05$), whereas HAG showed no significant difference ($p > 0.05$).

Table 2. Comparison of attention and self-efficacy through IAAP in three groups.

Variables		Before	After	T	p
HHGT	HAG (N = 8)	3.131.73	4.1301.25	-1.32	0.23

IIAP in school-age children into handicraft activities, reading activities, and physical activities. Through this, we confirmed how the IIAP affects the attention and self-efficacy of participating children. First, there was no significant difference in the attention of the three groups after IIAP. It was difficult to control the noise and external environment that occurred during the process of inducing interest programs in the first place, and this restriction was a negative factor in the attention of participating children^[8]. Therefore, blocking negative environmental factors in the execution of IIAP is considered to be a major factor in increasing attention. And HAG did not have a positive effect on the self-efficacy after IIAP. This is primarily due to the lack of initiative in children’s initiatives in autonomous selection of activities and materials and the composition of programs. These factors are considered to be important for children to increase their motivation and active participation in IIAP and thereby increase their self-efficacy^[9,10]. However, the activities of this study had structural problems that made it difficult for children to prepare and select the materials that they needed autonomously in preparation. In addition, high dependence of children occurred during the program process. These factors may have negative effects on children’s activity leadership.

Discussion

Based on previous studies, this study classifies

On the other hand, the self-efficacy of participating

children improved in reading and physical activities in RAG and PAG. These results expressed their own opinions through the process of selecting and reading the books that the participating children wished to read and presenting them in their own products. In addition, the process of presenting the child's own reading results to other friends is considered an important process for improving the child's self-efficacy^[11,12]. Physical activities consisted of sessions focused on the activities desired by the participating children to induce voluntary participation and divided the activities into two teams. In addition, physical activities organized sessions centered on the activities desired by participating children to induce voluntary participation. In the case of physical activities, the team is divided into two teams to work together for the positive results of their teams to plan strategies and actively present personal opinions on how to proceed with the activities. These results were consistent with the results of previous studies that the higher the motivation to participate in sports activities, the higher the self-efficacy, and the healthy relationship experience and interaction with peers led to many changes in improving the self-efficacy of children^[13]. Therefore, it is considered that the environmental factors affecting children's self-efficacy and especially voluntary participation are very important for the program consisting of children's voluntary motivation and active participation in reading and physical activity. Lastly, this study hypothesized that there would be a difference in attention and self-efficacy according to the characteristics of handicraft, reading, and physical activities. Through these results, it was considered that the contents and environment that enable children's motivation and voluntary participation are important variables in the concentration and self-efficacy of children. Therefore, it will be important to find out whether environmental differences, as well as program differences, influence children's motivation and voluntary participation in subsequent studies. This study has the following limitations. First, due to differences in age, gender, and physical condition of the group, it is not possible to generalize the characteristics of the child, it is not possible to control environment when conducting IAP. Based on these limitations, it is considered that future research should be conducted in consideration of the surrounding environment and the personal characteristics of children. In addition, it is difficult to interpret the meaning of the effect due to the short arbitration period.

Conclusion

This study focuses on self-focused and self-focused programs in 22 elementary school children enrolled in the children's center by applying an interest-inducing program consisting of craft activity, reading activity and physical activity for 4 weeks. The change in efficacy was evaluated and the following results were obtained. First, there was no statistically significant difference between before and after concentration in the three groups of interest-induced programs ($p > 0.05$). However, self-efficacy showed statistically significant difference between reading and physical activity ($p < 0.05$). Second, there was no statistically significant difference in concentration and self-efficacy between the three groups of interest-induced programs ($p > 0.05$). Through this, it is considered that it is important to consider not only the systematic program for enhancing the concentration and self-efficacy of the child but also the environmental factors related to the motivation and voluntary participation of the child in the program composition process.

Comparison of Nurse Teachers and General Teachers and Nurses Happy Planet Index

Oe-Nam Kim¹, Na-Rae Oh², Su-Yeon Seo³

¹Assistant Professor, Department of Nursing, Youngnam Foreign Language College, Korea, ²Adjunct Professor, Department of Dental Hygiene, Pohang University, Korea, ³Assistant Professor, Department of Dental Hygiene, Youngnam Foreign Language College, Korea

Abstract

Background/Objectives: The purpose of this study is to suggest alternatives for being happier by measuring teachers and nurses' happy planet index among women who enter professions and by grasping factors that have impacts on clinical nurses' happiness.

Method/Statistical Analysis: This study conducted a survey of a total of 727 teachers and looked into surveys that have 19 questions on the happy planet index and 7 questions on general characteristics. SPSS WIN 23.0 was used as the data analysis method and multivariate analysis of variance(MANOVA) was used to analyze differences in the happy planet index among groups and multiple regression analysis was used to analyze factors that had impacts on the happy planet index.

Findings: The results of this study showed that correlation among the happy planet index and the housing possession and monthly income and working experience was statistically significant and that factors that had impacts on the happy planet index were age and marriage and religion and educational background.

Improvements/Applications: As for the study results, it is reckoned that potential developments and motivation programs that improve self-respect and self-consciousness and that can contribute to organizations should be developed for improvements in the happy planet index of clinical nurses who have very little work experience.

Keywords: Nurse, Happy planet Index, Nurse teachers, General teachers, Psychological well-being.

Introduction

The interesting conversation topic of modern men living in busy daily life is 'happiness.' As an economy develops, the recognition that a rise of incomes is not everything of happiness is being strengthened and interests in mental quality of life or happiness along with material riches increase^[1] Men want happier and

more pleasant life unlike the past when men should be concerned about living from hand to mouth to appease their hunger. Because the definition of happiness is different, depending on individual viewpoints and what you feel about happiness and unhappiness is different even in identical conditions, depending on individual values, defining it in a word is difficult^[2].

Then, what is happiness? As for the concept of happiness, it was defined as delight gotten from enough satisfaction and pleasure in life or blessed and good fortune in Korean standard unabridged dictionary and 'happy' that meant happiness in English stemmed from the word 'happ', an ancient Scandinavian language and meant a fortune or an opportunity^[3]. Also, Socrates, a western philosopher said that happiness was 'summum

Corresponding Author:

Na-Rae Oh

Adjunct Professor, Department of Dental Hygiene,
Pohang University, Korea
e-mail: nalae761@gmail.com

bonum', a state satisfied with everything as the best state that humans can enjoy. Aristoteles said that happiness was summum bonum' that all nature was oriented towards and an excellent activity of a soul pursuing virtue. Epicurean school or utilitarians identified happiness with pleasure.

The study in happiness recently is carried out from ancient philosophers and in many academic fields. Then, happiness is decided by any factor? As for early studies in individual happiness or level of satisfaction of life [4], age and health and education level and income and extroversion and rathymia and religion and marriage and self-respect are suggested as factors that had impacts on happiness.

The study showed that sex or intelligence had not significant impacts on happiness, but men who have young and healthy ages and high levels of education and high incomes and who are outgoing and optimistic and don't worry and have their religions and got married and have high levels of self-respect and the will to work and appropriate aspiration were happier than those who didn't [5].

The study in happiness can largely be divided into two things. First, levels of subjective well-being focusing on subjective judgement on happiness is high. This means satisfaction levels of individual life is high.

Psychological well-being includes self-acceptance and positive interpersonal relationship and autonomy and self-control on the environment and purpose of life and personal growth. Also, the results of foreign studies showed that sex wasn't the factor that had big impacts on happiness experiences [6-9].

Studies for revealing factors that had impacts on happiness in Korea is recently conducted [10,11].

The results of the study showed that men felt happier than women about leisure and social status and self-development and inner-direction and social · political · cultural environment and spouse's love and trust and appearance and health. However, figuring out factors that discriminatorily have impacts on men and women's happiness is a more important thing rather than figuring out any group among men and women experiences more happiness and less happiness [5]. Studies related to the happy planet index have been conducted with various terms such as subjective quality of life and subjective well-being and satisfaction level of life and happiness [12].

The proportion of women among economically active population rose from 49.2% in 2009 to 53.6% in 2009 every [13].

Thus, the purpose of this study is to suggest alternatives for being happier by measuring teachers and nurses' happy planet index among women who enter professions and by grasping factors that have impacts on happiness.

Method

1. Study subject and Study tool: This study figures out three groups' general characteristics. This study measures and compares three groups' happy planet index.

The group of nurse teachers asked the survey in 178 elementary and middle and high schools of C region and the group of general teachers asked the survey in 10 schools and the group of nurses asked the survey in more than 500 sick beds under agreement and cooperation from departments of five medical institutions. 178 surveys from the group of nurse teachers and 291 surveys from the group of general teachers and 301 surveys from the group of nurses were returned. Except for imperfect cases among returned surveys, a total of 727 people including 168 nurse teachers and 277 general teachers and 282 nurses were chosen as final subjects.

Tool questions were composed of a total of 19 questions including one question on family and marriage and three questions on personal relationship and one question on regional society and two questions on daily life and two questions on economic stability and three questions on job and three questions on health and one question on housing. It was considered that the more points of an 11 point Likert scale from 0(very low) to 10(very high) are high. Surveys on subjects' general characteristics such as age and marital status and religion and educational level and position and working experience and monthly income were conducted.

2. Data Collection Method and Data Analysis

Method: The data collection period was from September 1, 2018 to September 30, 2018. Self-administered questionnaires were written. Collected data was entered and analyzed with SPSS WIN 18.0. Subjects' demographical characteristics were analyzed with the frequency and percentage and average and standard deviation. The multivariate analysis of variance (MANOVA) and post hoc

test (Scheffe test) were carried out to compare differences in variables that had impacts on the happy planet index among groups.

Spearman’s correlation analysis was used to analyze the relationship between the happy planet index and variables. Multiple regression analysis was used to analyze factors that had impacts on the happy planet index.

Result and Discussion

1. Subjects’ demographical characteristics: Nurse teachers were 168 women (23.1%) and general teachers were 277 women (38.1%) and nurses were 282 (38.8%) and the total number of them was 727 women. Single women were 404 women (55.6%) and married women were 323 women (44.4%) and women in cohabiting families were 625 women (86.0%) and women without cohabiting families were 102 women (14.0%). Women who graduated from universities were the highest (46.5%) and women who graduated from two-year or three-year colleges were 263 women (36.2%) and women who completed graduate schools were 126 women (17.3%). Women who had their religions were 382 women (52.5%) and women who hadn’t their religions were 345 women (47.5%) and 513 women (70.6%) owned their houses and 214 women (29.4%) lived in yearly and monthly rental houses. 454 women’s average amount of sleep was 7 to 8 hours each day and figures (62.4%) were the highest and 259 women (35.6%) slept under 6 hours and 14 women (1.9%) slept more than 9 hours [Table 1].

2. Comparison of each group’s Happy Planet Index: General teachers’ average happy planet index was 6.83 points, the highest points. There were significant differences in them ($p < .001$) [Table 2]. As for factors related to the happy planet index such as psychological stability and family (marriage) and personal relationship and regional society and daily life and economic stability and job and health and housing possession, happy planet index of the group of nurse teachers and of general teachers was higher than the group of nurses. The recent OECD (Organization for Economic Co-operation and Development [OECD]) happiness index compares the state of well-being based on 11 themes that OECD essentially checked in fields of material living conditions and quality of life^[14]. The similar study.

Table 1. Demographics of the Participants (N = 727)

Variables	N/Mean	%/SD
Age	34.29	9.09
Work experience	9.97	8.84
Individual income	249.40	83.08
Family income	549.72	614.71
Marital status		
Yes (Married)	323	44.4%
No (Single)	404	55.6%
Living status		
Living alone	102	14.0%
Living with others	625	86.0%
Education		
Diploma	263	36.2%
Bachelor degree	338	46.5%
Master or doctoral degree	126	17.3%
Religion		
Yes (Have)	382	52.5%
No (Haven’t)	345	47.5%
Housing ownership		
Living in own house	513	70.6%
Rent house	214	29.4%
Sleeping hours		
<6 hours	259	35.6%
7-8 hours	454	62.4%
>9 hours	14	1.9%

Result showed that clinical nurses’ happiness index that was 2.94 points (5 point scale), average happiness index points to use OECD Better Life Index was shown as the moderate size^[15]. It can be implied that factors related to clinical nurses’ happiness index such as psychological stability and family (Marriage) and personal relationship and regional society and daily life and economic stability and job and health and housing possession were related to the happiness index.

3. Correlation between factors related to happiness: Correlation between age and work experience was 921 ($p < .01$), very high figures and correlation between individual monthly income and work experience was 859 ($p < .01$) and correlation of age was 851 ($p < .01$) and correlation between the happy planet index and housing possession was 758 ($p < .01$), high figures. Correlation between martial status and work experience was 543 ($p < .01$), moderate figures and correlation between martial status and individual monthly income was 488 ($p < .01$), moderate figures. Correlation between individual monthly income

and the happy planet index was 348 ($p < .01$) and correlation between individual monthly income and housing possession was 320 ($p < .01$) and correlation between individual monthly income and household monthly income was 312 ($p < .01$). Correlation between age and the happy planet index was 328 ($p < .01$) and correlation between age and housing possession was 303 ($p < .01$). Correlation between the happy planet index and individual monthly income was 348 ($p < .01$) and correlation between the happy planet index and marital status was 306 ($p < .01$) and correlation between the happy planet index and work experience was 305 ($p < .01$) in consecutive order. Correlation between cohabiting family and marital status was $-.452$ ($p < .01$) and correlation between cohabiting family and age was $-.240$ ($p < .01$). There were significantly negative correlation [Table 3]. The result showed that the more clinical nurses' ages increased, the more high their work experiences because increase in clinical experiences made monthly income increase. As shown in the study of 2013 other than Nam moon hee's study, this corresponded to the result that the more women got married and had their positions and earned high annual incomes, the more high the happiness index was^[16]. It is reckoned that this was shown because a sense of self-satisfaction and a sense of accomplishment based on relaxed and stable life were felt and increased. Also, it is reckoned that improvements in organizational cultures and establishments of measures were needed to improve the happiness index of clinical nurses who had low work experiences.

4. Factor that has an impact on happiness: Variables showing the significant correlation diagram were age and marital status (yes) and religion (yes) and educational background (university) and household monthly income and the average amount of sleep per day (7 to 8 hours) and explanatory power (14.9%) [Table 4]. The happiness index when women got married was .019. When women had their cohabiting families and religions and graduated from universities and monthly incomes of families were high, those had impacts on happiness. This was similar to the result that income was the factor that affected on happiness in the study which conducted the survey of America's nursing university students^[16]. As shown in study's analysis results, it can be found out that clinical nurses' happiness index increased when there were cases described above. It is thought that potential developments and motivation programs that improve self-respect and self-consciousness and that can contribute to organizations should be developed because improvements in clinical nurses' happiness index are important things to improve qualitative levels of clinical nursing. Malee and others in 2009 said that rather than personal elements, organizational elements that had impacts on happiness of people working in nursing universities such as professional advance in job and characteristic of job and work environment and welfare had impacts on happiness. Things that nurses maintain high quality professionalism and keep doing challenging works are factors that have impacts on happiness^[16].

Table 2: Comparison of Happiness index among, Health-education teachers General teachers and Nurses

Variables	Mean±SD			F	Post-hoc test
	Health-education teachers 1	General teachers 2	Nurses 3		
Psychological stability	7.08±1.65	7.23±1.44	6.32±1.40	29.26***	1>3, 2>3
Family (marriage)	7.13±2.02	7.39±1.67	6.49±1.76	18.45***	1>3, 2>3

Religion (yes = 1)	.097			
Education (bachelor = 1)	-.024			
Family income	.184			
Sleeping hours (7-8 hours = 1)	.175			

Conclusion

This study conducted in order to provide basic data for nurses’ happy life by grasping clinical nurses and general teachers and nurse teachers’ happy planet index and determining factors that had impacts on the happy planet index.

First, general teachers’ average happy planet index was the highest 6.83 points and nurse teachers’ average happy planet index was 6.71 points and clinical nurses’ average happy planet index was 5.70 points.

Second, the result that analyzed correlation of happiness index factors in this study showed that correlation between the happiness index and housing possession was .758(p<.01) and the more work experience increased, the more high the happiness index was.

Third, the result from multiple regression analysis to analyze factors that had impacts on happiness showed

that the variable showing significant correlation diagram was age, -0.007 and affected happiness significantly.

It is thought that if studies in factors that have impacts on the happiness index such as work environment and characteristic as well as clinical nurses’ personal factors are tried based on these study results in the future, studies with a high level of reliability and validity is carried out.

Cognition and Behavior of Oral Health in Preschool Parents

Su-Jung Lee¹, Hong-Ryang Jung², Cheong-Hwan Lim², Jong-Hwa Jang³

¹Doctoral, ²Professor, Dept. of Health Care, Hanseo University, 46 Hanseo 1-ro Haemimyeon Seosansi Chungcheongnamdo, 31962, ³Professor, Dept. of Dental Hygiene, Dankook University, 119 Dandae-ro Dongnamgu Cheonansi Chungcheongnamdo, 31116, Republic of Korea

Abstract

Background/Objectives: This study was conducted to investigate the oral health cognition and behavior of 83 children's parents. The results of this study were as follow. First, the questionnaire consisted of eight items on oral health behavior and three items on parental oral health cognition. Improper oral health care behavior responses resulted, and the necessity of fluoride application of oral health awareness scored lower than the necessity of oral health education and regular dental checkups.

Method/Statistical Analysis: Targeting a total 83 parents at daycare centers in the C region, September 2018-October 2018, this study distributed the home notification, questionnaire, and research consent form to each home through their children. The completed research consent forms and questionnaires were collected by the daycare centers from the children.

Findings: The three times of brushing daily, two-three minutes of brushing each time, and the '1/3, 1/2 of the toothbrush for the amount of toothpaste used received the most responses. Many respondents changed their toothbrushes every four weeks. 72.3% of respondents used fluoride toothpaste, and 72.3% of respondents were controlling food and snacks containing sugar. 73.5% of parents were receiving regular oral examination, and 30.0% of parents received it once a year. 84.3% of parents were using secondary oral hygiene products. The average oral health perception was 4.26 while the necessities of fluoride application, regular dental examination, and oral health education averaged 3.59, 4.63, and 4.63 respectively.

Improvements/Applications: It would be necessary to vitalize the oral health project and oral health education for parents and children, and also to have accurate and systematic studies on more inclusive and diverse elements.

Keywords: Oral health, Oral health cognition. Oral health behavior; Preschool parents, Oral health education.

Introduction

Korea is conducting the oral health project for pregnant women and infants under the plan of oral

health project of Article 5 (establishment of oral health project basic plan) of the Oral Health Act, and also intends to conduct oral health education at kindergartens and schools, group brushing, fluoride mouth-rinsing, oral health diagnosis, and continuous oral healthcare through the school oral health project under Article 12, Clause 3, No. 1 of the enforcement ordinance of the Oral Health Act. According to Article 16, Clause 1 of the enforcement ordinance of the Oral Health Act, the oral health education plan for pregnant women and infants should be established and conducted every year (some revised legislation of the Oral Health Act, Korea, 2016). Compared to the policy, however, the oral

health education for pregnant women and preschoolers is not actively performed. As the one-time education at educational institutes for children is neither continuous nor systematic, it has been reported that the effects of education are unacceptable^[1]. In the preschool age, it is necessary to prevent oral diseases by regularly visiting the dentist, and also to be educated about regular oral examination/treatment, fluoride application, dietary control, and oral care while the oral health could be improved by parents' education, guidance, and care at home^[2].

Contrary to emphasizing the treatment in the past, the direction of medical science is gradually changing to preventive medicine. Dentistry is also changing from treatment-centered to prevention-centered. The necessity of prevention-centered education is emphasized.

Considering the change in eating habits, increased intake of sticky saccharic processed food, high experience rate of dental caries, and high rate of early tooth extraction caused by the modernization and urbanization from the late 20th century, the oral health education that could prevent it proactively should be preceded first. As a period of moving beyond the nurturer's care because of social changes related to childcare caused by changes in family structure or increase of parents' social activities, approximately 80% of young children age three-five are enrolled at kindergarten or childcare facilities^[3] while the children's use of childcare institutes is also increasing. Even though the snacks, drinks, and food provided by childcare institutes include many foods causing dental caries such as bread, yogurt, and drinks^[4]. The education at kindergarten or childcare facilities, and homes is not sufficient. On top of supporting educational media or training of diverse educational method, it would be necessary to develop the oral health education programs based on close cooperation with families.

The oral health behavior refers to the general attitude towards oral health and the behavioral characteristics, and the factors affecting individuals' oral health behavior are considerably diverse^[5]. Once there is a problem with oral health, it has effects on the overall health. The oral symptoms have effects on the oral functions, which impact the subjective oral health condition again and affects the quality of life. As the parents' oral health perception has effects on their children's oral health behavior, there should be more research on the characteristics of parents, and oral health education and programs suitable for the oral health

perception and behavior^[6]. Such oral health education programs fully considering the oral health perception and behavior, would make parents realize more the effects on the improvement of oral health level and the enhancement of oral health^[7-8]. Thus, the purpose of this study was to establish the basic data for the development of a customized oral health education program and its method by understanding the parents' oral health perception and behavior.

Method

- 1. Method:** Targeting a total of 83 parents at kindergartens in C region, September 2018-October 2018, this study distributed the home notification, questionnaire, and research consent form to each home by their children. The completed research consent forms and questionnaires were collected by the kindergartens by the children again.
- 2. Materials:** On top of the questions about the general characteristics such as age and sex, the questionnaire was composed of eight questions about parents' oral health behavior and three questions about parents' oral health perception. Using the SPSS 22.0 Program, this study conducted the frequency analysis on the general characteristics of the subjects and the measured variables.

Result and Discussion

- 1. Oral Health Behavior:** In the oral health behavior of the research subjects, regarding the number of brushing daily, three times (65.1%) was the most. In case of the brushing duration per each time, two, three minutes (38.6%) were the most. Regarding the toothpaste used for brushing, the 'use of 1/3 and 1/2 of the toothbrush' showed the same frequency as 34.9%. In case of the toothbrush change period, the change of it once in four weeks (42.2%) was the most. 72.3% of the parents were using the fluoride toothpaste while the 72.3% of the parents were controlling the food and snacks containing sugar. 73.5% of the parents were receiving the regular oral examination, and the annual regular examination showed the highest percentage (30.1%). 84.3% of the parents were using the secondary oral hygiene products, and currently, 72.3% of the parents were using the fluoride toothpaste. 53.0% of the guardians responded that they received the brushing education from a health center or clinic [Table 1].

Table 1. Oral Health Behavior

Variables	Section	Frequency	Valid Percentage
Guardian’s number of brushing daily	One time	2	2.4
	Two times	19	22.9
	Three times	54	65.1
	Four times or more	8	9.6
Guardian’s brushing time	30 seconds	2	2.4
	One minute	12	14.5
	Two minutes	32	38.6
	Three minutes	32	38.6
	More than three minutes	5	6.0
Guardian’s amount of toothpaste	As big as a bean	21	25.3
	1/3 of toothbrush	29	34.9
	1/2 of toothbrush	29	34.9
	3/2 of toothbrush or more	4	4.8
Guardian’s toothbrush change period	Two weeks	6	7.2
	Three weeks	14	16.9
	Four weeks	35	42.2
	Five weeks or more	28	33.7
Guardian’s use of fluoride toothpaste	Use	60	72.3
	Do not use	23	27.7
Guardian’s control of food and snacks containing sugar	Control	60	72.3
	Do not control	23	27.7
Guardian’s regular oral examination	Every six months	16	19.3
	Once a year	25	30.1
	A year or longer	20	24.1
	Do not schedule examination	22	26.5
Oral hygiene secondary products in use+	Use	70	84.3
	Do not use	13	15.7
Place where the guardian has received the education of brushing method	Never learned it	3	3.6
	School	19	22.9
	Home	11	13.3
	Health center or clinic	44	53.0
	Others	6	7.2

2. Oral Health Perception: In the oral health perception of the subjects, the necessities of fluoride application, regular dental examination, and oral health education were shown as average 3.59, average 4.55, and average 4.63 respectively while the oral health perception was average 4.26 [Table 2].

Table 2. Oral Health Perception

Variables	Mean±SD	Range
Necessity of fluoride application	3.59±0.11	1-5
Necessity of regular dental examination	4.55±0.77	1-5
Necessity of oral health education	4.63±0.68	1-5

Discussion

The modern medical science is changing from the treatment-centered to the prevention-centered^[9]. To improve the oral health, it is emphasized to conduct health education that could influence health, knowledge, attitude, behavior, and the healthy behavioral aspect of each community member. Also, there have been many studies reporting that the parents’ oral health knowledge and behavior would play a crucial role in the establishment of children’s oral health, and they would also have major effects on the family health and education^[10-13].

According to the subjects' oral health behavior revealed in this study, in the number of brushing daily, less than three times was 25.3%, and 16.9% of the respondents brushed their teeth for less than a minute. Such improper brushing habits could influence children. Also, the necessity of regular dental examination was 4.55 of the highest 5 while 26.5% of the respondents did not receive regular oral healthcare. This means that they do not practice regular oral healthcare even though they feel the necessity to do so.

In the oral health perception, the necessities of regular dental examination and oral health education were shown as 4.55 and 4.63 respectively of the highest 5 while the necessity of fluoride application was shown as low as 3.59. The awareness of effects and convenience of fluoride application may be low.

Considering the change of eating habits, increased intake of sticky saccharic processed food, high experience rate of dental caries, and high rate of early tooth extraction caused by the modernization and urbanization from the late 20th century, to effectively practice oral health and to prevent the oral diseases of preschoolers, the oral health education for the continuous oral healthcare of children and parents should be preceded first.

The oral health condition has effects on the quality of life, and the parents' oral health perception has effects on the oral health behavior of their children. The oral health education programs could realize the effects on the improvement of oral health level and the enhancement of oral health. It would be necessary to have more studies on the characteristics of parents, and the specialized oral health education suitable for the oral health perception and behavior.

Conclusion

This study examined the oral health perception and behavior targeting a total of 83 parents at kindergartens in C region September 2018-October 2018, and the results of analyzing the questionnaires composed of eight questions about oral health behavior and three questions about oral health perception are as follow. Using the SPSS 22.0 Program, this study conducted the frequency analysis on the general characteristics of the subjects and the measured variables.

First, the three times of brushing daily, two-three minutes of brushing per each time, and the '1/3, 1/2 of the toothbrush for the amount of used toothpaste

received the most responses.

Second, many respondents changed their toothbrushes every four weeks. 72.3% of the respondents used the fluoride toothpaste, and 72.3% of the respondents were controlling the food and snacks containing sugar.

Third, 73.5% of the parents were receiving the regular oral examination, and the 30.0% of the parents received it once a year. 84.3% of the parents were using the secondary oral hygiene products.

Fourth, the average oral health perception was 4.26 while the necessities of fluoride application, regular dental examination, and oral health education were average 3.59, 4.63, and 4.63 respectively.

Such results show the necessities of fluoride application, regular dental examination, and oral health education for parents, and also their improper oral healthcare behavior, which would have indirect effects on children. Thus, in the future, it would be necessary to vitalize the oral health project and oral health education for parents and children, and also to have the accurate and systematic research on more inclusive and diverse elements.

Big Data Analysis for Child Well-being on Academic Research

Jung-ho Bae¹, Eunae Burm²

¹Professor, Baekseok Culture University, Department of Childhood Education, Korea,

²Professor, Baekseok Culture University, Department of Nursing, Korea

Abstract

Background/Objectives: This study is to examine the well-being of child in the world of child's life such as development, education, and play in a phenomenological manner.

Method/Statistical Analysis: We based data collected through educational and academic information sources (RISS) search as big data, and analyzed the keywords and the network analyzed by the 'well-being', 'wellness' and 'Chamsari' keywords. The frequency, ranking, and connection of the keywords were analyzed through the process of processing the collected unstructured text into the data suitable for research and analysis.

Findings: This study tried to reveal the reality of child well-being through phenomenological perspective based on the understanding of experts about child well-being through academic big data analysis. The results of the study showed that psychological themes such as activities, body, emotion, subjectivity, and psychology were highly linked with child's well-being. Child who live well in the phenomenological attitude exhibition were distinguished from adults and they were justifying adult control and intervention by refracting them as immature beings. In addition, it points out that the uniqueness of individual existence undermines the originality of the existing child, and furthermore, it can realize the child's disaster by expanding the unique life style of the child's existence by the advancement of the fusion of expression through the subjective expression of the unique individual existence experienced by the child, and the dialogue based on the ethics with the other.

Improvements/Applications: This study suggests that the ideological foundation of living and human public service should be prepared.

Keywords: *Child Well-being, child wellness, big data, child development, child education, child play, phenomenological manner.*

Introduction

In 2015, the UN General Assembly was held in Incheon and adopted 17 Sustainable Development Goals (SDGs) which include "Well-being" and "Quality Education". It showed keen interest from the world in the role of education for "Child Well-being" and

understanding of the meaning of child well-being. Additionally, it was also seen as the mankind's efforts for spirit, practice, their orientation and attitude to open the communal future world by reflecting on human well-being in the course of development of human civilization and technologies through the understanding of child well-being^[1-2]. If we ask ourselves again about the question of child well-being, "how to live well?" means that, of course, "what do we have to do to live well?", or the questions of "what can we know" and "what can we do". They are all difficult questions to answer. But we all want to live well. Therefore, it is also a question that is constantly being asked by oneself and mankind^[3].

Professor, Baekseok Culture University, Department of Nursing, Korea

e-mail: burm99@bscu.ac.kr

It is no exaggeration to say that human culture

is a culture of technology. As such, the technology, science and human civilization have developed into one integrated dynamic mechanism that cannot be separated^[4]. Technical civilization has contributed to the co-prosperity of mankind, but has also given rise to the phenomenon of human alienation. Modern child are living precariously on the spire of the most innovative technological civilization with imminent singularity that artificial intelligence surpasses humans^[4]. Child well-being is a question of “how can child perceive and form their own world in order to explore their own world well?” In addition, it can be also seen as creating an educational and social support system for this goal^[1]. To this end, adults around them should look at the very existence of child as they are. Through the various phenomena and languages that look into child well-being, we should not only improve our understanding of child well-being but also come up with support measures for child well-being. Through the Web (the meaning of information access through the Internet,

such as web sites and web pages) where human perception and consciousness are actively expressed and shared in language, we are able to have access to a common understanding of child well-being^[2].

The vast amount of data on the Web is called big data. Big data analysis takes an empirical approach to analyze such big data with logic and mathematical approaches for the “3V” characteristics of “Volume,” “Velocity” and “Variety.” Furthermore, big data is also defined as “5V” with added “Value, Insight” and “Very Complexity”^[5-7].

Three big questions in philosophy are: “how to live”, “how to know?” and “how does that happen”; while child well-being asks “how can a child perceive and organize his/her own world and move forward to this world?” To this end, we need to look inside and outside the child’s living world and look back at the adults inside the phenomenon^[8-10].

“From the subject of recognizing the world and the object of the world, how far in that sense can child go into the situation itself?”, “how close can child experience and perceive things?”, and “how can they finally reveal that knowledge?”: these questions are the purpose of child well-being’s big data analysis.

Method

This study defined academic works gathered from

academic databases used by domestic and foreign experts as big data and collected academic data on the subject of ‘well-being’, ‘wellness’ and ‘Chamsari (referring to “well-being” in Korean)’ on the academic research information service (www.riss.kr). The collected text data were compiled by removing unnecessary terms, symbols, numbers, etc. and adding terminologies to refine the data, and dividing the sentences into minimum units through the morphological analysis technique among natural language processing techniques. Based on the frequency and relationship of the key keywords, the researchers wanted to reveal their understanding and perception of the phenomenon.

The frequency, ranking, and connection of the keywords were analyzed through the process of processing the collected unstructured text into the data suitable for research and analysis^[11]. First of all, a word frequency analysis table was presented through the keyword analysis and visualization analysis was performed on the data. Second, the relationship between major keywords was analyzed through the keyword network analysis. Betweenness centrality was a measure of centrality in a graph based on shortest paths. Eigenvector centrality is a measure of the influence of a node in a network. We analyzed the statistical analysis of the study by using R studio.

Result and Discussion

1. Child Well-being on Domestic Academic Research: According to the frequency analysis of big data keywords, experts’ data on child well-being showed that there were about 60 times more overseas studies (12,239 cases) than domestic studies (206 cases), indicating that interest in and research on child well-being is taking place overseas more actively than in Korea. The analysis of big data keywords for domestic academic research on child well-being is as follows in Table 1 and Figure 1. The main theme related to child well-being was the words such as body, physical, and activity. And the main related words were activity, body, education, nurture, play and toys. Interest in physical health was higher than that in emotions, society and spirit. The main topics of play, education and nurture in child reflected high interest and understanding in play, development and upbringing environment as to child well-being.

Table 1. Frequency analysis and betweenness centrality of Major Words among the Words Related to the Child Well-being on Domestic Academic Research

Frequency Analysis			Betweenness Centrality		
Ranking	Keyword	Frequency	Ranking	Keyword	Centrality
1	Child	44	1	Wellness	1515
2	Physical	20	2	Child	1403
3	Activity	18	3	Well-Being	872
4	Behavior	16	4	Activity	212
5	Play	16	5	Child	142
6	Body	14	6	Physical	112
7	Child	14	7	Education	108
8	Infant	14	8	Parenting	86
9	Well-being	14	9	Toy	80
10	Design	12	10	Play	60

Figure 1. Keywords Visualization and Network analysis of Child Well-being on Domestic Academic Research

2. Child Well-being on International Academic Research: The big data-based keyword analysis results of international academic studies on child well-being are as follows in Table 2 and Figure 3. The main topics related to child well-being were words such as body, subjective, health, family, spirit, and emotion.

The key associations were subjective, psychological, emotional, social, mental and spiritual. The studies were highly interested in the study of the subjective cognition and perception of existence of child well-being and the importance of the psychological, social, emotional and spiritual environment around child for child well-being.

spirituality. In Korea, it is also necessary to understand and pay attention to the child's disaster based on the OECD's Child Well-Being Indicators (physical, housing and environment, educational, health and safety, risk behavior, quality of school life) and the UN Convention on the Rights of Child (survival, protection, development, participation)^{[8-9][11]}.

Conclusion

Discussion and conclusion of big data research to provide basic data for the preparation of measures for child well-being are as follows: first, overseas academic research was being conducted more vigorously compared to Korea's domestic academic research on child well-being, showing the need for more increased interest and researches in child well-being. So we should consolidate the basis of the solution for child well-being. Second, while domestic studies for child well-being mostly focused on visible patterns of behavior, such as child's body, activities and play, overseas research sheds light on child well-being in various ways with a diverse approach to philosophy and theory, such as cognitive subject, sentiment, spirit and spirituality. Thus, Korea needs to provide in-depth insights into their human and physical surroundings and interactions between child for child well-being, thereby creating a virtuous cycle of new horizon and convergence on play, development and education for child well-being through social consensus neck stretching and extensor reinforcement exercise, which are commonly used in clinicians.

Effect of Sanitizers and Disinfectants in *Staphylococcus Saprophyticus*

Jung-ok Choi¹, Yu-hee Lee²

¹Professor, College of Health Sciences, Youngsan University, Department of Dental Hygiene, Republic of Korea,
²Professor, Masan University, Department of Dental Hygiene, Republic of Korea

Abstract

Background/Objectives: In the dental environment, handpiece or ultrasonic scaler used in treatment causes aerosols and various pathogenic microorganisms. Many types of pathogens cause infectious diseases. This study is to identify surface disinfectants suitable for the management of *Staphylococcus saprophyticus* bacterial species, one of the causes of infection in medical institutions to use them as standardized surface management resources for infection control in dental clinic.

Method/Statistical Analysis: Commonly used 7 types of disinfectants were classified to select commercialized disinfectants. Samples were taken by rubbing the surface of the unit chair with a sterile swab. In order to check the bacterial species cultured in the medium, a single colony was purely separated by streaking. To identify the bacterial species, DNA was extracted from the bacteria and PCR was performed. the mean and standard deviation of each group. One-way ANOVA and Scheffe's post-test were carried out to identify the clear zone of paper discs and significant differences between groups.

Findings: The test for bacterial identification was carried out for the surface flora of the unit chair. As a result, *S. saprophyticus* was identified on the surface. According to the result of comparative analysis of the clear zone size of each disinfectant, sodium hypochlorite (NaOCl), a chlorine disinfectant was found to have the highest disinfection effect (8.52mm), followed by Distell, an ammonium compound disinfectant (2.72).

Improvements/Applications: The result of the analysis of the clear zone of the disinfectant showed excellent antibacterial activity in 0.3% NaOCl and 0.5% Distel, indicating that they are disinfectants suitable for *S. saprophyticus* used in the study.

Keywords: *Bioaerosol, Disinfectant, Sanitizer, Staphylococcus saprophyticus, Unit chair.*

Introduction

In the dental environment, handpiece or ultrasonic scaler used in treatment causes aerosols and various pathogenic microorganisms^[1]. Many types of pathogens

caused by handpiece treatment using the spraying force of compressed air are likely to cause infectious diseases by floating the treatment space and falling to the surface of the dental equipment^[2]. Staphylococci are Gram-positive cocci that are present in the mucous membranes of the skin and oral throat, and are known to be the main bacteria of purulent inflammation^[3]. Multidrug-resistant bacterial infections called superbacteria are particularly deadly among infections in medical institutions because treatment is difficult. Among them, the typical methicillin-resistant *Staphylococcus aureus* requires further management because it has an infection rate of 62-66% in hospitals and 46-49% in clinics^[4]. Present on human mucous membranes and skin as normal bacteria,

Corresponding Author:

Jung-ok Choi

Professor, College of Health Sciences, Youngsan University, Department of Dental Hygiene, Republic of Korea

e-mail: jochoi@ysu.ac.kr

Staphylococcus aureus not only causes toxin-type food poisoning caused by enterotoxin, but also causes various purulent infections and fatal sepsis, which account for more than 80% of the purulent diseases in the treatment^[5]. In some cases, infections in soft tissues, salivary glands, extraction sites, and alveolar bones may expand to the facial area. Therefore, the importance of *staphylococcus aureus* infection control is very emphasized. Among staphylococci of the same series, *Staphylococcus epidermidis* and *Staphylococcus saprophyticus* (*S. saprophyticus*), which are problematic in clinical trial, are known to be infectious bacteria in hospitals and are at risk in invasive medical devices or in groups with low immunity and sometimes appear in urinary tract infections in young women^[6-7].

In order to manage infection in the dental environment, the Ministry of Health and Welfare implemented a certification system for dental hospitals in 2014 and presented the legislation of medical institution evaluation and infection control standards^[8]. In the United States, the Centers for Disease Control and Prevention (CDC) recommends disinfecting the surface of the unit chairs such as examining tables, switches, and lamp handles contaminated by aerosol formation, etc. after each patient's treatment, or using a protective cover in case of visible contamination. Infection control refers to a management method to prevent or reduce the causes of infection in medical institutions in order to protect patients, staff, visitors and other environments^[9], and various types of disinfectants and sterilizers are used for infection control in dental clinic. Disinfection is an operation that removes the risk of infection by destroying the viability of pathogenic microorganisms using relatively weak sterilizing power and that kills some of the microorganisms, and sterilization is the process of destroying all types of organisms, including gemmula, using physical and chemical method and means complete sterility^[10]. As disinfection and sterilization method commonly used in dental clinics, the autoclaving method is commonly carried out for metal equipment for dental treatment, and chemical disinfection such as glutaraldehyde, physical disinfection such as ultrasound and ultraviolet disinfection are conducted for rubber and plastic materials^[11]. However, accurate cleaning, disinfection and sterilization are important because improper disinfection and sterilization are more likely to lead to cross infections. Jeong et al.^[12] emphasized the importance of sterilization and disinfection method suitable for instruments and equipment by presenting the

research findings that the contamination of bacteria was very high when the surface around the unit chair was not disinfected and pathogens were further spread from the cause of infection when the surface disinfectant was not applied with the proper disinfection method.

Thus, the purpose of this study is to identify surface disinfectants suitable for the management of *S. saprophyticus* bacterial species, one of the causes of infection in medical institutions to use them as standardized surface management resources for infection control in dental clinics.

Method

Samples were taken by rubbing the surface of the unit chair with a sterile swab. 100 µL of each collected sample was dispensed to premade LB medium (Becton; Dickinson and Company, Sparks, MD, USA) and spreading was performed with a sterile glass rod. They were cultured in a culture medium for 24 hours at 37°C and the number of colonies was measured. In order to check the bacterial species cultured in the medium, a single colony was purely separated by streaking. To identify the bacterial species, DNA was extracted from the bacteria and PCR was performed.

S. saprophyticus (KCCM 41662) was purchased from Korean Culture Center of Microorganisms (KCCM). Each microorganism was activated by tryptic soy broth (TSB; BD, Sparks, MD, USA) with 5% sheep blood and was diluted at a 2x10⁶ ratio.

Commonly used 7 types of disinfectants were classified to select commercialized disinfectants. The disinfectants were prepared and used in the ratio shown in [Table 1] immediately before the test as recommended by the manufacturer.

Table 1. List of sanitizer and disinfectant in this study

Variables	Concentration (%)
PBS	100
Alcohol	70
Hydrogen peroxide	3
Sodium Hypochlorite	0.3
Y-Na Solution	2
Distel	0.5
Eco rich	100

100 µL (2x10⁶) of *S. saprophyticus* was applied on a solid LB medium. 30 µL of each experimental group

was dropped onto a paper disc, and it was placed on the LB medium inoculated with the bacteria. After keeping it at 37°C for 24 hours in each environment, the diameter of the clear zone was measured on a paper disc. The average value and standard deviation were obtained after three repeated experiments, to measure the diameter of the clear zone, where the growth was inhibited. The average value of clear zone was calculated, and used for comparative analysis in the results.

SPSS 24.0 program was used for the statistical analysis. Descriptive statistics were used to obtain the mean and standard deviation of each group. One-way ANOVA and Scheffe’s post-test were carried out to identify the clear zone of paper discs and significant differences between groups.

Result and Discussion

1. General characteristics of the bacterial species:

In this study, microorganisms were collected from the surface of the unit chair to measure the contamination caused by these floating bacteria. The test for bacterial identification was carried out for the surface flora of the unit chair. As a result, *S. saprophyticus* was identified on the surface [Table 2].

Table 2. Characterization of *S. saprophyticus*

Family	Staphylococcaceae
Genus	Staphylococcus
Species	Staphylococcus saprophyticus

2. Antimicrobial Activity: Seven disinfectants were applied to *S. saprophyticus* and as a result, the largest clear zone was found in sodium hypochlorite [Figure 1].

Figure 1. Comparison of death zones by disinfectant

According to the result of comparative analysis of the clear zone size of each disinfectant, sodium hypochlorite (NaOCl), a chlorine disinfectant was found to have the highest disinfection effect (8.52mm), followed by Distell, an ammonium compound disinfectant (2.72) [Table 3].

Discussion

As the importance of hospital infections is highlighted in recent years, there is a growing interest in problems with infection control systems in dental clinics. In dental clinics where bioaerosol is generated such as handpieces and ultrasonic scalers, bio aerosols float in the air drop and cause contamination, causing infectious diseases by dental medical instruments^[13-16]. Various instrument surfaces in the dental clinics also warn that infection can be a source of contamination and a source of contamination^[17].

Staphylococcal infections are known as the main infectious organisms, not limited to their area of occurrence. In particular, affecting groups with weak immunity, it is most problematic in neonatal rooms, intensive care units, operating rooms, etc. and sometimes causes community infections by discharge patients^[18-19]. Among them, *S. saprophyticus* is 5 ~ 8 MM in diameter, very glossy, opaque, smooth and convex.

It has been suggested that the water quality of the unit chair is an important issue for both patients and dental staff because it is exposed to water and aerosols derived from the unit chair^[20]. In addition, various previous studies have identified that *S. saprophyticus* is often included among the microorganisms isolated from the unit chair water line^[21]. Based on this finding, water and aerosols in the form of *S. saprophyticus* are believed to be produced in dental clinics. Previous studies have

recommended proper disinfection and sterilization to avoid infection, and experts emphasized the need to follow standard procedures such as risk assessment, patient protection, sterilization and disinfection^[22-23]. Therefore, various disinfectants were applied to find an appropriate method for disinfecting microbial strains.

Disinfection is the process of killing all pathogenic microorganisms except for the spores of bacteria on the surface of the object. It is usually done using liquid chemical disinfectants and the level and duration of the disinfectant is determined depending on the degree of disinfection of the treatment equipment^[24].

NaOCl releases hypochlorous acid to inhibit enzymatic activity in cells and denatures cell proteins, resulting in bactericidal effects. The guidelines of the Society for Healthcare Epidemiology of America (SHEA) and the Infectious Diseases Society of America (IDSA) recommend 0.1% NaOCl (1,000 ppm effective chlorine) for environmental disinfection to prevent the propagation of pathogenic microorganisms^[25]. In this study, 0.3% NaOCl was used according to the manufacturer's instructions. Used at a higher concentration than IDSA, it was considered to show significantly higher killing effect. Among the various disinfectants, the use of chlorine disinfectants was found to be high due to the economic aspects and convenience of use^[26].

The second most effective disinfectant was found to be 0.5% Distel. This disinfectant belongs to the quaternary ammonium disinfectant. Characterized by weak alkali, the quaternary ammonium disinfectant is known to be widely used as a skin disinfectant, preservative, and preserved agent because of its ability to inhibit bacterial culture and sterilization^[27]. In addition, the sterilization effect is excellent in all the pH range, it is a stable disinfectant due to the relatively small influence by temperature.

The third effective disinfectant was 1.14 in 2% Y-Na solution. The most commonly used disinfectant in the world is most effective when used as a 2% buffer solution at pH 7.5-8.5. It can be used as a high level disinfectant and sterilizer for all Gram-positive and Gram-negative bacteria, fungi, viruses (including HBV and HIV) and bacterial spores, including tuberculosis^[28]. However, there is a possibility that toxic substances can be generated when absorbed into plastic products of unit chair, so it is known that caution is required. It is

important to avoid spraying and use personal protective equipment.

In order to carry out higher quality care in addition to the development of dentistry, research on infection control and cross-infection prevention should be carried out continuously. In order to develop a systematic infection control program in Korea, it is necessary to introduce more strict foreign standards for appropriate management for each situation

Conclusion

In this study, *S. saprophyticus*, which affects the surface contamination and causes opportunistic infections, was used to analyze the antimicrobial activity of several disinfectants. The result of the analysis of the clear zone of the disinfectant showed excellent antibacterial activity in 0.3% NaOCl and 0.5% Distel, indicating that they are disinfectants suitable for *S. saprophyticus* used in the study. Based on the above results, a more effective and systematic surface management system is required by analyzing selective killing disinfectants of strains causing specific surface contamination.

The Effect of Task-based upper Limb Training on Activities of Daily Living and Upper Limb Function in Chronic Stroke Patients

Bo-Kyoung Song¹, So-Young Han², Jung-Woo Jeong², Ha-Na Kim²

¹Professor, Department of Occupational Therapy, ²Doctoral Course, Graduate School, Kangwon National University, Republic of Korea

Abstract

Background/Objectives: The goal of this study was to survey the influence on intervention of task-based upper limb training on activities of daily living and upper limb function in chronic stroke patients.

Method/Statistical Analysis: 32 patients were randomly divided into two groups. For the affected upper limb, the experimental group (N=16) applied the task-based training program (TBTP) and the control group (N=16) performed the non-task-based training (NTBT). Both groups executed 5 times per week, 30 minutes per session for 4 weeks. The paired t-test was used to compare before and after intervention results of each group. The independent t-test was used to compare changes in results between the groups.

Findings: In the TBTP group, the pre-intervention of Fugl-Meyer assessment (FMA) is 46.75 ± 3.75 and the post-intervention score is 50.88 ± 4.92 . In the NTBT group, the FMA had a pre-intervention score of 47.44 ± 4.44 and a post-intervention score of 49.13 ± 5.14 . Both groups showed statistically significant differences before and after intervention ($p < 0.01$). In the TBTP group, the pre-intervention score of Korean versions of modified Barthel Index (K-MBI) was 73.31 ± 6.91 and the post-intervention was 79.00 ± 6.96 ($p < 0.01$) after intervention. The K-MBI score of the NTBT group in before intervention was 78.63 ± 6.32 , after intervention 73.81 ± 6.01 . Both groups showed significant differences before and after intervention ($p > 0.05$). In all assessments, no differences were observed between groups before and after intervention.

Improvements/Applications: This study did not show that TBTP is more effective than NTBT in improving the daily activities and upper limb function of stroke patients.

Keywords: stroke, task-based training, upper limb motor function, chronic patients, daily activities.

Introduction

Stroke is a cerebrovascular disease caused by the bursting or blocking of blood vessels that supply blood to the brain^[1]. This causes various problems, as well as problems of motor function due to paralysis of the body.

In particular, approximately 69% or more hemiplegic patients experience dysfunction of the paralyzed upper extremity^[2]. Exercise disorders in the upper limbs reduce the independence in daily life by limiting the use of functional upper arms^[3]. In rehabilitation of stroke patients, the principle of neuroplasticity is the therapeutic basis. Neuroplasticity is the process in which the brain forms new neurons and lays down new connections between neurons, in response to learning, in order to form a pathway to repeat the learned behavior. This occurs by performing repetitive and active tasks with the paralyzed upper limb^[4]. Recently, a study applying a task-based approach among the treatments for improving the upper

Corresponding Author:

Ha-Na Kim

Doctoral Course, Graduate School, Kangwon National University, Republic of Korea

e-mail: mydream57@naver.com

limb function of stroke patients has been conducted^[5]. The task-based approach focuses on the patient's task performance. This leads to functional improvement by attempting to solve the problems by providing a functional task rather than repeatedly practicing normal movement patterns^[6]. This task-based approach is a functional approach that can be applied to the rehabilitation of patients with neurological impairment. This enables patients to adapt to their surroundings by learning task-specific strategies and improves upper limb movement patterns, dexterity, and manipulation skills^[7]. In addition, unlike the conventional treatment method that repeatedly trained movements, problems assigned to functional tasks are solved through the interaction of the body organs associated with the tasks. This task-based approach can present a variety of functional activities to patients and can help them improve their daily activities^[8]. Therefore, if the upper limb training is carried out with the tasks available in real life, the performance of daily life can be improved more^[9]. Based on the above, this study investigated the effects of task-based training on upper limb function and daily activities in chronic stroke patients.

Materials and Method

In this study, we randomly divided the 32 study subjects into two groups, which in the TBTP group and the NTBT group. (Table 1) These participants met the selection criteria and gave voluntary consent to take part in the study. The criteria for selection were as follows: First, hemiplegic patients of stroke more than 6 months from onset period Second, a score of ≥ 24 in Korean version of the Mini-Mental Status Examination (MMSE-K) Thirdly, a level of \geq Brunnstrom recovery of upper limb stage 4 Fourth, in the line bicection test, patients without unilateral neglect Fifth, patients without musculoskeletal disorders such as joint contracture or limited range of motion

Table 1. Individual information of patients

Characteristics	TBTPG (N=16)	NTBTG (N=16)
Gender (Male/Female)	6/10	8/8
Side of Hemiplegia	Rt.11/ Lt.5	Rt. 10/ Lt. 6
Age (year)	61.43 \pm 9.81	62.01 \pm 8.10

Onset (Months)	7.60 \pm 1.20	7.20 \pm 1.28

M \pm SD: mean \pm standard deviation. TBTPG: task-based training program group, NTBTG: non-task based training group MMSE-K: mini-mental status examination

Fugl-Meyer Motor Function Assessment(FMA) and Korean Version of Modified Barthel Index(K-MBI) were performed to evaluate in stroke patients. FMA is used to classify hemiplegic patients with stroke as a Brunnstrom recovery stage and to assess functional recovery^[10]. Fugl-Meyer et al. developed an assessment tool by defining 50 detailed movements according to the six stages of recovery in Brunnstrom's hemiplegic patients. Depending on the performance of the evaluation item, 0 to 2 points are given. 0 point is not performed, 1 point is partially performed, and 2 points are divided into complete performed. The overall score ranges from 0 to 100, including upper and lower limbs. There are 33 items in the upper part of the test, which is 66 points. The details of upper limb examination are 18 items for shoulder/ elbow/ forearm, 5 items for wrist, 7 items for hand (finger), and 3 items for upper limb coordination ability^[11]. Sanford et al. reported an inter-rater reliability of 0.96 for upper limb examination^[12]. In this study, only upper limb test items were used for upper limb function evaluation. MBI is one evaluation method for ADL measurement and consists of 10 items^[13]. The K-MBI used in Korea was validated the effectiveness of stroke patients and demonstrated excellent intra-rater reliability (0.87~1.00) and excellent inter-rater reliability (0.93~0.98). A higher score on the K-MBI represents a higher degree of independence in performing basic ADLs^[14].

The task-based program in the study was based on previous research^[15]. The program contents are shown in Table 2.

Table 2. Task-based training program

Program	Method
Turn door open door	Stand about 30cm away from the closed door. Then grab the knocker with the affected hand and turn it to the right to open the door. Pull the door to open about 20cm, then the door to push the door closed.
Pouring water into a cup	Pour half the water into a 1L plastic light kettle. Hold the handle of the kettle with the affected hand and pour up to 2/3 of the plastic cup.
Open and close the beverage bottle	Hold the closed beverage bottle with the hand on the side and fix it. Place the lid on your desk, grab it and turn it to the right to close it.
Lock and release the buttons on the clothes	Lock and release the buttons on the prepared clothes with both hands.

The results of the collected data were analyzed using SPSS (ver. 18.0) statistical program. The values of MBI and FMA were normally distributed and the parametric test were conducted. Homogeneity test was performed on both groups before the assessment. Corresponding sample *t*-tests were performed to compare the differences between the two groups before and after the intervention, and independent sample *t*-tests were used to compare the differences between the groups after the intervention. The statistical significance level was 0.05

Result

1. General characteristics of the subjects:

The overall procedure is as follows: Subjects were divided into the TBTP group (16 patients) and the NTBT group (16 patients). The intervention was conducted for 5 weeks each week for 30 minutes for 4 weeks. For the affected upper limb, the experimental group (N = 16) applied TBTP and the control group (N = 16) performed NTBT. The posture for performing the training is as follows. Sit on the backrest chair, maintain correct posture and place upper limbs on the table. Hip, knee and ankle joints flex at 90 degrees. The overall process of study is as follows. (Figure 1)

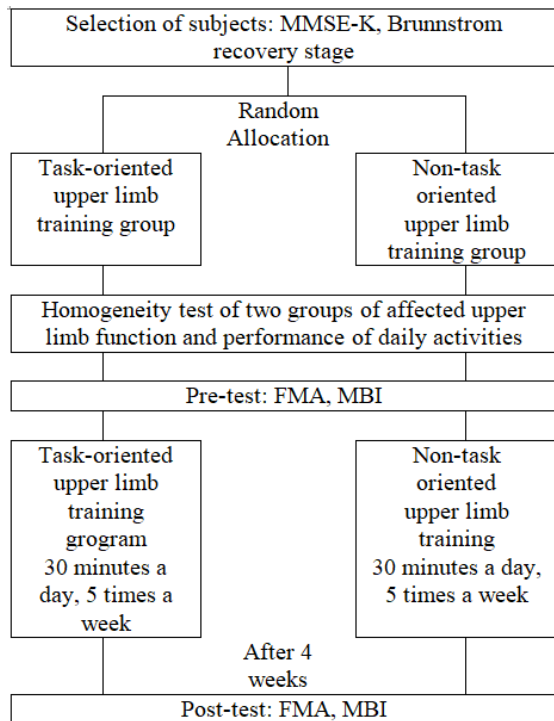

Figure 1. Process of the study

2. Comparison of FMA score during the intervention on each group:

The comparison of FMA scores for

intervention in each group is as follows. (Table 3) The FMA score of the pre-intervention TBTP group was 46.75±3.75 and the post-intervention score was 50.88±4.92. The score of FMA in pre-intervention NTBT group was 47.44±4.44 and post-intervention score was 49.13 ± 5.14. Significant changes in FMA before and after intervention were observed in both groups (p<0.01). However, there was no significant difference between groups before and after intervention (p> 0.05).

Table 3. A comparison of FMA during the intervention on each group

	TBTP group (n=16)	NTBT group (n=16)	F	p

Discussion

After the stroke, the physical independence and daily activities of the patient are very important factors in the area of brain damage and initiation of rehabilitation. Therefore, a variety of rehabilitation is needed to minimize the disability of patients after onset and to quickly restore the performance of daily living activities^[16]. At present, various interventions are applied in stroke patients in the treatment, and there is a growing interest in task-based approaches. Therefore, the purpose of this study was to investigate how upper limb function and activities of daily living improved when various programs suitable for daily living activities were applied to patients. Previous study has reported that task-based intervention is effective in improving upper limb function when applied to patients with chronic stroke who have upper limb function impairment^[17]. In addition, repetitive task-oriented training is effective for not only restoring function of stroke patients but also for functioning of daily activities^[18]. The results of this study showed statistically significant increase in the function of the affected upper limb both before and after intervention in both TBTP and NTBT groups. However, there was no statistical significance between the two groups in the group comparison, but the TBTP showed more improvement after intervention than NTBT. Because of the small number of subjects and the short period of intervention, the reason for this study is insufficient to determine the effect on stroke performance. Therefore, follow-up studies should be conducted to increase the number of subjects and to examine the impact of TBTP over a sufficient period of study.

Conclusion

This study did not show that TBTP is more effective in improving upper limb function and daily activities of stroke patients than NTBT. The reason for this is that the number of subjects in the study was small and the duration of intervention was short. Therefore, in future studies, if the number of subjects is increased and the basis of TBTP is established after sufficient study period, it may be an effective therapeutic approach to improve the function and daily activities of the stroke patients.

The Effects of Task-oriented Mirror Therapy on the Upper Extremity Function and Brain Activation in Chronic Stroke Patients

Kyung-ju Lee¹, Man-Seok Han²

¹Doctoral Course, Department of Occupational Therapy, Kangwon National University, 346 Hwangjo-gil, Dogye-eup Samcheok-si Gangwon-do 245-710, ²Professor, Department of Radiological Science, Kangwon National University, 346 Hwangjo-gil, Dogye-eup Samcheok-si Gangwon-do 25949, Republic of Korea

Abstract

Background/Objectives: This study was conducted to examine how task-oriented mirror therapy changes the upper extremity function and brain activation in chronic stroke patients.

Method/Statistical Analysis: This study applied mirror therapy to two stroke patients and used a paired t-test to examine the differences before and after treatment and the Telescan program to examine the brain activation.

Findings: As a result of examining the upper extremity function after mirror therapy, the Fugl-Meyer Assessment scores improved from 21.0 ± 1.41 before treatment to 24.5 ± 1.71 after treatment, and the Wolf Motor Function test scores also improved from 27.0 ± 5.66 to 33.5 ± 6.36 . The brain activity also increased after treatment.

Improvements/Applications: The use of mirror therapy in stroke patients improved the recovery of upper extremity function and increased the brain activation.

Keywords: Stroke, mirror therapy, neuroplasticity, upper extremity function, brain activation.

Introduction

Strokes cause problems related to sensation, vision, perception, cognitive thinking, and language, and most patients experience difficulties in moving or activities due to motor impairment^[1]. The less severe the initial disability, the more prognosis the stroke is. The degree of recovery is very difficult due to the large individual differences, and the motor dysfunction remains in

about 50% or more patients, and the upper extremity dysfunction is particularly prominent^[2]. About 30%-66% of stroke patients have difficulties in daily activities due to paralyzed hands and are unable to recover their motor function. Therefore, paralysis of upper extremity in stroke patients is one of the fatal effects in daily living^[3].

In order to promote recovery of impaired motor function or to acquire new motor function, plasticity changes of the brain nerves involved in motor functions are essential^[4]. The ultimate goal of treatment in stroke patients is to restore brain function by improving neural plasticity, to restore normal posture and motion, and to reduce abnormalities in posture and muscle tone to ensure efficient movement^[5].

Recently, various treatment strategies based on neuroplasticity have been used to recover from

strokes, such as action observation, imagery training, mirror therapy, virtual reality, robot-assisted therapy, and constraint-induced movement therapy^[6]. These intensive task-trainings have been shown to improve motor function in stroke patients, but have been shown to be generally costly and time consuming^[7]. Among these treatment method, mirror therapy is a simple, economical, and effective method which places a mirror between the arms or legs so that the normal movement of the non-affected side is shown to provide normal movement on the affected side^[8]. This is possible through the mechanism called mirror neurons, and Ramachandran invented the 'mirror box' to help alleviate phantom limb pain^[9]. It can also increase motivation and efficiency by providing task-oriented treatment during mirror therapy^[10]. The task-oriented approach is lead to the active use of damaged upper limbs by improving the ability of daily living and by providing a more effective treatment method composed of various functional activities^[11]. In addition, this study suggest that as a mediation for the improvement of cognitive function and daily living behavior of stroke patients, it can actively try to solve problems by providing functional tasks^[12].

Mirror neurons were initially found in several brain regions of the monkey, premotor cortex(PMC), inferior parietal lobule(IPL), and superior temporal sulcus, a mechanism called the mirror neuron system^[13]. Previous studies using functional magnetic resonance imaging (fMRI) found that networks similar to mirror neuron systems exist in humans^[14], and suggested that these networks engage in new motor skills through observational learning and facilitate skill acquisition after strokes^[15].

Recent advances in brain science and brain mapping technologies have led to the development of neurophysiological changes and motor function recovery mechanisms by functional magnetic resonance imaging (fMRI), positron emission tomography (PET), and electroencephalogram (EEG)^[16]. EEG is a simple, relatively inexpensive, and noninvasive method that provides useful information for directly observing functional changes in the cerebral cortex^[17]. EEG measurement can be applied to patients with various diagnoses such as brain damage, alcoholism, and depression to examine the functional state of the brain in real-time while focusing on a specific task^[18].

Human thoughts and actions depend on brain activity and are shown in the form of brain waves^[19].

To improve the recovery of the upper limbs of stroke patients, the damaged regions of the brain must be reconstructed^[20]. Therefore, the purpose of this study is to examine how task-oriented mirror therapy changes the upper extremity function and brain activation in chronic stroke patients.

Materials and Method

- 1. Participants:** The participants of this study were two males, and the study was performed after explaining the purpose and method of the study and obtaining a consent from the participants. The participants were selected by the following criteria: (1) Patients who survived beyond 6 months after stroke onset, (2) patients without unilateral neglect and visual impairment, (3) Patients who can follow instructions and communicate with MMSE-K scores above 24, (4) patients with no previous exposure to mirror therapy. This study excluded (1) those who have other neurological damage or surgical conditions other than stroke and (2) those who take antipsychotic drugs.
- 2. Intervention:** The mirror therapy was performed by placing a mirror in the median sagittal plane of the participant, then placing the paralyzed arm behind the mirror, and moving the paralyzed arm along with the reflected movement of the normal arm. The participants carried out the tasks with the normal hand during mirror therapy. The tasks involved 6 different movements: (a) wrist flexion and extension, (b) finger opposition, (c) hand grasp and release, and (d) using chopsticks. Each task was performed for 5 minutes for a total of 30 minutes and the treatment was performed 4 times a week for one month.
- 3. Measure:** The Fugl-Meyer Assessment (FMA) was used to evaluate functional changes in the sub-regions of the upper extremity. The Brunnstrom Approach was used to distinguish detailed movements by classifying the functions of stroke patients into 50 categories. Zero to 2 points are given according to the performance level, and out of a total of 100 points, the test corresponding to arms consists of 33 items for 66 points and 34 points for legs.

The Wolf Motor Function Test (WMFT) is a tool developed to evaluate the upper extremity function in stroke patients, which consists of a total of 17

items (2 items for muscle strength measurement, 15 items for functional tasks). Each item is performed for 2 minutes, and functional ability score is evaluated on a 6-point scale (0-5).

EEG was performed by attaching electrodes on the participant’s scalp before they received mirror therapy. The electrodes were attached according to international standards (10%-20%). The electrodes were attached after removing sweat and wiping grease layers with alcohol swabs before the EEG measurements to improve the signal quality. The brain activation was confirmed through brain mapping by visually examining changes in the regions of the brain during mirror therapy.

4. Data analysis and statistics: This study used a paired t-test to examine the effects of mirror therapy on upper extremity function and used the Telescan program (LAXTHA Inc.) to examine brain activation during mirror therapy.

Results

1. The effect of mirror therapy on upper extremity function: As a result of examining the upper

extremity function of the participants, the functional changes of FMA and WMFT are as follows.

As shown in [Table 1], the FMA scores improved from 21.0±1.41 before treatment to 24.5±1.71 after treatment and showed a statistically significant difference. The WMFT scores also improved from 27.0±5.66 to 33.5±6.36 and showed a statistically significant difference.

Table 1. Comparison of FMA & WMFT scores before and after mirror therapy

Evaluation	Pre-test	Post-test	t	P
FMA	21.0±1.41	24.5±1.71	-2.33	.02*
WMFT	27.0±5.66	33.5±6.36	-3.11	.04*

The values are mean±standard deviation, FMA, WMFT. p<0.05 by paired t-test.

2. The effect of mirror therapy on brain activation: The results of examining the brain activation of the participants are as follows.

As shown in [Figures 1 and 2], both participants exhibited higher brain activation after mirror therapy.

Figure 1. Brain activation before and after mirror therapy in participant 1

Figure 2. Brain activation before and after mirror therapy in participant 2

Discussion

Stroke is one of the leading diseases that cause problems in the upper extremity. This makes it difficult to perform tasks such as stretching, grasping, manipulating, and moving objects, and causes problems in daily activities^[21]. Mirror therapy is a treatment method to recover the function of paralyzed limbs by observing the movement of the normal limbs reflected in the mirror. Many previous studies have shown recovery of upper limb functions by mirror therapy. However, patients get bored due to repeating simple movements during the treatment and the treatment effects are not always consistent^[22]. Therefore, this study provided tasks combining simple and functional movements to improve the effects of recovering upper limb functions and to increase the concentration of the participants.

Similar to the results of this study, there are reports showing that stroke patients recovered FMA upper extremity functions by receiving mirror therapy including traditional occupational therapy. Both patients who received simple mirror therapy and those who received task-oriented mirror therapy showed improved upper limb functions, and the latter showed about 10% more improvement compared to the former. The functional improvement of complex movements was limited when the therapy was focused on simple movements, but task-oriented mirror therapy continuously improved upper extremity function^[23]. Since the hands of an individual are connected in time and space^[24], the effect of the treatment can be generalized by properly using both hands during task-oriented treatment^[10]. Although mirror therapy does not involve the movement of paralyzed limbs, it has similar neurological effects and produces benefits similar to those from bilateral movement.

The brain activation also increased during mirror therapy. Leocani et al. (2001) reported that increased beta-wave activity during movement influences the activation of the cerebral cortex^[25], and described that the area of the cerebrum first activated gradually activates other areas of the cerebrum while performing the task^[26].

The limitation of this study is that it cannot be generalized because of the small number of participants. However, it was found that task-oriented mirror therapy increased both the upper extremity function and the brain activity of stroke patients. Ultimately, the reconstruction of the brain is necessary to improve the function of stroke patients. Mirror therapy increased the brain activation,

so additional method to improve motor function should be considered.

Conclusion

This study was performed to examine how task-oriented mirror therapy changes the upper extremity function and brain activation in stroke patients. As a result of examining the upper extremity function of two stroke patients after mirror therapy, both patients showed improved FMA and WMFT scores and increased brain activation. Therefore, more functional movements need to be included rather than simple movements in the task-oriented mirror therapy of stroke patients to improve the quality of life.

An Effect of Communication Training Program on Communication Skills and Empathic Ability

Seon-Ju Sim¹, Su-min Hong¹

¹Professor, Dept. of Dental Hygiene, Baekseok University, Korea

Abstract

Background/Objectives: The purpose of this study is to investigate how the communication training program effects on communication skills and empathy ability in dental hygiene students.

Method/Statistical Analysis: 21 students who wanted to participate in the communication program and 23 students who did not want to participate in the program were set as the control group. After implementing the communication program, we evaluated the improvement of communication skills and empathy before and after the program. The communication program consisted of 4 sessions (2-3 hours per session)

Findings: Unlike the control group, the experimental group showed statistically significant effect of the program in both communication ability and empathy ability. Dental hygiene students have a good understanding other's perspectives, while their ability to overcome stereotypical thinking and creative communication is low.

Improvements/Applications: Communication program is effective in improving communication ability and empathy ability, so more detailed and specialized programs should be developed to cultivate communication skill and empathy ability.

Keywords: *Communication training program, Dental hygiene, Communication skill, Empathy ability, Pay attention, Creative communication.*

Introduction

Communication, which is continuously conducted in personal relations through verbal and nonverbal interactions, is essential to the development of personal relations^[1], and serves as an important means to develop individuals' personalities as well as their relationships with other people^[2]. The ability to communicate effectively is necessary in the formation of amicable personal relations. Communication ability refers to the capability to exchange both verbal and nonverbal messages between participants, and necessitates

performance of the complex task of conveying one's own message and accepting that of others^[3]. Empathic ability is indispensable in verbal and nonverbal communication and verbal and nonverbal communication based on empathic ability is important to the communication ability^[4].

Empathy, a concept often used in sociology and psychology, is the internal mental capacity to feel the emotions and experiences of other person as if they are one's own^[5]. Empathy is the basic foundation of personal relations. Empathic understanding in human relations induces altruistic motives and increases prosocial behavior^[6]. A previous study showed that the communication ability of college students has a significant effect on their adaptation to college life, and that those who listen well to others have a higher adaptability to both society and college life^[7]. In addition, information delivery capacity, listening

Corresponding Author:

Su-min Hong

Professor, Dept. of Dental Hygiene, Baekseok University, Korea e-mail: sarangtou@bu.ac.kr

capacity, communication ability suitable to subjects, and empathic ability has been proposed as the communication capabilities that college students in Korea currently need to cultivate^[8]. The ability to communicate effectively enables one to grow appropriately, and is necessary for all college students. However, this ability is more important for college students majoring in dental hygiene, because dental hygienists are required to display the ability to effectively communicate with various types of personal relations in dental clinic^[9].

A Communication training program in the curriculum for dental hygiene is necessary to foster the development of dental hygienists equipped with communication ability based on empathic ability. However, there has been little research about empathic ability and communication ability. The present study was conducted to investigate the improvement of communication ability and empathic ability in dental hygiene students by means of the communication training program, as well as to provide the fundamental data necessary to determine the directions of the major curriculum.

Method

The present study was conducted with 44 college students majoring in dental hygiene. The 23 subjects who were willing to participate in the communication training program were allocated to the experimental group, and the 21 subjects those who did not participate in the program were allocated to the control group. The present study was approved by the Institutional Review Board of B University (IRB Office-007).

The communication training program was conducted from May to June 2019. The numbers of subjects were 21 in the experimental group and 23 in the control group. After completion of the communication training program, subjects' improvement in communication ability and empathic ability was evaluated. The communication training program consisted of four sessions, each session 2 to 3 hours long. The program included E-disc testing and group discussion in Week 1, detailed practice according to the E-disc test results in

Week 2, communication method in industries in Week 3, and communication scenario preparation in various settings in Week 4.

The inventory used in the present study was that reconstructed by Jeon^[10] with reference to the communication ability scale for college students and adults, developed by Lee et al.^[11], and the Empathy Index prepared by Bryant^[12] and translated into Korean by Park^[13]. The questionnaire for measuring communication ability included 49 questions related to seven subfactors, specifically information gathering, paying attention, overcoming stereotypical thinking, creative communication, self-revealing, leading communication, and understanding another's perspective. The questionnaire for measuring empathic ability included 30 questions related to cognitive empathy ability and emotional empathy ability.

In the present study, the communication ability and empathic ability of the college students majoring in dental hygiene were measured before and after implementation of the communication training program. The homogeneity of the two groups was tested by a t-test before the experiment. An ANCOVA was performed to analyze the differences between the experimental group and the control group after completion of the training program. The statistical analysis was performed using the SPSS 22.0 software program.

Result and Discussion

- 1. Students' communication ability and empathic ability prior to the program:** [Table 1] shows the students' communication ability and empathic ability prior to the program. The average communication ability scores were 3.31 in the experimental group and 3.26 in the control group; these scores were not significantly different. No differences were found between the two groups in any of the seven sub-categories. The average scores for empathic ability were 3.57 in the experimental group and 3.54 in the control group, again with no significant difference between the two.

Table 1. Pre-test

Variables	EG	CG	t value	P
	Mean±S.D.	Mean±S.D.		
Communication Skill				
Total	3.31±0.27	3.26±0.21	-0.70	0.49
Information gathering	3.46±0.44	3.34±0.37	-1.05	0.30
Pay attention	3.55±0.36	3.44±0.39	-0.96	0.34
Overcoming stereotypical thinking	2.72±0.45	2.71±0.40	-0.05	0.96
Creative Communication	2.91±0.32	2.80±0.26	-1.33	0.19
Self-reveal	3.43±0.58	3.54±0.47	0.70	0.49
Leading communication	3.28±0.55	3.30±0.39	0.14	0.89

2. Change after the program: [Table 2] shows the students’ communication ability and empathic ability after the program. The communication ability score of the experimental group was 3.62, higher than that of the control group (3.18). Among the sub-categories, the scores of the experimental group were higher than those of the control group in information gathering, paying attention, overcoming stereotypical thinking, creative communication, leading communication, and understanding other’s perspective (p < .05). The empathic ability score of the experimental group was 3.62, higher than that of the control group (3.25). The scores of the experimental group were also higher in the categories

of cognitive empathy ability and emotional empathy ability.

As shown in Table 1 & 2, the communication ability score was increased by the communication training program in the experimental group from 3.31 to 3.59, but the score was decreased in the control group from 3.26 to 3.18. Similarly, the empathic ability was slightly increased in the experimental group from 3.57 to 3.61, while it was decreased in the control group from 3.54 to 3.25. The scores in the experimental and control groups, which showed no significant difference prior to program, did show a significant difference after the program (p < .05).

Discussion

In the diverse medical environment, empathy-based communication ability is emphasized as a capability with which dental hygienists should be equipped^[9]. The present study was conducted to investigate improvements in communication ability and empathic ability in college students majoring in dental hygiene by means of the communication training program, and to provide the fundamental data necessary to determine the directions of the curriculum.

As shown in Table 1 and 2, the communication ability in the experimental group was increased from 3.31 to 3.59. In contrast, that of the control group was slightly decreased from 3.26 to 3.18. While the two groups did not show a difference in communication ability prior to implementation of the training program, they showed a significant difference after the implementation. The average communication ability identified in a previous study using the same questionnaire was 3.77, slightly higher than those of the subjects of the present study^[14]. This finding highlights the need to provide a training program for effective communication to students majoring in dental hygiene.

With respect to the subfactors of the communication ability, as shown in Table 1, the scores in the areas of paying attention and understanding other's perspective were, respectively, 3.55 and 3.82, slightly higher than those of other subfactors. Since paying attention is an ability that has a positive effect on social adaptation, the ability of the subjects to pay attention to others may be used as an important communication skill in their future clinical settings. In contrast, the scores of overcoming stereotypical thinking and creative communication were, respectively, 2.72 and 2.91, and these scores were not significantly changed even after implementation of the communication program.

The ability to overcome stereotypical thinking is closely related to the capacity to communicate smoothly

with the various patients that dental hygienists meet in the clinic. The ability to overcome stereotypical thinking may be increased not only through communication training with individuals of a variety of backgrounds, but also as a result of undergoing various experiences^[15]. Therefore, the college students may need to participate in a variety of voluntary services, and an innovative teaching method including various communication skills may be necessary. The lack of creative communication may be related to the unique features of the dental hygiene major. The students majoring in dental hygiene may not have the space for developing creative thinking, because the lectures are designed as training for skills requiring accuracy and agility, such as prevention of dental diseases and cooperation in dental treatment. Further studies may need to be conducted using an in-depth open-type questionnaire to investigate the causes of the lack of creative communication ability in the subjects. In addition, a customized communication training program may need to be developed to improve the students' ability in the two subfactor areas.

Understanding other's perspective was increased in the experimental group from 3.59 to 3.9, but it was decreased in the control group from 3.7 to 3.4 (Tables 1 and 2). The ability to understand other's perspective has been reported as an essential element of communication ability, as it is closely related to the abilities to pay attention and empathize^[16]. Understanding other's perspective is also considered an essential aspect of communication ability in the communication with the patients that the hygienists will encounter in dental clinics. Therefore, emphasis should be placed on the ability to understand other's perspective in developing a communication training program customized to the major.

With respect to the empathic ability scores before and after implementation of the program, as shown in Tables 1 and 2, the scores were increased in the experimental group but slightly decreased in the control

group. A similar pattern was found in the sub-categories of cognitive empathy and emotional empathy. As the empathic ability is closely related to the communication ability, these two factors have been reported to have mutual mediating effects^[17]. In addition, empathic ability is necessary to develop good relationships with others and is closely related to prosocial behavior^[18].

In the present study, as the empathic ability was decreased in the control group after implementation of the program, a significant difference was observed between two groups. This result may be related to the period when the post test was conducted, is not necessary during the final examinations. The result may be consistent with those of previous reports that found that the stress induced by studies had a negative effect on communication^[19, 20]. A similar pattern was found in empathic ability. These results suggest that a communication training program for students majoring in dental hygiene should be prepared by investigating the categories in which the subjects lack ability, in order to provide programs customized to individual majors and individual subjects.

The present study was conducted to investigate the effect of the communication training program on the improvement of communication ability and empathic ability in the students majoring in dental hygiene. This study has several limitations. First, the results of the present study have limited generalizability to all students majoring in dental hygiene, because the subjects of the present study were students majoring in dental hygiene at a single university located in Chungnam. Second, since the present study was dependent upon a self-reporting questionnaire, the results of the present study may have a low objective reliability owing to the possibility of self-defending and subjective thinking by the subjects. Third, the present study did not take into consideration the background variables and the various factors that may affect the communication ability of the college students, including academic grades, income level, and family environment.

However, the present study is significant because the improvement of the communication ability and empathic ability of the students majoring in dental hygiene was investigated after implementation of the communication training program. The results of the present study may be used as fundamental data to prepare a systematic program to improve the communication ability and empathic ability of college students.

Conclusion

The results of the present study showed that the communication training program is effective in improving the communication ability and empathic ability of college students majoring in dental hygiene. With regard to the subfactors, the students majoring in dental hygiene showed high communication ability scores in paying attention to others and understanding other's perspective, but showed low scores in overcoming stereotypical thinking and creative communication. Therefore, communication training programs or courses customized to individual subjects may be needed in preparing a communication training program for students majoring in dental hygiene.

A Study on the Standardization of the 6-Minute Walking Test for Elderly Koreans

Sang Woong Park¹, Se-Youn Kim², Hae-In Kim³, Dong Jun Sung⁴, Wonjong Yu⁵

¹Professor, Dept. of Emergency Medical Services, Eulji University, South Korea, ²Lecturer, Se Jong General Hospital Cardiac Rehabilitation Center, South Korea, ³Lecturer, Dept. of Physical Therapy, Eulji University, South Korea, ⁴Professor, Division of Sport and Health Science, College of Biomedical and Health Science, Konkuk University, South Korea, ⁵Professor, Dept. of Physical Therapy, Eulji University, South Korea

Abstract

Background/Objectives: 6-minute walking distance is a method for evaluating cardiopulmonary function and assessing physical performance. However, the data used in clinics are calculated from Americans. So we measure distance for Asians.

Method/Statistical Analysis: In this study, measurement of 6-minute walking distance was performed according to the 2003 American Thoracic Society guidelines. We measured the 6-minute walking distance, body mass index, oxygen saturation, heart rate, and blood pressure.

Findings: The mean 6-minute walking distance of elderly Koreans was found to be 458.5 m. The mean 6-minute walking distances for elderly Korean men and women were determined to be 470.01 m and 452.18 m, respectively, with a statistically significant difference ($p < 0.05$).

Improvements/Applications: Although Koreans do not represent all Asians, it is necessary that calculations of the 6-minute walking distance are tailored for the Asian population or using the body muscle mass weight.

Keywords: 6-minute walking test, aerobic exercise, cardiopulmonary capacity, Asian, elderly population.

Introduction

In many countries, the rapid increase of the elderly population has led to an increase in the number of patients with cardiovascular diseases such as heart failure and coronary heart disease. Excessive exercise can adversely affect the health of the elderly. Therefore, a test is needed to evaluate the function of the cardiovascular system and prescribe individualized aerobic exercise levels. The 6-minute walk test (6MWT) is a field walk test developed to evaluate the condition, prognosis,

and appropriateness of treatment for cardiopulmonary diseases based on the 12-minute run test developed in 1978 [1]. The measurement method is simple and inexpensive as the walking distance is calculated by measuring the speed of an individual walking as fast as possible for 6 minutes, and it is widely used in clinical settings to estimate the maximum oxygen consumption using an equation [2]. Therefore, the 6MWT, which is continuously used all over the world [3], is considered a useful test for patients with chronic cardiopulmonary disease [4].

In addition, the 6MWT is a useful tool for evaluating pedestrian endurance in terms of function, and it is a criterion for determining the degree of mobility in individuals [5-7]. As such, the 6MWT is a commonly used walking test because of its ease and simplicity, and it is effectively used for predicting maximum athletic performance in many population groups [8].

e-mail: wjyu@eulji.ac.kr

Since the 6MWT is widely used, various researchers have developed several equations to calculate the standard walking distance using physical characteristics such as height, weight, and sex [9].

However, a single formula cannot reflect the differences in demographic, physical, environmental, and physiological characteristics of each region, which lead to discrepancies in values between subjects and countries. Consistent progress has been made on the standardization of the 6-minute walking distance [10,11].

Moreover, the 6MWT currently in use was developed for use 20 years ago, and the average body size of people has increased since then. A 6MWT different from that used for Westerners is needed for Asians as the 6MWT currently in use was developed for Westerners [12].

Many countries are already working on 6MWT standardizations that reflect their demographic, physical, environmental, and physiological characteristics; however, there is a lack of research on this aspect, in Asia. Therefore, this study aimed to standardize the 6MWT tailored for the demographic characteristics of elderly Asians by constructing a database using measurements of the standard 6-minute walking distance of elderly Koreans aged 65 and above.

Method

This study was reviewed by the Institutional Review Board. From June 1, 2017 to May 31, 2018, a cross-sectional survey was conducted on 300 elderly people over 65 years of age who agreed to participate in the study in S city, Gyeonggi-do. Subjects with a body mass index (BMI) of 35 kg/m² or higher and those with cardiopulmonary disease, neurological disorders, orthopedic diseases associated with pain while walking, or other diseases that could affect the test were excluded from the study.

The 6MWT: The 6MWT was based on the 2003 American Thoracic Society guidelines [13]. A biosignal meter was used to measure BMI, oxygen saturation (SPO₂), heart rate (HR), and blood pressure (BP). For safety during the study, leg pain, dyspnea, and chest pain were evaluated using a leg pain scale, a dyspnea scale, and a chest pain scale, respectively.

Intervention: Height, weight, and BMI were measured as general subject characteristics. For uniformity, all the measurements were made indoors

and the subjects were provided with shoes. The subjects undertook two 6MWTs and the longer distance covered was recorded. In addition, SPO₂, HR, and BP were measured before and after the test.

Data Analysis: The SPSS 20.0 program was used in this study to calculate the mean 6-minute walking distance according to sex and the 6-minute walking distance for all the subjects. Correlation analysis was conducted to determine the effect of each variable. The significance level (α) for verifying statistical significance was 0.05.

Result and Discussion

- General characteristics of subjects and 6MWT results:** The 106 men enrolled in this study had a mean age of 76.66 ± 4.18 years, a mean height of 166 ± 5.27 cm, a mean weight of 65.58 ± 9.45 kg, and a mean BMI of 28.16 ± 3.57 kg/m². The 194 women in this study had a mean age of 74.01 ± 4.75 years, a mean height of 154.3 ± 5.97 cm, a mean weight of 57.9 ± 7.56 kg, and a mean BMI of 29.53 ± 3.6 kg/m² (p<0.05) (Table 1).

Table 1. General characteristics and mean 6-minute walking distance of elderly Koreans

	Men (n=106)	Women (n=194)	t	p
Age (years)	76.66 ± 4.18	74.01 ± 4.75		non
Height (cm)	166 ± 5.27	154.34 ± 5.97		non
Weight (kg)	65.58 ± 9.45	57.9 ± 7.56		non
BMI (kg/m ²)	28.16 ± 3.57	29.53 ± 3.6		non
6MWT distance (m)	470.02 ± 77.31	452.18 ± 64.39	2.134	.034

* mean ± standard deviation BMI: body mass index 6MWT: 6-minute walking

- Correlation Analysis:** Correlation analysis revealed a positive correlation between the 6-minute walking distance and the height of subjects. In other words, the taller the subject, the longer the 6-minute walking distance. On the other hand, a negative correlation was found between the BMI and age of the subjects. In other words, the lower the BMI, the younger the age, and the longer the 6-minute walking distance. Of the characteristics considered, age correlated the most with the 6-minute walking distance (r = -.286), followed by height (r = .172), and BMI correlated the least (r = -.080) (Table 2).

Table 2. Correlation coefficient

		6MWT	Height	BMI	Age

** p< 0.01 level, 6MW: 6-minute walking, 6MWT: 6MW test, BMI: body mass index

We analyzed the factors affecting the 6-minute walking distance, and they included height, weight, and age. The 6-minute walking distance was found to have a positive correlation with height and a negative correlation with age. However, we found that weight had no effect on the walking distance (Figure 1). The aim of this study was to investigate the standardized 6-minute walking distance of elderly Koreans aged 65 years and above and to build a database. Speed and endurance are the main factors that determine mobility during walking [6], and they are frequently used for the prediction and evaluation of community walking ability [5]. For this purpose, 6MWT has been used in many studies [5,6,14].

The mean 6-minute walking distance of men was 470.02 m and that of women was 452.18 m. In an earlier study, mean values were 598.5 ± 57.92 m for men and 580.9 ± 47.80 m for women. The age of the subjects in this earlier study differed from that of the subjects in our study, but the result is consistent with our correlation analysis finding of a negative correlation between the 6-minute walking distance and age. Another previous study reported a mean 6-minute walking distance of 250 m in patients with hemiplegia [6], and yet another study reported a mean 6-minute walking distance of 516 ± 195 m in patients with chronic obstructive pulmonary disease [15]. Although the 6MWT has been performed for healthy adults and for certain disease groups, there has not been sufficient research aimed at determining the 6-minute walking distance of elderly Koreans; therefore, direct comparisons cannot be made. This study makes it possible to assess the current health levels of elderly Koreans.

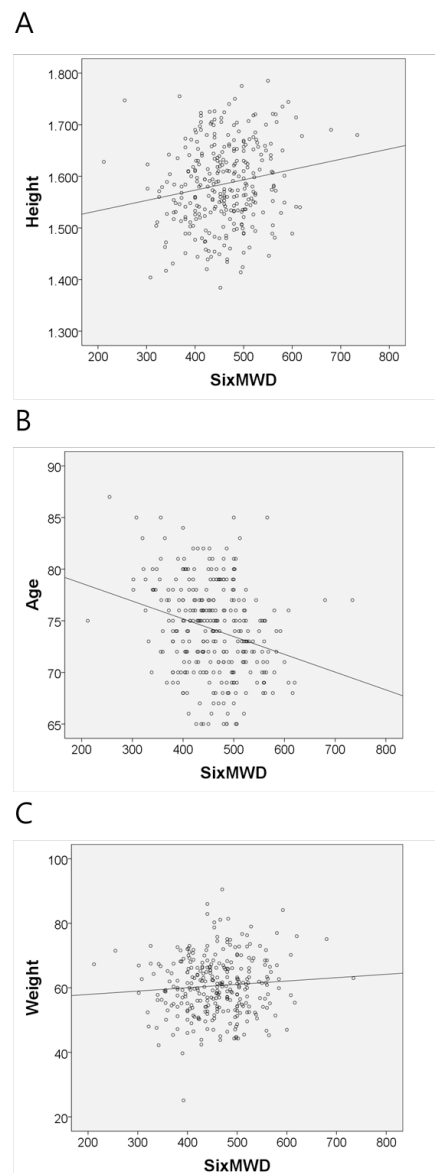

Figure 1. Analysis of Factors Affecting 6-Minute Walking distance

A, Correlation between the walking distance and height. The R value is 0.3. B, Correlation between walking distance and age. The R value is 0.07. C, Correlation between walking distance and weight. The R value is 0.0003.

In a 1998 study by Enright and Sherrill, 2 formulas were put forth to calculate the expected 6-minute walking distance according to sex, and they are as follows: expected 6-minute walking distance for healthy elderly men = $(7.57 \times \text{height}) - (5.02 \times \text{age}) - (1.76 \times \text{weight}) - 309$ m and expected 6-minute walking distance for healthy elderly women = $(2.11 \times \text{height}) - (2.29 \times \text{weight}) - (5.78 \times \text{age}) + 667$ m^[16]. Using the formulas above and the mean values of the general subject characteristics, the expected 6-minute walking distance for men was found to be 447.37 m, which is 22.65 m less than the 470.02 m determined in this study and accounts for a -5.06% difference. Likewise, the expected 6-minute walking distance for women was found to be 432.29 m, which is 19.89 m less than the 452.18 m determined in this study and accounts for a -4.6% difference. In comparison with the above-mentioned previous study, the mean heights of our subjects were 10 cm less in men and 8 cm less in women. From the calculations, it is evident that height, weight, and age are important factors. However, our study showed that weight had no effect on walking distance (Figure 1). It appears that this was because we used only weight. It remains to be analyzed whether the weight was because of excess fat or muscle. The results of this study may necessitate new calculations that take body muscle mass into consideration.

The 6MWT formula is widely used because of its ease of use. However, deviations are considered as resulting from differences in development time, cultural, and environmental characteristics. Therefore, to develop a formula that reflects the environmental and racial characteristics of Asians, studies were conducted on a larger number of elderly people to build a database. Further research is likely to be needed in various countries.

Conclusion

The aim of this study was to investigate the standard 6-minute walking distance of elderly Koreans. Our results showed a mean 6-minute walking distance of 470.01 m. The difference between the mean walking distances of men and women was 17.8 m; this means that, on average, men cover longer walking distances

than women. Based on the above results, elderly Koreans can measure their own 6-minute walking distance and compare their measurements with the mean value determined in this study. In addition, cardiopulmonary disease may be used as a criterion for the field walking test to measure aerobic capacity and the results can then be compared with those of healthy elderly individuals.

Study on the Relationship between General Health and Oral Health According to Diabetes

Hye-jeong Hwang¹, Kyung-hee Kang²

¹Dept. of Healthcare & welfare, Konyang Cyber University, 35365, South Korea,

²Dept. of Dental Hygiene, Konyang University, 35365, South Korea

Abstract

Background/Objectives: In this study, the relation between the health level and oral health in middle aged according to the diabetes were examined.

Method/Statistical Analysis: For this study, raw data were requested to Korea Centers for Disease Control and Prevention and among them, the data for 3,049 citizens in D Metropolitan City were analyzed. The statistical software R program was used for the analysis.

Findings: In the results of performing multiple logistic regression analysis taking the diabetes as dependent variable, the cases having the chronic disease, dyslipidemia, arthritis, and inconvenient mastication and the case that they did not brushing the tooth after breakfast and before sleep were shown significantly high ($p < 0.05$).

Improvements/Applications: This study was intended to verify the needs of prevention for the efficient oral health management in patients with diabetes and to be utilized as basic data to develop the product for oral health improvement in the patients with diabetes.

Keywords: *Diabetes, Chronic disease, Health, Oral Health, Happiness Index.*

Introduction

Diabetes is the chronic disease that the glucose is increased by the lack of insulin, and secondarily, the complications such as retinopathy, renal disorder, stroke, angina, myocardial infarction, oral diseases, etc. are caused. The complications of diabetes appear in various forms as a result that various metabolic disorders are caused. Among them, as a 6th complication of diabetes, the periodontal disease has been reported^[1-2]. The intra-oral symptoms that appear in the patient with diabetes are periodontal disease, dental caries, xerostomia, tooth

loss, gingivitis, cheilitis, burning sensation of soft tissue, etc.^[3], and particularly, it has been reported that since the patient with diabetes has higher glucose concentration in saliva than normal person, dental caries appears more^[4]. In addition, it has been reported that Decayed Missing Filled Teeth Index (MDFT index), which shows the objective oral health condition, is measured high in the patient with diabetes than the normal person, and the longer the period of illness, the higher the tooth loss index is^[5]. Out of the oral characteristics of diabetes, the periodontal disease is the representative chronic disease and mostly cause the destruction of periodontal tissues in the adults such as gingival bleeding, gingival recession, periodontal pocket formation, destruction of alveolar bone, etc. and in severe case, cause teeth loss^[6]. Periodontal diseases appear associated with diverse diseases like specific systematic diseases or metabolic syndrome^[7], particularly, in case of diabetes, it has trend that the periodontal diseases are serious^[8], and the prevalence of gingivitis and periodontal disease in

the patient with diabetes is higher than in the normal person. The research results on the quality of life related oral health also reported that the better the diabetes is managed, higher the quality of life and the mental health problem in the patient with diabetes such as depression, etc. is high than in the normal person^[9]. In the research on the quality of life related to oral health, most of the responders answered that the oral health has important effect on the quality of life and there is a research results that reported that the improvement of oral health has positive effect on the quality of life^[10-11]. Currently the awareness on the association of diabetes, chronic diseases with oral health and the importance of oral health is being increased. However, the awareness of oral diseases management is still low for the reason that it does not affect life. Therefore, this study examined the association of the systemic health with the oral health according to diabetes, through which it confirms the needs to prevent the oral disease for the efficient oral health management in the patient with diabetes and provides the basic data to develop the products for oral health improvement in the patient with diabetes.

Method

For this study, raw data of the 2015 Community Health Survey were requested to Korea Centers for Disease Control and Prevention and among them, the data for 3,049 citizens in D Metropolitan City were analyzed. For the analysis, the statistical software R program was used and the significance level was 0.05.

For the general characteristics and healthy lifestyle practice variables, the frequency analysis and chi-square test were performed for the age, education level, marital status, household income, current smoking habit, lifelong drinking habit, medium level of physical activity practice according to the gender. Chi-square test was performed for the chronic disease and subjective health level, happiness index, oral health and the level of oral health practice. Multiple logistic regression analysis was performed for the chronic disease, oral health and level of oral health practice taking the diabetes as dependent variable.

Result and Discussion

1. General characteristics of the subjects: In the results of analyzing the general characteristics according to gender, in the education level, the women graduated the elementary school were

72.4%, the highest ($p < 0.001$). In the marital status, the divorced, widow, separated women were 74.2%, the highest and followed by the single man, the women having spouse, etc in order ($p < 0.001$). In the household income, the women from 500,000 to 1,000,000 won were 63.4%, the highest and followed by women from 1,000,000 to 3,000,000 won and women more than 5,000,000 won ($p < 0.05$). In the current smoking habit, 89.4% of the men had smoking habit and 64.1% of the women did not have smoking habit ($p < 0.05$). In the lifelong drinking habit, 80.1% of the women did not have drinking habit and 50.5% of the men had drinking habit ($p < 0.05$). In the medium level of physical activity practice, 59.2% of the women did not engage in physical activity ($p < 0.05$) [Table 1].

2. Chronic Disease, Subjective Health level and Happiness Index according to Diabetes: In the group without having diabetes, the case that did not have hypertension was 92.2%, significantly high and in the group having diabetes the prevalence of hypertension was 25.8% ($p < 0.05$). For the dyslipidemia, in the group without having diabetes, the case that did not have dyslipidemia was 90.3%, significantly high and in the group having diabetes. The prevalence of dyslipidemia was 26.99%. For the arthritis, in the group without having diabetes, the case that did not have arthritis was 88.6%, significantly high, and in the group having diabetes, the prevalence of arthritis was 22.4% ($p < 0.05$). For the asthma, in the group without having diabetes, the case that did not have asthma was 87.8%, significantly high, and in the group having diabetes, the prevalence of asthma was 22.0% ($p < 0.05$). For the depression, in the group without having diabetes, the case that did not have depression was 87.2%, significantly high, and in the group having diabetes, the prevalence of depression was 23.5% ($p < 0.001$). For the subjective health level, in the group without having diabetes, the case that the subject health level is good was 94.5%, significantly high, and in the group having diabetes, the case that the subjective health level is 'poor' was 26.8% ($p < 0.05$). For the happiness index, the case that did not have diabetes was 6.99 ± 4.711 , high. Generally, in case that did not have diabetes, the chronic diseases appeared low and the subjective health level and happiness index were high [Table 2].

Reference group: Subjective Periodontal Tissue Health Level (Good), Inconvenient Mastication (Not inconvenient), Annual Oral Health Examination (Yes), Annual Scaling Experience (Yes), Toothbrushing after Lunch (Yes), Toothbrushing before Sleep (Yes).

Conclusion

In case of group having diabetes, out of the chronic diseases, the hypertension, dyslipidemia, arthritis, asthma, depression were shown significantly high and the subjective health level was also shown poor ($p < 0.05$). In case of the group having diabetes, since the subjective periodontal tissue health level was poor, the level of inconvenient mastication was inconvenient and the subjective oral health level was poor, it was observed that they had the oral health management problem. In the oral health practice level, it was shown that they did not receive the annual oral health examination or the scaling, and particularly, did not brush the tooth after breakfast and lunch and before sleep ($p < 0.05$). In the results of performing multiple logistic regression analysis taking the diabetes as dependent variable, the cases having the chronic disease, dyslipidemia, arthritis, and inconvenient mastication and the case that they did not brushing the tooth after breakfast and before sleep were shown significantly high ($p < 0.05$). In conclusion, for the oral health management in the patient with diabetes, diverse measures such as the management of complications of the chronic diseases, the development of systematic practice educational program related to oral health, etc. should be prepared at national level. Particularly, the strategic management measures for the single males of 60 years or older who have low income and low education level are needed desperately.

Analysis of Factors Affecting the Depression and Quality of Life in the Family Taking Care of Dementia Patients

Kyung-hee Kang¹, Kwon-Seob So², Hye-jeong Hwang²

¹Dept. of Dental Hygiene, Konyang University, 35365, South Korea,

²Dept. of Healthcare & welfare, Konyang Cyber University, 35365, South Korea

Abstract

Background/Objectives: This study was intended to identify the factor having influence on the stress, depression and the quality of life in the family who care the patient with dementia.

Method/Statistical Analysis: For this study, raw data were requested to Korea Centers for Disease Control and Prevention and among them, the data for 150,802 citizens of 45 years or older in D Metropolitan City were analyzed. For the analysis, the statistical software R program was used and the significance level was 0.05.

Findings: Out of the factors having influence on the family who are cohabitating with the patient with dementia, the factors having influence on the quality of life were age, benefit of basic living security, lifelong drinking, days of medium level of physical activity, diabetes, arthritis, subjective oral health level, subjective health level, experience of depression, etc..

Improvements/Applications: This study was intended to provide the basic data to develop the programs for the health improvement and the health education of the family who care the patient with dementia

Keywords: *Dementia, Cohabitation, Family, Stress, Depression, Quality of life.*

Introduction

The psychological symptom that shows the highest frequency out of the psychological symptoms experienced by the primary caregivers of the patient with dementia is the depression^[1]. In the United States, it was reported that 30-50% of the caregivers of the patient with dementia have depression^[2]. The factors that deteriorate the depressive symptoms of the family caregiver of the patient with dementia are relationship with family^[3], disease duration, level of problem behavior or functional and cognitive disorder, daily

living activity, existence of assistant caregiver, etc^[4-5]. It has been reported that the greater the dependency of the patient with dementia in the daily living activity and the more severe the level of problem behavior, the higher the level of depression or level of stress in the family caregiver^[6]. As the patient with dementia is increased, for the patient, the quality of life is degraded by diverse irreversible symptoms around the cognitive and behavior disorders^[7] and for the primary caregiver, the quality of life is degraded by the stress in caring the patient^[8]. Since the caregivers are likely to become hidden patient or second patient by experiencing diverse negative emotions together with care burden^[9-10], the problem in the primary caregiver should be considered as a part of the problem of patient with dementia and the effort to support the family of patient with dementia is needed. The caregivers of patient with dementia are complaining of negative perception on the dementia, lack of information on the social support resources related to treatment of dementia and lack of time to taking care

of their own life due to long-term care of the patient with dementia^[11]. Integrated educational program for the family of caring the patient with dementia should be provided and therefore, this study was intended to provide the basic data to development the program for health improvement and health education of the family members who are taking care of patient with dementia by identifying the factor having influence on the stress, depression and the quality of life in the family members who are taking care of the patient with dementia.

Method

For this study, raw data of the 2015 Community Health Survey were requested to Korea Centers for Disease Control and Prevention and among them, the data for 150,802 citizens of 45 years or older in D Metropolitan City were analyzed. For the analysis, the statistical software R program was used and the significance level was 0.05. The general characteristics of the research subjects were divided by the cohabitation with the patient with dementia and the frequency analysis and Chi-square test were performed for the gender, age, educational level, marital status, household income, beneficiary of basic living security. Chi-square test and independent sample t-test were performed for the factors related to smoking habit, drinking habit, hypertension, diabetes, hyperlipidemia, arthritis, depression, etc, by the stress. For the factors related to the family cohabited with the patient with dementia

and the depression, the logistic regression analysis was performed and for the factors related to the quality of life, multiple linear regression analysis performed. For the quality of life index (EQ-5D index), the index that aggregates the 3 level of technical system for the current state of 5 items (exercise capability, self-management, daily activities, pain/inconvenience, anxiety/depression) of the quality of life related to health. EQ-5D index has the value between 1 and 1 and the closer to 1, the higher the quality of life.

Result and Discussion

- General Characteristics and Healthy Life Behavior:** The family cohabitating with the patient with dementia was average 1.3% showing low cohabitation rate. The cohabitation with the patients with dementia was high in the subjects of 75 years or older (p<0.001), of the graduates of the elementary school or below (1.6%)(p<0.001), of single (2.1%) (p<0.001), from 500,000 won to 1 million won of household income (1.7%) (p<0.001), who did not drink for entire life (1.6%)(p<0.001), and who cannot practice the medium level of physical activity (1.4%) (p<0.001) [Table 1].

3. Subjective Stress, Subjective Oral Health Level and Subjective Health Level According to Cohabitation with Patient with Dementia:

In case if the family who are cohabitating with the patient with dementia, the case of feeling high subjective stress level was 2.2%, the case of poor subjective oral health level was 1.5%, the case of poor subjective health level was 2.0%. The case that feels little subjective stress level was 40.6%, the case of poor subjective oral health level was 55.5%,

the case of poor subjective health level was 44.2%, shown relatively higher proportion in the relevant group [Table 3].

4. Happiness Index and Quality of Life according to Cohabitation with Patient with Dementia:

In case of family who do not live together with the patient with dementia, the happiness index was $7.22 \pm .897$, not significant but high and the quality of life was 0.8946 ± 0.17497 , significantly high ($p < 0.001$) [Table 4].

Table 3. Subjective Stress, Subjective Oral Health Level and Subjective Health Level Unit: N(%)

5. Multiple Logistic Regression Analysis according to Depression in Family who Cohabitate with Patient with Dementia: For the variable having significant influence on the depression, the female showed 1.918 times significantly higher than the male, the age group of 45 to 64 years old showed 1.706 times significantly higher than the group of 74 years or older. (p<0.001). For the subjective periodontal tissue health level, ‘Poor’ was shown 1.573 times than ‘Good’, for the subjective stress level, ‘Case that feels a little’ was shown 2.371 times and ‘Case that feels a lot’ was shown 8.991 times higher than ‘Case that does not feel’ and for the subjective health level, ‘Fair’ was shown 2.253

times and ‘Poor’ was shown 2.553 times higher than ‘Good’ (p<0.001) [Table 5].

6. Factors having Influence on Quality of Life of Family Who are Cohabiting with Patient with Dementia: The factors having influence on the quality of life were age (p<0.001), recipient of basic living security benefit (p<0.05), lifelong drinking (p<0.05), Days of medium level of physical activity (p<0.05), doctor’s diagnosis of diabetes (p<0.05), doctor’s diagnosis of arthritis (p<0.05), subjective oral health level (p<0.05), subjective health level (p<0.001) and experience of depression (p<0.001) and the explanation power was 25.1% [Table 6].

Conclusion

The influence on the depression in the family who are cohabitating with the patient with dementia was significant high in the male, age group of 45 - 64 years old, when the periodontal tissue health level is poor, when feeling the stress a lot, and when the health level is poor (p<0.001). Out of the factors having influence on the family who are cohabitating with the patient with dementia, the factors having influence on the quality of life were age, benefit of basic living security, lifelong drinking, days of medium level of physical activity, diabetes, arthritis, subjective oral health level, subjective health level, experience of depression, etc.. In conclusion, when developing the health improvement program to prevent the depression in the family who are living with the patient with dementia, the quality of life will be improved if it is developed for the age from 45-65 years old, married couple of family type together with development of the lifestyle improvement program for drinking and oral health management of the spouse without dementia and the prevention program for alleviation of overstress. It is deemed that these results can contribute to providing the basic data to develop the program for health improvement and health education of the family who are caring the patient with dementia when establishing the policy on the dementia.

Effects of Low-Dye Taping Applied to Chronic Stroke Patients on Gait Speed

Eun-Ja Kim¹, Dae-hun Kim¹, Shin-Jun Park²

¹Department of Physical Therapy, Faculty of Health Science, Kyungdong University, Wonju-Munmak, Gangwon-do, Republico Korea, ²Department of Physical Therapy Gangdong University, Shin Jun Park

Abstract

Background/Objectives: This study examines the effects of the normal biomechanical maintenance of the feet through Low-Dye taping on the gait treatment in chronic stroke patients and presents the basis of clinical intervention.

Method/Statistical Analysis: In this study, 5 cm-wide elastic tapings was applied to improve gait ability in 20 chronic stroke patients. Low-Dye taping was applied for foot alignment. Gait was measured by BTS G-walk (G-walk, BTS, Italy). In this study, taping was applied after the initial assessment, and post measurement was performed after 30 min of taping to examine the immediate effects of taping on the gait parameters. The main outcome of this study is gait speed, and the secondary outcomes are cadence and stride length.

Findings: The research group showed significant increases in gait speed and cadence except for the stride length at 30 min after applying the taping.

Improvements/Applications: After applying the Low-Dye taping to chronic stroke patients, their gait speed and cadence showed significant differences due to the effects of ankle joint alignment and medial longitudinal arch lift and support. Therefore, Low-Dye taping was effective in improving the gait ability of chronic stroke patients.

Keywords: Stroke, Low-Dye taping, gait, Balance, Simulator Exercises.

Introduction

Feet support the body weight in standing position, absorb shock during gait, provides the driving force required for body movement, and maintains balance while the center of gravity of the body is moving. Furthermore, the biomechanical changes of the feet can cause musculoskeletal diseases and gait disorder. During gait, the feet are subject to medial-lateral and anterior-posterior shear forces in addition to a vertical pressure

in stance phase. However, the feet provide dynamic and static stability by forming medial longitudinal arch on the sagittal plane and transverse arch on the coronal plane. Furthermore, the dynamic stability of the ankle joint is maintained by the muscular forces of the intrinsic and extrinsic muscles. During gait, the feet control excessive forward movement of the contralateral lower limb while supporting the ground in the stance phase and enable movement in the swing phase. In addition, the tibialis posterior muscle plays the role of absorbing shock under a body weight by adjusting the medial longitudinal arch while the feet are in contact with the support surface^[1].

The ankle joint motion disorder of stroke patients causes abnormal weight support and gait patterns. Limitation in the plantar flexion of the ankle joint decreases push-off during gait, which shortens the step length. Moreover, among the gait parameters, cadence,

e-mail: vertetrac@kduniv.ac.kr

velocity, and stride length are decreased while the single support and double support are increased, the weight supports of the feet are asymmetrical and the medial longitudinal arch cannot be maintained. As a result, the shock absorption of the ground reaction force becomes limited^[2]. In standing position, the weight passes through the talonavicular joint and pushes down the talus, which lowers the medial longitudinal arch. Flat foot is a condition where the medial longitudinal arch is continuously lowered or abnormally low, in which the ligament of the foot, the plantar fascia, and the posterior tibial tendon are over-extended^[3]. In the stance phase during gait, the flat foot decreases the forward movement of the center of gravity of the body and increases the ground reaction force^[4]. These problems resulting from the biomechanical changes of the feet and ankle joint decreases the input of proprioceptive information, causing balance disorder and falls. Furthermore, lower limb damage occurs during activities of daily living and sports activities^[5].

Low-Dye taping applied to flat foot treatment was first introduced to clinical practice by Ralph Dye. Low-Dye taping is to attach a tape that induces supination of the ankle. It has the effects of decreasing the pressures on the heel and the front part of the pronated foot and decreasing the pronation by normalizing the navicular alignment^[6]. Furthermore, it can support the medial longitudinal arch, normalize the biomechanical changes of the feet, reduce the shock caused by increased ground reaction force during gait, and prevent joint damage that may occur in sports activities or activities of daily living. The maintenance of normal medial longitudinal arch also has positive effects on gait^[7].

Improvement of gait ability is critical for independent daily activities of chronic stroke patients and the gait function is the criterion for recovery of motor disorder. Therefore, much time is spent on gait treatment. This study examines the effects of the normal biomechanical maintenance of the foot by Low-Dye taping on the gait treatment of chronic stroke patients and the present basis of presents the basis of clinical intervention.

Materials and Method

Study Subjects Ethical Consideration: Taping was applied after the initial evaluation, and post measurement was performed 30 min after taping application to determine the immediate effects of taping on the gait parameters.

The main outcome of this study is gait speed and the secondary outcomes are cadence and stride length.

1. G-walker: To measure the spatiotemporal gait parameters after taping application, BTS G-walk (G-walk, BTS, Italy) embedded with a three-axis accelerometer, a magnetometer, and a gyroscope was used. The G sensor was positioned at the fifth lumbar vertebra using a belt for measurement. The sensor stabilization was measured in an upright position before measurement, and then the gait parameters were measured. For measurement, the start button was pressed and then the subject was instructed to walk freely on an 8 m walkway. When it was determined that sufficient data were collected, the researcher pressed the stop button and collected the data. This equipment can measure the analysis duration, cadence (number of strides per min), speed (average gait speed), stride length (average distance from the heel of a foot to the heel of the same foot), gait cycle duration (average distance to the heel strike of one foot) step length (average distance from the heel of one foot to the heel of the other foot), stance phase duration (ratio of time during which the left and right feet support the ground in a gait cycle), swing phase duration (ratio of time during which the left or right foot is in the swing phase in a gait cycle), double support duration (ratio of time during which both feet support the ground in the stance phase), single support duration (ration of time during which only one foot is supporting the ground in the stance phase), strides elaborated (accurate number of strides used in analysis). In this study, the gait speed (m/s), cadence (steps/min), and stride length (m) were collected from the G-studio program.

2. Intervention Method: Five cm-wide elastic tapings was applied to improve the gait ability of stroke patients. First, Low-Dye taping was applied for foot alignment^[7]. The longitudinal anchor taping was attached from the fifth metatarsal head, which is on the outside of the foot, to the first metatarsal head by pulling the taping from the lateral to the medial direction. The transverse arch support taping was attached along the sole from the lateral to the medial direction. The transverse arch support taping was attached to the heel, the arch, and metatarsal head of the foot, in the direction from the heel to the metatarsal head [Figure 1] [Figure 2].

Figure 1. Low-dye taping

Figure 2. Low-dye taping

Data Analysis: The statistical data analysis was performed using the statistical software package SPSS 20.0 (SPSS Inc., Chicago, IL, USA). For the general characteristics of the subjects, the mean and standard deviation were obtained by using descriptive statistics. The normality test was performed by the Shapiro-Wilk Test. In addition, paired t-test was performed to examine the effects of taping on the spatiotemporal gait parameters. The alpha value for statistical significance level was set to .05.

Findings:

1. **General Characteristics of Subjects:** [Table 1] lists the general characteristics of the subjects.

Table 1. General characteristics

Classification	Experimental Group (n=20)
Gender (male/female)	16/4
Paretic side (right/left)	9/11
Age (years)	60.75±10.90
Height (cm)	164.60±6.45
Weight (kg)	65.15±6.08
K-MMSE (point)	27.15±1.09
Onset (month)	12.15±2.43
K-MMSE, Korean version of the Mini Mental State Examination	

2. **Effects of intervention on gait parameters:** The research group showed significant increases in gait

speed and cadence after taping application for 30 min, but stride length showed no significant increase [Table 2].

Table 2. Changes of gait parameters in the experimental group before and after the intervention

Classification	Pre-test	Post-test	P
Gait Speed	84.24±16.06	90.97±19.51	.024*
Cadence	.76±.22	.83±.22	.002*
Stride Length	1.10±.21	1.13±.18	.107

Discussion

The anatomical deformations of feet influence the tactile stimulation input during motions in various environments and decrease the stability of posture control during standing position and gait. Furthermore, the decreased stability of posture control causes injuries in the activities of daily living and sports activities. The structural deformations of the feet have a greater effect on dynamic stability than static stability. Treatment of foot deformation can increase the limits of stability of posture control and improve physical functions^[8]. Foot deformation due to abnormal muscle tone and muscle weakness of the hemiplegic side causes more pronation deformation than supination deformation, and limits weight support and physical movement while the foot is in contact with the ground^[9]. The pronation deformation of stroke patients does not affect gait more than supination deformation. However, due to the reduced medial longitudinal arch, the sole pressure is concentrated on a specific site, which increases the instability of the ankle joint and affects gait^[10].

Low-Dye taping applied to the pronated foot can control excessive pronation by decreasing the medial pressure and increasing the lateral pressure on the sole^[11]. Furthermore, it can raise the medial longitudinal arch that has been lowered by the decrease of the excessive muscular activity of the tibialis anterior muscle and the descended navicular, and can maintain the stability of the ankle joint during standing on one foot. This stability of the ankle joint allows the body to maintain normal weight load while the foot is in contact with the ground^[12].

The parameters according to the change in the sole pressure and the extrinsic muscles of the ankle joint after applying Low-Dye taping were not measured. The foot deformation of stroke patients is different from

the pronation deformation of normal persons caused by muscle tone and anatomical changes following the damaged central nervous system. However, the significant changes in the gait parameters after applying Low-Dye taping seem to have enabled the maintenance of ankle joint alignment and the lift and support of the medial longitudinal arch, which had a positive impact on the stable weight support and weight movement during gait. In this study, Low-Dye taping was applied to subjects who could walk, but further studies are needed on the balance parameters related to weight support and movement following the foot deformations of stroke patients in the future.

Applying the Kinesio taping to chronic unstable ankle joints decreases the body sway in the base of support during standing on one foot^[13] and has the effect of muscle tone control and proprioceptive information input in patients with central nervous system impairment^[14]. After applying the Kinesio taping to the ankle joints of chronic stroke patients, gait speed increased due to the increased motion of the ankle joint^[15]. Furthermore, after applying the Low-Dye taping, velocity, stride length, and cadence increased among the gait parameters^[7].

Conclusion

In this study, after applying Low-Dye taping to the feet using an elastic tape for 30 min, gait speed and cadence increased significantly, but the stride length did not increase. The elasticity of the elastic tape used in this study is focused on supporting motion rather than fixing. Inelastic taping fixes the arch of the foot and simply increases the arch during motion, whereas elastic taping supports the motion in the supination direction until the foot becomes pronation by using elasticity. Therefore, in this study, the gait speed increased because the elasticity of tape during middle stepping, toe touch, and toe push raised the arch (hoist effect). In addition, number of steps per min increased, and the stride length also increased, although it was not statistically significant. It showed an increase in the number of steps and movement at the same distance during gait, which supports the result of the increased gait speed. However, this study had a few limitations, the concrete effects on gait parameters were not presented, the application time of Low-Dye taping was short, and the effects of the elastic and inelastic taping method were not clarified. Low-Dye taping had a positive effect on gait despite the short application time, which suggests that it is helpful for improving the

gait function of chronic stroke patients. In the future, qualitative research is required to present the basis for expanding the application scope of Low-Dye taping in clinical practice.

The Effect of Participation in Mentoring Program on Adjustment to College Life, Major Satisfaction, and Interpersonal Relationship Skill in the Nursing Students

Eun-Hee Shin¹, Gyun-Young Kang²

¹Professor, Department of Nursing, Munkyeong College, Mungyeong-si, Kyeongsangbuk-do, KOREA, ASI KR KS010 MUNGYEONG, ²Professor, Kyungdong University College of Nursing, Wonju-siGangwon-do, KOREA.ASI KR KS007 WONJU

Abstract

Background/Objectives: This is a descriptive research to investigate the effects of mentoring program participation on the adjustment to college life, major satisfaction, and interpersonal relationship skill in the nursing students.

Method/Statistical Analysis: The study subjects were 200 college students majoring in nursing and data collection was conducted from October 1 to 10, 2018. Collected data were analyzed by t-test and ANOVA.

Findings: Upon the study results, participation in the mentoring program showed the positive impacts on the adjustment to college life($t=-7.029$, $p<.001$), major satisfaction($t=-4.993$, $p<.001$), and interpersonal relationship skill ($t=-5.715$, $p<.001$).

Improvements/Applications: Therefore, it is required to develop a variety of approaches and programs to operate efficient and effective mentoring system.

Keywords: *Adjustment, Interpersonal relationship, Mentoring program, Nursing students, Satisfaction.*

Introduction

In the midst of rapidly changing social conditions, college plays an important role in making individuals cultivate their abilities to recognize their identities and adjust themselves to college life. For students to recognize their identities and adapt to school life, adjustment to college life, satisfaction with major, skill in human relations are important. Adjustment to college life is not only important as it is, but is more

important because it affects their studies in college, and future career^[1]. It also affects drop-out of school among students. Drop-out rate is one of important indicators in evaluating school qualities. As factors affecting drop-out of school, individual factors such as student's devotion to education, college selection, and elements related with major have been reported^[2].

Accordingly, to help students adjust themselves to college life and improve themselves, many colleges have adopted the mentoring system. Mentoring is the activity where the person called mentor guides, directs, and consults mentee, and helps mentee develop capacities and potentials in knowledge and technology learning, and in human relations^[3]. It has been long from the time when private companies adopted the mentoring system to train new employees, and, recently, it is applied to various other areas including schools. In schools, mentoring is the system where students in senior school

Corresponding Author:

Gyun-Young Kang

Professor, Kyungdong University College of Nursing,
Wonju-siGangwon-do, KOREA.ASI KR KS007
WONJU

e-mail: mental74@kduniv.ac.kr

years who have experiences and knowhow in school life and major guide and advise students in junior school years, and teaching and learning between mentor and mentee are made by daily interactions among them. To help students adapt to school life and feel satisfied with school life, many colleges adopt mentoring programs^[4]. Through the relationship between mentor and mentee, support for growth, future direction, and feedback on consultation are provided^[5].

Adjustment to college life provides students with opportunities to satisfy social and psychological desires in addition to intellectual desires, and with the basis to live as social members with desirable attitudes^[6]. Adjustment to college life is related with various demands in college environment such as learning, skillful human relations, and emotional aspects, and is determined by whether a student can successfully respond to them autonomously and independently^[7]. When a student accepts and positively responds to scholastic, social, and psychological demands of college, the student can satisfy intellectual desires by college education and establish positive self image^[8].

Satisfaction with major is the process of evaluating the department the student belongs to in the perspective of his or her future career or expectation of job. If a student is not satisfied with his or her major, problems like low grades and mal-adjustment to school life, etc. can happen. In contrast, the student highly satisfied with his or her major participates actively in classes and other campus life, and makes efforts to achieve his or her goal^[9]. The student who is highly satisfied with school life tends to adapt well to social life after graduation, and succeed in the society^[10].

Interpersonal relationship are an important condition determining happiness of life, an important goal of life, and an important element in living as a member of society. In particular, college days are an important period of psycho-social development when students are required to be psychologically, emotionally, and socially independent from his or her parents, and build new and various human relations. And, the times are also the period when students experience their own development by establishing self-identity based on close Interpersonal relationship^[11].

As described above, mentoring program is discussed as a method for human growth and teaching^[12], and the mentoring relationship is considered as providing

positive role-model^[13]. Previous researches have proved that mentoring program is effective in improving self-efficacy and adaptation to school life^[14]. In the case of nursing school students, with increasing sense of burden and stress caused by the requirements of learning knowledge, and mastering skills in clinical training and clinical works, they can lose interest in their major or have difficulty in adapting to school life. Therefore, this study relationship skill dy intends to examine the effects of mentoring program on adaptation to school life, satisfaction with major, and interpersonal relationship skill in the nursing students.

Method

Research Design: This research is a descriptive survey research to examine the effect of participation in mentoring program on adjustment to college life, satisfaction with major, and interpersonal relationships skill in the nursing students.

Research Subjects: The objects of this research are 200 students belonging to a specific nursing department. The size of the sample was calculated using the GPOWER 3.1.2 system. The minimum number of samples needed to do multiple regression analysis with 5 predictive factors, effect size .15, significance level .05, and statistical power .90 was 116. This research conveniently collected data from 200 objects.

Research Tools:

Mentoring Scale: This study used the mentoring scale which had been developed by Noe^[15], and revised by Kim^[16]. The scale consists of 20 questions, and respondents are asked to respond to each question on the 5-point Likert scale.

Adjustment to school life: To measure adjustment to school life, this study used the scale developed by Kim^[16]. The scale consists of 8 questions, and respondents are asked to mark their answers on the 5-point Likert scale. In this study, Cronbach's alpha was .966.

Interpersonal relationship skill: To measure Interpersonal relationship skill, this study used the scale revised by Kim^[16]. Cronbach's alpha of this study was .920.

Satisfaction with major: To measure satisfaction with major, this study used the scale revised by Lee^[17]. The scale consists of 18 questions: 5 questions on

general satisfaction; 7 on perception satisfaction; 3 on satisfaction with curriculum; 3 on satisfaction with human relations. Those questions were also measured with Likert scale where higher points means higher satisfaction. In Lee [17]'s study, Cronbach's alpha was .90, and the value of this study was .920.

Data Analysis: Collected data was analyzed with SPSS/WIN 22.0. To examine general characteristics of survey respondents, this study acquired real numbers, percentages, means and standard deviations using descriptive statistics. To examine whether there is any difference in general characteristics for the following variables like participation in mentoring program, adjustment to school life, satisfaction with major, and skill in human relations, this study used t-test and ANOVA. To examine the effect of participation in mentoring program on adjustment to school life, satisfaction with major, skill in human relations, this study used t-test.

Result

1. General characteristics of respondents: [Table 1] General characteristics of respondents are shown in Table 1. The proportion of gender is 39 males (19.5%) and 161 females (80.5%). The proportion of students per school year is 100 freshmen (50%) and 100 sophomores (50%). In evaluation of relationship with mentors, 63% responded that it was 'So, so'. The number of those who attended the mentoring program one time or more during the past year was 105 (52%), while 95 students (48%) did not participate in such a program.

Table 1. General Characteristics of Subjects (n=200)

Characteristics	Categories	N(%)
Gender	Male	39(19.5%)
	Female	161(80.5%)
Grade	1	100(50%)
	2	100(50%)
Relationship with mentors	Very good	14%
	Good	19%
	Moderate	63%
	Bad	2%
	Very Bad	2%
Mentoring program one time or more during the past year	1 or more times	105 persons (52%)
	1 time or less	95 persons (48%)

2. The effect of general characteristics on adjustment to college life, satisfaction with major, and Interpersonal relationship skill: [Table 2] The effects of general characteristics on adaptation to college life, satisfaction with major, and skill in human relations are shown in Table 2. The effect of mentor on such variables are significant: adjustment to college life (p=.001), satisfaction with major (p=.001), and interpersonal relationship skill(p=.000). The group of students who have close relations with their mentors were found to be high in points of Likert scale answering those questions on adjustment to college life (3.51±.80), satisfaction with major 3.78±.51), and interpersonal relationship skill (3.78±.51).

Table 2. The effect of general characteristics on adjustment to college life, satisfaction with major, interpersonal relationship skill (n=200)

Characteristics	Categories	Adjustment to College Life		Satisfaction with Major		Interpersonal Relationship Skill

Discussion

This study was performed to examine whether participation in mentoring program among nursing students are effective in improving adjustment to college life, satisfaction with major, and interpersonal relationship skill.

It was found that participation in mentoring program has positive effect on adaptation to life in the department and college. Satisfaction with major, and skill in human relations. Previous researches have also found that students who participated in mentoring programs are higher in adaptation to life in the department and college^[1,16]. We could identify that mentoring program is an effective program to raise satisfaction with school life because such a program builds close relationship between mentor and mentee and helps mentee search for future career and prepare for it. In addition, as the relationship between mentor and mentee can be crucial in making the mentoring program successful, the systematic and efficient plans to build mutually positive trust relationship should be considered first. In particular, as nursing school students, objects of this research, tend to have fixed careers, systematic advice of mentor on mentee’s career, information on clinical training, and

emotional support, etc. can be effective mentoring in mentee’s college life. Besides, mentoring program was found to have positive effects on self growth and development like improvement of self respect^[18], and career identity^[19].

As satisfaction with major is the process of evaluating the department one belongs to, in view of one’s future career and expectation on future job^[20], it is an element affecting career choice. Data analysis of this research found that participation in mentoring program has positive effect on satisfaction with major. So, such a program is effective in growth and development of college students. Previous researches have also found that participation in mentoring program have positive effects on learning achievement and learning attitudes, and stimulates motive to study, raises pride, and reduce psychological burden of learning^[21]. When we combine such findings, we can infer that mutual interaction between mentor and mentee can affect on only their learning achievement, but continued learning. Therefore, it seems desirable to continue to do researches on mentoring in various aspects.

Interpersonal relationship skill are knowhow on how to avoid hurting other person’s emotion and make other person comfortable. As poor human relations can result in mal-adjustment to school life, skill in human relations are important to adjust oneself to environment called college. In particular, as nurses should have cooperative and close relations with their patients as well as members of the medical team, such skill are important requirement nurses should be equipped with. This research found that participation in mentoring program has positive effect on forming positive human relations. Oh, Kim & Lee^[22] also found such positive effect of mentoring program on forming positive human relations. Noe^[15] discovered that the more mentee perceives the role of mentor, the more he or she can improve mental capacity and self-efficacy, and that mentor program has positive effect on psycho-social relations. With the experiences of relations with mentor, mentee can improve skill in human relations, and cultivate the capacity to understand oneself, positive attitudes, and leading attitudes^[23].

Based on findings of this research, we can understand the process of growth and development of participants in mentoring program. As the relationship between mentor and mentee is socialization process of nursing school students to be professional nurses, it seems necessary to consider adopting mentoring

program as a non-course program in nursing college to help nursing school students grow themselves such as adaptation to school life, satisfaction with major, and skill in human relations. Accordingly, when a college operates mentoring program, it seems necessary to perform customized mentoring for each student focusing on improving adaptation to life in the department and college. Satisfaction with major, and interpersonal relationship skill. It should also consider specific conditions of schools.

Conclusion

This research was performed to identify the effect of participation in mentoring program on adjustment to college life. Satisfaction with major, and interpersonal relationship skill in the nursing students. Data analysis found out that participation in mentoring program has positive effect on those variables. The objects of this research are nursing students. Thus, this research suggests that it is desirable to do future researches applying mentoring program to students in various majors.

Evaluation of Effective Sound Insulation Method for Noise Generated by MRI

Jung-Hoon Lee

Professor, Dept. of Radiological Science, Shinhan University, 95, Hoam-ro, Uijeongbu-si, Gyeonggi-do, 11644, Republic of Korea

Abstract

Background/Objectives: MRI is a popular method in modern diagnostic medicine. However, MRI equipment produces 65 to 130 kHz noise when operated, which can cause patients to feel anxious or fear enclosed spaces. To lower the level of noise, method such as earplugs and headsets have been used.

Method/Statistical Analysis: In this study, the researchers tried to find out the effective sound insulation method by measuring the degree of noise heard by the patients and evaluating the difference of noise by sound insulation material. A sound meter was placed in a water phantom made outside the magnetic field of the MRI to measure the noise using four sequences (EPI, T1, T2, GRE) and compared it to the sound felt by the patient.

Findings: As a result, the average noise felt by the patient was measured to be 92.5 dB at EPI, 73.1 dB at T1, 87.4 dB at T2, and finally 74.4 dB at GRE. The average noise when the earplug was worn was measured to be 84.4 dB at EPI, 66.3 dB at T1, 79.4 dB at T2, and 67.7 dB at GRE. The average noise value when the headset was worn was measured to be 78.2 dB at EPI, 61.3 dB at T1, 74.4 dB at T2, and 65.3 dB at GRE. Finally, the average noise when both earplug and headset were simultaneously worn was measured to be 77.4 dB at EPI, 60.5 dB at T1, 73.3 dB at T2, and 63.4 dB at GRE respectively. Based on the above result, the most effective sound insulation was made when both earplug and headset were worn at the same time, the next effective sound insulation method was headset wearing, and the least sound insulation method was earplug wearing.

Improvements/Applications: If it is not possible to apply a fundamental management method to eliminate the causes of noise, which is difficult to practice in actual clinical practice, it is suggested that hearing protection gear should be actively used to reduce the degree of noise-exposed to patients.

Keywords: *Magnetic resonance imaging, headset, earplug, noise, Sound insulation.*

Introduction

Nuclear Magnetic Resonance (NMR), initially published in 1946 by Purcell and Block researchers,

was able to provide imaging ability by the development of gradient magnetic fields by Laterbur of New York State University in 1973. Thus, the device was named Nuclear Magnetic Resonance Imaging (NMRI), which combines nuclear magnetic resonance and imaging. It is now commonly referred to as MRI by omitting the initial letter N of Nuclear. MRI uses nuclear magnetic field and non-ionizing radiation to generate nuclear magnetic resonance in the nucleus of the body, imaging the density and physicochemical characteristics of the nucleus ^[1]. Therefore, MRI (Magnetic Resonance Imaging) is harmless to the human body, unlike X-ray

or CT (Computed Tomography) and is widely used in the modern diagnostic medicine [2]. However, these MRI devices generate the noise of 65 ~ 100 dB for 1.5 Tesla, and close to 120 ~ 130 dB for 3.0 Tesla MRI equipment. In addition to the extremely narrow magnet bore of MRI, patients often complain of anxiety or claustrophobia during MRI because the patient's movement is limited to the maximum. As a result, MRI scanning may be delayed or interrupted. [3-4]. To reduce such anxiety, the current clinical practice uses music therapy that provides the music that the patient likes during MRI scanning [5], communicates with the patient through broadcasting [6], and simultaneously communicates with music therapy [7], which has been reported to reduce the psychological tensions of patients and makes them feel stable and consequently reduces anxiety. However, above method do not remove the real noise generated during MRI. Therefore, the method of managing the cause of the noise should be applied to reduce the amount of sound reaching the patient. However, the method of Hennel F et al (1999), which reduces the noise by smoothing the slope of the electric signal input to the coil, has a limitation in that the resolution of the image is lowered[8].

Since the numerical value of noise generated from MRI may cause an anxiety in patients, it is necessary to take measures to deal with it [9]. In the actual clinic, earplugs and headsets are used to reduce noise reaching patients.

Previous studies have identified the amount of noise generated by MRI, but there is no study that measures the amount of noise that patients experience after wearing sound insulation gear. Through this study, the researchers tried to find an effective sound insulation method that reduces the noise value that reaches the patient by measuring the degree of noise actually heard by the patient and comparing and evaluating the noise of each sound insulation material.

Method

- 1. Materials for Experiment:** As the material of the above experiment, RION's NL-42, an international standard Class 2 (normal) sound measuring instrument, was used. As a phantom, a hand-made water phantom was used. The size was 270 mm × 230 mm × 240 mm, the material was PP, and its purpose was to insert a noise meter [Figure 1].

Figure 1. Experimental material

- 2. Experimental Method:** The experiment was conducted in MRI room (3.0T Intera system Philips MRI), which was generally inspected, and noise was measured and evaluated by placing it at the end of the MRI, which is not affected by the magnetic field. [Figure 2] shows the experiments placing a sound meter in the phantom based on the method of sound insulation to the patient using earplug, headset and both earplug and headset at the same time without

sound insulation material. The noise was measured and compared by 4 method of earplug wearing, headset wearing and both earplug and headset wearing with 4 sequences (EPI, T1, T2, GRE) after measuring the noise that the patients felt. In order to increase the reliability of the experiment, total five measurements were performed, and the values at 5, 15, 25, 35, 45, and 55 seconds were recorded for 60 seconds by each sequence.

Figure 2. Measuring method (a) General MRI noise (b) Earplugs (c) Headset (d) Earplugs + Headset

3. Statistics: The average noise value of sequence by each method was obtained utilizing SPSS software Ver.25.

Result

[Table 1] shows the results of measurement and comparison of noise using sound insulation method. [Figure 3] is a graph showing the results of the comparison. At EPI, the highest noise-sequence, the average noise value of patients was 92.5 dB and the average value of noise when insulated by earplug was 84.4 dB. The one when insulated by headset was 78.2 dB and the one when insulated by both earplug and headset at the same time was 77.4 dB respectively. At T1 sequence, the average noise value of patients was 73.1 dB and the average value of noise when insulated by earplug was 66.3 dB, the one insulated by headset was 61.3 dB, and the one insulated by both earplug and headset at the same time was 60.5 dB. At T2 sequence, the average noise value of patients was 87.4 dB, the average noise value when insulated earplug was 79.4 dB, the average noise value when insulated by headset sound was 74.4 dB and the one when insulated by both earplug and headset at the same time was 73.3 dB. Finally, the average noise of the patients at GRE sequence was 74.4 dB. The average noise value when insulated by earplug was 67.7 dB, the average noise value when insulated by headset was 65.1 dB, and the one when insulated by both earplug and headset was 63.4 dB respectively. This shows that the noise is insulated most when earplugs and headsets are worn at the same time. The headset was then the second, and the earplug was third in sound insulation.

Table 1. Measured Value [Unit : dB(A)]

Sequence	General	Earplug	Headset	Earplug + Headset
EPI	92.5	84.4	78.2	77.4
T1	73.1	66.3	61.3	60.5
T2	87.4	79.4	74.4	73.3
GRE	74.4	67.7	65.1	63.4

Figure 3. Measurement Value Graph

Discussion

The noise at the EPI sequence was from 92.5 dB to 77.4 dB and decreased up to by -15.1 dB, about 16.3%, and the sound at the T1 sequence was from 60.5 dB to 73.1 dB, and decreased up to by -12.6 dB, about 17.2%. The noise at T2 sequence was from 73.3 dB to 87.4 dB and decreased up to by -14.1 dB, about 16.1%, and the noise at the GRE sequence was 63.4 dB to 74.4 dB and decreased up to by -11 dB, about 14.8%. The MRI test showed the most significant sound insulation effect of -15.1 dB at EPI sequence, and the sound insulation effect about 16% was achieved by simultaneous wearing of both earplugs and headsets. At EPI sequence, the noise was from 77.4 dB to 92.5 dB and decreased up to -15.1 dB, about 16.3%, and the sound at the T1 sequence was from 60.5 dB at 73.1 dB and decreased up to -12.6 dB, about 17.2%. At the T2 sequence, the noise was from 73.3 dB to 87.4 dB and decreased up to by -14.1 dB, about 16.1%, and the noise at the GRE sequence was from 63.4 dB to 74.4 dB and decreased up to -11 dB, about 14.8%. The MRI test showed the most significant sound insulation effect of -15.1 dB at EPI sequence, and the sound insulation effect of about 16% was achieved by the simultaneous wearing of both earplug and headset.

MRI is one of the most important imaging diagnoses in modern medicine. It is possible to diagnose diseases in a way that is harmless to the human body, not to diagnose diseases using radiation such as X-ray or CT and provides anatomical and pathological information of human tissues unlike other diagnosis method, so the perception that MRI is safe unlike other diagnostic method is widespread to modern citizens. Contrary to the advantages of MRI, however, MRI generates quite a large amount of noise. Although the degree of noise varies slightly between manufacturers and equipment, it generates noise of 65 ~ 100 dB in case of 1.5 Tesla MRI and 120 ~ 130 dB in the case of 3.0 Tesla MRI. Besides, 7.0 Tesla MRI equipment under development is expected to generate even higher noise, which may cause various problems [3]. The short-term exposure to such noise not only temporarily reduces hearing but also causes hearing loss difficult to recover when exposed for a long time [10]. The noise of MRI causes an imbalance between the sympathetic and parasympathetic nerves, causing stress, anxiety [11], and also affects breathing or pulse. It brings physiologically, the sympathetic nerves causing excitement and tension, elevation of blood pressure, excessive secretion of gastric acid, increased heart rate, constriction of blood vessels, and hormonal changes [12]. ‘Noise work’ refers to a work that generates noise higher than 85 dB over 8 hours a day. ‘Intense noise work’ refers to a practice that produces the noise higher than 90 dB at the same time as above. This noise does not cause noise-induced hearing loss, but the noise reaching the patient causes various physiological disorders in the human body [13]. In fact, these noises cause many patients to feel anxiety or claustrophobia during MRI, which often causes delayed examination or movement of the patient resulting in poorly diagnosed images. It is reported that the fundamental management method of noise should be applied to improve the noise generation, but if it is difficult, it should be shielded by hearing protection gear [14]. Although these method are not sufficient to prevent noise with a frequency band between 500 and 1000 Hz, which affects the patient much during the MRI scan [15], this reduces the degree of noise-exposed [2]. Claustrophobia and noise sensitivity were reported to be reduced after the MRI examination [16]. In the case of the previous studies, the amount of noise generated during the MRI test can be identified and evaluated. However, no study measured the degree of noise felt by patients wearing the sound insulation materials during the test. Therefore, in this study, the researchers measured the actual noise level that patients

felt using sound insulation method that are widely used in clinical practice, and then compare and evaluate the noise of each sound insulation material to find an effective sound insulation method that reduce the degree of noise reaching the patient.

The limitations of the study were first, the noise measurement with nonmagnetic material was not made in MRI bore, and the noise was measured in an accessible place. Second, the structure of the human body was much more complicated than the phantom implemented, so indirect measurement was made. Further research needs to measure the noise at the center of MRI using a nonmagnetic noise meter to make the measurement close to the sound heard that patients hear.

Conclusion

This study compares and evaluates the method of insulating the noise generated during MRI test. The most effective method to insulate the noise generated from MRI was wearing both earplug and headset at the same time. The second effective way was wearing a headset and the least effective one was wearing an earplug. When comparing and evaluating the noise values heard by patients, the actual sound insulation value was significant, and the sound insulation effect up to by -15.1 dB, about 16.3% was achieved at EPI sequence. These values are thought to be effective for various physiological functions as well as claustrophobia and anxiety for patients. As a result, it is suggested that hearing protection gears should be used to reduce the level of noise exposed to patients if fundamental management method such as the installation of soundproof hoods on MRI are not available.

Impact of Trademark Rights on a Company's Financial Performance: Focusing on Pharmaceutical Industry in South Korea

Myung-Sun Na¹, Kwan-Sik Na², Inchaek Park³

¹Ph.D. Student, Department of Smart Convergence Consulting, Hansung University, Seoul, Republic of Korea,

²Professor, Department of Management Information Systems, Seowon University, Chungbuk, Republic of Korea,

³Assistant Professor, Division of Smart Management Engineering, Hansung University, Seoul, Republic of Korea

Abstract

Background/Objectives: In recent years, there has been a growing awareness that intangible assets, especially intellectual property, can affect a company's value and competitiveness. To this end, companies are striving to secure intellectual property around patents, and many studies have verified the relationship between patent information and corporate performance from a variety of angles. However, in the field of intellectual property, the focus was mainly on patent information-driven research, and further research on the relationship between trademark and design authority is necessary to clarify the relationship between intellectual property rights and corporate management performance..

Method/Statistical Analysis: The purpose of this study is to verify whether a company's trademark application/registration activity and the persistence of a company's trademark rights affect the company's financial performance through SPSS.

Findings: The amount of trademark application/registration activity of a company and the persistence of trademark rights held by a company both affect the financial performance of the company.

Improvements/Applications: This study verified the relationship between trademark rights and corporate performance, which had been expected only by conjecture, through statistical method. However, the value of a trademark is determined by the market value accumulated by the use of the trademark rather than by the trademark itself. Therefore, follow-up studies are needed to verify statistically through various trademark information for various industries as to whether the acquisition of trademark assets has a positive effect on the company's management performance.

Keywords: *Trademark, Trademark Rights, Trademark Data, Company Performance, Financial Performance.*

Introduction

Due to the continuous development of science and technology and the emergence of new technologies due to the Fourth Industrial Revolution, the importance

of intellectual property is increasing day by day, and securing the intellectual property has become a barometer for measuring the company's management performance and competitiveness. Smith and Parr view Intellectual property as a representative intangible asset that contributes to the company's profit generation^[1], while Edvinsson and Malone refer to intangible assets such as patents and copyrights as innovative capital^[2] ^[3]. Researches that explore the relationship between existing intellectual property rights and corporate management performance have focused on research based on patents. As a result, it is confirmed that sales

of patent applications and registrations are affecting sales^[4], and that R & D expenditures and patents affect corporate value^[5] and that R & D intensity and patents have a positive effect on economic value-added value per share(EVA)^[6]. Trademarks can be used as a tool to distinguish a company's product from other companies' products, and can be used as a guarantee of quality, identity, etc., which can increase the consumer's preference for the product. Brands already positively recognized by consumers have the effect of reducing marketing costs such as promotions, and can increase the efficiency of communication between companies and consumers^[7]. Furthermore, the company's brand equity increases its influence on growth footing and distribution through brand expansion, and is an additional source of revenue for the company through its actual assets and licensing^[8]. In the situation where the quality and function of products are being leveled due to the steady development of technology, the importance of trademarks and brands as a criterion for differentiation of a company's products or services or a selection of consumers' products is increasing day by day. Companies are aware of this and are making efforts to secure trademark rights. In particular, the Korean pharmaceutical industry corresponds to an industry where the trademark application volume is higher than the cosmetics, electrical and electronic products, clothing, and food industries. And instead of developing new drugs, they are growing by copying and selling expired drugs. Therefore, the ratio of sales by developing new drugs is small compared to that of developed countries, and the ratio of sales by duplicate drugs that rely on sales and marketing rather than technical skills is high. Therefore, although the acquisition and utilization of patents are an important factor in corporate management performance, in the Korean pharmaceutical industry, which focuses on the sales of generic drugs with little quality discrimination, securing the trademark or brand itself will affect corporate performance. The purpose of this study is to statistically verify the trademark information of the pharmaceutical industry, which is expected to have a greater impact on the company's business performance than the acquisition of patent assets.

Method

Existing trademark researches were mainly qualitative researches, such as literature research and survey-based hypothesis testing, in the methodological aspect. In terms of contents, researches on measuring

economic value in the field of marketing and improving its utilization and researches on institutional improvement in the field of law have been conducted^[9]. There were also studies dealing with economic value and business strategy. First, there was a study on the effect of profitability and operating cash flow on brand value through comparison between industries^[10], and studies on product sales strategies based on the theory of brand extension^[11-14]. In addition, trademark rights have enormous rights in their utility and economic feasibility, including profits and publicity effects as property rights due to civil and criminal sanctions on monopoly, property rights, and infringement. If you do not register your trademark as a trademark, you cannot sanction appropriate for unauthorized use by others. Moreover, if someone else applies first, the brand may be taken away and the brand reputation that has been accumulated may be damaged. Furthermore, this study found that trademark rights affect brand value because the act of displaying trademark application number or registration number helps brand marketing^[15]. In terms of indicators to measure the economic profit direction of firms, there was an in-depth study of new application trademarks of Benelux SMEs^[16] and a study to analyze the purpose of trademark application of SMEs through a survey^[17]. In addition, there was a study on the development of a trademark valuation model of a company for the purpose of evaluating trademark value^[18-19].

There are not many research cases that directly analyze and utilize various information of trademark right in relation to this study, but Lee and Lee presented an analysis method using product information of trademark right to analyze industrial convergence^[20]. Yoon et al. Presented a methodology for business intelligence by looking at and analyzing trademark rights as business data^[21]. Yoo and Lee presented a way to judge consumers' perception using trademark data^[22].

In order to extract the trademark index for use in this study, we referred to the indicators in the patent field where research to verify the relationship with management performance among intellectual property rights is active^[23-27].

The subjects of this study were mainly Korean pharmaceutical companies. Among them, more than 50 trademark applications were filed and 59 Korean listed pharmaceutical and bio companies as of 2018. The data was collected using the trademark search system Intomark (www.intomark.com) and patent information

search service (www.kipris.or.kr). The trademark data was extracted by searching each company name as the applicant for the trademark data from 1950 to 2018. The financial statements of each company collected data provided by the Financial Supervisory Service’s electronic disclosure system (dart.fss.or.kr).

Based on the theoretical background so far, the number of trademark application, trademark registration rate, trademark registration per employee, and renewal trademark ratio were selected as independent variables. In addition, as the dependent variable that indicates the company’s management performance, the average sales revenue over five years related to the growth performance was selected. Among the independent variables, the total number of applications, the number of trademark

registrations per employee, the rate of registration were used as a factor of the company’s trademark application/ registration activity, and the renewal trademark ratio was used as a factor of the persistence of trademark rights held by the company.

H1. The amount of trademark application/ registration activity of a company affects its financial performance.

H2. The persistence of the trademarks owned by the company affects the company’s financial performance.

The categories included in the research model are described by the variable and operational definitions shown in [Table 1].

Table 1: Definition of Variables

Variable	Factor	Conceptual Definition	Operational Definition
Independent variable	The amount of trademark application/ registration activity	Number of trademark applications	-
		Number of registered trademarks per employee	Number of registered trademarks/ Number of employees
		Trademark Registration Rate	Number of registered trademarks/ Number of trademark applications
	The persistence of the trademarks owned by the company	Trademark Renewal Rate	Number of renewed trademarks/ Number of registered trademarks
Dependent variable	Financial performance of the company	5-year average sales	Total sales for five years/5

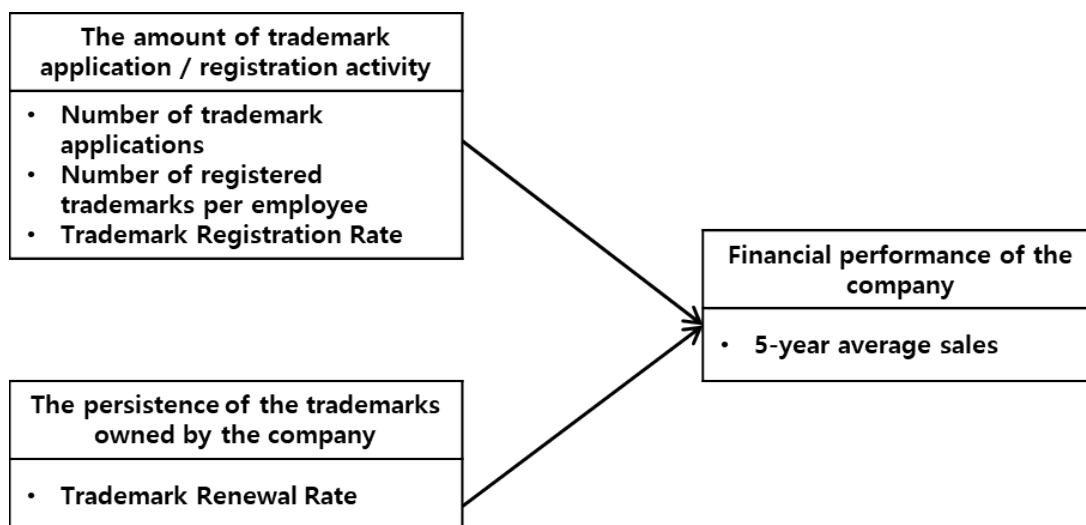

Figure 1. Research model

[Figure 1] shows the research model for empirically analyzing the hypotheses as shown above. In other words, this study used the number of trademark

applications, trademark registration rate, and trademark registration per employee in terms of the amount of trademark application/registration activity. In addition,

we measured the persistence of the trademarks owned by the company as the renewal trademark ratio. The average variable over the last five years, which represents the company’s growth potential, is the dependent variable. The amount of trademark application/registration activity and the persistence of the trademarks owned by the company will be examined through multiple regression analysis.

Result and Discussion

The independent variables in this study are the number of trademark applications, the number of registered trademark per employee, trademark registration rate, and trademark renewal rate in the

trademark quantitative data. The dependent variable is the average sales for five years. Multiple regression analysis showed statistically significant results.

Table 2. Model Summary

Model	R	R ²	Modified R ²	Standard Error of Estimates	Durbin-Watson
1	.698	.487	.449	223375.4681	1.199

As shown in [Table 2], R² = .487 shows 48.7% explanatory power. Durbin Watson is 1.199, which is close to 2 and not close to 0 or 4, so there is no correlation between the residuals, making it suitable for the regression model.

Table 3. ANOVA

Model	Sum of squares	Degreed of freedom	Mean squares	F	p-value
Regression	2557511622918.120	4	638937902729.530	12.805	.000
Error	2694416386353.230	54	49896599747.282		
Total	5250168009271.350	58			

As shown in [Table 3], the F value was 12.805 and the significance probability was .000 (p <.05), so the regression line was found to be suitable for the model.

Table 4. Coefficient

Model	Unstandardized Coefficients		Standardized Coefficient	t	Sig.	Collinearity statistics	
	B	Standard Error	Beta			Tolerance	VIF
Constant	-437392.143	149751.755		-2.921	.005		
Number of trademark applications	177.405	26.191	.815	6.774	.000	.656	1.523
Number of registered trademarks per employee	-216740.155	49374.742	-.528	-4.390	.000	.657	1.523
Trademark Registration Rate	10023.397	2136.717	.525	4.691	.000	.759	1.317
Trademark Renewal Rate	3226.064	1482.022	.239	2.177	.034	.786	1.271

As shown in [Table 4], the effect of the number of trademark applications on the average sales over the five years was adopted because the t value was 6.774 and above ± 1.96, and the significance probability (p value) was 0.000 and p <.05. Second, the effect of the number of registered trademark per employee on sales was adopted because t value was -4.390 and above ± 1.96, and the significance probability (p value) was 0.000 (p <.05). Third, the relation between the trademark registration rate and the sales was selected as t value of 4.691 and significant probability (p value) of 0.000. Finally, the trademark renewal rate was chosen as t value was

2.177 and significant probability (p value) was 0.034. Tolerance limits are all above 0.1, so there is no problem with multicollinearity between independent variables.

According to [Table 4] above, the following regression model can be predicted.

$$5\text{-year average sales} = -437392.1431 + 177.405 \times \text{Number of trademark applications} - 216740.155 \times \text{Number of registered trademarks per employee} + 10023.397 \times \text{Trademark Registration Rate} + 3226.064 \times \text{Trademark Renewal Rate}.$$

Therefore, it can be predicted that the five-year average sales increase as the number of trademark applications, trademark registration rate, and renewal trademark ratio increases. However, the lower the number of registered trademark per employee, the higher the five-year average sales.

Discussion

This study analyzes the amount of trademark application/registration activity and whether the persistence of the trademarks owned by the company affects the firm's financial performance. The amount of trademark application/registration activity of a company was measured by the number of trademark applications, trademark registration rate, and registered trademark per employee. The persistence of the trademarks owned by the company was measured by renew trademarks ratio. In addition, the financial performance of the company was measured by sales, which is used as a key indicator of corporate growth. As a result, first, the hypothesis that the amount of trademark application/registration activity of a company affects its financial performance was adopted. However, in case of trademark application/registration activity, the higher the number of trademark applications and trademark registrations, the higher the average 5-year sales, but the lower the number of registered trademark per employee, the higher the 5-year average sales. This is contrary to the previous findings of the patent but is difficult to generalize because the sample is limited to the pharmaceutical industry. For this, follow-up verification through trademark data of various other industries will be required. Second, the hypothesis that the persistence of the trademarks owned by the company affects the financial performance of the company was also adopted. The high renewal brand ratio means that many products have been satisfying consumers for a long time, and there are many brands with high consumer awareness of the brand and the economic value of the brand is also great.

Conclusion

This study verified the relationship between trademark rights and corporate performance, which had been expected only by conjecture, through actual statistical method. In addition, it is expected to contribute to the development of follow-up research on the development of trademark indices using trademark data, which has not been fully studied yet. However, the limitation of this study is that the data covers only

a very small part of the various trademark data, and the sample is limited to the pharmaceutical industry only. Therefore, in future studies, it is necessary to confirm the meaning of trademark information by further verifying it to other industries by various data among the trademark information.

The Effect of Recognition Level of Korean Elderly Long-Term Care Insurance System on Effectiveness Recognition

Hye-yeong Do¹, Yun-Jeong Kim²

¹Doctor Course, Department of the Elderly Welfare, Hanseo University, Republic of Korea,

²Professor, Department of Health, Counseling and Welfare, Hanseo University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to investigate the effect of the elderly long-term care insurance system recognition level on effectiveness recognition in Korea. The study focused specifically on the comparison of middle age and old age-related study subjects.

Method/Statistical Analysis: The subjects of this study were middle age people between the ages of 45 and 64 years old, and the old age people were over the age of 65 who were residing in Chungnam, Korea. From July to August 2018, questionnaires were distributed and collected from general residents, and finally, 400 sets of data from 200 middle age and 200 old age data were obtained.

Findings: First, the perception of necessity and necessity of elderly long-term care insurance system was considered positive, and the middle age generation was more positive than the old age generation. In addition, the middle age generation had a high level of recognition that if they needed care, they would utilize care facilities, but would utilize home care services when the spouse also required additional care. Second, elderly care facilities and home service fees were generally recognized and considered as expensive, but such a cost burden did not adversely affect the effectiveness recognition of the elderly long-term care insurance system.

Improvements/Applications: In order to solve the problems in the new elderly care facilities construction process, it is necessary to exchange opinions and converge with each other through constant communication and coordination with the residents, and in addition, business entities should first approach local residents with authenticity regarding their noted care issues and concerns.

Keywords: Long-term care insurance system, Recognition level, Admission motivation, Effectiveness recognition, Middle age, Old age.

Introduction

The elderly long-term care insurance system, which is a representative form of social care in Korea, has been implemented nationwide since 2008, and it was institutionalized at the national level on the basis of the social solidarity principle, improving the quality of life

of elderly people and problems caused by the increase in geriatric diseases^[1]. The benefit types of elderly long-term care insurance system includes: home-care benefits such as visiting care, visiting bathing, visiting nursing, day and night care, short term protection, and other home-care benefits, institution benefits, as well as special cash benefits including family care benefits, special medical benefits, and nursing hospital benefits^[2].

According to a study by Lee ^[3]in 2017, nearly 10 years after the elderly long-term care insurance system was implemented nationwide, showing that the proportion of care by family members was higher than that of public services. Nevertheless, the use of public services for the elderly population is on the rise every

Corresponding Author:

Yun-Jeong Kim

Professor, Department of Health, Counseling and Welfare, Hanseo University, Republic of Korea
e-mail: twoyun21@hanmail.net

year. As of April 2010, there were 300,000 elderly people who received long-term care status, 5.6% of the total elderly population, and 260,000 of them were using long-term care services for the elderly^[4].

There is also a growing awareness of the need for elderly long-term care services. Meanwhile, according to the National Health Insurance Corporation's 2009 national awareness survey on elderly long-term care insurance system, the overall perception of the need for the system was very high at 86.6%, but the awareness of the system was 53.1%^[5]. In light of the elderly long-term care insurance system awareness survey in 2017, awareness increased significantly to 77.2%, and necessity to 92.8%^[6].

In addition, the perceived level of elderly long-term care insurance system, which can be operationally defined through recognition of elderly long-term care insurance system, necessity, NIMBY phenomenon for nursing facility, and charge level, is expected to vary from generation to generation in terms of needed services for the elderly in society. Empirical studies also found trends related to differences between generations, but the directions were considered to be different. There are also studies^[7] in which age does not affect the perception of elderly long-term care insurance systems and studies^[8] that the older the age, the higher the awareness of the system and the higher the age, the more interested the person was on understanding care systems for the elderly people who would need those services the most in society.

An improved knowledge of the social system or policy, or the development of an increased knowledge of the policy may affect the behavior of policy subjects or future policy subjects and ultimately affect policy effectiveness^[9]. Therefore, in order to grasp the effectiveness of the welfare policy for the elderly, it is necessary to understand more closely the influence of the recognition level on the system, and it is possible

to predict the necessity to aid in the expansion and contraction of the future system by comparing and analyzing it according to the generation.

The study focuses on the middle age generation between 45 and 64 years old and the old age generation older than 65 years to investigate first, "what is the perceived level of elderly long-term care insurance system?," second, "does the elderly long-term care insurance system have a different recognition level according to generation?," and third, "does the perceived level of elderly long-term care insurance system affect the level of effectiveness?"

Method

1. **Data collection procedures:** The subjects of this study were middle age people between the ages of 45 and 64 years old, and the old age people were over the age of 65 who were residing in Chungnam, Korea. It is noted that from July to August, 2018, questionnaires were distributed and collected from general residents, and finally, 400 sets of data from 200 middle age and 200 old age data were obtained.
2. **Characteristics of subjects:** The sociodemographic characteristics of the middle age generation 200 subjects were 57.0% males, 51.29 years of age on average, and 95.5% of respondents were married. Education level was relatively high with 52.5% of college graduates or higher and 43.5% of high school graduates, 51.0% had religion and 71.0% resided in urban area.

The sociodemographic characteristics of the middle age generation 200 subjects were that 68.0% males, 75.81 years of age on average, and 91.5% of respondents were married. The education level of the subjects showed 65.0% of the subjects having less than middle school education, 69.0% had religion, and 60.0% lived in rural areas.

3. Measurement tools:

Table 1. Measurement tools

Variable	Content	Measurement method
Dependent variable	Effectiveness recognition	It used the single item “Do you think that the elderly long-term care insurance system will ease the burden on families?” and it is composed of a 5 point Likert scale.
Independent variable	Necessity recognition	It used the single item “Do you think there is need for an elderly long-term care insurance system?” and it is composed of a 5 point Likert scale
	Care facility building approval	It used the single item “Would you approve of elderly care facilities near your home?” and it is composed of a 5 point Likert scale
	Care facility fee charging	It used the single item “Do you think the cost of entering elderly care facilities is reasonable?” and it is composed of a 5 point Likert scale
	Home service fee charging	It used the single item “Do you think the cost of home-care benefits service is reasonable?” and it is composed of a 5 point Likert scale

4. Statistics: In this case, the frequency analysis, crosstab analysis, and hierarchical regression analysis were applied using SPSS 21.0.

Result

1. Recognition of elderly long-term care insurance system: The recognition rate of elderly long-term care insurance system of middle age and old age was high with 77.3%, 89.2% of the respondents responded ‘agree’ to the effectiveness of the system, and 2.2% ‘strongly agree’ with 91.4% positive towards the system (average 4.12), and in response to the necessity of the system, ‘agree’ was 54.7% and ‘strongly agree’ was 35.6% with 90.6% (average 4.22) responding positively. However, it is emphasized that 66.3% of the respondents agreed to building a care facility near to their home, with a slightly lower response rate of 3.69.

In service type, on the question of need for care for oneself, 51.8% responded ‘elderly care facilities admission’ and for spouse, 51.5% responded ‘use of home-care benefits’, which was similar levels. Meanwhile, for responses related to elderly care facilities fees, 51% responded that it was ‘rather burdening’ and 58.3% responded ‘average’ for home service use fees, showing that home service use burden is lower than elderly care facilities burden.

2. Differences in recognition of elderly long-term care insurance system by generation: The differences between the elderly long-term care

insurance system awareness was significant in the difference between middle age and old age [Table 2]. The awareness was high both in old age generation (70.5%) and middle age generation (84.0%), but middle age generation was higher.

Table 2: The difference awareness according to generation

	Middle generation N (%)	Old generation N (%)	Chi-square
Know	168(84.0)	141(70.5)	10.370**
Do not Know	32(16.0)	59(29.5)	
**p<.01			

3. The effect of perceived level of elderly long-term care insurance system on the effectiveness recognition by generation: To investigate the effect of awareness level of elderly long-term care insurance system on effectiveness recognition, those who know the elderly long-term care insurance system were separated for analysis in the study. A hierarchical regression analysis was performed [Table 3].

Stage 1 control variables accounted for 4.5% of the effective recognition of elderly long-term care insurance systems, elderly long-term care insurance system recognition explained 39.9%, and the total of 10 variables accounted for 44.4% of the effective recognition of the elderly long-term care insurance system of the middle age generation. Therefore, the necessity recognition of the elderly long-term care insurance system, rather than

the sociodemographic characteristics of the middle age generation, were shown to have had more influence on the effectiveness recognition.

Looking at the influence of individual variables focusing on model II, it was shown that the awareness

of the effectiveness of elderly long-term care insurance system in Korea was higher with higher recognition of necessity and higher agreement to care facility building near the home, and the relative influence of necessity recognition was higher between the two variables.

Table 3. The effect of recognition level of elderly long-term care insurance system on middle generation on effectiveness recognition

		Model I			Model II		
		B	Beta	t	B	Beta	t
Constant term		5.062		7.057***	1.655		2.459*

		F value=1.260 R ² =.045			F value=12.549*** DR ² =.399 R ² =.444		
*p<.05, ***p<.001							

Next, in the hierarchical regression model for old age generation [Table 4], the Stage 1 control variables accounted for 5.5% of the effective recognition of elderly long-term care insurance system, whereby the elderly long-term care insurance system recognition explained 32.5%, and the total of 10 variables accounted for 38.0% of the effective recognition of the elderly long-term care insurance system of the old age generation. Looking at

the influence of individual variables focusing on model II, it is noted that the awareness of the effectiveness of elderly long-term care insurance system in Korea was seen as higher, with a higher recognition of necessity and higher agreement to care facility building near the home, and relative influence of necessity recognition was higher between the two variables.

Discussion

The corresponding discussions and recommendations that were based on the important results are as follows.

First, the perception of necessity and necessity of elderly long-term care insurance system was considered positive, and the middle age generation was more positive than the old age generation. Also, the middle age generation had a high level of recognition that if they needed care, they would utilize care facilities, but would utilize home care services when the spouse also required additional care. This implies that they would prefer to care for their spouse in the home rather than at a facility when it is possible for them to care for their spouses. In these cases, it is noted that there is a need for a governmental program to be initiated, and this is in the same context as the activation of the day care center, which is being actively promoted by the current government. On the other hand, the old age generation was more likely to consider elderly care facilities, in the case that they needed care or their spouse needed care. This is interpreted that it is difficult to care for oneself and care for a spouse, in a situation where it is often difficult for the elderly to cope with their own physical needs, and they become less independent as they age. Therefore, elderly care facilities need to be expanded for the current elderly generation. At the time in the future, when the middle age generation becomes elderly and needs public care, it is desirable to expand community care such as day care centers and home welfare centers rather than elderly care facilities, which is more likely to be available in the form of the community care provided by the current government.

Second, it is worth noting that the higher the approval level for the construction of the care facility

near the residential area, the more positively recognized is the effectiveness of the system. The necessity of the system was noted at 4.22 out of 5 points, but the approval level related to construction of care facility was noted to be 3.69 points out of 5 points, and this figure was lower than necessity. This shows that there is still a NIMBY phenomenon in effect for elderly care facilities. As a result, confrontation with the local residents is often initiated for these reasons, and in order to easily resolve such conflicts, the business entity promises unconditional incentives to local residents. However, these incentives not only take into consideration the rational judgment of local residents, but also it is not possible to expect realistic solutions in some cases under these circumstances. In order to solve the problems in the new elderly care facilities construction process, it is necessary to exchange opinions and converge with each other through constant communication and coordination with the residents, and in addition, business entities should first approach local residents with authenticity regarding their noted care issues and concerns. A program should be developed in which local residents can participate and encourage volunteering to assist the elderly, to contemplate ways in which elderly care facilities can coexist with local residents in a partnership to manage meeting the needs of the elderly on all levels of care.

The Effect of Power of Agility of Core Stabilization Exercise by the Musical Type

Myung-Chul Kim¹, Hae-In Kim²

¹Professor, Dept. of Physical Therapy, Eulji University, South Korea,

²M.D. Student, Dept. of Physical Therapy, Eulji University, South Korea

Abstract

Background/Objectives: The purpose of this study was to investigate the effects of core stabilization exercise combined with music of various tempo and mode on the power of agility.

Method/Statistical Analysis: 65 healthy adults who did not major in music were recruited and each participant was randomly divided into five groups. All groups were performed core stabilization exercise for 3 weeks. To confirm the effect of core stabilization exercise combined with music of various tempo and mode, they were measured before and after the exercise.

Findings: After applying the core stabilization exercise, the power of agility was improved in all groups, and the fast tempo groups improved the power of agility more than the slow tempo groups. However, there was no significant difference between the major mode and minor mode groups.

Improvements/Applications: Tempo was affected on the power of agility. But mode was not affected on the power of agility.

Keywords: Power of agility, Music, Tempo, Mode, Core stabilization exercise.

Introduction

Recently, a variety of core stabilization exercises have been applied to enhance the physical fitness and exercise performance of the general public and to prevent injuries^[1]. The core muscles are the muscles of the spinal, pelvis, hip, and abdominal muscles that maintain the stability of the vertebrae^[2]. Core stabilization exercises can improve muscle strength, power of agility, flexibility, and balance in high school girls and middle-aged women, accompanied by the training of the gluteus maximus muscle^[3-4]. In addition, it has been reported that female tennis players can positively improve their basic stamina and athletic performance^[5] such as improving

leg strength, muscular endurance, and power of agility^[6]. However, even though exercise is important, exercise is stressful if it is boring and does not cause interest. Therefore, various methods are sought to exercise without physical and psychological stress caused by exercise. Among them, music therapy has been applied to reduce psychological stability and stress from exercise since long time ago^[7]. The effect of this music causes human physical, psychological, and emotional responses, and the rhythm and dynamics of the music motivate them to bring about regular and systematic behavior^[8]. It has been reported that the physical exercise activity using music not only increases exercise ability and coordination but also induces motivation during exercise learning^[9]. Also, it is reported that the rhythm of music has a similarity with human movement and thus affects physical function^[10]. Previous papers showing the effects and effects of music tempo reported that slower tempo music improves concentration than faster tempo music^[11]. It has also been reported that applying a slower tempo improves body flexibility^[12]. The mode consists

M.D. Student, Dept. of Physical Therapy, Eulji University, South Korea

e-mail: khi920119@gmail.com

of major and minor. Major is associated with joy and happiness, and minor is associated with sadness^[13-14]. There were not many papers that examined exercise performance ability by applying mode or combining mode and tempo. Therefore, it is necessary to investigate how tempo and mode affect exercise performance and to find a more efficient way to exercise by applying music later on. We measured the wits after three weeks of core stabilization in the experimental group with four music combinations of tempo and mode and the control group without music. We investigated which music is effective in improving the performance of exercise given above.

Method

The subjects of this study were 65 adults who meet the following conditions for Seongnam Senior Experience Complex and fully understood and agreed on the contents of the experiment. The selection criteria were neurological diseases and no hearing impairment, and no orthopedic, symptoms and functional limitations. Before performing this study, the subjects were fully explained about the contents and procedures, and all subjects completed the agreement for the experiment. All groups were randomly assigned to exclude preferences. The general characteristics of the subjects are as follows [Table 1].

^aMean±SD, FMjG: Fast Major Group, FMnG: Fast Minor Group, SMjG: Slow Major Group, SMnG: Slow Minor Group, NMG: No Music Group

Figure 1. Experimental diagram

The subjects were randomly assigned to five groups: fast major group, fast minor group, slow major group, slow minor group, and no music group. Prior to the experiment, we used the standing high jump test and standing long jump test. And the experiment was conducted for 3 weeks and the core stabilization exercise was performed three times a week. After the experiment, the same method was used to evaluate the change in power of agility [Figure 1].

The power of agility test was standing high jump test and standing long jump test, and this test has been used in many studies^[15]. The standing high jump test is as follows. The subject stands 20cm from the wall and stands side by side with the wall. And the subject jumps as high as possible on the spot, hitting the measuring plate with his fingertips. We measured and recorded the gap between the height of the fingertips in jumping and the height of the fingertips in standing place^[16]. The standing long jump test is as follows. The subject spreads both feet lightly at shoulder width and then stands so that the tip of the foot does not deviate from the reference line. Then land as far as you can. At this

time, measure the distance from the reference line to the nearest landing point(heel line) at right angles. The unit of measurement was recorded in cm and the decimal point was rounded to the second place^[17].

Experiment was conducted in a closed and quiet location. In addition, participants were instructed about the exercise program, and after simple stretching, they lie on the mat and listen to their music through the earphone. The exercise method was performed referring to the method used in the previous paper^[3,18]. The first exercise is the bridge. The subjects lay on a mat and attach both arms to the ground. They bent their knees, attached the soles of the feet to the mat, looking at the ceiling, gave strength to the buttocks and raise their pelvis. They relaxed on the buttocks and repeated the action of lowering their pelvis^[3]. The second exercise is plank. The subjects collect the feet, stretches his arms with the elbows and shoulders at a right angle, and falls down, holding the inverted togu. Keep straight from head to toe^[18]. The bridge exercise was performed in three sets of 10 seconds and the flank exercise in three sets of one minute. After each set, 10-second break was given, followed by a 30-second rest before the next exercise.

Music application of each group is as follows. Fast tempo music was chosen as three songs of allegro music, and slow tempo music was chosen as three songs of quiet and adagio music. And, the major group music was chosen as the major mov music, and the minor group music was chosen as the minor mov music. They listened to the music only during the core stabilization exercise.

The data collected in this study are statistical program SPSS ver. 25.0, and different analytical techniques were applied according to the purpose. First, the analysis of pre- and post-exercise differences was performed using the corresponding sample T-test. The differences between groups after exercise were analyzed using one-way ANOVA. Statistical significance was set at $p < 0.05$.

Result and Discussion

Corresponding sample t-test was used to show the significance of the difference between before and after application of luck program in each group measured by “standing high jump test”. There were statistically significant differences in all groups ($p < 0.05$) [Table 2]. In addition, after exercise program in all groups increased significantly before application [Table 2]. The

results of the ANOVA showed that all groups showed significant differences [Table 3]. There was a significant difference between all groups except the fast major group, the fast major group, and the slow main group ($p < 0.05$) [Table 4].

Corresponding sample t-test was used to show the significance of the difference between before and after application of luck program in each group measured by “standing long jump test”. The results were statistically significant ($p < 0.05$) [Table 2]. In addition, after exercise program in all groups increased significantly before application [Table 2]. Using the ANOVA analysis to see the mean difference between the groups, all groups showed significant differences [Table 3]. There was a significant difference between all groups except the fast major group, the fast major group, and the slow main group ($p < 0.05$) [Table 5].

(*p<0.05)

According to the preceding paper on power of agility, the experimental group that listened to fast tempo music was more effective in improving power of agility than the control group that did not listen to fast tempo music^[19]. In this study, as in the previous papers, it was found that fast tempo music listening had the effect of improving power of agility. Previous studies reported that fast tempo induces high arousal in emotions and slow tempo induces low arousal in emotions^[20-21]. Therefore, in this study, high emotional arousal had a positive effect on the improvement of power of agility when applying fast tempo music.

According to the preceding paper, mode is related to emotion^[13-14]. In addition, negative emotions and athleticism of athletes were reported to have a significant relationship^[22]. This suggests that the mode of music affects emotions, and thus the mode of music can affect motility. However, no significant difference was found in the power of agility between major mode and minor mode in this study. This suggests that the difference in emotion through music is not related to the improvement of the power of agility, but more in-depth study is needed.

In this study, the experimental group was randomly selected to exclude the preference for music. However, it was found that the preferred music appreciation had a positive effect on the police's job stress and fatigue reduction^[23]. And previous studies have shown that fatigue and stress caused by sleep deprivation have an effect on exercise performance such as power of agility and balance^[24]. Based on these results, it is expected that if the research is conducted by applying the preference for music in the future, more significant results will be obtained than the previous studies.

Conclusion

The purpose of this study was to investigate the effects of tempo and mode on exercise performance in normal adults. The subjects were divided into five groups: fast major, fast minor, slow major, slow minor, and no music listening. They performed core stabilization exercises three times a week for three weeks. We measure the power of agility before the experiment and evaluated the changes after the experiment, and we came to the following conclusions: First, the fast tempo improves the power of agility more than the slower tempo. Second, there were no significant differences in power of agility between major mode and minor mode applications.

Abstract

Background/Objectives: The purpose of this study is to suggest the policy task and direction so that the projects for women-friendly city can level by analyzing Dangjin City's women-friendly city building process, by suggesting the Dangjin City's vision and road map for the women-friendly city.

Method/Statistical Analysis: The research conducted trend analysis, questionnaire survey and FGI. For this purpose, we surveyed , 800 citizens (about 0.5% of Dangjin 166,000) were taken as sampling frame and through the quota sampling frame by gender, age and area, total 782 questionnaires (final effective ratio 97.8%) were collected and utilized for analysis. FGI was conducted through 22 people from three groups of citizens, experts and officials.

Findings: As a result, we set up our vision of 'Because woman is happy, your family is happy, your Dangjin', For this vision, 4 major goals of 'Diffusion of citizen's feeling on the women-friendly city', 'Building safety city to live comfortably', 'Building the human-oriented employment environment', 'Inter-regional shared growth without alienation' were established.

Improvements/Applications: The women-friendly city in Korea, it requires the policy direction to establish the policy reflected with regional characteristics and step-by-step and feasible policy sharing with the local resident.

Keywords: Women friendly city, gender equality, gender equality policy, policy road map, women's policy.

Introduction

Woman-friendly city is the administration unit that operates the policy for women so that the men and the

women participate in 'local policy and development process' equally, its benefits are distributed evenly to all the residents, and the growth and safety of women are realized^[1]. The concept was started from 'Rights on the city' started from 1960s across the world, and as the policy making for the gender equality in the country and local government was arisen as an issue, it is focusing currently on building the institutional foundation for gender mainstreaming that leads the sustainable city development ^[2-3]. In our country, the local governments and Ministry of Gender Equality

e-mail: hj-cs@hanmail.net

and Family are promoting the project to build the local community where the genders are equal. Started from Iksan City in 2009, it has been expanded to 86 cities as of 2018 showing quantitative achievement^[4] of course, there was qualitative achievement in the aspect of policy together with quantitative growth. According to the Excellent Women-friendly City Casebook published by Korean Women's Development Institute, the accomplishments such as establishment of gender equal administrative system, expansion of women's job, improvement of social care welfare service, welfare service improvement and cultural life space preparation, etc. are being introduced^[5].

However, it is doubtful if the policy for the women-friendly city promoted by the government has been promoted in a way of settling down the gender mainstreaming of local community in every place like the cases shown in the excellent casebook. In this situation, this study focused on the women-friendly city building process in Dangjin City. In case of Dangjin City, it was designated as a women-friendly city for the first time as a county unit, but after being elevated to a city, it was dropped out in the re-designation process because its driving force or the policy achievements were not sufficient but was succeeded in second re-designation as a women-friendly city thanks to the strong driving force of the local government and the citizen's participation and efforts. Since such failure and the success are deemed to have great implications in the development of the women-friendly city policy in Korea, this case study was attempted.

Specifically, the purpose of this study is to suggest the policy task and direction so that the projects for women-friendly city can level by analyzing Dangjin City's women-friendly city building process, second, by investigating the demands of the citizens of Dangjin for the women-friendly city building policy, and finally, by suggesting the Dangjin City's vision and road map for the women-friendly city.

Women Friendly City Building Process in Dangjin City: Dangjin City was designated as a women-friendly city for the first time in Chungcheongnam-do in 2010 when it was Dangjin County, and built the foundation for the first stage of women-friendly city from 2010 to 2014. However, Dangjin City was dropped out in the re-designation' because of the incomplete performance of projects compared with the plan due to the lack of securing the women's representation, lack of

cognition on the women-friendly city in overall public sectors and the lack of promotion will in the assessment of the first stage of women-friendly city project^[6-7]. After that, aiming at re-designation as a women-friendly city, Dangjin City prepared the road map to obtain the driving force and carried out the major projects of 7 areas such as the diffusion of gender equality education for entire citizen, gender-impact analysis and evaluation, preparation of public facilities guidelines, representative city project discovery by the operation of (provisional name) Business Promotion Group, the composition and operation of citizen participation group, expansion of women' representation in the public office, promotion of department index for the control tower role of the women policy department in the preparation stage, and was re-designated as women-friendly city in 2018 recognized its performance.

Survey: To investigate the demand for the policy to build Dangjin City as women-friendly city, the questionnaire survey and FGI were performed at the same time.

1. Questionnaire Survey of Citizen of Dangjin city:

Design of Questionnaire Survey: Out of the 166,000 citizens of Dangjin, Chungnam, 800 citizens (about 0.5%) were taken as sampling frame and through the quota sampling frame by gender, age and area, total 782 questionnaires (final effective ratio 97.8%) were collected and utilized for analysis. The questionnaire survey period was from November 12, 2018 to November 20, 2018, and the method that the questionnaires are given to the persons in charge of local communities after explaining enough on the questionnaire and the allotment table and collected 3 ~ 7 days later was used. For the analysis of the demand of the citizen of Dangjin for the women-friendly policy, the frequency analysis, cross analysis, t-test, F-test, etc. were performed.

2. Results of Questionnaire Survey: The case that the citizen knows that Dangjin City is the women-friendly city was 50%, the half, and the satisfaction of the women-friendly city perceived by citizen of Dangjin was 2.83 points out of 6 points, lower than the median value.

In addition, in the results of analyzing the settlement satisfaction according to cognition if Dangjin City is the women-friendly city, in case of recognizing the women-

friendly city, the settlement satisfaction was high [Table 1]. Therefore, the fact that the cognition on the women-friendly city increases the settlement satisfaction of Dangjin City is the aspect showing how important leaping to women-friendly city again is. The fact that although Dangjin City was designated as women-friendly city in 2010 and currently re-designated as the 2nd stage city as of 2018, that the cognition level was 50% revealed the problem in promoting the policy. Therefore, it implies that to leap as a women-friendly city, the active publicity on the related city policy is required [Table 1].

Table 1. Difference in residence satisfaction according to whether they are affinity for Women Friendly City policies in Dangjin

Whether or not		Frequency	Means	S/D	t
Residence satisfaction	Know	392	3.30	.794	3.200**
	Don't know	390	3.10	.899	

***p<.001

However, in the results of analyzing the importance and the satisfaction on the 5 major areas of the women-friendly city, it was shown that the problem in the local community safety improvement area was distinguished. That is, it showed the clear difference as the importance was ranked as first priority but the satisfaction was ranked as priority No. 5 [Table 2]. Therefore, for Dangjin City to leap as women-friendly city, it needs to concentrate the city policy on the local community safety area.

Table 2. Importance and Satisfaction of Women's Friendly City Policy

All fields	Importance		Satisfaction	
	Means	S/D	Means	S/D
Gender equality policies and institutions	3.86	1.024	2.91	.867
Women's Economic and Social Participation	3.97	.971	2.95	.880
Community Safety for Women	4.10	.982	2.86	.897
Creating a family-friendly environment	4.06	1.103	2.92	.909
Women-friendly local culture and conditions	3.90	.976	2.90	.899

In addition, for the obstructive factor for Dangjin city to leap to the women-friendly city again, the lack of cognition on 'women-friendly city' was the priority No. 1 and 'Lack of women-friendly city policy and the system' was the priority No. 2, and 'insufficient women-

friendly city environment' was priority No. 3 [Table 3]. Therefore, the intensive effort is required for these 3 factors.

Table 3. Obstacles to re-establishing of Women Friendly City in Dangjin

All fields	Frequency	%
Lack of awareness of Women Friendly City	361	18.5
Lack of collaboration among departments	191	9.8
Lack of Women Friendly City policies and institutions	278	14.3
Lack of women friendly urban environment	245	12.6
Lack of facilities related to women	219	11.2
Lack of publicity	197	10.1
Lack of citizen participation	205	10.5
Lack of programs	137	7.0
Women's lack of municipal participation	117	6.0

FGI:

- 1. FGI Design:** To draw the current task and improvement plan for Dangjin City to leap to women-friendly city again, FGI was performed. FGI was performed with 22 experts from 3 groups composed of the women-friendly citizen participation group, the expert group of the academic circle, the civil servant group. Focus Group Interview was carried out approximately 2 hours by 1 interviewer and 1 assistant per group for 2 days, November 8 and 15, 2018. They were asked about the current tasks and the solutions for Dangjin City to leap to the women-friendly city again, and 1 hour and 30 minutes to 2 hours were taken per team.
- 2. FGI Result:** In the results of extracting the meaningful sentences related to the cognition of the citizen of Dangjin and the obstructive factors on the women-friendly city and contemplating repeatedly through the semantic conditioning of them and the topic bundling, 19 sub-topics and 5 essential topic were extracted. The essential topics were analyzed as 5 topics of the lack of women-friendly infrastructures, lack of safety environment, unstability of job for women and lack of socialization conditions of childbirth and care, provider-centered education program, lack of women-friendly cognition improvement project, and their specific contents are as shown in Table 4.

Table 4. FGI results for re-establishing into women friendly city

Essential theme	Sub-theme	Derived Improvement
Lack of woman friendly infrastructure	Lack of establishment of private governance	Women-Friendly City Ordinance Amended
	Weakness of administrative organization in charge of women friendly affairs	Reorganization of female family administrative organization
	Lack of cultural facilities for women	Securing cultural space for women and families
	Lack of publicity	Dangjin City Hall homepage upgraded
	Inadequate bus routes for women	Reflected in Dangjin City bus line reorganization project
	Lack of opportunity for women and minority policy participation	Women’s policy group including women and minority groups, strengthening the role of civic participation groups, etc.
Lack of safety environment	Lack of inadequate local safety system	Establish systematic public facility guidelines
	Designing road traffic centered on cars and administrative administration centered on civil servants	
Instability of women’s job and lack of socialization for birth and care	Lack of adequate job training and job training for women	Development of Dangjin-type Female Jobs and Personalized Business Start-up Education
	Lack of competence of female entrepreneurship lecturer	Strengthening the capacity of women educators - Connecting with Saemaul Lifelong Education Department
	Care for child cuts off career and limits participation in education	Institutional linkage to solve education and caring problems Introduction of Dangjin-type women-friendly certification system
Provider-centered education program	Lack of customized programs for women’s needs and situations	Gain diversity of programs using gender equality fund
	Lack of training programs to tackle minority classes	
	Lack of educational program considering time and space	Space-based Delivery Course
	Lack of information and sharing of programs offered by private institutions	Dangjin homepage upgrading
Lack of Women Friendly City recognition improvement projects’	Lack of solidarity among women	Expansion of education on civic consciousness that considers rights and responsibilities together
	Duality and personality of women	
	Lack of awareness of woman-friendliness of decision-maker male officials	Including women-friendly education in gender equality awareness education, expanding female senior officials
	Lack of gender equality education in private institutions and businesses	Gender Equality Education in Lifelong Education Instructor Education Introduced Dangjin-type female-family-family certification system

Conclusion

Dangjin City’s Vision and Road Map for Women-friendly City for New Leap: This study, which has a purpose of reestablishing the direction of the women-friendly city in Korea through the case analysis of Dangjin City’s women-friendly city, established the vision and goal for its leap based on the implications of Dangjin City’s women-friendly city building policy demand investigation drawn from the analysis of Dangjin City’s women-friendly city building process,

the questionnaire survey with the citizen of Dangjin, FGI with the women-friendly citizen participation group, the expert group of academic circle and civil servant group.

Dangjin City’s vision to leap to the women-friendly city was established as ‘Because woman is happy, your family is happy, your Dangjin’. For this vision, 4 major goals of ‘Diffusion of citizen’s feeling on the women-friendly city’, ‘Building safety city to live comfortably’, ‘Building the human-oriented employment environment’, ‘Inter-regional shared growth without alienation’ were

established. The establishment of such policy direction reflected the regional characteristics based on the policy of Ministry of Gender Equality and Family, and made the Dangjin City and the national policy linked organically.

The tasks to achieve the goals were proposed as a road map to be implemented more stably and feasibly. Year of 2019, which is the first stage, is the period of 'forming foundation'. This stage is the period of forming the foundation to leap to the women-friendly city again and builds the cognition and prepares the backbone of the women friendliness in Dangjin City through 14 tasks such as 'Revision of ordinance of women-friendly city', 'Reorganization of women-friendly administrative system', 'Development of public facilities guideline', 'Development of Dangjin type women and family-friendly certification system', 'Building and operation of the care governance', etc. The year 2020, which is the 2nd stage, is the period of 'settlement'. The 2nd stage stabilizes the Dangjin City's promotion of women-friendly policy through 8 tasks of Expansion of female civil servant proportion, 'Activation of Dangjin type employment project', 'Issuance of Dangjin female job training card', 'Building women-friendly traffic environment system', 'Dangjin type substitute worker support project', 'Installation and operation of care class', etc. based on the foundation built in the 1st stage. From 2021 to 2022, which is the 3rd stage, is the completion period. In the 3rd period, Dangjin is leaped to the women-friendly city without blind spot through the tasks of 'Building the women and family town', 'Expansion and operation of children's play facilities within family park' and 'Village academy for women' and 'Building female community space in 14 villages'.

The women-friendly city in Korea is provided by law as realizing the equal participation by female and male, women's competence reinforcement and the care and safety, and the most women-friendly cities are promoting same types of policies. However, the assessment if such policies reflect the operational status, rapidly changing regional characteristics and the changes of cognition in the citizen is passive

The case of Dangjin's building the women-friendly city will be the good example showing the difficulties in managing the policy started in the state that the regional characteristics were not reflected, the cognition of citizen were insufficient and the effort of overcoming them for the first time in the county. Currently, most of

the local governments are making efforts to be selected in the many projects designated and supported by central government. However, most of local governments are focusing on the proclamatory designation rather than on the improvement of regional characteristics and the cognition of local residents. It would be observed through the case of Dangjin City that the unilateral promotion by public sector is hard to achieve the policy promotion effect for the local resident. Therefore, for the women-friendly city in Korea, it requires the policy direction to establish the policy reflected with regional characteristics and step-by-step and feasible policy sharing with the local resident.

Ethical Clearance: Not required

Source of Funding: This paper was completed by revised report of the mid- to long-term development plan for women-friendly cities in Dangjin City, Korea.

Effectiveness of Video Recording and Self-Evaluation for Skill Training in Undergraduate Nursing Education

Mi-Ran Eom¹, Sun Kyung Kim², Mi-Hyeon Park³

¹Professor, Department of Nursing, Mokpo National University, Korea, ²Assistant Professor, Department of Nursing, Mokpo National University, Korea, ³Assistant Professor, Department of Nursing, Pohang University, Korea

Abstract

Background/Objectives: In present nursing education, educators worked to apply new educational strategies that made use of technological development. Evidence emerged for the effectiveness of video-recording and self-evaluating to motivate students' self-directed learning.

Method/Statistical Analysis: This study evaluated the effectiveness of a skill-training program using video recording and self-evaluation. A quasi-experimental design was used such that 43 students were allocated into experimental (n = 22) and control groups (n = 21). Prior to the intervention, confidence to practice and problem-solving ability were assessed and actual performance of each core nursing skill added to the post experimental evaluation. For statistical data analysis, paired t-test, independent t-test, X2-test/Fisher's exact test and Mann-Whitney U test were conducted. SPSS was used and statistical significance was determined at the $p < .05$ level.

Findings: Comparing posttest scores, study results showed statistically significantly better performance in nursing skills ($p < .001$) and confidence to practice ($t = 2.95, p = .003$) in the experimental group. The change of scores in the experimental group on confidence to practice statistically significantly improved in the experimental group compared to changed scores in the control group. No statistically significant difference emerged in problem-solving ability.

Improvements/Applications: Based on the study findings, video recording and self-evaluation provided effective training on core nursing skills. However, caution is needed as no clear evidence emerged for problem solving, which is a critical element in nursing education. Thus, we recommend the use of these strategies as a supplement to clinical placement. Future interventions need to provide additional strategies with robust study designs using randomized controlled trials.

Keywords: *Nursing students, Core nursing skills, Performance, Self-confidence, Problem-solving.*

Introduction

In undergraduate nursing education, researchers have identified limitations in the clinical practice of nursing students, due to safety issues for students and

patients^[1]. At present, clinical practice largely depends on the observation that students lack direct practice of nursing skills. Nevertheless, a growing need exists for verification of practical capability in nursing students before graduation^[2].

Nursing is a discipline based on practice and the integration of theory and practice in buoying nursing skill is a crucial part of the nursing curriculum^[1]. Adequate programs must guarantee students obtain knowledge and skills. Nursing students desires more opportunities for real-world training rather than classroom-based

Corresponding Author:

Sun Kyung Kim

Assistant Professor, Department of Nursing, Mokpo National University, Korea
e-mail: skkim@mokpo.ac.kr

theoretical lectures^[3]. Nursing educators have tried to satisfy students' desires; however, nursing education is working to support rapid increases in the number of nursing students in Korea.

For the performance evaluation of nursing students, the Korean Accreditation Board of Nursing Evaluation^[4] has developed 20 core nursing skills that are essential for students to achieve to the standard. Traditionally, education to attain these nursing skills involves theoretical lecture and demonstration. Additionally, given the importance of repetitive practice, educators developed strategies for effective training. To encourage practice of nursing skills, most schools offer students chances to self-practice what they have learned and incorporated active learning as a requirement educators expect from individual students^[5].

The training of students for nursing skills requires tremendous effort. Previous studies identified that technologies could ease the burden of educators^[6]. Rapid changes in science and technology enable educators to revise the curriculum by adapting technology development^[6]. Previous reviews revealed the effectiveness of skill-training education using video recording^[7-8]. Students have an opportunity to closely observe their own performance, using video recording in skill practice. Along with video recording, students self-evaluation provides a means for educators to resolve issues in nursing education, such as the high student-faculty ratio.

However, without a proper evaluation process, the effectiveness of video recording cannot be guaranteed. Previous study identified the effectiveness of video recordings based on self-assessment; that is, students review their own performance using video and a checklist; this detailed evaluation ensures fast and precise correction^[9]. Moreover, students can be motivated during the evaluation process, which is one effective strategy leading to self-regulated learning. As a self-regulated learning strategy, self-evaluation is a key factor that promotes students' commitment to learning^[10]. Strong evidence suggests the efficacy of self-evaluation, during which individuals obtain comprehensive knowledge.

Previous studies identified several variables influencing the development of professionalism in nursing students including confidence to practice and the ability to solve problems^[11]. When nursing education uses models rather than real human bodies, new nurses

often report lack of competency when practicing on actual patients. Adequate and repetitive practice with a chance to reflect on their practice would effectively improve nurses' confidence to practice skills^[12]. Having students reach a standard level in nursing skill would eventually ensure the quality of care in their future practice.

In addition to confidence, nurses should be able to provide care that is optimal to the situation and time. Knowing the priorities and urgency, nurses would produce best patient outcomes with adequate problem-solving ability. Thus current nursing-education program should be designed to incorporate content to improve confidence and the ability to solve problems.

Although evidence suggested the advantage of using video recording and self-evaluation, a scarcity of education programs used both strategies for skill training. Such sparse use may discourage nursing educators from actively replicating the use of these strategies. Thus, the present study was designed to evaluate the education program for skill practice using video recordings and self-evaluation.

Method

- 1. Design:** In this study, we used a quasi-experimental design including an intervention and comparison of groups with pre- and posttest assessment.
- 2. Implementation:** The intervention was implemented over 3-month period. The intervention group engaged in video recordings of core nursing-skill practice and self-evaluation whereas the comparison group remained in traditional training. Students in the experimental group were taught how to video record during skill training and evaluate the performance of themselves during 2 hours of open lab. These students were also encouraged to participate in a group-discussion session when they experienced difficulty in examining each other.
- 3. Participants and setting:** All undergraduate nursing students attending the 4th-year curriculum at one university located in J district in Korea were invited to participate. A convenience sample of 43 students was recruited. The intervention took place in a practice room that had all the materials to practice two core skills—intramuscular injection and suction—with supervision by a trained research assistant.

4. Instrument:

Performance Score: To evaluate the performance of nursing core skills, a researcher developed a checklist. Two research assistant with teaching experienced in fundamental nursing evaluated performance independently. The inter-rater reliability was good (ICC=.907).

The performance was evaluated for skills of intramuscular injection and suction with a maximum score of 100. Higher scores indicate better performance of individual participants.

Confidence to Practice: To evaluate the confidence to practice, a numerical rating scale (NRS) was used. Study participants rated their level of confidence on a scale scoring between 10 (not confident at all) and 100 (very confident).

Problem Solving: We used a measurement developed by Woo^[13] to evaluate the problem-solving ability

of study participants. A total of 25 items consist of discovery of problems (5 items), running problem solutions (5 items), designing problem solutions (5 items), and reviewing problem solving (5 items). Higher scores indicate better capability to engage in the process of solving problems. The Cronbach's alpha for this measurement was .90^[13].

5. Data Collection: To compare groups in terms of students' scores on performance, confidence to practice, and problem solving, we collected data for confidence to practice and problem solving before and after they had skill training using video recording and self-evaluation in the intervention group and traditional training in the control group. We obtained only the posttest data for the performance score of participants. We conducted the pretest before the first day of open lab and the posttest 2 weeks later. One researcher (initial) who was blinded, evaluated the video recording to examine individual students' performances [Figure 1].

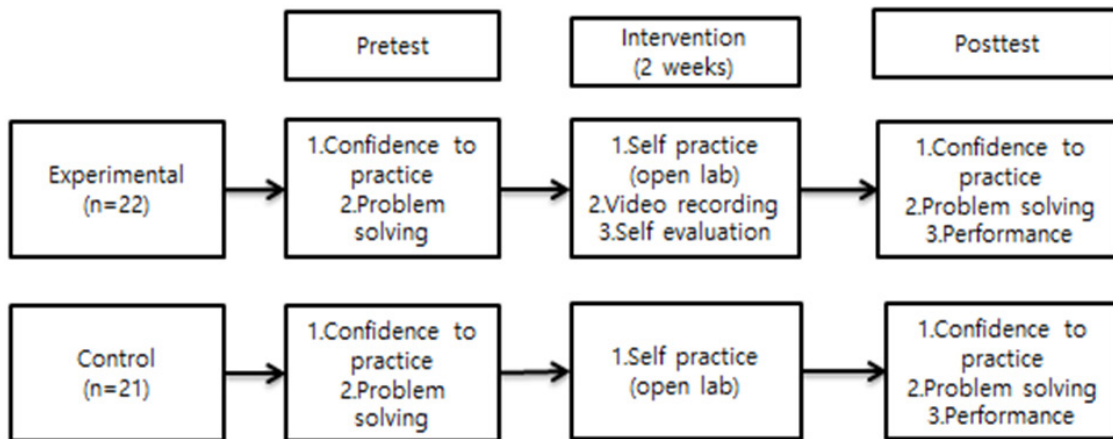

Figure 1. Research design

6. Statistical Analysis: We used SPSS, χ^2 -test/ Fisher's exact test, and the Mann-Whitney U test for statistical analysis. Statistical significance was determined at the $p < .05$ level.

Result

The sample includes 22 students in the experimental group and 21 students in the control group with a mean age of 22.95 and 22.99 years, respectively. The majority of both groups showed good satisfaction in nursing major (77.3% and 76.2%) and fair to good self-expression (90.9% and 90.5%). The homogeneity test between the experimental and control groups showed no statistical

significance between groups in general characteristics and baseline scores of study variables [Table 1].

A statistically significant difference emerged between the experimental and control group in performance scores in both skills ($p < .001$) and confidence to practice ($p = .003$). No statistically significant difference arose for confidence to practice and problem solving between the experimental and control groups (see Table 2).

The experimental group showed greater score increases for confidence to practice and problem solving. Comparing changed score between groups, increased scores of confidence to practice were statistically significant [Table 3].

Discussion

The present study evaluated the effects of using video recording and self-evaluation to assist nursing students to attain core skills in nursing education. The implications of the strategies of self-directed learning and technology are that students are able to view their performance and figure out what they should work to improve. Findings demonstrated statistically significant effects on performance and confidence to practice in nursing students using video recording and self-evaluation.

The performance scores for the experimental group were statistically significantly higher than those of the control group. According to the classification by the Korean Accreditation Board of Nursing Evaluation^[4], intramuscular injection and suction ranked moderate and high, respectively, in levels of difficulty. Thus, findings from this study indicated broad applicability of the present intervention across all 20 core nursing skills. However, appropriate caution should be exercised before a conclusion can be drawn on the effectiveness of video recording and self-evaluation. Supervision and timely feedback from qualified educators should be arranged first to ensure the acquisition of students

accurate nursing skills^[14].

Compared with the control group, the intervention group showed statistically significant improvement in confidence to practice after 2 weeks. Similar results emerged in a previous study using review of video tapes for self-performance of foley-catheterization skills^[15]. In that study, students reported enhanced self-awareness, thereby motivating them to practice more. Video recording and self-evaluation are strategies that could motivate students, leading to self-regulated learning^[16]. Moreover, viewing their own performance with self-evaluation, students better analyzed what they did wrong and where they need to improve.

Unlike performance and confidence, problem solving showed no statistically significant difference between the experimental and control groups. Problem solving is an essential ability in which nursing students achieve capacity to plan and provide safe and quality nursing care^[17]. Previous studies conducting simulation-based learning using standardized patients showed statistically significant improvement in students' ability to solve problems^[18]. Facing a real person in a complex clinical situation, students more actively engage in learning, achieving greater problem-solving ability. In addition, the short period of intervention showed the ability to think critically and engage actively, both skills necessary to effectively solve problems. Considering the present results, additional strategies may necessary. We suggest future studies investigate the effects of interventions with complex designs that focus on problem-solving skills.

This study was not without limitations. Using quasi-experimental design, convenience sampling may influence the results, because randomized controlled trials (RCTs) are the gold standard in evidence-based nursing practice. In addition, although we included a performance assessment by an expert to draw more reliable evidence than self-reported results alone, the blinding of the assessor could not be ensured, which could also affect the results of study. We suggest that well-designed RCTs in future studies may to provide more conclusive results.

Conclusion

A quasi-experimental design was used to identify an effective skill-training program using video recording and self-evaluation. Study results partially showed that students in the experimental group achieved better

performance scores and more confidence to practice. Caution is needed in the application of these strategies when considering replacing traditional training to help students attain nursing skills. These strategies can be an effective supplement to theoretical lectures and clinical placement. We suggest future researchers and educators implement interventions incorporating additional strategies with robust RCT designs.

The Effects of Depression and Anxiety on Psychological Well-being of College Students: Focusing on the Emotional Perception Clarity

Young Joo Lee

Professor, Dept. Social Welfare Baekseok Culture University, Korea

Abstract

Background/Objectives: This study focuses on the psychological problems of college students, which are rapidly deteriorating in recent years, and examines how depression and anxiety affect the psychological well-being and examines the mediating effects on emotional perception clarity. It was done to improve the quality of life by solving them.

Method/Statistical Analysis: 317 data were collected for this study. The research method used factor analysis and covariance structure analysis.

Findings: Anxiety level of college students did not have a significant effect on emotional clarity. Second, the level of depression in college students had a significant effect on emotional clarity. Third, the emotional perception clarity of college students had a significant effect on psychological well-being. Fourth, anxiety levels did not have a significant effect on psychological well-being. Fifth, the depression level of college students had a significant effect on psychological well-being. Sixth, the mediating effect of emotional perception clarity on the causal relationship between depression level and psychological well-being of college students was found to be partial mediating effect.

Improvements/Applications: Based on the results of this study, online self-diagnosis service expansion is required for college students to be aware of their psychological emotional problems, and practical help and training are required to control negative emotional experiences by clearly recognizing emotions. This will provide a foundation for college students to increase their psychological well-being by increasing their ability to respond appropriately to changing circumstances.

Keywords: *Depression, anxiety, stress, psychological well-being, emotion perception clarity.*

Introduction

Recently, unlike other age groups, the psychological and emotional problems of young people in their 20s are rapidly deteriorating through medical information and statistics. In the context of the social structure and

problems that are common among the twenties, young people in their 20s focus on college entrance exams, and do not fully consider their areas of interest or aptitude. In this process, they may experience emotional symptoms such as anxiety and depression and may cause problems with their adaptation. In particular, since college students are in the transitional period from adolescence to adulthood, they can experience physical, social, and mental changes and face social dysfunction on life stress. College students are experiencing a variety of stresses from passive lifestyles to autonomous lifestyles, self-identification, independence from parents, diverse learning, and uncertainty in the future. It can be said that they are exposed to various psychological emotional

Professor, Dept. Social Welfare Baekseok Culture University, Korea

e-mail: ijoo65@hanmail.net

problems in the process of adjusting to the environment and lifestyle. In addition, social anxiety and stress cause mental health to suffer from threats and disconnection of social health.

Everyone wants to be happy, and most people make happiness the most important goal of their lives and look for ways to be happier. It is no exception for college students to live a better life as a basic need for humans. Personal well-being such as life satisfaction and happiness is very important for college students entering adulthood through desirable development and growth. Various factors affecting these psychological well-being have been reported, but social relations have been consistently explained as important factors for the development of adolescents. It is an important task to accumulate emotional and psychological resources through relationships with others and to achieve successful self-reliance through adulthood.

Emotions play an important role in our lives and are closely linked to our stress and mental health experiences. In particular, adolescence experiences emotional instability more frequently than other periods, and emotional development and processing is very important because it lacks consistency. The stress of everyday life can lead to negative emotions such as depression, anxiety and anger due to academic problems, friendships, conflicts with parents, and career problems^[1]. Clear perception of emotions is an important factor in controlling and managing emotions and responding appropriately to the environment. In particular, emotional awareness clarity means the ability to clearly understand and organize one's emotional state

[2]. When an individual understands and recognizes his emotions more clearly, he or she can respond to the emotions he or she experiences, as well as express his or her emotions more appropriately to others. In addition, the clearer the emotional perception, the less social anxiety and neurosis, the higher the satisfaction of life and the higher the self-regulation^[3,4,5]. Taken together, these findings suggest that recognizing emotions clearly is a positive psychological mechanism that can help us to understand and organize our emotions and to help them effectively experience situations and emotional responses. The purpose of this study is to examine how the anxiety and depression of college students affect psychological well-being, a representative mechanism of individual psychological health, through the mediating effect of emotional awareness clarity.

The hypothesis of this study is as follows. First, college students' anxiety level will have a negative effect on emotional awareness clarity. Second, the depression level of college students will have a negative effect on emotional clarity. Third, the level of emotional awareness clarity of college students will have a positive effect on psychological well-being. Fourth, college students' anxiety levels will negatively affect psychological well-being. Fifth, the level of depression of college students will negatively affect psychological well-being. Sixth, anxiety levels of college students will affect psychological well-being by mediating emotional awareness clarity. Seventh, depression level of college students will affect psychological well-being by mediating emotional clarity. For this, set up the research model as figure. 1.

H₆ : anxiety → emotion perception clarity → Psychological well-being

H₇ : depression → emotion perception clarity → Psychological well-being

Figure 1. Research Model

Method

A total of 320 subjects were randomly selected, including four and two year college students. The data used in the analysis for this study 317 except for the insincere response and non-response.

The measuring tools used in this study are depression, anxiety, clarity of emotion recognition, psychological well-being scales. Measured using the depression scale developed by Radloff and revised by Cho Myung-jae and Kim Gye-hee^[6,7]. It consists of four sub-variables: depression, positive emotions, interpersonal relationships, and physical deterioration. In this study, the reliability test of depression scale was Cronbach's $\alpha = .919$.

In order to measure anxiety, the state-trait anxiety inventory (STAI), developed by Spielberger and revised and validated by Han Duk-woong, Lee Chang-ho and Jeon-gyeok-gu was used. STAI is divided into characteristic anxiety and state anxiety, but in this study, only state anxiety was used for analysis^[8,9]. As a result of reliability test of state anxiety test, Cronbach's $\alpha = .919$ was confirmed.

To measure the level of stable emotional awareness, used the Trait Meta-Mood Scale (TMMS) developed by Salovey et al. and revised by Lee Su-jeong and Lee Hoon-gu^[10,11]. It consists of items that evaluate attention to emotion, clarity of emotion recognition, and emotional control expectations. In this study, only the items measuring emotional clarity were used. It is a five-point scale, and the higher the score, the more clearly you are aware of your emotions. Reliability test results in this study Cronbach's $\alpha = .852$.

To analyze the psychological well-being of adolescents, we analyzed the satisfaction level of the Korean Children and Youth Panel Survey (KCYPs) using the Life Satisfaction' question^[12]. The higher the score of each item, the higher the satisfaction of life. In this study, the Cronbach's $\alpha = .786$, except for one item that had a significant effect on the internal fit.

This study examined the effects of college students' anxiety and depression levels on psychological well-being, and additionally identified the mediating effects of emotional recognition clarity variables. We attempted to establish a causality research model with independent anxiety and depression as an independent variable, emotional awareness clarity as a mediating variable, and psychological well-being as a dependent variable. For this purpose, covariate structure analysis was performed using AMOS 21.0. In addition, confirmatory factor analysis was used to confirm the validity of the measures used in this study, and Cronbach's α was used to determine the reliability.

Results and Discussion

Research Model Verification: Prior to the verification of the research model, indices commonly used in existing causal studies were used to verify the suitability of the research model for the model. First, χ^2 verification was conducted to confirm the suitability of the research model. RMR, GFI, AGFI, and RMSEA were used as absolute conformity indices, and NFI, CFI, and TLI were used as incremental conformance indices.

As a result of the verification, GFI = .831 AGFI = .790 and NFI = .832 of the goodness-of-fit index of the research model did not meet the acceptance criteria. Therefore, this study improved oneness of the research model by removing one item of psychological well-being identified as an observation variable of measurement error with a large correction index. This study adopts the modified model extracted through the modification process as the final model to derive the final model for hypothesis testing (RMR = .30, RMSEA = .052, GFI = .917, AGFI = .891, NFI) = .921, TLI = .955, CFI = .962). Although the AGFI goodness-of-fit index value did not meet the criteria, it was judged that this study model was not a problem considering that it was difficult to satisfy the goodness-of-fit index in the structural equation model and that there was no absolute criterion for accepting the model.

Table 1. Research model and Final Model Fit Indices

Models	χ^2	df	p	RMR	RMSEA	GFI	AGFI	NFI	CFI	TLI
Research Model	692.605	204	.000	.04	.087	.831	.790	.832	.874	.858
Finalized Model	294.326	160	.000	.30	.052	.917	.891	.921	.962	.955
Acceptance Level	-	-	>.05	<.05	<.08	=.90	=.90	=.90	=.90	=.90

Research Hypothesis Testing: Based on the results of the final model analysis, the results of the hypothesis testing proposed in this study are in Fig.2, Table 2. The hypothesis test results of this study are as follows. Hypothesis 1 showed that “anxiety level of college students will have a negative effect on emotional clarity” ($t = 1.032, p > .05$).

Hypothesis 2 showed that “depression level of college students will have a negative effect on emotional clarity” ($t = -2.809, p < .01$). As a result, the higher the level of depression, the lower the clarity of emotional awareness.

Hypothesis 3, “The level of emotional awareness clarity of college students will have a positive effect on psychological well-being” was found to be significant ($t = -2.300, p < .05$). Therefore, college students with high emotional clarity showed higher psychological well-being.

Hypothesis 4, “The level of anxiety of college students will have a negative effect on psychological well-being” showed no significant results ($t = .900, p > .05$).

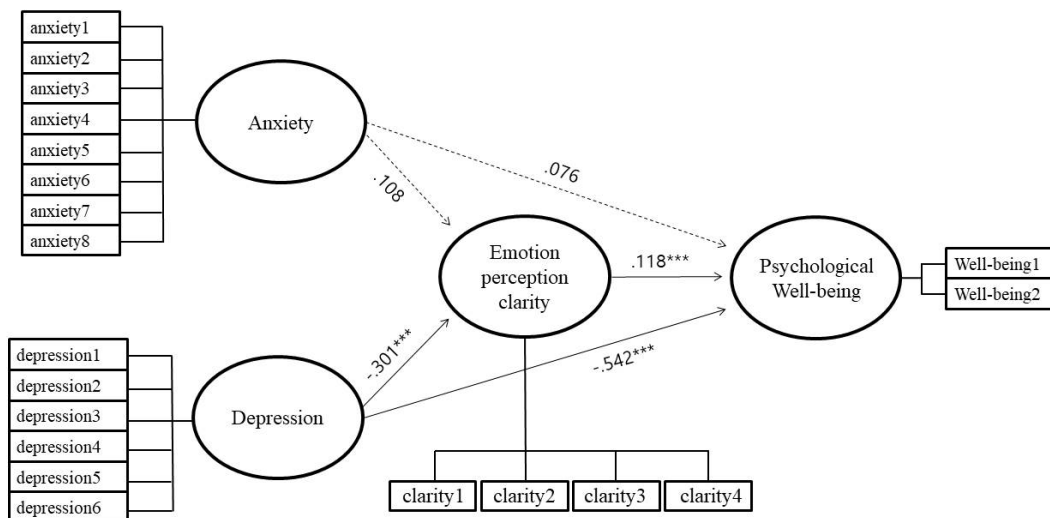

Hypothesis 5: “Depression level of college students will have a negative effect on psychological well-being” showed significant results ($t = -5.831, p < .001$). Therefore, more college students with higher levels of depression had lower psychological well-being.

Hypothesis 6 “The mediating effect of emotional awareness clarity in the causal relationship between depression level of college students and psychological well-being was found to be partial mediating effect ($t = -.301, p < .001$).

Hypothesis 7 “As a result of verifying the mediating effect of emotional awareness clarity in the causal relationship between the anxiety level of college students and the psychological well-being, there was no significant effect ($t = .108, p > .05$).

Table 2. Results of hypothesis tests

Path	Estimate	S.E.	C.R	P	Result
Emotional perception clarity ← Anxiety	.108	.105	1.032	.302	Rejected
Emotional perception clarity ← Depression	-.301	.107	-2.809	***	Accepted
Psychological well-being ← Emotional perception clarity	.118	.051	2.300	***	Accepted
Psychological well-being ← Anxiety	.076	.084	.900	.368	Rejected
Psychological well-being ← Depression	-.542	.093	-5.831	***	Accepted
Depression -->Emotional perception clarity -->Psychological well-being	-.301 ***				Accepted
Anxiety-->Emotional perception clarity -->Psychological well-being	.108				Rejected

“Solid lines()” show accepted hypothesis. “Dotted lines()” show rejected hypothesis.

Figure 2. Revised Model

Conclusion

This study examined the effects of college students' anxiety and depression levels on psychological well-being, and additionally identified the mediating effects of emotional recognition clarity variables.

The hypothesis test results of this study are as follows.

First, as a result of testing hypothesis 1 that "anxiety level of college students will adversely affect emotional clarity", no significant result was found ($t = 1.032$, $p > .05$). It is interpreted that the degree of anxiety that college students pay attention to as a stress experienced by academics, future and career problems does not affect emotional problems.

Second, the hypothesis that proved that "depression level of college students will have a negative effect on emotional clarity" showed a significant result ($t = -2.809$, $p < .01$). The higher the level of depression, the lower the emotional clarity of college students. Consistent with the findings that depression affects adaptation problems caused by stress in psychiatry.

Third, as a result of testing Hypothesis 3, "the level of emotional cognition clarity of college students will have a positive effect on psychological well-being" ($t = -2.300$, $p < .05$). Therefore, college students with high emotional clarity showed higher psychological well-being. Those who clearly recognize and define their emotions are consistent with research findings that they experience more happiness and are more emotionally adaptive than those who do not.

Fourth, the hypothesis 4, which proved that "anxiety level of college students will have a negative effect on psychological well-being", showed no significant result ($t = .900$, $p > .05$).

Fifth, the result of testing hypothesis 5 that "depression level of college students will have a negative effect on psychological well-being" showed a significant result ($t = -5.831$, $p < .001$). Therefore, more college students with higher levels of depression had lower psychological well-being.

Sixth, "The result of hypothesis 6, which verified the mediating effect of emotional awareness clarity in the causal relationship between depression level of college students and psychological well-being, showed partial mediating effect.

Based on the mediating effect of emotional awareness clarity by setting anxiety and depression as independent variables as psychological and emotional factors that affect the psychological well-being of college students, the more psychological well-being they perceive when they experience stress, the more psychological well-being. The higher the depression, the lower the emotional clarity and the lower the psychological well-being.

Anxiety in daily life did not affect psychological well-being, but depressive variables were found to have a significant effect, suggesting the need for emotional control training for college students who complain of depression.

Emotional regulation is an important factor in determining individual well-being, and an emotional mode of control is important for psychopathology and is an important factor in understanding human function and health and in determining successful function. The ability to control one's emotions at this time is very important, as college students going into adulthood experience emotional instability and thereby experience various problems.

The implications of this study are as follows.

First, as a result of examining the factors affecting the psychological well-being of college students, the higher the depression, the lower the psychological well-being. This is consistent with the findings of previous studies that the more depressed, the more maladaptive emotional control strategies are used and the lower the psychological well-being. Therefore, in order for university students to recognize their psychological and emotional problems correctly, the online self-diagnosis service is being expanded to help students adapt to their social life. Training to change your mind will be effective through the practice of mediating your feelings.

Second, the effect of emotional clarity on psychological well-being was found to be significant. This means that when college students experience a stressful event, they first select an adaptive emotional control style and increase their psychological well-being when they clearly recognize their emotions. Therefore, for the mental health management and maintenance of college students, practical help and training will be needed to know their emotions correctly and express them to have adaptive emotions.

The limitations of this study and suggestions for further research are as follows.

This study has a limitation that the study subjects were limited to college students, so the effect of emotional awareness clarity could not be studied in all age groups. In the future, it is necessary to make efforts to generalize the research results by conducting research on a more comprehensive age group. In addition, this study has a limitation that only the anxiety and depression variables are considered as psycho-emotional variables affecting psychological well-being. In the future, it is also necessary to establish a comprehensive research model that considers more diverse variables.

A Comparative Study on Life Satisfaction on the Disabled Elderly and the Disabled Middle Aged

Da-Yeon Shim¹, Su-Sun Park²

¹Instructor, Department Social Welfare, Soongsil University Lifelong Education Institute, Seoul City, 06978, Korea,
²Professor, Department of Social Welfare, Seowon University, Cheongju City, 28674, Korea

Abstract

Background/Objectives: The purpose of this study is to provide a specific welfare service suitable for each generation by conducting a comparative analysis of the factors affecting the lives of the disabled.

Method/Statistical Analysis: This study analyzed the data of 2017 which is the 12th data of the Korea Welfare Panel conducted by the Korea Institute for Health and Social Affairs. As related variables, gender, education level, household income, and work ability were selected as demographic factors, and the relationship with life satisfaction was identified through social support, depression, health status satisfaction, and family life satisfaction.

Findings: As a result of comparison of social support, depression, health status satisfaction, and overall life satisfaction by generation, the middle-aged turned out to perceive higher only in health satisfaction variable. And as a result of the factors that influence the overall life satisfaction of the middle-aged and the elderly, first, for the middle-aged, household income and working ability affect overall life satisfaction in the first model, which only used demographic variables. Social support, depression, health satisfaction, and family life satisfaction in the second model, which added four variables, all four variables were found to influence overall life satisfaction. For the elderly, the first model, which only included socio-demographic variables, showed that household income and working ability were overall life. In addition to the elderly, gender also affects overall life satisfaction. Social support, depression, health satisfaction, and family life satisfaction in the second model, which added four variables, all four variables, were found to affect overall life satisfaction, and gender and household income were still influential factors.

Improvements/Applications: Social support perception, depression, health satisfaction, and family life satisfaction turned out to have a great influence. An approach providing multi-dimensional resources encompassing individual, family, emotional and social factors is required.

Keywords: *The disabled elderly, The disabled middle-aged, Life satisfaction, Social support, Depression, Korea Welfare Panel.*

Introduction

Satisfaction, which is the evidence that an individual is living happily in his or her society, is the ultimate

goal of the human being and the greatest concern^[1]. However, persons with disabilities are generally placed in alienation and isolation, subject to prejudice and discrimination. This kind of discrimination against persons with disabilities is a factor in lowering life satisfaction^[2]. The need for a life-cycle approach to disability research lies in that people with disabilities, like non-disabled people, are recognized as members of the community who perform different developmental tasks for each age group, while at the same time focusing on overall life experiences. In the context of life-cycle

Corresponding Author:

Professor, Department of Social Welfare, Seowon University, Cheongju City, 28674, Korea
e-mail: sunybono@gmail.com

perspective, the social context such as changes in individual, economic, and social resources can affect the individual's life. The assessment of how policies to support the disabled contribute to the ultimate goal of improving the quality of life for the disabled can be seen through studies of life satisfaction decisions for the disabled, whose scope is limited^[3].

The concept of life satisfaction is expressed by ^[4], who develop the Life Satisfaction Index of the elderly, from the activities that make up their daily lives, the positive self- image, the optimistic attitude and feelings. It was defined as maintenance^[5]. Since life satisfaction is a complex concept that combines subjective aspects of interpreting each individual's objective situation and the situation, there are a growing number of studies^[6] that analyze factors that affect the life satisfaction of people with disabilities and comprehensively understand life satisfaction.

In particular, aging and disability are social issues that require social intervention because they reduce the living satisfaction of older people and cause family conflicts by increasing the support burden of families^[7]. Studies in the field of disability welfare first began in foreign countries, focusing on the living satisfaction of spinal cord-impaired and brain-impaired people^[8,9,10]. These studies compared the living satisfaction of the disabled with that of the non-disabled, or compared the factors related to the living satisfaction of the disabled. In Korea,^[11] compared the living satisfaction of the disabled and the non-disabled,^[12] examined the factors affecting the living satisfaction of those who live in metropolitan cities and those with brain lesions. The results of the preceding study show that factors related to life satisfaction of the elderly with disabilities are relevant not only to the general characteristics and life cycle factors, disability and health characteristics, but also to the social characteristics ^{[12][13]}.

In the United States, a survey is conducted annually by the National Organization on Disability to examine the differences in living conditions between people with and without disabilities. In Korea, disability surveys are conducted every five years. In Korea and the United States, the results of the ^[13] are very suggestive, with few studies dealing with the quality of life of people with and without disabilities. As a result of the analysis of the overall quality of life and the sub-areas of the scales, non-disabled people were high in satisfaction, autonomy, community participation, and accessibility.

No significant difference was found only in the material satisfaction zone. This means that overall life satisfaction is clearly higher for people with disabilities than people with disabilities, and there is less opportunity to determine free time or choose daily activities. It also means that they have low opportunities to participate in the community, such as leisure, and low access. Some studies on depression in Korea were conducted^[14,15]. Domestic studies mainly studied the depressive factors of the disabled aged 65 and over. However, it is necessary to take into account that the recent study on the elderly with disabilities has been conducted for the disabled in their 40s and 50s, which are relatively early ages^[16].

There is a need to reduce depression according to the life cycle of Korean disabled. Rather than understanding middle age and old age, mental health promotion efforts for people with disabilities are needed. Depression level tended to increase with age^[17]. Depression levels tended to decrease somewhat compared to those in their 40s, but increased rapidly after age 65. Depression prevention and reduction strategies are needed throughout the life cycle, but it can be seen that the efforts to prevent depression are particularly urgent for older people with disabilities.

Therefore, in this research, we want to examine the influence on satisfaction including social factors such as emotional factor like depression and social support perception as well as demographic factors. In addition, the comparison between the middle-aged and the elderly can be a very important basic data for the customized life-cycle approach for the disabled by providing information on the factors that affect life satisfaction among the generations as well as the current status analysis of each generation.

Method

This study analyzed the data of 2017 which is the 12th data of the Korea Welfare Panel conducted by the Korea Institute for Health and Social Affairs. Penal data total 6,581 households, 12,790 people. Among them, 1,459 were disabled, while 1,291 were middle-aged and elderly.

In order to find out the difference between generations of the disabled elderly and the disabled middle-aged, this research classified the middle-aged as those who are 45-64 years of age and the elderly aged 65 and over.

As related variables, gender, education level, household income, and work ability were selected as demographic factors, and the relationship with life satisfaction was identified through social support, depression, health status satisfaction, and family life satisfaction.

Result and Discussion

1. General Demographic Variables of the Disabled Elderly and the Disabled Middle-Aged: As a result of analysis of the demographic variables of the research subjects, there were 386 disabled middle-aged and 905 disabled elderly. As shown in [Table 1], of the former, 237 subjects were

men and 149 subjects were women. Of the latter, 433 subjects were men and 472 subjects were women respectively. As for education level, most of the middle-aged were high school graduates whereas most of the elderly were elementary school graduates. As for household income, in the case of the middle-aged, the most had more than 50 million won whereas in the case of the elderly, the most had 15 million won or less. As for work ability, most of the middle-aged and the elderly perceived that they were able to work. 66.8 percent of middle-aged people said they were able to work, while 47.1 percent of older people said they were.

Table 1. General Demographic Variables of the Disabled Elderly and the Disabled Middle-Aged

Variable	Division	Middle-Aged (N=386)		Elderly-Aged (N=905)	
		N	%	N	%
Sex	Male	237	61.4	433	47.8
	Female	149	38.6	472	52.2

	Possible to work	258	66.8	426	47.1
	Only simple work	56	14.5	154	17.0
	Weak working hours (housework only)	50	13.0	262	29.0
	No ability to work (do not even do housework)	22	5.7	63	7.0

2. Comparison of Social Support Perception, Depression, and Satisfaction by Generation: As a result of comparison of social support, depression, health status satisfaction, and overall life satisfaction by generation as shown in [Table 2], the middle-aged turned out to perceive higher only in health satisfaction variable. There was no significant difference between the elderly and the elderly in social support, depression, family life satisfaction, and overall life satisfaction.

Only the health satisfaction score was 2.81 points for the middle-aged and significantly higher than the 2.41 points for the elderly.

The fact that middle-aged people did not show significantly higher scores in other satisfactions than the elderly in other than health satisfaction means that intensive and detailed studies on the various satisfactions of life for middle-aged people are needed.

Table 2. Comparison of social support, depression and satisfaction by generation

Variable	Middle-Aged		Elderly-Aged		t
	M	SD	M	SD	
Social support	31.91	7.99	31.53	7.36	.80

Life satisfaction	3.33	.72	3.36	.68	-.552

*p<.05 **p<.01 ***p<.001

3. Factors Affecting Overall Life Satisfaction:

[Table 3] and [Table 4] show the factors that influence the overall life satisfaction of the middle aged and the elderly. First, for the middle aged, household income ($\beta = .30, p <.001$) and working ability ($\beta = -.15, p <.01$) affect overall life satisfaction in the first model, which only used demographic variables ($F = 9.45, p <.001$). Social support, depression, health satisfaction, and family life satisfaction in the second model, which added four variables, all four variables were found to influence overall life satisfaction ($F = 27.18, p <.001$). Higher social support ($\beta = .16, p <.01$), lower depression ($\beta = -.26, p <.001$), and higher satisfaction with health status ($\beta = 0.23, p <.001$), the higher the family life satisfaction ($\beta = 0.23, p <.001$), the higher the overall life satisfaction of the middle aged. For the elderly, the first model, which only included socio-demographic variables, showed that household income ($\beta = .19, p <.001$) and working ability

($\beta = -.21, p <.001$), as in the case of middle-aged people, were overall life. In addition to the elderly, gender ($\beta = -.08, P <.05$) also affects overall life satisfaction ($F = 14.13, p <.001$). In other words, female perceived that their overall life satisfaction was higher than male, their household income was high, and their ability to work increased their overall life satisfaction. Social Support, Depression, Health Satisfaction, and Family Life Satisfaction in the second model, which added four variables, all four variables, like the middle-aged, were found to affect overall life satisfaction, and gender ($\beta = -.08, P <.05$) and household income ($\beta = .07, P <.05$) were still influential factors ($F = 50.02, P <.001$). Higher social support ($\beta = .14, P <.001$), lower depression ($\beta = -.24, P <.001$), higher health status satisfaction ($\beta = .24, P <.001$), the higher the family life satisfaction ($\beta = 0.26, P <.001$), the higher the overall satisfaction with life.

Table 3. Factors affecting overall life Satisfaction (Middle-aged)

Conclusion

As a result of this research, variables affecting overall satisfaction in both the middle-aged and the elderly, social support perception, depression, health satisfaction, and family life satisfaction turned out to have a great influence, suggesting that, as a method to enhance life satisfaction for the disabled, it is clear that an approach providing multi-dimensional resources encompassing individual, family, emotional and social factors is required. In particular, the study on the living satisfaction of the disabled in the middle-aged is very insufficient, and the government urgently needs to take measures to improve the quality of life, including the elderly as well as the middle-aged, as the quality of life has recently been reduced due to the deterioration of economic life caused by the early retirement of the middle-aged.

In particular, in terms of life satisfaction for people with disabilities, despite the social difficulties in life compared to non-disabled people, satisfaction surveys are conducted only for people with disabilities.

As a result, the tasks in the field of quality of life research for the disabled are different from the unified perspectives, including comparison of non-disabled and disabled, inclusion and recognition of social discrimination of the disabled, and differences in life satisfaction and the findings of influence factors. You need to approach it.

Abstract

Background/Objective: This study aimed to verify the quality and the appropriateness of pediatric CPR chest compressions according to 2015 Korean Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care.

Method/Statistical Analysis: The participants of this study were 64 EMT and nursing students who were qualified as BLS providers. Four sets of 5 CPR cycles were performed with one hand and two hands at the ratio of chest compression (30 times) to respiration (2 times), and fatigue was confirmed by NRS (numeral rating scale). Collected data were analyzed using frequency, descriptive statistics, paired t-test, and repeated measure ANOVA by SPSS 22.0.

Findings: While the total number of chest compressions (629.6 times vs. 618.3 times, $p=.016$) and hands-off time (6.6 sec vs. 6.9 sec, $p=.006$) were effective for one-handed chest compression, average pressure depth (42.2mm vs. 43.8mm, $p<.001$), sufficient chest compression depth rate (83.0% vs. 89.1%, $p=.038$) and fatigue (7.0 points vs. 6.2 points, $p=.040$) were more effective in two-handed chest compressions. In addition, there were significant differences in the average chest compression depth over time ($p=.003$) and the total elapsed time ($p=.332$), but no significant difference in inappropriate chest compression.

Improvements/Applications: Performing pediatric CPR according to the 2015 Guidelines for Pediatric Cardiopulmonary resuscitation is acceptable, but it is necessary to consider two-hand chest compression more than one hand compression.

Keywords: Chest compression; children; cardiopulmonary resuscitation; depth; quality.

Introduction

Rapid cardiopulmonary resuscitation (CPR) by bystanders is one of the key factors in the survival chain to save a patient from cardiac arrest^[1]. Fast and effective cardiopulmonary resuscitation by bystanders in children, as in adults, helps the return of spontaneous

circulation and neurological recovery. In children, the difference in survival rate varies according to the cause of cardiac arrest. In the cardiac arrest due to respiratory arrest, the survival rate of neurologically normal person is about 70%, and 20-30% in the case due to ventricular fibrillation^[2]. The quality of chest compressions is an important factor in CPR. It is also important to deliver chest compressions of sufficient depth^[1]. If an infant is unresponsive and not breathing, 30 chest compressions should be performed immediately, since proper chest compressions under cardiac arrest maintain blood flow to major organs and increase the possibility of spontaneous circulatory recovery. Appropriate chest compressions in children should be delivered at a

rate of 100-120 times per minute at a depth of at least one-third of the diameter (chest thickness) between anterior and posterior thorax, or depth of 4-5cm^[3-5]. In a preceding study, spontaneous circulatory recovery was best when chest compressions were performed at a rate of 125 times per minute^[6], while other studies reported that the best survival discharge rates were at a rate of 100-120 times per minute^[7]. Another important factor in the quality of cardiopulmonary resuscitation is the problem of incomplete recoil that can occur during chest compressions. No human studies have yet been conducted but animal testing has confirmed that the relationship between incomplete recoil and cardiac output is inversely proportional. Therefore, effective pediatric cardiopulmonary resuscitation requires the chest compression at least one-third of the depth (approximately 4-5cm), anterior and posterior diameter, of thoracic cavity with palms of one or both hands on the lower half of the sternum. Whether one hand or two hands are used, the proper depth should be maintained for each pressure applied without pressing the xiphoid process while ribs and chest being relaxed back to its normal position after each chest compression^[8-9]. Another important aspect of CPR quality is the chest compression fraction. This is the proportion of chest compressions in the total cardiopulmonary resuscitation. The higher the chest compression fraction, the less the hands-off time and the higher the chest compression fraction, the higher the survival rate^[10-11]. Yet another concern in the quality of CPR is the rescuer's fatigue which was associated with inappropriate speed, depth and chest recoil from chest compression^[12]. However, differences in the quality and the appropriateness of chest compression between one-handed or two-handed pediatric CPR have not been sufficiently demonstrated yet and required further research. Therefore, this study examined the quality and the appropriateness of chest compressions using one or two hands for pediatric CPR to provide the basic data for improving the quality of pediatric CPR in the future.

Method

This study was a single group, post-design experimental study to check the quality and the appropriateness of one- or two-handed chest compressions in pediatric CPR.

The participants of this study were those who completed Basic Life Support (BLS) provider qualification and agreed to participate among the

third and fourth-grade students in the department of emergency technology and nursing at one university in Jecheon. The number of subjects was 64 using G*Power 3.1.9 with the effect size of .30, the significance level of .05, and power of .80. 70 patients were selected in consideration of the dropout rate, and the final analysis included 64 people except dropouts.

All cardiopulmonary resuscitation procedures were assessed and recorded with the Laredal Resusci Junior QCPRTM mannequin. According to the results of previous studies evaluated to assess the quality and the appropriateness of one- or two-handed chest compressions in pediatric CPR, in single pediatric cardiopulmonary resuscitation, if a child (i.e., the mannequin) was unresponsive and not breathing, the CPR provider placed the patient on flat floor and 30 chest compressions at a rate of 100-200 times per minute, at least one-third, 4-5cm depth, of the thoracic cavity, should be delivered immediately^[4]. The chest compression time averaged 7.28 minutes after the on-site arrival time following the report to 119 emergency services while averaging 10.86 minutes from the emergency scene to the hospital^[13]. Assessment of the quality and appropriateness of chest compressions in adult CPR found changes in the average chest compression depth and appropriate compression rates over time^[14]. Based on this prior study and its theoretical basis, to evaluate the quality and the appropriateness of one- or two-handed chest compressions in pediatric CPR, 30 chest compressions and two artificial respirations were delivered in four sets (eight minutes) of five cycles using one-handed method on the first day and two-handed method on the second day. The age, height, weight, and qualification year of BLS provider were recorded as general characteristics of the subjects. The quality of chest compressions was checked for total number of chest compression, average pressure depth, sufficient chest compression depth ratio, sufficient chest compression recoil rate, average compression rate, and hands-off time. The adequacy of chest compression over time was determined by measuring the average chest compression depth with number of inappropriate chest compression, meaning that the fewer inappropriate chest compression, the more appropriate the chest compression were. The fatigue level of the subjects was assessed using with the numerical recording scale (NRS) immediately after the CPR was completed. CPR difficulty was evaluated on the scale of 0 to 10, where 10 points was the most difficult. The ratio of chest compression to artificial respiration was

30:2, but respiration was excluded from the evaluation criteria to assess the quality and the appropriateness of chest compression.

This study was conducted from May 14-17, 2019, by the researcher who has no conflict of interest in the subject. SPSS Windows 22.0 was used to analyze the collected data and the general characteristics of the subjects were presented using descriptive statistics of frequency, percentage, mean, and standard deviation. Differences between the quality of one-handed and two-handed chest compression were analyzed by paired t-tests while the appropriateness of chest compression over time being analyzed by paired t-test and repeated measurement of ANOVA.

The data were collected after obtaining approval from the Institutional Review Board (IRB) (IRB No: D*-2019-04-001-02) of D University located in Jecheon for ethical consideration of the subjects. The Researcher without conflict of interest explained to the participants about the purpose, method, expected results, and method of handling unexpected problems. The confidentiality of the study and the voluntary participation were also explained. The survey with the evaluation was conducted after receiving written consent from the subjects who agreed to participate in the research.

Result

[Table 1] shows that forty female students (62.5 percent) and 43 (67.2 percent) BLS providers certified in 2017 were included in the study. The average age, height, and weight of the participants were 20.94 (±1.75) years, 167.5(±8.43)cm, and 62.41(±0.87kg, respectively. As [Table 2] indicates, analysis of the quality of chest compressions delivered by one- and two-handed pediatric CPR showed that the total number of chest compressions (629.6 times vs. 618.3 times, one-handed vs. two-handed, respectively; p=.016) and the hands-off time (6.6sec vs. 6.9sec, one-handed vs. two-handed,

respectively; p=.006) were more effective in one-handed chest compressions. The average compression depth (42.2mm vs. 43.8mm, one-handed vs. two-handed, respectively; p<.001) was more appropriate for two-handed chest compressions. The sufficient chest compression depth rate (83.0% vs. 89.1%, one-handed vs. two-handed, respectively; p=.038) and fatigue score(7.0 points vs. 6.2 points, one-handed vs. two-handed, respectively; p=.040) were better in two-handed chest compression. However, there was no significant difference between sufficient chest compression recoil rate (98.2% vs. 96.0%, one-handed vs. two-handed, respectively; p=.079) and average compression rates (108.9 times vs. 108.8 times, one-handed vs. two-handed, respectively; p=.924).

Figure 1. Assessment of adequacy of chest compressions over time (n=64)

Discussion

This study was conducted to evaluate the quality and the appropriateness of one- or two-handed chest compressions in pediatric CPR to provide the basic data for effective pediatric cardiopulmonary resuscitation. In the aspect of quality of chest compression in pediatric CPR, the total number of chest compression and the hands-off time were more effective for one-handed chest compression. The average compression depth was

more appropriate for two-handed chest compression, as was the sufficient chest compression depth rate. However, there was no significant difference between the compression recoil rate and the average compression rate between one- and two-handed CPR. These results support recommendations in the 2015 Guidelines for Pediatric Cardiopulmonary Resuscitation that suggest the use of one- or two-handed chest compression. However, the fatigue rate was higher when only one

hand was used compared to chest compression with two hands. This agrees with the results of previous study that suggested that the quality of chest compression decreased due to higher fatigue rates in adult CPR when only chest compression was delivered, compared to standard CPR [14]. The quality of chest compression is the most important factor in effective CPR, emphasizing the importance of chest compression of sufficient depth [1]. Therefore, the quality of chest compression may decrease as fatigue increases in pediatric CPR, so it is necessary to consider two-handed CPR.

The mean chest compression depth was within 4-5cm, as suggested in the 2015 Guidelines. Two-handed chest compression was more effective than one-handed compression as shown different significantly over time and over total time elapsed. However, there was no statistically significant difference over time and over total time elapsed in inappropriate chest compression rate, but there were more improper chest compressions in one-handed chest compression than in two-handed chest compression. The results were attributed to higher fatigue scores in one-handed chest compression provider than in two-handed chest compression provider, resulting in the increase in inappropriate chest compression. In addition, inappropriate chest compression is the measure of the quality of chest compression, indicating that the two-handed method was more appropriate. Furthermore, there is no previous study comparing the appropriateness of one- or two-handed chest compression in pediatric CPR, so no study can compare directly with this study. Thus, additional studies on two-handed chest compression are needed.

Conclusion

This study was aimed to assess the quality and the appropriateness of chest compression in pediatric CPR according to 2015 Korean Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care. Evaluation of the quality of chest compression in pediatric CPR showed that the total number of chest compression and the hands-off time were more effective in the one-handed method, but the average compression depth applied was more appropriate in the two-handed method. Furthermore, the ratio of sufficient chest compression depths and the fatigue were significantly higher for two-handed chest compression. In the appropriateness of chest compression, the average chest compression depth was significantly improved over time and over the total time elapsed in two-handed chest

compressions, but there was no significant difference in inadequate chest compression. Based on these results, this study is meaningful to provide the basic data for improving the quality of the 2015 Korean Guidelines by evaluating the quality and the appropriateness of one- or two-handed chest compression in pediatric cardiopulmonary resuscitation. In addition, one- or two-handed chest compression method in the 2015 Guidelines may be used in pediatric cardiopulmonary resuscitation, but it is necessary to perform chest compression with two hands rather than one hand, suggesting follow-up studies in various ages and groups. Furthermore, since children have the high possibility of cardiac arrest due to respiratory problems, further studies are needed to assess the quality and the appropriateness of one- or two-handed chest compression, including respiration.

Factors Influencing Internet Game Addiction in Middle School Students

Eun Young Do¹, Yeon Ran Hong²

¹Professor, Department of Nursing, Kwangju Women's University, 165 Sanjung-dong, Gwangsan-gu, Gwangju, Republic of Korea, ²Professor, Department of Nursing, Sunchon National University, 255 Jungang-ro, Suncheon, Jeollanam-do, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to analyze the factors affecting internet game addiction in middle school students.

Method/Statistical Analysis: The survey was conducted among 304 middle school students in G metropolitan city of Korea. The data were analyzed using frequency and percentage, mean and standard deviation, t-test, ANOVA, and hierarchical regression analysis.

Findings: The results for the degree of middle school students' internet game addiction showed that 67.1% were average users, 23.4% were potential risk users, and 9.5% were high risk users. The variables affecting internet game addiction were found to be anxiety, ego-resilience and gender. These three variables explained 15.9% of the internet game addiction in middle school students.

Improvements/Applications: To prevent middle school students from being addicted to internet games, intervention strategies that focus on male students for reduction of anxiety and strengthening of ego-resilience are needed.

Keywords: *Internet gaming, Addiction, Anxiety, Ego-resilience, Middle school students.*

Introduction

In the modern society, most of the information are collected from the internet and thus using the internet has become an essential means in all living areas. In particular, Korea emphasized the importance of building high-speed information infrastructures and informatization education at the national level. As a result, 91.5% of the citizens over the age of 3 use the internet, and among them teenagers takes 99.9% of the total internet use. Communication was the primary

purpose of internet use (94.5%) followed by data and information acquisition (93.7%) and leisure activity (92.5%), whereas leisure activity took the highest portion (99.5%) among teenagers^[1]. Game, one of the teenagers most common leisure activities, has been continuously increasing with the development of internet and smart devices. A study in 2017 reported that 67.2% of the people in the age of 10~65 were using internet games, and the ratio of game users was highest in teenagers at 91.1%^[2]. However, it has also been noted that various problems in academic achievement, family relationship, social relationship, and physical and mental health could occur as the result of game addiction when games were excessively used^[3-4]. For instance, a shocking incident occurred that a middle school student addicted to game murdered her mother who forced to stop playing computer games and killed herself^[5]. There exists another case in which a middle school student who was addicted to internet games killed his brother in order to experience murder^[6].

To address the problems of game addiction, it is necessary to pay attention to the precedent variables affecting game addiction. For parental variables, previous studies reported that the lack of communication between parents and children as well as breaking of family could affect game addiction^[7-8]. Psychological variables such as neurosis, anxiety, depression, self-efficacy, self-esteem, impulsivity, and aggressiveness are also known to affect game addiction^[9-11]. Among the psychological variables, anxiety was identified one of the most important variables explaining game addiction. Prior studies for anxiety have shown that both temporary and time-varying state anxiety and relatively unchanging characteristic anxiety affected online game addiction^[9]. However, although it was known that anxiety could be caused by game addiction^[4], whether anxiety is a leading factor of game addiction or not is not sufficiently researched yet.

In addition, strengthening ego-resilience was known to be important for an effective intervention on internet addiction or overuse because ego-resilience is an adaptive ability to control the individual’s emotional ability and change the situation^[11]. It was further reported that strengthening ego-resilience was the most comprehensive and effective remedy to smartphone addiction^[10]. Thus, ego-resilience has received much attention recently and studies have been reported on the relationship between ego-resilience and internet addiction or smartphone addiction.

In this study, the factors affecting internet game addiction were investigated, including anxiety and ego-resilience, in order to provide the basic data necessary for the development of internet game addiction prevention program of middle school students. The relationship of internet game addiction to the general characteristics of the subjects was determined. Then, the degrees of internet game addiction, anxiety, and ego-resilience of the subjects were analyzed. Lastly, the factors influencing the subject’s internet game addiction were identified.

Method

1. **Measures:** Ego-resilience was measured using the tool developed by Block and Kremen (1996)^[12] and revised by Yoo and Shim(2002)^[13]. The Likert 4-point scale was adopted with scores ranging from the minimum of 14 to the maximum of 56 for which a higher score implied that the individuals had a higher ability to re-establish self-control after experiencing a stress event. The reliability of the tool as determined by Cronbach’s α was .76 at the time of development and .75 at the time of this study.

Anxiety was measured using the Spielberger’s (1973) Trait Anxiety Inventory for Children (TAIC) translated by Kim and Shin(1978)^[14]. The Likert 3-point scale(range 20-60) was adopted. The reliability of the tool as determined by Cronbach’s α was .85 in Kim and Shin’s study and .90 in this study.

Internet game addiction was measured using a scale developed by the Korean National Information Society Agency (2006)^[15]. The scale consisted of 20 items which were asking about current gaming behavior rather than self-recognition of game addiction, and score was evaluated using a 4-point scale with respect to frequency. The reliability of the tool as determined by Cronbach’s α was .89 at time of its development and .94 in the present study.

2. **Data Collection:** The survey was carried out at two middle schools in G city. The purpose of the study was first explained to the principals and teachers and the questionnaires were completed by students who agreed to participate. Specifically, a pre-trained research assistant explained the purpose and method of the study, distributed the questionnaires to students, and requested the students to complete the questionnaires immediately. The questionnaire was completed with anonymity and the students were informed that the questionnaires were to be used only for the purpose of present study.

Table 1: Internet game addiction with respect to general characteristics of the subjects

	Variables	n(%)	M±SD	t or F	p
Gender	Male	150(49.3)	31.65±11.57	2.983	.003

	Other	37(8.9)	32.55±11.48		

3. Data Analysis: The collected data were analyzed using SPSS Ver. 20.0. General characteristics of the subjects, ego-resilience, anxiety, and internet game addiction level were analyzed by frequency, percentage, means and standard deviation. The degree of internet game addiction with respect to general characteristics of the subjects were analyzed using the t/F test. Hierarchical regression analysis was used to find the cause of internet game addiction. The analyses were performed in two steps. First, the effects of general characteristics on the degree of internet game addiction were analyzed (Model 1). Then, the analysis was repeated after adding psychological factors to the general characteristics (Model 2).

Results

1. General Characteristics: Among general characteristics, gender ($p = .003$) was the primary factor revealing statistically significant difference in internet game addiction level. Especially, male students showed a higher degree of internet game addiction [Table 1].

2. Internet game addiction, ego-resilience and anxiety: The analyses of the subject's ego-resilience,

anxiety and internet game addiction showed that the ego-resilience score was 40.57 ± 6.05 , anxiety was 32.66 ± 7.63 , and internet game addiction was 29.81 ± 10.77 . The results for anxiety level of the students revealed that slightly high 13.2%, fairly high 6.3%, and very high 4.6%. Also, the analysis of the subjects' internet game addiction showed that the ratio under potential risk was 23.4% and high risk was 9.5% [Table 2].

Table 2. Internet game addiction, ego-resilience and anxiety

Variables	n(%)	M±SD
Ego-resilience		40.57±6.05
Anxiety		32.66±7.63
Normal	231(76.0)	
Slightly high	40(13.2)	
Fairly high	19(6.3)	
Very high	14(4.6)	
Internet game addiction		29.81±10.77
Normal	204(67.1)	
Potential risk	71(23.4)	
High risk	29(9.5)

	Ego-resilience	-0.373	.099	-0.209	-3.766	.000	0.897	1.114
		R2 =.184, Adj R2 =.159, F=22.76(p<.001)						

3. Factors influencing internet game addiction:

The results of hierarchical regression analysis to determine the variables effective in predicting internet game addiction are summarized in Table 3. In the first step analysis in which only the general characteristics were utilized as the independent variables, gender appeared as the influencing factor, explaining 3.5% (F = 2.581, p = .013, R² = .058) of internet game addiction, such that male students were -3.769 (B = -3.769) higher than female students. As the next step, when the analysis was repeated after including psychological factors (anxiety and ego-resilience) as well as the general characteristics, the variables affecting internet game addiction were found to be anxiety (β = .244, p = .002) ego-resilience (β = -.209, p <.001) and gender (β = -.200, p <.001). These three variables explained 15.9% of the internet game addiction in middle school students (F = 22.76, p<.001). Since the variation inflation factor (VIF) was found to be 1.00-1.99, tolerance limit to be 0.50-0.99, and the Durbin-Watson value to be 2.089, there was no problem of multi-collinearity.

Discussion

This study was performed to find the degree of internet game addiction of middle school students and to identify the factors that influence internet game addiction. The internet game addiction level of the subjects were found that 23.4% were potential risk users, and 9.5% were high risk users. A survey carried out in 2009 using the same tool among 6,499 middle and high school students reported that only 7.1% were potential risk users and 5.6% were high risk users^[16]. Accordingly, it is understood that the results of the present study signify that adolescents' game addiction problem became more serious than the past. According to previous studies, internet game addiction causes deterioration of family and friend relationship, maladjustment of school life, health and mental problems such as impulsiveness, aggression, depression, and violence^[4,9,10]. Therefore, to preempt problems caused by game addiction, it is necessary to correctly diagnose the current state of internet game addiction among adolescents and prepare appropriate mediation alternatives.

Through hierarchical regression analysis, the variables that affect internet game addiction in middle school students were confirmed to be gender, anxiety and ego-resilience. Male students had significantly higher scores of internet game addiction than female students. This result is consistent with the previous results of a survey in 674 Korean secondary school students in which male students were 2.22 times higher in the risk of internet game addiction than female students^[17]. A recent study also reported that the game utilization rate of teenage male students was 94.9%, whereas that of teenage female students was 88.6%^[2]. Thus, for the prevention of internet game addition in middle school students, the priority should be placed on male students.

The conversation with parents and cohabitation did not show a difference in the degree of internet game addiction, which agrees with the results of previous studies in which dysfunctional communication with parents did not show a difference between high-risk users and general users^[16,18]. However, there also exists studies that reported a direct influence of the quality of family relationships on game addiction^[19], implying the necessity of further investigation for the relationship between parental variables and internet game addiction.

Besides gender, anxiety appeared to be a significant factor affecting internet game addiction. This finding was consistent with the result of a survey of university students in the United Kingdom^[9]. The subjects' anxiety score in this study was 32.66 points for which the anxiety level of 76.0% was normal, 13.2% was slightly high, 6.3% was fairly high, and 4.6% was very high. The average anxiety score from a survey of elementary school students in grades 4, 5, and 6 in 2016 was 27.91, implying that the anxiety level of middle school students is higher^[20]. Ego-resilience also appeared to be a variable affecting internet game addiction. The score for ego-resilience was 40.57 which was higher than the ego-resilience of 38.03 reported in a previous study^[13]. Although the relationship between ego-resilience and internet game addiction was little investigated previously, there exist studies that reported that ego-resilience of middle school students had a statistically significant negative influence on the dependence of mobile phones^[11] or ego-resilience of college students influenced internet addiction^[10]. Thus, it is considered that further research on the relationship between ego-resilience and internet game addiction is necessary.

Conclusion

In this study, it was found that about two-thirds of the middle school students had problems with internet game addiction. These findings suggest that it is necessary to mediate the strategies to reduce middle school students' anxiety and strengthen their ego-resilience in order to prevent middle school students' addiction to internet games.

The increase of game addiction among teenagers and related problems have emerged as a social issue recently but research for this issue is not sufficient. This study was conducted to address the factors affecting internet game addiction among middle school students. Although the survey was carried out among the middle school students in one area only, the results from this study are considered to be meaningful in understanding and elucidating the factors related to internet game addiction. Further study is necessary to develop an effective program to prevent internet game addiction of middle school students.

Abstract

Background/Objectives: The purpose of this study was to investigate factors contributing to on-line game addiction in 3rd, 4th, 5th, 6th graders living in 2 cities of Korea.

Method/Statistical Analysis: This study applied cross-sectional research design with a structured questionnaire. The subjects were 381 elementary school students in Korea. Data were collected after describing the purpose and contents to the students and were analyzed using SPSS 25.0 program.

Findings: The relative influence toward the children's ego-resilience was shown in the order of importance as follows; trait anxiety, gender, internet time of use, perceived home atmosphere, and satisfaction with school life.

Improvements/Applications: From the study, on-line game addiction appeared to be influenced by multiple factors such as gender, perceived atmosphere, satisfaction of school life, Internet time of use and trait anxiety and These variables should be considered when developing nursing interventions for online game addiction.

Keywords: Children, Anxiety, Resilience, Game, Addiction.

Introduction

In modern society, the Internet is now an indispensable medium for information acquisition, communication, entertainment, and so on. In particular, Korea has the world's best high-speed Internet communication network ^[1], which creates conditions for anyone to receive internet service conveniently. Also digital games tend to draw more and more time, money and energy from game players, and as a result, they can have negative life consequences such as game addiction again^[2].

Online game addiction is known to cause problems for game users, such as obsessive use, real-life cognitive

impairment, resistance, and daily disorders represented by poor academic performance and attention-intensive difficulties. In particular, online game addiction among teenagers is emerging as a research topic that should be paid more attention to.

The reason is that the internet use rate of Korean teenagers is close to 100% and the game population is mostly teenagers.

Now games interfere with the many hours that many children have to spend on growth and development, and affect the lifestyles of them. The impact of these online games on teenagers, especially children, may be more serious than the facts that appear in the results of various studies^[3].

Drawing the attention of both parents and schools is the time it takes to play online games in the daily lives of children and teens. Most existing data claim that the average amount of time a player takes to play online games is about 25 hours a week^[4].

Corresponding Author:

Eun Young Do

Professor, Department of Nursing, Kwangju Women's University, 165 Sanjung-dong Gwangsan-gu, Gwangju, Republic of Korea, email: eydo@kwu.ac.kr

Often on the psychological aspect, the paradigm of Internet game addiction is related to the amount of time. Many heavy gamers actually show symptoms of other behavioral addictions, including similar interpersonal and social risks-excessive enthusiasm for games^[5].

Some researchers see the reason why children and teens play computer games is that they prefer computer games to friends, care for virtual friendships, prefer behavior, overcome loneliness, and avoid problems. And they find that there was a negative meaningful relationship among game addiction, ego-resilience of their children, and participation in social activities with their parents^[6].

Resilience is defined as the process of adjusting when a child is exposed to adverse conditions and is conceptualized in terms of protective factors related to risk^[7]. A study showed that groups with high resilience were adaptable to school life and did not show good psychopathic symptoms than those with low resilience^[8]. Through resilience, children can get positive results despite adversity, so it is important to recognize protection factors such as resilience that help them overcome adversity^[9].

In summary, there is evidence that online game addiction during childhood, when growth and development are required, can be compromised in relation to a child’s home and school life as a whole. Therefore, it is necessary to gain insight into how family factors, school life-related factors, anxiety, and ego-resilience affect online-game addiction. The purpose of the study was to analyze relevant variables to gain insight into the causes and potential protection strategies of children’s online game addiction.

Method

Study design and sample: This study is a research study applying a cross-sectional design using a structured questionnaire. The investigator visited three elementary schools located in South Korea, to explain the purpose of the study to students and teachers. They obtained written consent from 400 voluntary participants, who then received completed questionnaires. The self-reported questionnaire took an average of 17 minutes.

The questionnaire was managed with the help of teachers in the classroom under the same environmental conditions as the test. The researchers collected each questionnaire as soon as the children completed it. 381

copies were analyzed using SPSS Win program except 19 copies of which were not completely filled in or duplicated.

Instruments: Online-game addiction was measured using a scale developed by the Korean National Information Society Agency (2006)^[10]. The scale consisted of statements about current gaming behavior rather on self-recognition of game addiction. The questionnaire contained 20 items and each item was scored using a 4-point scale with respect to frequency. The reliability of this as determined by Cronbach’s α was 0.89 at time of its development and 0.94 in the present study.

Ego-resilience was assessed using a scale developed by Block J. and Kremen, AM^[11] and composed of 14 questions with the self-reported 4-point scale. The higher the score, the stronger level of the ego-resilience.

Trait Anxiety was measured by Spielberger’s Trait Anxiety Inventory for Children(TAIC)^[12].

Results and Discussion

Table 1: On-line game addiction according to general characteristics of children(N=381)

	Variables	n(%)
Gender	Boy	172(45.1)
	Girl	209(54.9)
Class year	3rd	95(24.9)
	4th	91(23.9)
	5th	92(24.1)
	6th	1036(27.0)
Perceived home atmosphere	Not harmonious	5(1.3)
	Ordinary	58(15.2)
	Harmonious	146(38.3)
	Very harmonious	172(45.1)
Communication with parents	Difficult	8(2.1)
	Normal	105(27.6)
	Comfortable	268(70.3)
Satisfaction with school life	Satisfied	299(78.5)
	Average	76(19.9)
	Dissatisfied	6(1.6)
School score	High	126(33.1)
	Middle	228(59.8)
	Low	27(7.1)
Economic status	High	114(29.9)
	Middle	251(65.9)
	Low	16(4.2)

	Variables	n(%)
Parents	Both parents	341(89.5)
	Other	40(10.5)
Internet time of use	1hr↓	210(55.1)
	1-2 hr	71(18.6)
	2-3 hr	44(11.5)
	More than 4 hr	56(14.7)

General characteristics of the children: The questionnaire included items related to gender, class year, perceived atmosphere, communication with parents, satisfaction with school life, school score, economic status, parents and internet using time. 55.1% of children used the Internet for less than an hour a week [Table 1].

Characteristics of On-line game addiction, ego-resilience and anxiety of children.

The average score of on-line game addiction was 28.66 and anxiety averaged 31.53. According to a 2015 survey on Internet addiction, the risk group for Internet addiction was 6.9 percent (2,621 people) of all Internet users (3-59 years old), down 0.1 percent from the previous year's 7.0 percent).

Given that these results are assessed to have slightly higher levels of trait anxiety with a score of 39 or higher, the level of trait anxiety among children studied is not considered to be on average worrisome.

The average score of ego-resilience was 38.79 as seen in Table 2.

Table 2: On-line game addiction, anxiety, and ego-resilience of children (n=381)

Variables	M	SD	Min	Max
On-line game addiction	28.66	10.16	20.00	70.00
Anxiety	31.53	7.29	20.00	54.00
Ego-resilience	38.79	5.67	13.00	52.00

Correlations between Online game addiction and other variables: Table 3 exhibits the relationship between online game addiction and other variables. Boys were more likely to be addicted to online games than girls. The more harmonious the perceived atmosphere games. the more comfortable the communication with parents and the more satisfied with school life,the less likely it was to become addicted to online game.

The lower the level of schooling, the lower economic level, the absence of both parents, the longer internet

time of use, the higher the level of anxiety and the lower the level of schooling were associated with higher online game addiction.

Teenagers' Internet addiction is a social and environmental factors, such as nuclear families, the increase of working couples, the education environment based on admissions and the absence of play culture. Young (1998)^[13] also said that the relevant factors of youth Internet addiction are the environmental characteristics of the family, the environmental factors of school, and the behavior of personal problems.

This can be seen as somewhat similar to the correlation results of this study, and is consistent with studies showing that boys are more addicted to online games than girls in gender characteristics^[14].

Table 3: Correlations between On-line game addiction & other variables (n=381)

Variables	On-line Game Addiction
Sex	-.179**
Grade	-.012
Perceived home atmosphere	-.316**
Communication with parents	-.284**
Satisfaction with school life	.304**
School score	.232**
Economic status	.214**
Parents	-.097
Internet time of use	.214**
Anxiety	.373**
Ego-resilience	-.303**

* p< .01 . ** p<.001

Factors Influencing ego-resilience of children: Table 4 shows hierarchical multiple regression analysis to identify the factors affecting the ego-resilience of subjects. Gender children's perceived atmosphere, satisfaction with school life, internet time of use, anxiety explained 54.6% of the online game addiction. The most important factors affecting the online game addiction of children were followed by anxiety ($\beta = .194$), gender($\beta = -.179$), internet time of use ($\beta = .178$), perceived atmosphere ($\beta = -.117$), satisfaction with school life ($\beta = .116$).

These results are similar to those of this study, which gender is a one of major factors in online game addiction. In this study, the less harmonious the home atmosphere was perceived to be, the higher the degree

of online game addiction, and these results were similar to the result preceding study^[15].

A study show that parent-related variables have not affected online game addiction, and that parental attachment has played no role in alleviating online game addiction, which differs from the results of this study^[16].

Among the factors related to school life, the lower the satisfaction level of school life, the higher the score of online game addiction, which is in line with a study by Park and Kim (2005)^[17], who claim that online games are a virtual place to solve stress caused by school life or grades. There is also a similarity to the argument that lack of leisure in life undermines life satisfaction and is linked to online game addiction^[18].

Therefore, it is very important to provide opportunities for offline leisure activities and to spread various cultural activities that can be experienced in order

Time spent on the Internet has been linked to online game addiction, similar to a 2014 study on Internet addiction. According to the results, the average daily Internet use time for teenagers was 138.6 minutes per week, compared with 189.1 minutes for those at risk of addiction and 225.1 minutes for those at high risk ^[19].

Online game playing time was an important predictor of game addiction, supporting many aforementioned research results. These studies explain that a key factor in increasing online game addiction is the time and duration of the day, and that teenagers who spend more time playing games are more likely to be trapped in the world of virtual online games^[20].

When considering the relationship between anxiety and online game addiction, this study found that trait anxiety is a major variable of online game addiction, similar to the results of a study of elementary school students^[21] that online games are related to anxiety, family relationships, etc

The negative experience during the growth period was shown to raise the level of anxiety and have indirect effects as well as direct effects on the risk of online game addiction, confirming the need to approach psychological and mental health issues of negative experience and anxiety for teenagers.

The relationship between anxiety and online game addiction is similar to other research, which was reviewed through prior research. The study identified the effects of anxiety associated with negative growing experiences on Internet addiction^[22].

Until now, research on the relevance of children's online game addiction to resilience has been very insufficient, making it difficult to compare other results on par with the results of this study.

Resilience did not appear to be a significant influence on online game addiction in this study, and these results differ from previous studies showing a negative correlation between resilience and smartphone addiction.

These results are somewhat different from existing literature that children with low levels of resilience often experience negative emotions and do not achieve successful adaptation by expressing undifferentiated behaviors due to their inability to exercise flexible self-control. Behaviors due to their inability to exercise flexible self-control^[23].

It is speculated that the online game addiction level of the study is not likely to be serious, and that this may not have highlighted the variable of resilience.

Rather than diagnosing game addiction as a problem for young children, it is reasonable to assess the possibility and trend of developing game addiction in the future.

Table 4: Factors influencing On-line game addiction (n=381)

	Variables	B	SE	β	t	p	VIF	Tolerance
M O D E L 1	Gender	-3.699	.922	-.181	-4.013	.000	.974	1.027
	Perceived home atmosphere	-2.239	.687	-.168	-3.259	.001	.747	1.339
	Communication with parents	-2.003	1.030	-.100	-1.944	.053	.746	1.340
	Satisfaction with school life	3.471	1.059	.156	3.278	.001	.874	1.145
	School score	2.017	.841	.115	2.397	.017	.867	1.154
	Economic status	1.254	.954	.065	1.314	.190	.819	1.222
	School score	1.893	.421	.207	4.493	.000	.935	1.070
R2 =.508, Adj R2 =.245035, F=18.58 (p<.001)								
M O D E L 2	Gender	-3.648	.903	-.179	-4.042	.000	.966	1.035
	Perceived atmosphere	-1.552	.698	-.117	-2.223	.027	.687	1.456
	Communication with parents	-1.137	1.028	-.057	-1.106	.269	.713	1.403
	Satisfaction with school life	2.579	1.056	.116	2.442	.015	.835	1.198
	School score	1.410	.840	.080	1.680	.094	.827	1.209
	Economic status	.998	.937	.052	1.066	.287	.807	1.239
	School score	1.624	.416	.178	3.907	.000	.914	1.094
	Internet time of use	.270	.069	.194	3.889	.000	.760	1.315
	Anxiety	-.163	.089	-.091	-1.829	.068	.761	1.315
	Ego-Resilience							
R2 =.546, Adj R2 =.281, F=10.54(p<.001)								

Conclusion

This study can be meaningful in that it has taken a comprehensive approach to the general characteristics of children, the home environment, the school environment, and psychological factors as an influence on online game addiction. The most important factor influencing resilience of children was trait anxiety followed in order by gender, internet time of use, perceived home atmosphere, and satisfaction with school life. These variables accounted for 28.1% of the children's resilience.

Based on the risk factors of online game addiction among children shown in the above research, it is believed that the development of preventive nursing intervention programs and treatment programs for the problem of online game addiction in children that may increase due to the information age can be carried out.

A Study on the Factors Affecting Depression of the Disabled People in Korea

Da-Yeon Shim¹, Su-Sun Park²

¹Instructor, Department Social Welfare, Soongsil University Lifelong Education Institute, Seoul City, 06978, Korea,
²Professor, Department of Social Welfare, Seowon University, Cheongju City, 28674, Korea

Abstract

Background/Objectives: The purpose of research is to construct a living environment and provide appropriate welfare resources to reduce the depression by identifying the factors affecting the depression of the disabled people.

Method/Statistical Analysis: This research analyzed the data of 2017 which is the 12th data of the Korea Welfare Panel conducted by the Korea Institute for Health and Social Affairs. In order to identify the factors affecting the depression of the disabled, this research analyzed the difference of depression according to demographic factors. In addition, the factors affecting depression were surveyed through the regression analysis of the SPSS statistics program.

Findings: The high scores of people with disabilities on depression indicate that access to mental health is essential in the areas of disability support, which suggests that life cycle management should be carried out through all subjects regardless of their socio-demographic variables. The result of a hierarchical regression analysis through demographic variables, satisfaction, and social support variable is as follows. First, in the area of demographic variables, male more than female, the lower is household income and the higher is one's work ability, depression turned out to be high. Next, the result of analysis showed significant results in all variables excluding all ages and education level. When all variables are included, male more than female, the lower is one's household income, the more one has work ability, depression was high, and the lower is one's health satisfaction, residential satisfaction, family life satisfaction, and social support, depression turned out to be low, suggesting that individual, family, and social resource environment are important explanatory factors in the perception of depression for the disabled.

Improvements/Applications: It is clear that, as a method to reduce depression of the disabled, a comprehensive and environmental approach is necessary which encompasses familial, psychological, and social dimensions.

Keywords: *Disabled person, Satisfaction, Social support, Depression, Korea Welfare Panel.*

Introduction

In the study of life satisfaction of people with disabilities, we have focused on physical health in

the past, but recently there is an increasing interest in psychological aspects^[1]. One of the psychological problems of people with disabilities is depression, and when depression progresses, it causes the satisfaction of life to be reduced to the extent that it requires professional treatment^[2,3].

Corresponding Author:

Su-Sun Park

Professor, Department of Social Welfare, Seowon University, Cheongju City, 28674, Korea
e-mail: sunybono@gmail.com

Personal factors and social environmental factors such as deterioration of physical function experienced by disabled people, child problems, economic problems, loss of close people, and changes in life events are likely to increase depression^[4]. In this vulnerable situation,

people with disabilities often meet with their families^[5] and have social relations, showing that depression decreases^[4].

Mental health is one of the essential requirements for reaching spiritual, physical and social well-being, the ultimate goal of social welfare. Especially, depression and schizophrenia are representative mental health issues that require prevention and treatment given the frequency of occurrence and the outcome of the disease^[6].

Fortunately, a variety of preventive programs have been provided in Korea, focusing on large and regional mental health centers, since the mid-2000s, as the national level of prevention has been strengthened in line with the global trend of mental health policies. The main contents of the Center's project consist of raising awareness of mental health problems for the general or high-risk groups of local residents and conducting various knowledge education and screening tests for early detection^[7,8].

Depression is a common symptom that can be experienced, but it can be exposed to a variety of risks if it becomes severe. Specifically, severe depression can impair psycho-social functioning^[9] and cause 7.8 times greater risk of suicidal thoughts than non-depressants^[10].

According to^[11], the ratio of the disabled to experience depression was 24.5 percent, about twice as high as the 10.3 percent of the non-disabled.

Differences in depression can be described as inequality due to socioeconomic perspectives other than biological ones, which are also applicable to differences in the experience of depression for the disabled and non-disabled^[12]. The socioeconomic view is that the social and economic status of an individual, such as the level of education, income level, and professional status, creates differences between individuals^[13].

When thinking about policies for the disabled, pay attention first the target is aging disabled people who have lived with disabilities for a long time. Priority is given to developing policy support measures to address the aging issues of people with developmental disabilities, including intellectual and autistic persons, who are using the welfare facilities for the disabled. Expansion of available service facilities is required^[14].

The elderly population need social attention to experience the double risk of disability and aging. As older people age, their health risks increase. Older people with disabilities are more likely to experience premature aging than non-disabled people^[15]. In other words, people with disabilities experience changes due to aging in addition to previous disorders, which lead to health risks.

The main thing is that these health risks are not natural and can be prevented and managed. In terms of their rights, they should seek social alternatives to recognize and support the healthy retirement of disabled seniors.

The guarantee of the right to health of the elderly must include not only physical but also mental health. Compared to the discussion of the physical health of the elderly, the interest in mental health is limited.

In particular, depression of the elderly is a very important problem that threatens the quality of life.

Older people with disabilities are two to three times more likely to experience depression than non-disabled older people^[16]. The prevalence of depression in older people is associated with a variety of factors including age, health, function, and social role^[17].

People with disabilities are more vulnerable to depression because they receive more social discrimination and exclusion than non-disabled people. In addition, people with disabilities have a negative perspective on themselves by internalizing social exclusion, non-acceptance, and prejudice. It is very likely that these points will soon appear depressed^[18].

This research aims to provide basic data to related social welfare systems and practice areas by examining factors affecting depression as one of the factors that can lower the depression of the disabled and increase the satisfaction of life.

The study on the effect on depression, which is a major threat to the healthy lives of people with disabilities, can contribute to the implementation of specific projects, such as the creation of policy alternatives that can enhance the life satisfaction of people with disabilities, as well as programs implemented by institutions for the disabled.

Method

This research analyzed the data of 2017 which is the 12th data of the Korea Welfare Panel conducted by the Korea Institute for Health and Social Affairs. of 6581 households which include 12,790 persons, only 1,459 persons who are disabled were selected as subjects of this analysis.

In order to identify the factors affecting the depression of the disabled, this research analyzed the difference of depression according to gender, education level, age, household income, and working ability as demographic factors. In addition, the factors affecting depression due to health satisfaction, residential satisfaction, family life satisfaction and social support were surveyed through the regression analysis of the SPSS statistics program.

Result and Discussion

- 1. Depression differences by demographic variables:** Shown in [Table 1], gender was 784 males, slightly more than 675 females. The educational level was

the highest with 511 graduates (35%). The highest age group was in the 70s with 477 persons (32.7%). The highest household income was 478 people (32.8%) with less than 15 million won per year. 782 (53.6%) of the respondents answered that they were able to work, and 222 (15.2%) answered that only simple work was possible. There were 333 (22.8%) simple workers who could only do household work, and 103 (7.1%) responded that they had no working ability at all. The statistics for each section showed only significant differences in the work ability factors.

As a result of demographic variables of the research subject, the factors affecting depression of the disabled was the variable of work ability and degree. In the case of work ability or simple work ability, the degree of depression turned out to be significantly lower than weak simple work or no work ability. In the end, it can be seen that the ability and degree of work ability in the case of the disabled have a great influence on the depression.

Table 1. Depression differences by demographic variables

Variable	Division	N	%	M	t/F
Sex	Male	784	53.7	21.13	-.22
	Female	675	46.3	20.89	
Education level	Not attending school	3	.2	-	1.70
	unschooled	230	15.8	23.83

*p<.05 **p<.01 ***p<.001

2. General characteristics of the variables: [Table 2] shows the general characteristics of the main factors such as health satisfaction, housing environment satisfaction, family relationship satisfaction, social support, and depression. The average of health satisfaction was 3.32 for the disabled and 2.57 for the disabled, which was significantly higher in the non-disabled. The satisfaction level of living environment was 3.62 for the disabled and 3.54 for the disabled. The satisfaction level of family

relations was higher for the non-disabled people with 3.90 and 3.71 for the disabled, and the social support was 3.74 and 3.49 for the disabled. Depression was 25.75 for the disabled and 30.25 for the disabled.

The high scores of people with disabilities on depression indicate that access to mental health is essential in the areas of disability support, which suggests that life cycle management should be carried out through all subjects regardless of their socio-demographic variables.

Table 2. General characteristics comparison

Variable	Non-disabled		Disabled		t
	M	SD	M	SD	
Health satisfaction	3.32	.94	2.57	.94	26.33***
Housing environment satisfaction	3.62	.74	3.54	.74	3.67***
Family relationship satisfaction	3.90	.64	3.71	.70	9.05***
Social support	3.74	.62	3.49	.73	11.55***
Depression	25.75	8.11	30.25	10.49	-14.34***

*p<.05 **p<.01 ***p<.001

3. Factors Affecting Depression of the Disabled:

The result of a hierarchical regression analysis through demographic variables, satisfaction, and social support variable, is as shown in [Table 3].

First, in the area of demographic variables, male more than female ($\beta=.01, p<.01$), the lower is household income ($\beta=-.20, p<.001$) and the higher is one's work ability ($\beta=.30, p<.001$), depression turned out to be high ($F=50.03***$). Next, when the factors were analyzed adding satisfaction and social support to demographic variables, the result of analysis showed significant results in all variables excluding all ages and education level ($F=63.62***$).

When all variables are included, male more than female ($\beta=.02, p<.001$), the lower is one's household income ($\beta=-.09, p<.01$), the more one has work ability ($\beta=.19, p<.001$), depression was high, and the lower is one's health satisfaction ($\beta=-.26, p<.001$), residential satisfaction ($\beta=-.07, p<.01$), family life satisfaction ($\beta=-.20, p<.001$), and social support ($\beta=-.10, p<.001$), depression turned out to be low, suggesting that individual, family, and social resource environment are important explanatory factors in the perception of depression for the disabled.

Table 3: Factors Affecting Depression of the Disabled

Variable	Model 1		Model 2	
	B	β	B	β
Sex (F=0)	0.00	0.01**	0.01	0.02***

*. p<.05 **p<.01 ***p<.001

Conclusion

The results of this research showed that, in addition to demographic variables, health satisfaction, residential satisfaction, family life satisfaction, and social support variable have a great influence on the depression of the disabled. From this, it is clear that, as a method to reduce depression of the disabled, a comprehensive and environmental approach is necessary which encompasses familial, psychological, and social dimensions. In particular, when investigating the depression of the disabled, it should be interpreted and constituted in consideration of the prior environmental differences due to social discrimination and exclusion, not just the comparison with the figures with the non-disabled.

Future research to apply and understand the environment of persons with disabilities suggests the use of qualitative research method. Rather than merely conducting a case study, a research method that understands, applies and interprets the environment and culture in which people with disabilities live, and creates alternatives would be desirable.

Abstract

Background/Objectives: The purpose is to find out utilization and necessity of public support related to the physical and mental health experienced by the middle-aged and elderly people.

Method/Statistical Analysis: In distribution of 28 cities and 3 Guns of Gyeonggi-Do, 8,653 subjects are middle-aged people between 50 to 64 years old, and 6,547 subjects are the group under 49 years old and 11,953 subjects are the group over 65 years old. This study examined the differences in physical and mental health characteristics of the middle-aged and comparative groups through χ^2 validation and one-way ANOVA analysis by SPSS 21.0 program.

Findings: The middle-aged showed relatively low level of difficulty than the group over 65 years old in all areas of physical health problems, physical health care difficulty, mental health problems, and mental health care difficulty. However, it showed a significantly higher level of difficulty than the group under 49 years old. The 6,731 people (77.8%) had no intention of using the social services provided to alleviate physical health problems, and 266 people (3.1%) are currently using related services. Among those who are willing to use the service, 1,135 people (13.1%) did not know the related service, the next highest rate, and 377 (4.4%) who knew the service but did not apply, 114 people (1.3%) applied for the application but could not use it. In the analysis of social service use to alleviate the difficulties of mental health, 7,165 (82.8%) of the middle-aged group had no intention of using it.

Improvements/Applications: The results showed that the physical and mental difficulties experienced by the elderly and the level of difficulty were lower than normal, but higher than those under the age of 49.

Keywords: Physical Health, Mental Health, Middle-aged people, Old age, Family Social Work Service.

Introduction

In Korea, middle-aged people face various social problems such as job insecurity, poverty, child rearing, housing, and preparation for retirement^[1], and the number of suicides is increasing in the 30s to 50s^[2], but related research is very insufficient^[3]. The middle

age group is the age group that is the foundation of our society^[4]. Therefore, their health and well-being can be a subject of social policy importance.

Recent longitudinal studies show that older age health, dependence, and quality of life are significantly affected by middle-aged lifestyles^[5-6]. In the West, men and women were sampled together to explore gender differences and factors of mental health and lifestyle^[7-8]. It was centered on women. In the early stages, studies were divided according to traditional stereotypes based on gender roles as well as gender separation^[9-10]. This study was initiated to identify the level of physical and mental health experienced by middle-aged people and to propose basic support measures based on it. This

will help prepare for happy old age as well as the corresponding middle-aged, and could contribute to providing basic data in Korea’s insufficient middle-aged mental health sector.

Method

This study well reflects the characteristics related to physical and mental health of middle-aged and elderly in Gyeonggi-Do reflecting the population and its distribution of 28 cities and 3 Guns of Gyeonggi-Do. Among 27,153 subjects, 8,653 subjects are middle-aged people between 50 to 64 years old, and 6,547 subjects are the group under 49 years old and 11,953 subjects are the group over 65 years old. In order to examine the physical and mental health status and related characteristics of the middle aged and elderly, we investigated situations such as degree in physical and mental functions and difficulties in physical and mental health related to daily life, difficulty in in the choice of hospital or clinic, lack of health care support system, the need for support, the need for support for physical and mental health care, and the use of social security for physical and mental health support. For each item, physical and mental questions were classified into the difficulty of health problems, the difficulty of health care, the necessity of health care, and the use of health insurance.

This study examined the physical and mental health characteristics of the middle-aged and comparative groups, and conducted a technical analysis to identify the actual use and needs of related services. In addition, this study examined the differences in physical and mental health characteristics of the middle-aged and comparative groups through X^2 validation and one-way ANOVA analysis. SPSS 21.0 was used for statistical analysis of the study data.

Result

Participants’ Characteristics: As for the general characteristics of the research subjects, the middle-aged people between 50 to 64 years old showed a low level of male, 3,514 persons (40.6%) compared with female, 5,139 persons (59.4%) in [Table 1]. In the case of education, 6,260 (72.3%) were middle or high school graduates, and 1,914 (22.1%) were higher than college graduates and 476 persons (5.5%) were lower than elementary school graduates.

In the general characteristics of the subjects, the proportion of women was relatively higher than that of

group under 49 years old and the group over 65 years old. In the case of education, the level of education was higher than that of group over 65 years old with 6,398 (53.5%) elementary school graduates or lower but lower than the group under 49 years old with 4,445 (67.9%) college graduates or higher.

Table 1: Participants’ Characteristics

Comparison of Physical and Mental Health by Generation: [Table 2] shows the characteristics of the middle-aged and comparative groups through physical and mental health characteristics experienced by age group.

In the middle aged, the average level of physical difficulty was 1.85($SD=1.356$), which was lower than usual considering the response category. The comparison group was 49 years old and under, with an average of 1.46($SD=1.054$) and a group of 65 and older with an average of 2.35($SD=1.563$). The number of physical health management difficulties was 1.69($SD=1.241$) for middle-aged group, 1.40($SD=.962$) for those under 49 years old, and 2.04($SD=1.453$) for those over 65 years old. The level of difficulty in mental health was 1.62($SD=1.164$) in the middle-aged group, 1.39($SD=.954$) in the under 49 group,

and 1.88(*SD*=1.301) in the 65-year-old group. In the difficulty of mental health management, the middle-aged group had an average of 1.52(*SD*=1.060), the under 49 group had 1.34(*SD*=.861), and the over 65 group had an average of 1.70(*SD*=1.198).

The middle-aged showed relatively low level of difficulty than the group over 65 years old in all areas of physical health problems, physical health care difficulty, mental health problems, and mental health care difficulty. However, it showed a significantly higher level of difficulty than the group under 49 years old.

Table 2: Comparison of physical and mental health by generation

Current Usage Status of Social Services for Physical and Mental Health: In order to alleviate the physical and mental health difficulties experienced by the elderly, the use of socially provided services was checked in [Tables 3 and 4]. First of all, 6,731 people (77.8%) had no intention of using the social services provided to alleviate physical health problems, and 266 people (3.1%) are currently using related services

Among those who are willing to use the service, 1,135 people (13.1%) did not know the related service,

the next highest rate, and 377(4.4%) who knew the service but did not apply, 114 people (1.3%) applied for the application but could not use it. The highest rate was found to be unwilling to use in all groups, including the elderly. However, the older group showed higher intention to use the service to management their physical and mental healthcare. And also there is a high intention to use but do not know the service. The distribution of social service usage to alleviate physical health difficulties by age group showed a statistically significant difference ($F = 948.961, p < .001$)

Table 3: Current Usage Status of Social Security Services for Physical Health by generation

Variable	≤ 49		50-64		≥ 65		F
	N	%	N	%	N	%	
No Intention to Use	5,636	86.10	6,731	77.80	7,949	66.50	948.961***

***: p<.001

In the analysis of social service use to alleviate the difficulties of mental health, 7,165(82.8%) of the middle-aged group had no intention of using it. In addition, 107 people(1.2%) were using related services, which was lower than physical health related services.

Even though they were willing to use mental health-related services, 1,091(12.6%) of them did not know the service, and 225(2.6%) of them knew the service but did not apply for it. The middle-aged group showed a lower rate than the 65-year-old or older group, but compared to

the 49-year-old or younger group, they were willing to use the service but did not know the service. There were statistically significant differences in the distribution of

social service usage by age group to alleviate mental health difficulties ($F = 282.746, p < .001$).

Table 4: Current Usage Status of Social Security Services for Mental Health by generation

Need for Support of Physical and Mental Health by Generation: The results of analyzing the need for physical and mental health support and physical and mental health support are presented in [Table 5]. For the elderly, 1,594(18.4%) were aware of the need for physical health support, and 1,225(14.2%) indicated the need for

mental health support. In other words, the elderly had a higher recognition of the need for physical health rather than mental health. 1,422 respondents(16.4%) said they needed physical health care support, compared with 1,123 respondents (13.0%).

Table 5: Comparison of Need for Support of Physical and Mental Health by Generation

Variable	≤ 49		50-64		≥ 65		X ²
	Yes	No	Yes	No	Yes	No	
Support for Physical health problem	729 (11.1)	5,818 (88.9)	1,594 (18.4)	7,059 (81.6)	3,413 (28.6)	8,540 (71.4)	825.976***
Support for Physical health care	665 (10.2)	5,882 (89.8)	1,422 (16.4)	7,231 (83.6)	2,932 (24.5)	9,021 (75.5)	615.331***
Support for Mental health problem	614 (9.4)	5,933 (90.6)	1,225 (14.2)	7,428 (85.8)	2,249 (18.8)	9,704 (81.2)	302.587***
Support for Mental health care	577 (8.8)	5,970 (91.2)	1,123 (13.0)	7,530 (87.0)	2,003 (16.8)	9,950 (83.2)	231.349***

***: $p < .001$

In addition, this study examined the differences in perceptions among middle-aged and other age groups regarding physical and mental health care support. The results of the analysis showed that the elderly have physical health support ($X^2=825.976, p < .001$), mental health support ($X^2=302.587, p < .001$), physical health

care support ($X^2=615.331, p < .001$), and mental health care. All elements of support ($X^2 = 231.349, p < .001$) were found to recognize the need compared to those under 49 years of age. However, they were perceived to be lower than those aged 65 or older.

Conclusion

The purpose of this study was to investigate the physical and mental difficulties of middle-aged people, their current use of social services, and their desire for services. In addition, the purpose of this study was to compare the current status of middle-aged group by each element with those under 49 years of age and those over 65 years of age, and to explore the characteristics of the physical and mental health of the elderly and future development directions.

The results showed that the physical and mental difficulties experienced by the elderly and the level of difficulty they experienced were lower than normal, but higher than those under the age of 49. This will make it very difficult in the future to be equal to the group aged 65 and over. However, the intention to use related services was still low. In addition, there were many cases where they did not know about the related services or even applied. In terms of service usage, the level of awareness of the service was lower than the age group of 49 and younger. Also, the elderly thought that the support for physical and mental health was very much needed compared to the group under 49 years old. Based on the research results, in order to alleviate the physical and mental difficulties of the elderly and to support the health care, an objective plan for the health verification of the elderly is needed. The physical and mental levels of the elderly identified through this study are the subjective opinions of the subjects, and there is no objective confirmation of the physical and mental health status.

In middle-aged and older age, physical and mental problems are often caused by deterioration of physical function, burden of social activities and relationship difficulties. For these middle-aged people, an objective judgment must first be made about their health level, and policies should be in place for health insurance, preventive services, and diagnosis through local agencies.

Secondly, middle-aged group often did not know or could not apply for the service even though they were willing to use it. In order to overcome the current situation, it is necessary to strengthen public relations at various levels of services and related institutions to support the physical and mental health of the elderly. In addition, it is necessary to find ways to increase the ease of application and access to services.

While older adults feel less physical and mental health difficulties than older people, but prevention is very important because they will be increasingly more intense as they aged. Especially that is important because the sooner they encounter social services, the faster they can adapt.

Skin Care Behaviors for Wellaging in Male Adults

Jae-Young Park¹, Myung-Sun Lee²

¹Ph.D. Student, Department of Beauty & Health Care, Graduate School Daejeon University,

²Professor, Department of Beauty & Health Care, Daejeon University, Daejeon, Korea

Abstract

Background/Objectives: The purpose of this study was to examine the skin care behaviors of male adults for wellaging in an effort to improve their quality of life through various skin care behaviors in pursuit of healthy life and to seek ways of vitalizing the beauty industry for men from diverse angles.

Method/Statistical Analysis: The collected data were analyzed by SPSS(statistical package for the social science) 23.0 version for Windows. To find out the adult men's degree of skin and beauty care for wellaging, χ^2 (chi-square) test, frequency analysis, one-way ANOVA and t-test were carried out.

Findings: The largest number of the men possessed oily skin. As a result of analyzing their skin care for wellaging, many didn't apply face packs for wellaging, and the men who were unmarried and who spent average 200 thousand won or more on appearance management on a monthly basis applied face packs more often for wellaging than the other men. The men who were in their 30s, who were unmarried and whose monthly mean appearance management spending was larger massaged their faces or got massages more frequently for wellaging than the others. Although men are said to be interested as well in skin beauty along with social development, the findings of the study show that they weren't yet exposed a lot to skin care, and how to make skin care more accessible to them should be considered.

Improvements/Applications: This study investigated the beauty care behaviors of the selected men for wellaging and is expected to be utilized as basic data on the vitalization of the beauty industry and the beauty market for men.

Keywords: *Adult male, Well-aging, Beauty Care, Skin Care, Well-being.*

Introduction

In the midst of "wellbeing" cultural trend geared toward healthy life and of material affluence, modern people have mounting interest in the skin for the growing pathological reasons of skin lesions caused by all sorts of stress and for psychosocial reasons as they want to display their healthy beauty with confidence in the era characterized by self-expression, and the need

for systematic ways of skin care is accentuated^[1]. In addition, it is a time where people invest in themselves both inside and out to grow old in a healthy, natural and beautiful manner, and wellaging is gradually being entrenched as a major cultural trend in society.

"Wellbeing" refers to accepting aging as a natural phenomenon and taking good care of the body and the mind in hopes of advancing in age in a beautiful and healthy way^[2]. Now, not only women but also men are interested a lot in both of wellbeing and wellaging, which are respectively to eat and live well for a better quality of life and to grow old wisely and healthily.

Skin conditions may depend on internal factors such as physical health, nutrition, life style, the release of hormones and internal organs, and on external factors

Myung-Sun Lee

Professor, Department of Beauty & Health Care,
Daejeon University, Daejeon, Korea
e-mail: leesun1460@hanmail.net

as well like season, climate, environments and incorrect skin care^[3]. Various things can be cited as the causes for men’s skin damages.

First, the stratum corneum of the shave zone where there appear moustache and beard is removed more than needed by repetitive daily shaving^[4], and skin damages and external stimuli trigger skin troubles, which might make people vulnerable to skin diseases such as dermatitis and folliculitis. So correct shaving, hydration and skin soothing are all necessary^[5]. Second, there are frequent chances of drinking in social activities like gatherings and staff dinners. After drinking, moisture is evaporated from the body and skin for the purpose of alcoholysis, which results in making the skin bad and dry, and skin dryness sometimes leads to the phenomenon of skin keratinization^[5]. At the time of alcoholysis, acetaldehyde is generated, which is a component that has strong medical reaction and is highly responsive, and it expedites angiectasia, which brings about temporary changes like getting red in the face and getting hot and is eventually followed by skin dryness ^[4].

Third, smoking also results in skin damages. Reactive oxygen that is generated by smoking destroys cells and causes protein oxidation by reacting with protein, and the amount of betacarotin that plays the role of neutralizing reactive oxygen in the body is diminished, which contributes to accelerating skin aging^[4].

The purpose of this study was to examine beauty care behaviors that men of different age groups showed for their present and future skin and wellaging, as beauty care makes it possible for them to build confidence by taking care of their appearance in modern society that pursues healthy life. This study was intended to afford information that is about the shifts of the beauty industry and could be useful for the vitalization of the skin care industry and men’s beauty care.

Method

The Subjects and Data Collection: A self-administered survey was conducted on the adult men in North Gyeongsang Province from October 8 through November 10, 2018, after the purpose of this study was explained. Out of the collected 250 questionnaires, 243 answer sheets were analyzed as the final data.

Measurement Items: The questionnaire method was used to gather the data, and the questionnaire items that were used as the measuring instrument largely dealt

with general characteristics and skin care behaviors for wellaging. They were prepared by modifying an inventory used in an earlier study(Jung, 2013)^[6].

The Instrument: The reliability of the instrument was tested. As shown in Table 1, the Cronbach alpha coefficient of it was 0.93 in terms of beauty care for wellaging, which was a reliable level.

Table 1. Survey reliability

Classification	Number of questions	Cronbach’s a
beauty care for wellaging	15	0.93

Data Analysis: The collected data were analyzed by SPSS(statistical package for the social science) 23.0 version for Windows. To find out the skin care behaviors of the male adults for wellaging, χ^2 (chi-square) test, frequency analysis, one-way ANOVA and t-test were carried out.

Result and Discussion

The General characteristics of the subjects: As for occupation, office job and profession were most common with 27.6 percent, followed by production/technical post with 26.7, sales/service job/self-employment with 24.3, students with 12.8 and others with 8.6 percent.

By monthly mean spending on appearance management, less than 100 thousand won was most dominant with 69.5 percent, followed by 100 to less than 200 thousand won with 13.2, 200 to less than 300 thousand won with 9.1, and 300 thousand won or more with 8.2 percent.

The Skin Care of the Male Adults for Wellaging

Skin Type: The men whose skin type was oily made up the largest group with 27.2 percent, followed by dry skin with 24.7, combination skin with 23.5, sensitive skin with 11.9, normal skin with 9.9 and aged skin with 2.9 percent.

By age, oily and combination types were more dominant in the men in their 30s than the other age groups, and dry skin was more common in the men in their 50s than the other age groups. Normal skin was more common in the older men ($\chi^2=38.55$, $p<.01$). Kim(2011)’s study found that 42.44 percent suffered from skin troubles related to skin dryness and sebum, and Song(2015)’s study found that the use of functional products increased in the men in their 30s and over, and

that the subjects used products for combination skin and hoped to use these products when they were asked what they hoped to use among products tailored to specific skin types. This study also found that oily skin and combination skin were common in the men who were in their 30s.

Thus, the men whose skin type was oily made up the greatest group, and oily skin was more common in the men who were in their 30s, who were production and technical workers and who were married than in the other men.

The Skin Care of the Male Adults for Wellaging:

Wellaging by Massage: How often the adult men massaged themselves or got massages was analyzed.

As shown in Table 3, the men who didn't do that for wellaging represented 77.4 percent that was the majority, and the second biggest frequency was once or more per two weeks with 10.3, once a week with 7.4 and twice or more a week with 4.9 percent. Heo(2013)'s study found that the rate of using skin care clinics and that of not using them respectively stood at 10.3 and 89.7 percent. Thus, most of them didn't use skin care clinics, and it corresponded with the finding of this study that more men didn't do that.

Thus, the majority of the men didn't massage themselves or got massages for wellaging, and the men who were in their 30s, who were unmarried and whose monthly mean appearance management spending was larger did that more frequently for wellaging.

Conclusion

In this study, a survey was conducted on the male adults in North Gyeongsang Province to find out their skin care behaviors for wellaging, and 243 collected questionnaires were analyzed as the final data.

The men who were interested in appearance due to interpersonal relationships that social activities entail were analyzed in relation to wellaging which is a social trend to manage oneself inside and out to lead a healthy life. The findings of the study were as follows:

As for the skin type of the adult men, many that accounted for 27.2 percent were in possession of oily skin, and the second most common type was oily, followed by combination, sensitive, normal and aged types. By age, oily and combination types were common in the men who were in their 30s, and dry skin was dominant in the men who were in their 50s. Normal skin was common in the older men ($\chi^2=38.55$, $p<.01$). By occupation, combination type was dominant in the men who engaged in office work and professions, and dry skin was common in the men who were students. Oily skin was common in the men who were in production and

technical posts ($\chi^2=42.92$, $p<.01$). Oily and combination types were dominant in the unmarried men, and oily, sensitive and normal types were dominant in the married ones ($\chi^2=13.45$, $p<.05$).

The men who didn't massage themselves or got massages for wellaging accounted for 77.4 percent that was the majority, and the second most common frequency was once or more per two weeks, once a week and twice or more a week.

By age, the men in their 20s did that once or more per two weeks for wellaging, compared to the other men, and the older men didn't do that ($\chi^2=26.59$, $p<.01$). The unmarried men did that twice or more a week for wellaging, compared to the married ones, and the married men didn't do that, compared to the unmarried ones ($\chi^2=10.81$, $p<.05$). By monthly mean appearance management spending, the men who spent a lot on appearance management did that twice or more a week for wellaging, and the men who spent a small sum of money didn't do that ($\chi^2=19.19$, $p<.01$).

Since the men from a limited region were investigated in this study, the findings might not be

generalizable, and it's needed to examine more regions and more people of diverse age groups. In the future, a follow-up study should be implemented to make up for the limitations of the study.

Relationship between Body Image, Growth Mindset, Grit, and Successful Aging in Korean Elderly: Moderated Mediation Effect of Hope

Yeoun Kyoung Hwang¹, Chang Seek Lee²

¹Professor for Academic Research, Multicultural Education and Welfare Institute, Hanseo University, 31962, Korea, ²Professor, Dept. of Health, Counseling and Welfare, Hanseo University, 31962, Korea

Abstract

Background/Objectives: This study examines the moderated mediation effect of hope on the relationship between body image, growth mindset, grit, and successful aging in 422 elderly people in Korea.

Method/Statistical Analysis: Descriptive statistics analysis, reliability analysis, correlation analysis, and moderated mediation effect analysis were done using SPSS Win.25.0 and PROCESS macro version 3.4.

Findings: First, there was a statistically significant positive correlation between body image, growth mindset, hope, grit, and successful aging. Second, hope moderated the mediating effect of growth mindset and grit in the relationship between body image and successful aging.

Improvements/Applications: This result shows that the body image of the elderly in Korean society influences successful aging through growth mindset and grit. It will be a way to increase successful aging.

Keywords: Elder, Body image, Growth mindset, Grit, Hope, Successful aging, Moderated Mediation, PROCESS macro. Forward head posture, Dynamic neuromuscular stabilization exercises, McKenzie exercise, Neck stabilization exercise, Spinal structure.

Introduction

Aging is an indispensable phenomenon that no human being can avoid. Recently, research on “successful aging” has been actively conducted because of the efforts of scholars to escape from the negative view of aging. Successful aging refers to the process of continual growth and maturity in the second half of life, focusing on “well-growing”^[1]. In other words, the weakening of human function and health is usual in aging. Successful aging is a more positive concept than is “usual aging”^[2].

Social and psychological variables are closely related to successful aging. Studies have shown that they are more associated with successful aging than are demographic, physical health, or cognitive function variables^[3]. Therefore it is worth noting the relationship between social and psychological variables and successful aging. Among psychological factors, hope, grit, and growth mindset are in the spotlight.

Hope is the driving force of life, and people with high hopes maintain a challenging and positive psychological state by focusing on success rather than failure^[4]. The hope of the elderly decreases negative sentiment^[5], finds more alternatives when faced with difficulties^[6], and constructively believes that this will work well. Thinking^[7]. Grit is also known as a predictor of success^[8]. Grit in older people also contributes to successful aging^[9]. Finally, the growth mindset is the belief that human intelligence (IQ) can change with learning and effort^[10], which is also very closely related

e-mail: lee1246@hanmail.net

to success. In this context, cognitive and physical function deteriorates with age, but it is predicted that successful aging will differ according to one's psychological state.

Another variable to consider in relation to successful aging is body image, which is a feeling and attitude related to the subjective evaluation of one's body and includes all emotional, evaluative, and behavioral aspects^[11]. Appearance is an important part of the reason for shrinking in the elderly, and older people are aware of the importance of appearance, and more active management is, the more can negative emotions, such as depression or atrophy from aging, be alleviated and the vitality of life can be improved^[12]. There is a direct study that body image affects successful aging^[13], but the number is very low, which points to the need for research. The results of studies related to external image, appearance management, and appearance satisfaction, which are used as a concept similar to body image, show that external image is a major determinant of psychological and social health, and negative external image also affects emotional health^[14]. In addition, life satisfaction, self-esteem, and happiness of those who had good appearance management and appearance

satisfaction was higher than that of those who did not^[15,16].

Existing studies can be found on the relationship between body image, grit, growth mindset, hope, and successful aging, but most of them are limited to individually identifying the relationship between variables or similar concepts. Therefore, empirical research is needed to comprehensively verify the relationship between variables in one model and, in particular, to investigate when and how each variable manifests.

Therefore, this study aimed to provide a new model for successful aging of the elderly by verifying the moderated mediation effect of hope in the relationship among body image, growth mindset, grit, and successful aging in Korean elderly people.

Research Method

Research Model: The main analysis method of this study is the moderated mediation effect analysis of model 91 of PROCESS macro ver.3.4. The concept of the research model is shown in [Figure 1].

Figure 1. Conceptual Research Model

Survey subject and data collection method: The subjects of the survey were 422 elderly people in D and S city in Chungcheongnam-do, selected by taking into consideration the convenience of the survey. The subjects were 38.8% men and 61.2% women; and 31.3% were between 66 and 70, 27.5% between 71 to 75, and 17.3% for ages under 65. Of them, 52.5% resided in

small and medium cities (cities and counties), 32.9% in rural areas (eup and myeong), and 14.6% in metropolitan cities (metropolitan cities).

Research Tools:

Body Image: We used the body-image scale developed by Cash^[17] and used by Cho and Go^[18], and

Lee^[19]. The 19 items were adjusted to fit the subjects and measured. The reliability by Cronbach’s α was .832.

Growth Mindset: We used the growth-mindset scale developed by Dweck^[20] and translated by Lee et al.^[21]. It consists of 8 items and includes beliefs about changes in intelligence and personality. In this study, the growth mindset’s reliability, Cronbach’s α , was .613.

Successful Aging: The successful-aging questions, produced by Lee^[22] based on Paek and Choi’s^[23], were used. It consists of 17 items and includes such subareas as healthy and smooth family relationships, stable living and use of remaining capacity, and purposeful living. The reliability of successful aging in this study was a Cronbach’s α of .957.

Hope: We used the Korean version of the Hope Scale (K-DHS), which was developed by Snyder et al.^[24], revised and validated by Choi et al.^[25]. It consisted of four agency-thinking items that measured whether a goal was set and four pathways-thinking items that measured how to reach the goal. In this study, Cronbach’s α was .892.

Grit: We used the grit scale developed by Duckworth and Quinn^[26]. It consists of 8 items and includes two subareas of passionate attention and persistence. The grit reliability in this study was .699.

Data Analysis: SPSS Win. 25.0 was used for descriptive statistics analysis, reliability analysis, and average comparison analysis. The moderated mediation effect was analyzed using SPSS PROCESS macro 3.4. To verify this, a bootstrap method was applied.

Results and Discussion

Correlation and descriptive statistics: Pearson’s correlation analysis showed a statistically significant positive correlations between the main variables. The results are shown in [Table 1]. The correlation coefficient between growth mindset and grit was the highest at .455, and the correlation coefficient between the successful aging and body image was the lowest at .189.

This is supported by the claim that demographic and physical health and cognitive function variables are associated with successful aging, but that psychological variables are more related to successful aging^[3].

Table 1. Correlation and Descriptive Statistics

	Body image	Successful aging	Growth mindset	Grit	Hope
Body Image	1				
Successful Aging	.189**	1			
Growth Mindset	.207**	.247**	1		
Grit	.205**	.235**	.455**	1

M	3.27	4.20	3.34	3.54	3.42
SD	0.45	0.63	0.49	0.49	0.60

** $p < .01$

Model Verification:

Verification of multiple mediating effects: To verify the moderated mediation effects of hope in the relationships between body image, growth mindset, grit, and successful aging of Korean elderly, we analyzed model number 91 of the PROCESS macro for SPSS. The values of the hope and growth mindset variables were centered before the analysis. The analysis results are shown in [Figure 2], [Table 2].

First, in the mediation model, the body image had a significant positive effect on the growth mindset (.2269, $p < .001$) and the growth mindset had a significant positive effect on the grit (.3551, $p < .001$). Hope also had a significant positive effect on the grit (.1696, $p < .001$), and the interaction term of the growth mindset and hope had a significant effect on the grit (.1704, $p < .01$).

The conditional effect of the hope variable, which is a moderating variable, is significant if hope is lower than average, average, or higher than average, the interaction term between growth mindset and hope was found to

affect grit. The Johnson-Neyman method, which is a floodlight method, was used to identify in which area the conditional effect according to the moderating variable value was significant. Identifying the significance area of the conditional effect of the interaction between growth mindset and hope according to the hope value showed that hope moderated the relationship between growth mindset and grit in the region where the hope value was greater than -1.1098. The proportion of this effect was significant at 96.6% with a hope value of over -1.1098. Second, in the model in which successful aging was the dependent variable, body image had a significant positive effect on successful aging (.1806, $p < .01$), growth mindset also had a positive influence on successful aging (.2030, $p < .01$), and grit had a significant positive effect on successful aging (.1778, $p < .01$).

Third, when investigating the conditional and unconditional indirect effects on the relationship between body image and successful aging, the path from body image to successful aging through growth mindset

(.0461, .0127 ~ .1085) is significant, because there was no 0 at the 95.0% confidence interval. However, the path from body image to successful aging via grit (.0107, -.0090 ~ .0338) was not significant, because there was 0 at the 95.0% confidence interval.

The conditional indirect effect (body image → growth mindset → grit → successful aging) in the relationship between body image and successful aging is significant at all three conditional values of hope. Thus, the moderated mediation effect of hope on the mediation effect of growth mindset and grit in the relationship between body image and the successful aging was verified.

Although it is meaningful to analyze the results by each path, this study is intended to empirically grasp the role and relationship of variables in social phenomena. Therefore, it may be desirable to discuss all the results of the study, which show that the hope of the elderly reduces negative emotions^[5] and does agency thinking with the belief that this will work^[7]. It is in sync with studies that the grit of the elderly contributes to successful aging^[9].

Conclusion

This study was conducted to verify the moderated mediation effect of hope in the relationship between body image, growth mindset, grit, and successful aging in Korean elderly people.

First, Pearson correlation analysis showed a statistically significant positive correlation between body image, growth mindset, hope, grit, and successful aging.

Second, analyzing the moderated mediation effects showed that hope moderated the relationship between

growth mindset and grit in the relationship between body image and successful aging. In other words, hope moderated the mediating effects of growth mindset and grit in the relationship between body image and successful aging.

Suggestions for follow-up studies are as follows.

First, although scholars' interest in growth mindsets, grit, and hope is growing, studies on the role of these variables are still inadequate. In particular, it is necessary to identify the various roles of these variables in various subjects.

Second, this study revealed that growth mindset, grit, and hope are mediators in the relationship between body image and successful aging in the elderly. This is remarkable, in that it verified the effective variables for the successful aging of the elderly in Korean society, where the population of the elderly is increasing at the fastest speed in the world. This should be followed by the development and application of programs to promote the growth mindset, grit, and hope of the elderly.

Effects of Various Deadlifts on the Muscle Activity of the Trunk and Lower Extremity

Byoung-Hyoun Moon¹, Young-Jin Lim¹, Ji-Won Kim²

¹Graduate Degree, ²Professor, Dept. of Physical Therapy,
Nambu University 23 Cheomdan Jungang-ro, KS008, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to identify changes in the muscle activity of the trunk and lower extremity during deadlift with various equipments (Kettlebell, Barbell, and Trap bar).

Method/Statistical Analysis: 29 people were selected to measure the muscle activity of the elector spinae, gluteus maximus, rectus femoris and rectus abdominis. One-way ANOVA with repeated measurements was conducted to determine the difference in muscle activity in various deadlift. The Bonferroni correction was used as a post-test to check the difference in muscle activity between the various interventions, and the significance level was set to 0.05. Statistical programs used SPSS Version 22.0 (Statistics Package for the Social Science).

Findings: There were significant differences in elector spinae, gluteus maximus, and rectus during the various deadlift. The rectus femoris showed higher muscle activity in trapbar deadlift than barbell deadlift and kettlebell deadlift. The elector spinae showed higher muscle activity barbell deadlift than kettlebell deadlift. The gluteus maximus showed higher muscle activity in barbell deadlift and kettlebell deadlift than deadlift.

Improvements/Applications: This study suggests that muscle activity vary depending on the barbell during deadlift.

Keywords: Barbell deadlift, Elector spinae, Gluteus maximus, Kettlebell deadlift, Trapbar deadlift.

Introduction

In modern society, due to the development of scientific civilization, many people use computer for a long time [1], and according to the National Health and Nutrition Survey, there are fewer people practicing moderate or higher physical activity [2]. Decreased physical activity may be a factor that causes musculoskeletal disorders such as back pain, osteoporosis, and osteoarthritis [3].

Therefore, it is necessary to exercise for the purpose of preventing muscle degradation and preventing musculoskeletal disorders, and a lot of weight training is selected as such means [4].

Weight training is a resistance exercise that uses barbells and dumbbells in general, and is an effective and stable exercise that can improve muscle strength and endurance by properly activating the body muscles [5]. In addition, it is effective in reducing body fat, which helps prevent disease and improve obesity, and improves motor control by improving muscle coordination and balance [4,6].

The most popular sports among weight training are squat, lunge and deadlift [7]. Deadlift is an exercise that lifts weights on the floor, It is a good resistance exercise that strengthening the erector spine (ES), gluteus

Professor, Dept. of Physical Therapy, Nambu
University 23 Cheomdan Jungang-ro, KS008, Republic
of Korea

e-mail: rehab@nambu.ac.kr

maximus (GM), Rectus femoris (RF), Hamstring, Lattismusdolsi, etc. [8,9]. Deadlift, in particular, is frequently referred to for the improvement of gluteal amnesia caused by increased sedentary lifestyles, Gluteal amnesia causes problems with hip joint lose of function, pain, and problem on hip extension movement [10]. In general, ES and GM are used as the main muscles at the hip joint extention, GM lose of function causes dysfunction in the back and knee joints [11]. Therefore, the deadlift exercise is essential for modern people who have a lot of sedentary lifestyles to prevent dysfunction of back and lower extremity [8].

Deadlifts is use in a variety of method at sports and clinical rehabilitation field. The deadlift types include romanian deadlift, sumo deadlift, conventional deadlift, kettlebell deadlift, trapbar deadlift etc. Conventional deadlift is the most representative deadlift, a hip hinge movement with the foot at shoulder width, holding the barbell, keeping the back unbending, and chest protraction while maintaining the neutral posture of the spine [12]. The Romanian Deadlift is a 45 degrees bend angle of the knee joint, descending along the thigh while holding a barbell, and maintain the lumbar curve and returning in reverse order [13]. In Sumo Deadlift, the upper extremity in the starting position is the same as the Conventional Deadlift movement, but the lower extremity is extended to about twice the width of the shoulders, descending along the thigh and the hip joint angle is bent at about 90 degrees and returned [13]. Weight training has been reported to differ in muscle activity according to posture even in the same exercise. Kwon and Kim (2018) compared GM muscle activations at 60% intensity when their respective exercises of the conventional deadlift, the romanian deadlift and the bent over row, which reported that GM muscular activity was high in the conventional deadlift compared to the romanian deadlift and the bent over row [12]. This is due to the difference in the joint angle between conventional deadlift and romanian deadlift, conventional deadlift knee joint 90 degrees flextion and romanian deadlift knee joint 45 degrees flextion, the conventional deadlift's GM seems to have high muscle activity. In the study of Yu (2004), a comparison of the muscle activity ratios of the vastus medialis and vastus lateralis muscles during squats (general squat, hip joint adduction 20 degrees + toe out 20 degrees) according to the subject's posture [14]. It was reported that the muscle activity ratio of vastus medialis and vastus lateralis was increased in the squats hip joint adduction 20 degrees + toe out 20 degrees. This suggests

that hip joint adduction is important for effective vastus medialis training and that selective muscle activity is possible on the exercise posture.

As can be seen in the preceding study, the study on comparison of muscle activity according to various deadlift method has been actively conducted. However, the study of apply various equipment to the deadlift is still insufficient. Therefore, this study is based on the kettlebell, barbell, and trap bar that are used mainly during deadlift; this is a comparative analysis of muscle activity of ES, GM, RF, RA. Therefore, the hypothesis of this study is that there would be a difference in muscle activity of both ES, both GM, both RF and both RA on the equipment used during deadlift.

Method

BTS Free EMG 1000 (BTS Bioengineering, Milano, Italy) was used to measure muscle activity of the trunk and lower extremity muscles during deadlift.

Barbell (BANSUK SPORT, KOREA) and plate (KU SPORTS, KOREA) were used to perform the barbell deadlift and to determine 50% of the initial 1RM. The length of the barbell is 1400mm long to match the length of the trap bar. The bar weighs 13 kg. The internal diameter was 50.4mm international standard size. The weight of the plate varied from 0.5kg to 15kg.

The trap bar (BADYSTREET, KOREA) was used to trap bar deadlift. The trap bar is 1400 mm long and weighs 14 kg. The trap bar, also called hexa bar, is a hexagon and must be used inside the bar. Thus, the trap bar is said to prevent the injury by matching the center of gravity and the center of mass. The kettlebell is mainly used for kettlebell swing, but also used to the kettlebell deadlift. The weight of the kettle bell was limited, but it was carried out with various weight kettlebells to meet 50% of 1RM. The 10RM load method of the 1RM test method, which is recommended by the National Strength and Conditioning Association (Anderson et al, 2018), was used. All deadlift were standardized on both feet by measuring the shoulder width before exercise and marking the shoulder width with tape on the floor. Each subject was asked to position their feet in shoulder width and then to get ready and the gaze to look straight ahead. Each deadlift was practiced several times before the measurement to familiarize the movement with three measurements. The ascending, descending and holding sections were kept for 5 seconds, and the data from 2 to 4 seconds, 6 to 9 seconds, and 11 to 14 seconds

were analyzed except for the data of 1 and 5 seconds for each of the 15 seconds measured. Enough rest time was provided to prevent fatigue between measurements, and the experimenter performed the movement after the sign of start [19].

Statistical program used SPSS Version 22.0 (Statistical Package for the Social Science). To compare differences in muscle activity (RA, RF, ES, GM) between various deadlift (Barbell deadlift, Kettlebell deadlift, Trapbar deadlift), Statistical method used one-way ANOVA with repeated measure, the post-test performed the Bonferroni test.

Results and Discussion

The results are shown in table 1-3

Table 1. Ascending

Amount of activation	Barbell deadlift	Kettlebell deadlift	Trap bar deadlift	F	P

Discussion

The purpose of this study was to compare muscle activity of RA, RF, ES, and GM on both sides of barbell deadlift, kettlebell deadlift, and trap bar deadlift. Existing exercises were mainly trained in the abdominal and trunk deep muscles, but recently, the studies emphasize the importance of the lower extremity muscles and hip muscles for trunk stability and injury prevention^[15]. Fredericson and Moore (2005) reported that weak hip muscles increase anterior shearing forces in the lumbar spine to instability in the trunk, in order to strengthen hip muscles, deadlift exercise is effective for strengthening trunk and hip muscles. Because deadlift uses local muscle for trunk stability, among which activates gluteus medius^[16]. Therefore, this study aimed to suggest effective exercise method by comparing muscle activity of trunk and lower extremity muscle during barbell deadlift, kettlebell deadlift, and trapbar deadlift.

In this study, there was a significant difference between LRF and RRF in comparison with barbell deadlift, kettlebell deadlift and trapbar deadlift ($P < 0.05$). In the descending section, LRF increased muscle activity at trapbar deadlift compared to barbell deadlift ($P < 0.05$). In the descending section, RRF increased muscle activity in trapbar deadlift compared to barbell deadlift and muscle activity in trapbar deadlift compared to kettlebell deadlift ($P < 0.05$). This result is thought to be due to increased angle of hip and knee joint during trap bar deadlift compared to barbell deadlift. According to Jang (2015), RF muscle activity increased due to the increase of the external moment arm as the knee joint angle increased during the squat^[17]. In addition, other studies reported that the muscle activity of the muscles around the knee increases because the external moment arm increases as the knee bending angle increases during the closed chain exercise^[18]. In this study, we also believe that RF muscle activity was high due to increased knee angle during trapbar deadlift when compared to barbell deadlift and kettlebell deadlift.

In this study, the muscle activity of ES in both sides during the barbell deadlift, kettlebell deadlift, and trapbar deadlift was significantly increased muscle activity at barbell deadlift compared to that of kettlebell deadlift in the ascending section and the descending section ($P < 0.05$). This may be because the center of gravity of the barbell deadlift exercise was relatively ahead of kettlebell deadlift. In previous studies, moving the center of mass forward increased the external moment arm,

which increased the muscle activity of the lowback^[19,20]. In this study, trapbar deadlift muscle activity was significantly decreased in the holding section compared to kettlebell deadlift and barbell deadlift ($P < 0.05$). In a study comparing barbell deadlift and trapped deadlift, barbell deadlift increased lumbar moment due to its center of mass, which increased the muscle activity of ES^[21]. In addition, Camara's study more used hamstrings and lower backs in barbell deadlift. And trapbar deadlift shows higher peak force, peak velocity, and peak power for barbell deadlift. In our study, barbell deadlift muscle activity was high in ascending section and descending section. In the holding section, trapbar deadlift both ES had the lowest muscle activity, similar to the above study. This is thought to reduce the moment of lumbar by spreading the load evenly across all joints, allowing the center of mass to be closer to the center of gravity with the horizontal distance from the ankle as the measurement point. Therefore, in the case of injured or painful person in lumbar, it is considered safer to do trapbar deadlift when performing deadlift.

In this study, muscle activity of both GM was significantly higher in barbell deadlift and kettlebell deadlift than in trapped deadlift in holding section ($p < 0.05$). This result may be because the length-tension relationship of GM muscle is higher in barbell deadlift and kettlebell deadlift than trapbar deadlift. Therefore, barbell deadlift and kettlebell deadlift training may be helpful to strengthen the hip muscles.

Conclusion

This study investigated the muscle activity of ES, GM, RF, RA during deadlift exercise under various deadlift (barbell deadlift, trapbar deadlift, kettlebell deadlift). This study suggests that muscle activity vary depending on the barbell during deadlift. Further research will be needed to study motion analysis by using various barbells during deadlift exercise.

Abstract

Background/Objectives: The purpose of this study was to identify factors influencing nursing performance of clinical nurses.

Method/Statistical Analysis: The participants were 187 clinical nurses. Data were collected from December, 2017 by questionnaire survey. Data analysis was done by using descriptive statistics, t-test, ANOVA, multiple logistic regression with the SPSS 23.0 program.

Findings: This study shows significant variables of age, marital status, education level, working pattern, position, salary, career of participants. The factors influencing with nursing performance were age, salary, communication competency and job satisfaction have a 52.0% explanatory power for the nursing performance of clinical nurses.

Improvements/Applications: This study confirmed that communication competency and job satisfaction were identified to improve nursing performance. Therefore we should develop programs in order to increase communication competency and job satisfaction.

Keywords: Nurse, Nursing performance, Communication competency, Job satisfaction.

Introduction

With the rapid development of modern society, the medical environment becomes more complicated and the hospital organization requires high-quality nursing with high level of expertise in various aspects^[1]. The change caused the Nurses are considered highly essential medical personnel as they take care of patients for 24 hours^[2] and nursing performance, which refers to nurses' fulfilment of their role in nursing organization with expertise, is the key requirement for improved

quality of care^[3]. It is possible to induce the development and synchronization of nurses through evaluation of nursing performance to grasp the ability of nurses^[4]. In this regard, poorer performance of nurses can lower individual work productivity, loss of motivation, indifference to the nursing subject, unkindness, and cause patient safety issues, thereby making it difficult to provide high quality care and hampering development of nursing profession^[5]. As such, in order to find ways to enhance nursing performance, there should be continuous research on what affects it^[6]. In terms of variables related to nursing performance, one of the previous studies which examined 92 hospice nurses in the U.S, found that communication competency affects nursing performance^[7] and another observed communication competency is one of the biggest factors of nursing performance^[3]. A number of studies stress principles of communication during nursing education

or on the ground as an important element of effective nursing service, yet there has been little practical support to promote interactive skills among nurses within the health care system^[8]. However, an effective communication of nurses can boost nursing performance by establishing a cooperative relationship with other medical staff and maximize job satisfaction of nurses^[9]. Job satisfaction means a pleasant and positive emotional state that occurs when evaluating job experience with the attitude of having about one's work^[10]. In fact, a content analysis study on nurses' job satisfaction^[11] suggested that main factors of job satisfaction include a work environment that allows nurses to perform care services easily, as well as nurses' interpersonal relationship. If nurses are not satisfied with their job, they cannot perform their work effectively and make progress as professionals. Moreover, lower job satisfaction may end up undermining quality of patient care as it's also linked to organizational productivity^[12]. Since patient care and treatment is the top priority at the clinical settings, it's vital to figure out what influences nursing performance. Positive interpersonal relationships and communication are the factors that increase job satisfaction. In the end, the efficiency of nursing work is improved and the performance and development of the organization is promoted^[13]. As such, this study attempts to investigate the effect of clinical nurses' communication competency and job satisfaction on their nursing performance, thereby providing baseline data for measures to improve nursing performance of clinical nurses.

Method

Research Design: This study is descriptive survey research aimed at exploring clinical nurses' communication competency, job satisfaction and nursing performance, and investigating factors influencing nursing performance.

Participants and data collection: This study collected data from 191 clinical nurses working at a general hospital from December, 2017, who were informed of the purpose of this study and gave consent to participation, and ultimately data from 187.

Communication Competency: To measure the participants' individual communication competency, this study used the Global Interpersonal Communication Competence Scale (GICC), which was originally developed by^[14] and complemented by^[15]. In terms of

the tool's reliability^[15] found Cronbach's alpha to be .72, whereas that in this study stood at .81.

Job Satisfaction: For job satisfaction, this study adopted the Job Descriptive Index (JDI) whose validity has been widely proved. The Research Institute at University of Minnesota suggested 100 detailed factors of job satisfaction, after excluding demographic factors and were later modified and complemented by^[16]. While Cronbach's alpha in^[16] was .89, that in this study turned out to be .88.

Nursing performance: To measure nursing performance, nursing performance measuring tool, developed by^[17]. While^[17] generated Cronbach's alpha of .92, Cronbach's alpha calculated in this study was .90.

Data Analysis: The collected data were analyzed using SPSS 23.0. The participants' communication competency, job satisfaction and nursing performance were examined by t-test, ANOVA, Scheffe's test and multiple logistic regression.

Result

Communication competency, job satisfaction and nursing performance according to general characteristics of participants: It was found that position (p=.002) and monthly income (p=.039) made significant difference in communication competency while job satisfaction was significantly affected by marital status (p=.049) and position (p=.007). In addition, age (p<.001), marital status (p<.001), education (p=.003), working pattern (p=.001), monthly income (p<.001) and career (p<.001) had significant impact on nursing performance[Table 1].

Communication competency, job satisfaction and nursing performance perceived by participants: On average, clinical nurses recorded 3.41±0.44 for communication competency, 3.35±0.43 for job satisfaction and 3.56±0.48 for nursing performance on a five-point scale [Table 2].

Table 2. Communication Competency, Job Satisfaction and Nursing Performance

Factors affecting participants' nursing performance: Analysis results of factors that influenced the participants' nursing performance are presented in [Table 3]. Multiple logistic regression with general characteristics of the participants taken into

consideration showed that age (p=.004), monthly income (p=.023), communication competency (p<.001), and job satisfaction (p<.001) were factors that could affect nursing performance, and the four factors explained 52.0% of nursing performance.

Discussion

In terms of communication competency, participants of this study scored an average of 3.41 out of 5, similar to the results of previous studies of [19]. It is also in line with the results of [20] that compared doctors and nurses in terms of communication competency and found that the former group recorded a higher score of 3.42 on average. The clinical nurses examined and those doctors showed similar scores for communication competency, which are higher than those of ordinary nurses, but this is because clinical nurses perceived their communication competency a little higher. As for communication competency according to general characteristics, the participants exhibited significant difference depending on their position and monthly income, which corresponds to the results of previous literature. For example, [18] found that higher position led to greater communication competency and [19], too, discovered charge nurses or those at a higher position recorded higher scores for communication competency than ordinary nurses. Taken altogether, these results indicate it's not easy to enhance communication competency and repetitive training and diverse work experiences can contribute to improvement of the competency. Returning to what this study found, while only position and monthly income made significant differences, older age and longer career also led to greater communication competency. It means there should be an intervention program for young and less experienced nurses as their perception of communication competency was low.

The participants of this study marked 3.35 out of 5 on average for job satisfaction, which is higher than 3.12 of [20] or 3.07 of [21]. Also, this study found that position at work was one of the significant variables to job satisfaction, which is in line with the results of [21]. As nurses become older and build more career, they get to learn more skills and know-hows through various experiences and, by working with those newly

acquired skills, not only patients but also the nurses themselves feel greater satisfaction with their work. Unfortunately, nurses at a number of hospitals are currently suffering chronic fatigue caused by labor shortage and heavy workload and facing much conflict in a bureaucratic organizational culture. The consequent reduction in job satisfaction makes it extremely difficult to improve nursing performance. Nevertheless, nursing organizations must introduce a system for better nursing performance where nurses can build capabilities and expertise so that they can become more satisfied with their work and enhance performance.

The participants in this study scored an average of 3.56 out of 5 for nursing performance, supported by [22]. Meanwhile, in terms of nursing performance according to general characteristics, this study observed significant difference made by several variables, including age, marital status, education, working pattern, position, monthly income and total career, which also corresponds to the findings of [22, 23]. From these results, it can be inferred that nurses has greater confidence and expertise as they get older, build more career, get more education and have higher position, thereby showing greater performance with their work. In addition, married participants recorded higher scores for nursing performance than the unmarried ones, and it seems attributable to social stability and confidence that married people experience thanks to emotional support and psychological peace they get from family even though they need to juggle work and family. Therefore, creating a working environment where nurses can get additional education and maintain their career can be suggested as another measure to boost nurses' job satisfaction and nursing performance.

As for correlations among clinical nurses' communication competency, job satisfaction and nursing performance as well as factors influencing them, this study found that the greater communication competency and job satisfaction the nurses had, the higher nursing performance they showed. When general characteristics of the participants were considered, communication competency and job satisfaction were the biggest influencing factors of nursing performance of clinical nurses, followed by age and monthly income. These results are supported by previous papers of [3], which reported communication competency and job satisfaction can affect nursing performance, respectively. As hospitals get larger in size and departmentalized further, nurses are required to carry

out more than conventional jobs. They now have to help patients recover from illnesses and maintain and improve health, plan and manage care services and educate families of patients and consult with them. This is why communication competency is emphasized for nurses. More importantly, nurses are the ones that form the most direct and sustainable relationship with medical consumers, or patients, and, thus, can determine how the consumers perceive medical services they get. In this sense, communication competency of nurses can make considerable influence not only on the efficiency, but also on the performance of hospital.

Conclusion

It found that communication competency and job satisfaction can make effect on nursing performance. Based on these findings, various intervention programs must be developed to improve nurses' job satisfaction and boost their nursing performance so that they could provide comprehensive care as professional nurses. Furthermore, a training program should be provided for nurses to learn how to communicate in a clear and effective manner, and organizations must introduce a measure to promote horizontal and open communication for greater job satisfaction among nurses. As this study utilized measuring tools of communication competency, job satisfaction and nursing performance of nurses who are providing regular patient care at hospital, there is a need for a standardized measuring instrument with high reliability and validity for nurses who are working at a special department. Considering that appropriate education, training in communication competency and better working conditions can boost job satisfaction, the results of this study can serve as baseline data for development of strategies to enhance nursing performance of clinical nurses.

The Effects of Domestic Abuse Experience and Stress on Depression of Adolescents: The Moderated Mediation Effect of Teacher Relations

Chang-Seek Lee¹, Eun-Kyung Ryu²

¹Professor, Dept. of Health, Counseling and Welfare, Hanseo University, 31962 Korea,

²Ph.D. Student, Dept. of Child and Adolescent Counseling and Psychology, Hanseo University, 31962 Korea

Abstract

Background/Objectives: The purpose of this study was to investigate the moderated mediation effect of teacher relations on the mediating effect of stress on the relationship between domestic abuse experience and depression in adolescents.

Method/Statistical Analysis: To this end, approximately 860 middle and high school students from D city in Korea participated in the study survey. Collected data were analyzed using mean comparison analysis, reliability analysis, correlation analysis, and moderated mediation effect analysis.

Findings: First, as a result of the difference test of depression according to general characteristics, there were significant differences according to gender, school grade, income level, and parent-teacher relationship. Second, as a result of the correlation analysis, there was a positive correlation between domestic abuse experience, stress, and depression, However, the teacher relationship negatively correlated with other variables. Third, stress was found to mediate between domestic abuse experience and depression. Fourth, teacher relationship was found to control between stress and depression. Fifth, teacher relations showed moderated mediation effects, on mediating effects of stress in the relationship between domestic abuse experience and depression.

Improvements/Applications: Based on these findings, we discuss approaches to alleviating stress and reducing depression caused by domestic abuse experience.

Keywords: *Domestic abuse experience, Stress, Depression, Teacher relation, Moderated Mediation Effect.*

Introduction

Domestic abuse is the act of perpetrating at home, emotional, physical, abandonment, or neglect^[1]. This behavior is a serious deterrent to healthy growth during adolescent development. Additionally, domestic abuse does not end once and continue, and instead tends to

escalate in frequency and intensity. A total of 11,715 adolescents who experienced abuse in 2015 accounted for 49.1% of the youth who experienced abuse more than once weekly^[2]. Students who experience long-term abuse have problems psychologically, mentally, and physically. Personal factors can lead to a negative ego and psychological maladjustment such as stress, depression, and anxiety.

There are various causes of adolescent stress, such as peer harassment, teacher relations, and academic burden. However, among them, domestic abuse experience increases adolescent stress^[3]. Students who experience abuse are more likely to accept the stress of daily life than those who do not, and have difficulty adjusting to

Corresponding Author:

Eun-Kyung Ryu

Dept. of Child and Adolescent Counseling and Psychology

e-mail: yek0444@hanmail.net

school life. Abuse experiences can lead to extreme post-traumatic stress disorder, making the abused individual vulnerable to the stress experienced during growth. In other words, students who have been hurt by domestic abuse experience cannot cope with stress appropriately, and stress beyond control level becomes psychologically negative.

There is no accurate data on the prevalence of depression in adolescents. However, data published by the World Health Organization (WHO) reported that the prevalence of depression in adolescents was approximately 4-8% per year^[4]. Adolescents who experience depression experience a significant amount of time to recover from depression, and depression during adolescence prevails through adulthood. Additionally, according to the Adolescent Health Behavior Survey reported by the Centers for Disease Control and Prevention (CDC), high school students experienced higher levels of depression and hopelessness than middle school students^[5]. It seems that the higher the grades, the more persistent the symptoms of depression due to psychological pressure or accumulated stress. A number of previous studies analyzing factors of adolescent depression showed that factors such as family conflict, parental abuse, and neglect had significant effect on depression^[6].

Depression caused by stress in adolescents also has a negative effect on interpersonal relationships, such as peer and teacher relationships, which can lead to maladjustment in school life^[7]. In adolescence, students develop social skills through school life, and they experience satisfaction in school life through good interpersonal relationships. However, an emotionally depressed student can promote interpersonal conflict and discord within the school. Additionally, students who have experienced domestic abuse experience difficulty adapting to teacher relations because of adult rejection^[8]. Every student wants to be recognized by the teacher at school and expects to be treated fairly. Students who are treated properly by teachers and have good teacher relationships reduce their negative emotions and depression symptoms at school^[9].

Thus, the purpose of this study was to identify the moderated mediation effect of teacher relations on the mediating effect of stress between domestic abuse experience and depression.

This study established the following research questions:

First, what is the difference in the depression depending on students' personal characteristics?

Second, what is the correlation among the main variables?

Third, does the stress mediate in the relationship between the domestic abuse experience and depression?

Fourth, does the teacher relationship moderate the relationship between the stress and depression?

Fifth, does the teacher relationship moderate the mediating effect of stress in the relationship between the domestic abuse experience and depression?

Method

Research Model: The research model of this study is shown in [Figure 1]. Stress mediates in the relationship between domestic abuse experience and depression, and teacher relations have moderated mediation effects in the path in which stress affects depression.

Figure 1. Research model

Research Subjects: The survey was conducted on approximately 900 middle and high school students from D city in Korea. The survey was conducted February-April 2019, and a total of 860 copies were finally used, except for questionnaires that were answered unfaithfully.

The gender distribution of the study subjects was 398 male students (46.3%) and 462 female students (53.7%). The distribution of school grades was similar with 421 middle school students (49.0%) and high school students 439 (51.0%). Looking at the income form of the parents, the dual-earner earned 568 (66.0%) and the single-earner earned 292 (34.0%). Additionally, their income level was 106 low (12.4%), 'normal' 465 (54.1%), and 'high' 289 (33.6%). Conversely, the relationship between parents

and teachers was 291 (33.8%) for poor, 424 (49.3%) for ‘normal’, and 145 (16.9%) for ‘good’.

Research Tools:

Domestic Abuse Experience: Domestic abuse experience was measured using the family violence experience used by Bae Mi-hee^[10]. This scale was designed to measure the degree of domestic violence such as verbal violence, emotional violence, mild physical violence, and severe physical violence experienced by parents. Each question is a total of 5-point Likert scales, ranging from 1 point (not at all) to 5 points (at all times). The higher the score, the higher the experience of domestic abuse.

Stress: We used the stress scale which was used by Lee et al. ^[11] based on the BEPSI-K (Brief Encounter Psychosocial Instrument-Korean). A total of five questions, each of which is a 5-point Likert scale, ranging from 1 point of ‘not at all’ to 5 points of ‘very so’. The higher the score, the higher the stress. In this study, the reliability Cronbach’s α value was .881.

Depression: We used the depression scale which was used by Choi^[12] for the subscale of SCL-90. It consists of a total of 10 questions, and is 5-point Likert

scale, ranging from 1 point at ‘not at all’ to 5 points at ‘very yes’. The higher the score, the higher the depression tendency. Cronbach’s α for the reliability was .926.

Teacher Relations: The teacher relations used measures related to teacher relations among the subscales of school adaptation used by Kim^[13]. It is composed of five questions, and it is a 5-point Likert scale from 1 point at ‘not at all’ to 5 points at ‘very yes’. The higher scores mean higher teacher relationships. The reliability of this scale, Cronbach’s α , was .831.

General Characteristics: The gender, school grade, marital income form, income level, and parent-teacher relationship of the study subjects were examined.

Data Analysis: For this study, we analyzed using SPSS Win 23.0 and SPSS PROCESS Macro 3.1. The t-test and ANOVA were used to analyze the difference in depression according to the general characteristics of the study subjects. The post-test was performed with Duncan/Dunnet T3. Additionally, correlation analysis was conducted to identify the correlations among the major variables used in this study. Regression analysis was performed using model 14 of SPSS PROCESS macro proposed by Hayes^[14] to identify mediating effect, moderating effect, and moderated mediation effect.

Result and Discussion

Table 1. Depression according to general characteristics

Characteristics		Depression			
		Frequency	Mean (Standard Deviation)	T-value/F (Duncan)	
Gender	Male	398	2.19(.85)	-6.109***	
	Female	462	2.54(.85)		
School level	Middle school	421	2.24(.88)	-4.754***	
	High school	438	2.52(.82)		
Double-income status	Yes	567	2.39(.83)	.754	
	No	292	2.35(.92)		
Income level	Bad	289	2.65(.89)	8.720***	A
	Middle	464	2.39(.83)		B
	Good	106	2.25(.83)		B
Parent-Teacher relationship	Bad	291	2.55(.86)	11.041***	A
	Middle	423	2.33(.83)		B
	Good	145	2.17(.90)		C

***: p<0.001

Depression according to general characteristics of subjects: [Table 1] shows the difference in depression according to the general characteristics of middle and high school students. According to the gender of the students, female students showed higher depression than male students ($t = -6.109, p < .001$). These results are consistent with the results of several previous studies^[15-16]. However, contrary to another study^[17], there was no consistent results in depression depending on gender. According to the school level, high school students showed higher depression than middle school students ($t = -4.754, p < .001$). These results can be explained by the burden and stress on schooling in higher grades. Additionally, depending on the income level, depression was highest in the order of ‘bad’, ‘medium’ and ‘good’ ($F = 8.720, p < .001$). Meanwhile, depending on the parent-teacher relationship, students’ depression was highest in the order of ‘bad’, ‘medium’ and ‘good’ ($F = 11.041, p < .001$).

Correlation of key variables: [Table 2] presents the results of the correlation analysis among the major variables. The results showed a positive correlation between domestic abuse experience, stress and depression, and stress and depression. Conversely, teacher relations showed a negative correlation with domestic abuse experience and depression. Among them, stress and depression ($r = .717, p < .01$) showed the highest correlation, followed by depression and teacher relationship ($r = -.255, p < .01$), and domestic abuse experience and depression ($r = .238, p < .01$) in order.

Table 2. Correlation coefficients among major variables

	1.	2.	3.	4.
Domestic abuse experience	1			
Stress	.188**	1		
Depression	.238**	.717**	1	
Teacher relations	-.129**	-.062	-.255**	1
Average	1.33	2.85	2.38	3.47
Standard Deviation	.55	.98	.86	.76

The moderated mediating effects of teacher relations between domestic abuse experience and depression of students: The moderated mediation effect of teacher relation on the mediating effect of stress in the relationship between domestic abuse experience and depression of students was analyzed using Model 14 of the SPSS PROCESS Macro 3.1^[14]. The results are shown in [Table 3].

The results showed that domestic abuse experience had significant positive effect on stress ($\beta = .3404, p < .001$), and stress had significant positive effect on depression ($\beta = .6050, p < .001$). Additionally, domestic abuse experience had significant positive effect on depression ($\beta = .1322, p < .001$). The fact that domestic abuse experience has significant effect on stress and that stress has significant effect on depression indicates that stress plays a mediating role between students’ domestic abuse experience and depression.

Table 3. Moderate mediation effect of teacher relations between domestic abuse experience and depression

Variables	Effect	SE	t-value	p
Mediating variable model (Dependent variable: Stress)				
Constant	-.4515	.0872	-5.1786	.0000
Domestic abuse experience → Stress	.3404	.0608	5.6012	.0000
Dependence variable model (Dependent variable: Depression)				
Constant	2.2015	.0522	42.1868	.0000
Domestic abuse experience → Depression	.1322	.0365	3.6214	.0003
Stress → Depression	.6050	.0201	30.0995	.0000
Teacher relations → Depression	-.2288	.0258	-8.8664	.0000
Stress × Teacher relations → Depression	-.0529	.0238	-2.2201	.0267

Conversely, the interaction terms of stress and teacher relationship had significant effect on depression ($\beta = -.0529, p < .05$). In other words, domestic abuse experience has a relationship that domestic abuse

experience increases depression via stress, which means that the effect of stress as a mediator on depression as a dependent variable depends on the relationship of teacher as a moderating variable.

The Johnson-Neyman method was used to analyze the significance region for the range of moderating variable. As a result, the effect of stress on depression was significant in all areas of teacher relations. This means that the higher the teacher relationship, the less stress on depression.

The shape according to the moderating effect of teacher relations was identified in the graph and presented in [Figure 2]. The depression level by stress was higher in order from the low to middle, and high groups of teacher relations. In other words, the better the teacher relationship in the effect of stress on depression, the lower the depression.

Figure 2. The moderating effect of teacher relationship in the relationship between stress and depression

Table 4. Testing moderated mediation effects of teacher relations between domestic abuse experience and depression

Conditional indirect effect	β	Boot Se	LLCI*	ULCI**
M-1SD (-.7613)	.2197	.0377	.1467	.2927
M (.0000)	.2060	.0356	.1369	.2750
M+1SD (.7613)	.1923	.0350	.1252	.2624

*LLCI=The lower limit of the indirect effect within the 95% confidence interval, **ULCI=The higher limit of the indirect effect within the 95% confidence interval

Finally, the conditional indirect effects of the domestic abuse experience, an independent variable, on the dependent variable, depression, are presented in

[Table 4]. The conditional indirect effects of stress on depression was significant in the range of -.7613 (M - 1SD) to .7613 (M + 1SD) of teacher relations.

Conclusion

The limitations of this study and suggestions for further research are as follow. First, this study examined the mediating effect of stress and moderated mediation effect of teacher relations on the effects of domestic abuse experience on depression in middle and high school students. However, domestic abuse experience tends to persist after the first experience in childhood and must be studied in lower grades. This will be the basis for solving fundamental problems in the early stages of domestic abuse. Second, the difference of depression according to

general characteristics was compared. In this study, the higher the grade, the higher the depression. However, in the upper grades, the study on if teacher-adaptation had significant effect on depression in the upper grades could not be analyzed in depth. Thus, further research is needed to determine if teacher relations by school level can control depression. Third, this study collected and analyzed few students. Thus, there is a limit to generalizing the results of this study for all students. There is a need for national sampling in the future, and regional comparative studies must be conducted.

In a series of preceding studies, most of the studies on the effects of domestic abuse experience on students' depression and stress were conducted. However, this study is meaningful in analyzing the effect of teacher relations on these relationships based on these previous studies. Thus, this study should find different ways to deal with stress according to students' situation. Additionally, a system for active communication and improving relations between students and teachers should be established to cope with stress flexibly and to reduce student depression.

The Effect of Workers' Smartphone Addiction on Depression: Dual Mediation of Growth Mindset and Impulsiveness

Chang-Seek Lee¹, Ha-Young Jang²

¹Professor, Dept. of Health, Counseling and Welfare, Hanseo University, 31962 Korea,

²Ph.D. Student, Dept. of Child and Adolescent Counseling and Psychology, Hanseo University, 31962 Korea

Abstract

Background/Objectives: This study was performed to investigate the dual mediating effects of growth mindset and impulsiveness between smartphone addiction and depression of workers.

Method/Statistical Analysis: The major subjects of this study were 286 employees of 20 work-places in Seoul, Daejeon, Chungnam province, and Chungbuk areas. The collected data were analyzed using t-test, ANOVA, correlation analysis, dual mediation effect analysis by SPSS PC+ Win. 25 and SPSS PROCESS macro 3.4.

Findings: First, there was no significant difference in depression according to the general characteristics of the subjects. Second, the growth mindset had a negative correlation with impulsiveness and depression. And Impulsiveness had a positive correlation with depression. Third, mediating effect analysis revealed that there was a dual mediation effect of growth mindset and impulsiveness between smartphone addiction and depression of workers.

Improvements/Applications: Based on these findings, growth mindset is expected to act as a major defensive factor. And, we discussed ways to reduce depression caused by smartphone addiction.

Keywords: *Smartphone addiction, Growth mindset, Impulsiveness, Depression, Workers, Mediating effect.*

Introduction

Smartphone addiction generally means a situation in which the increase in usage cannot be controlled because of the excessive immersion in the smartphone^[1]. Such smartphone addiction has the same context as the existing internet addiction, from which it differs because smartphones can run various applications, such as the internet and games, in any place, at any time^[2]. These smartphone addictions can cause a variety of problems. In summary, previous studies discussed physical, psychological, and social problems in personal terms.

First of all, the physical problems include Turtleneck Syndrome and Wrist Tunnel Syndrome caused by prolonged use of smartphones; dry-eye syndrome and spinal curvature were also found to be frequent. In particular, for workers, smartphone addiction worsens their vision, decreases physical fitness, and interferes with their work life because of lack of sleep^[3]. Psychologically, it can cause mental illnesses, such as psychological anxiety, obsessive compulsive disorder, depression, and social avoidance^[4]. In particular, if you do not have your smartphone, it may be difficult to concentrate on work or daily life, and hearing problems with ringing may occur. Socially, it has been reported to deteriorate interpersonal relationships^[5]. The SNS function of smartphones has made it possible to connect with more people than the members of the society one belongs to. As a result, smartphone users can connect with various open and diverse people and feel accustomed to communicating in a virtual environment.

As a result, their communication with their family and friends has decreased, and more and more people cannot adapt to their relationships, which harms the level of mutual relations with others, social stability, autonomy, and social development^[6-7].

This study was carried out with an interest in depression and impulsiveness, which are psychological problems among smartphone dysfunctions. According to previous studies, the relationship between smartphone addiction and depression appears to be very close. Lee said that the higher smartphone addiction, the higher the depression^[8]. Sung further said that such depression affects their unhappiness and falls into lethargy^[9].

On the other hand, smartphone addiction affects impulsiveness. Park said that impulsiveness was the most significant in the difference between the smartphone addiction group and the non-addictive group^[10]. In addition, when the smartphone is used addictively, people do not control their own desire to use it, and in wanting to have a relationship with others, there is a tendency to satisfy the desire immediately^[11].

Recently, growth mindset is a variable that is frequently studied as a defensive mechanism against impulsiveness and depression. Dweck calls “mindset” a belief in one’s intelligence or ability^[12]. He divided mindset into a fixed mindset, which means an unchanging attitude, and a growth mindset, which means that skills can be developed. People with a growth mindset excel in many areas, including goal orientation, achievement standards, thinking about effort, challenges, and frustration^[13]. Recently, various empirical studies have found that growth mindset has a very positive effect on negative psychological problems, such as anxiety and depression. Thus, one can assume that growth mindset will reduce impulsiveness and depression from smartphone addiction.

These previous studies found that impulsiveness mediates between workers’ smartphone addiction and depression. However, a growth mindset acts as a defense against impulsiveness. Overall, therefore, growth mindset and impulsiveness will both mediate between smartphone addiction and depression. However, most of the studies conducted so far focused on the research that identified the negative effects of smartphones.

Therefore, this study set the smartphone addiction of workers as the independent variable, depression as a dependent variable, and explored whether a

worker’s growth mindset and impulsiveness play a dual mediation role. In order to achieve this goal, the research questions are as follows. First, what is the difference in depression according to the general characteristics of workers? Second, what is the role of growth mindset and impulsiveness between smartphone addiction and depression?

Method

Research Model: Based on previous studies conducted to date, the research model shown in [Figure 1] was set up. In other words, a dual mediation model of growth mindset and impulsiveness was established in the relationship between smartphone addiction and depression.

Figure 1. Research model

Research Subjects: For the study areas, 20 workplaces in Seoul, Daejeon, Chungnam, and Chungbuk were selected, and 286 workers were selected from the workplaces. The genders were 234 males (82.4%) and 50 females (17.6%). The most common age group was in the thirties, with 128 (44.8%), followed by 77 in the 40s (26.9%), 48 in the 20s (16.8%), and 30 in the 50s (10.5%). In terms of marital status, there were 174 married people (61.3%), 110 unmarried people (38.7%). Finally, the monthly salary distribution was 110 persons (35.2%) with 3 million won, 97 persons (34.2%) with 2 million won, 43 persons (15.1%) with more than 4 million won, and 34 (12.0%) with less than 2 million won.

Research Tools:

Smartphone Addiction: The measurement was done using an adult smartphone addiction self-diagnosis scale developed by the Korean Information Technology Intelligence Agency^[14]. This scale is composed of sub-domains of daily living disorders, virtual world orientation, withdrawal, and tolerance, but they are summed up in this study. The smartphone addiction scale is a 5-point Likert scale and consists of 15 questions. Each

item is given a score from “not at all” to “very much” with a score of 5, with questions 4, 10, and 15 being reverse scored. A higher score means more smartphone addiction. In this study, the overall reliability was found to be Cronbach’s $\alpha = .854$, indicating a reliable level.

Growth Mindset: We used the scale developed by Carol Dweck^[15] and translated by Lee^[16]. The growth mindset is a tool for measuring how close an individual is to a fixed mindset or a growth mindset. It is divided into subfactors of intelligence and personality. It consists of 8 questions, and each sub-factor consists of 2 positive questions and 2 negative questions about intelligence, and 2 positive questions and 2 negative questions about personality. In this study, each sub-factor was summed up without any distinction of subfactors, and the range of questions was measured on a five-point Likert scale ranging from one point of “not at all” to five points of “very ”. Negative questions were scored in reverse. The higher the total score, the higher the growth mindset. The reliability of this scale Cronbach’s α is .813 and is judged to be reliable.

Impulsiveness: We used the Barratt Impulsiveness Scale (BIS) developed by Barratt^[17] and used by Yang^[18]. It consists of 5 questions that adapt the scale of smartphone addiction to the purpose of this study. The questions were measured on a five-point Likert scale, ranging from one point of “not at all” to five points of “very much”. The higher the total score, the higher the

impulsiveness. In this study, Cronbach’s α was .870, which was judged to be reliable.

Depression: We used five questions selected by Yang^[18] based on the development and validation of Bae^[19]. The questions consist of a total of five Likert scales, ranging from one point of “not at all” to five points of “very much”. The higher the total score, the higher the depression. In this study, the Cronbach’s α of this scale was .795.

Other Variables: The gender, age, marital status, and salary of workers were examined.

Data Analysis: We did data analysis using SPSS PC + Win. Ver. 24.0. Frequency analysis, reliability analysis, t-test, ANOVA, and correlation analysis were done using the SPSS PC + Win. 25. In addition, dual-mediation effect and bootstrapping were assessed using the SPSS PROCESS macro 3.4.

Result and Discussion

Depression According to General Characteristics:

There was no significant difference in depression according to the general characteristics of the subjects, as is presented in Table 1. Specifically, gender ($t = -1.553, p = .122$), age range ($F = .200, p = .896$), marital status ($t = -1.475, p = .141$), or salary ($F = .641, p = .589$) did not show a significant difference.

Table 1. Depression according to general characteristics; N = 286

		Frequency	Depression	
			M (SD)	t value/F (Duncan)
Gender	Male	234	2.552(.755)	-1.553(p=.122)
	Female	50	2.733(.723)	
Age range	Twenties	48	2.591(.722)	.200(p=.896)
	Thirties	128	2.561(.730)	
	Forties	77	2.639(.713)	
	More than fifty	30	2.546(.709)	
Marital status	Married	174	2.532(.772)	-1.475(p=.141)
	Single	110	2.666(.705)	
Month salary	Less than 2 million	34	2.719(.710)	.641(p=.589)
	2 and 3 million	97	2.552(.701)	
	3 and 4 million	110	2.604(.720)	
	More than 4 million	43	2.497(.711)	

***: $p < 0.001$

Correlation of key variables: The results of correlation analysis of the major variables are presented in Table 2. Smartphone addiction was negatively correlated with growth mindset and positively correlated with impulsiveness and depression. The growth mindset had a negative correlation with impulsiveness and depression. Impulsiveness had a positive correlation with depression. Impulsiveness and depression together showed the highest correlation ($r = .573, p < .01$), followed by smartphone addiction and depression ($r = .512, p < .01$), and smartphone addiction and impulsiveness ($r = .487, p < .01$).

Table 2. Correlation coefficients between major variables

	1.	2.	3.	4.
Smartphone addiction	1			
Growth mindset	-.345**	1		
Impulsiveness	.487**	-.339**	1	
Depression	.512**	-.311**	.573**	1
M	2.67	3.26	2.76	2.58
SD	.53	.60	.63	.74

** : $p < 0.01$

These results are mostly consistent with previous studies^[10,12-13]. In other words, the more severe the smartphone addiction, the more negative the depression and the higher the impulsiveness. Growth mindset had a negative effect on depression. This is sufficiently predictable at the common-sense level and has been found in recent studies^[13]. Therefore, in order to reduce the depression of workers, it is necessary to devise a way to suppress smartphone addiction. However, the reality is that smartphone addiction is difficult to suppress, because smartphone use is difficult to suppress.

Effects by Path: [Figure 2] shows the magnitude of the overall effect of workers' smartphone addiction on depression. In [Figure 3], the coefficients for each path are presented to verify the double mediating effect. Verifying the coefficients for each path showed that all of them were statistically significant, except for the influence of growth mindset on depression ($-.0901, p = .1464$). Smartphone addiction had a negative effect on growth mindset ($-.3879, p < .001$) and a positive effect on impulsiveness ($.4952, p < .001$) and depression ($.4010, p < .001$). Growth mindset had a negative effect on impulsiveness ($-.2038, p < .01$), and impulsiveness had a positive effect on depression ($.4814, p < .001$).

***: $p < 0.001$

Figure 2. The total effect of smartphone addiction on depression

** : $p < 0.01$, ***: $p < 0.001$

Figure 3. The dual mediating effect of growth mindset and impulsiveness

Table 3. Dual mediating effect of growth mindset and impulsiveness

Classification	Mediating effects		
	B	S.E.	BC 95% CI
smartphone addiction → growth mindset → depression	.0350	.0273	-.0120 ~ .0957
smartphone addiction → impulsiveness → depression	.2384	.0530	.1374 ~ .3474
smartphone addiction → growth mindset → impulsiveness → depression	.0381	.0199	.0091 ~ .0858
Total Indirect Effect	.3114	.0584	.2011 ~ .4294

Dual mediation effect verification: 15,000 bootstrapping was done to verify the dual mediation effect, and the confidence interval was set to 95%. As shown in Table 3, the total indirect or mediation effect was .3114 (.2011 ~ .4294), which was significant, because there was no 0 in the 95.0% confidence interval. In addition, the verification of the simple mediation effect of growth mindset between smartphone addiction and depression was .0350 ($-.0120 \sim .0957$), which was not significant, because there was a 0 in the 95.0% confidence interval. However, the simple mediation effect of impulsiveness between smartphone addiction and depression was .2384 (.1374 ~ .3474), which was significant, because there was no 0 in the 95.0% confidence interval. In addition, the dual mediation effect of growth mindset and impulsiveness between smartphone addiction and depression was .0381 (.0091 ~

.0858), which was significant, because there was no 0 in the 95.0% confidence interval. Therefore, there is a dual mediation effect of growth mindset and impulsiveness between smartphone addiction and depression of workers.

These results indicate that growth mindset can play a positive role in both the impulsiveness and the depression that are caused by smartphone addiction. In other words, growth mindset can lower the impulsiveness and depression caused by smartphone addiction. Therefore, the policies about the smartphone addiction of workers need to be dualized. First of all, training to decrease the use of the smartphone itself is needed. However, this requires a strong will of the trainees and is likely to have a partial effect, because the reality is not so high. Therefore, the second solution is to minimize the damage even if a worker is addicted to smartphones. Therefore, in this study, growth mindset has been found to play such a role. Accordingly, it is necessary to prepare an education program to increase growth mindset in the workplace.

Conclusion

This study investigated the dual mediating effects of growth mindset and impulsiveness between workers' smartphone addiction and depression. As a result, growth mindset and impulsiveness were found to indicate serial dual mediation. Based on these findings, we discussed ways to reduce depression caused by smartphone addiction.

Suggestions about the limitations of this study are as follows. First, this study was conducted in Seoul, Daejeon, Chungnam, and Chungbuk and thus has regional limitations. Therefore, it is unreasonable to generalize the results of this study to national phenomena. In the future, national sampling will be needed. Second, we set growth mindset as a parameter that acts as a defensive factor. However, there are many variables that play this role. Later we will need to uncover further variables.

On the other hand, the research on the growth mindset conducted to date has been limited to the academic achievement of adolescents, but recently, research on adults has been actively conducted. In this study, the growth mindset may have a significant role in the positive role of adults.

Perceived Health Status, Psychological Well-Being and Health Promotion Behavior of College Students

In-Sook Park¹, Tae-Kyung Kim¹

¹Professor, Department of Nursing, Dong-Eui Institute of Technology, 54, Yangji-ro, Busanjin-gu, Busan, 614-715, South Korea

Abstract

Background/Objectives: This study is descriptive research aimed at determining the association with perceived health status and psychological well-being affecting health promotion behavior and at providing basic data that could help develop programs for health care and healthy lifestyle of college students in early adulthood.

Method/Statistical Analysis: The data were collected from 194 students at colleges in B City from March 5 to 22, 2019. The collected data were analyzed through t-test, ANOVA, Pearson's correlation analysis using an SPSS/WIN 23.0 program.

Findings: The respondents scored an average of 2.38 out of 5 for perceived health status. They scored an average of 2.27 out of 5 for psychological well-being and 2.57 out of 5 for health promotion behavior. Perceived health status was significantly positively correlated with psychological well-being ($r=.617$, $p<.001$) and health promotion behavior ($r=.516$, $p<.001$). Psychological well-being was significantly positively correlated with health promotion behavior ($r=.667$, $p<.001$). Perceived grade, household financial status and smoking and alcohol intake status made significant differences and psychological well-being differed significantly by religion, grade, major satisfaction and residence type. Health promotion behavior differed significantly by major, gender, household financial status and academic achievement.

Improvements/Applications: It is necessary to develop customized programs that can help college students feel and improve psychological well-being with the objective of promoting health promotion behavior in pursuit of health care and healthy lifestyle.

Keywords: College student, early adulthood, perceived health status, health promotion behavior, psychological well-being.

Introduction

As greater attention is paid to health in the rapidly changing and developing society and emphasis is placed on its importance, there is a shift from the concept of

quantitative treatment to the qualitative concept of health maintenance and promotion. In modern society based on the development of medical technology, in particular, conventional infectious, poisonous and acute diseases are almost controlled, whereas chronic diseases, such as cancer or circulatory diseases, which occur due to long-term lifestyle become major health problems. Such a change leads to the efforts to protect and promote health through public health education, disease prevention, nutritional improvement and healthy life practice rather than to treat disease as before [1]. Health promotion behavior is determined by psychological and subject factors, such as personal beliefs, values and motives

Corresponding Author:

Tae-Kyung Kim

Professor, Department of Nursing, Dong-Eui Institute of Technology, 54, Yangji-ro, Busanjin-gu, Busan, 614-715, South Korea
e-mail: phoebetk@dit.ac.kr

and it is more reliable to determine the level of health promotion behavior by using self-rated perceived health status rather than clinical conditions^[2,3]. College students are in the healthiest period in their whole life, as measured by the conventional health index; however, many of them live away from their parents and family and may choose health-threatening acts, such as smoking, alcohol intake and irregular eating habits, in making the primary decision as to their own health. However, college students are in the critical period to form health-related habits for adulthood and health care in this period is important, affecting health in remaining life^[4]. The factors affecting health promotion behavior included health perception, self-esteem, self-efficacy and social support^[5,6] and body image, emotional status, stress and peer relationship satisfaction^[7]. However, college students have relatively low mortality or morbidity and are in a favorable position to have better health status by correcting wrong lifestyle and by controlling stress and the efforts to help make their health promotion behavior habitual on the basis of good knowledge about health are very important to prevent chronic diseases expected in adulthood^[8]. Psychological well-being is a concept of how positively individuals function against challenges and is a very important variable for college students with a developmental task of forming and establishing identity^[9]. To confirm that psychological well-being is an important factor for health promotion behavior, research has been conducted in nurses, nursing students and shift workers, but little research has been conducted in general college students^[10,11]. This study aimed to determine the level of association among perceived health status, psychological well-being and health promotion behavior in college students and provide basic data that could help develop health care and healthy lifestyle practice programs for college students.

Method

This study is descriptive research aimed at determining the association among perceived health status, psychological well-being and health promotion behavior in college students.

Convenience sampling was performed from March 5 to 22, 2019 among those students at two colleges in B City who understood the purpose of this study and consented to participation. For data collection, self-administered questionnaires were distributed and collected immediately after they were completed. It took 10 to 15 minutes to complete the questionnaire.

The minimum sample size was found to be 120 persons when a G Power 3.1.0 program based on Cohen's (1988) statistical method was used with significance level .05, effect size .30 and testability .95. Taking the insufficient number of responses into account, data were collected from 200 persons; 194 questionnaires were finally analyzed, with the exception of 7 copies having poor or no responses

The collected data were statistically processed by using an SPSS/WIN 23.0 Program in following specific way: For the respondents' general characteristics, perceived health status, psychological well-being and health promotion behavior, the real number, percentage and the mean and standard deviation were estimated. For perceived health status, psychological well-being and health promotion behavior by the respondents' general characteristics, t-test and ANOVA were performed, along with Scheffe's method as post-hoc test. Person correlation coefficient was estimated to determine correlation between perceived health status, psychological well-being and health promotion behavior.

Health perception was measured by using the tool which had been developed and adapted by Ware (1976) and translated by Lee^[12]. This tool had a total of 12 items--6 positive ones and 6 negative ones--which covered concerns about present, past and future health; the positive items were scored 5 totally agree and 1 totally disagree and the negative ones were scored backward. The total scores ranged from 12 to 60, with a higher score meaning a higher level of perceived health status; Cronbach's $\alpha=.92$ in this study.

Psychological well-being was measured by using the tool applied by Jeong^[13]. This tool had a total of 16 items in two areas--8 concerning the changes of the self and the world and 8 concerning the changes in the view of life and in the interpersonal relationships--in the five-point likert scale whose scores ranged from 1 totally disagree to 5 totally agree, with a higher score meaning a higher level of psychological well-being. For its reliability, Chronbach's $\alpha=.91$ in this study

Health promotion behavior was measured by using the health-related behavior inventory developed by Lee^[14], which was composed of 57 items: 33 concerning behavior and 24 concerning awareness. It had a five-point likert scale whose scores ranged from 1 not at all to 5 all the time and whose total scores ranged from 27 to 135, with a higher score meaning a higher likelihood to do

health-related behavior. For its reliability, Chronbach’s α was .79 at the time of its development and .89 in this study

Result and Discussion

Differences in perceived health status, psychological well-being and health promotion behavior by respondents’ general characteristics:

The variation in perceived health status, psychological well-being and health promotion behavior by the general characteristics is as presented in Table 1. Perceived health status differed significantly by grade, household financial status and smoking and alcohol intake status. For perceived health status, freshmen and sophomores scored higher than seniors; non-smokers and non-drinkers scored higher; and students whose household financial status was at high levels scored higher than those whose household financial status was at low levels. This result was similar to the findings from the research in college students [15]. Because higher graders feel poorer health status due to the increased

burden of employment and graduation, it is necessary to develop differentiated education concerning this issue. Psychological well-being differed significantly by religion, grade, academic satisfaction and residence type. Those having no religion, higher graders, those less satisfied with their major and self-boarding students had lower levels of psychological well-being. This result demonstrates that young adults may rely on their family and need assistance from supporters, such as religion. Health promotion behavior differed significantly by major, gender, household financial status and academic achievement. For health promotion behavior, nursing students scored lowest and the male students scored higher than the female ones. The merchants’ group scored high for health promotion behavior in terms of household financial status and academic achievement. This result is consistent with the findings that nursing students had a heavier burden of academic work and practice than the students at other departments [16] and that the higher academic achievement, the higher score for health promotion behavior [17].

Table 1. Differences in perceived health status, psychological well-being and health related behavior by respondents’ general characteristics

Table 2. Degree of perceived health status, psychological well-being and health promoting behavior

	M±SD
Perceived Health Status	42.8±0.52
Psychological Well-being	2.27±0.28
Health Promoting Behavior	2.57±0.41

Respondents’ perceived health status, psychological well-being and health promotion behavior: The respondents’ perceived health status, psychological well-being and health promotion behavior are as presented in Table 2. The respondents scored an average of 42.8 out of 60 for perceived health status. This is lower than an average of 3.37 out of 5 in nursing students [18] and 4.42 in general students [19] and implies that college students have recently had poor perception of their health status due to various types of stress. They scored an average of 2.27 out of 5 for psychological well-being, which was similar to the findings from the research in college students; college students in early adulthood commonly scored lower for psychological well-being than the middle aged or other occupation groups, demonstrating instability characteristic of early

adulthood. They scored an average of 2.57 out of 5 for health promotion behavior. This result is also consistent with the findings from other studies [20]: college students are passive about health promotion behavior practice, fail to be psychologically stable and fail to be well aware of the importance of practice for health.

Correlation among perceived health status, psychological well-being and health promotion behavior: The correlation among psychological well-being, perceived health status and health promotion behavior is as presented in Table 3. Psychological well-being was significantly positively correlated with perceived health status ($r=.617, p<.000$) and health promotion behavior ($r=.516, p<.000$), significant positive correlation was found between perceived health status and health promotion behavior ($r=.667, p<.001$). As this study and Min [21] found that perceived health status was more strongly correlated with health promotion behavior, it has been confirmed that psychological well-being promotion is an important factor in improving health promotion behavior among college students. It is necessary to develop programs focusing on psychological well-being promotion for college students.

Table 3. Correlation among perceived health status, psychological well-being and health promotion behavior

	Perceived health status	Psychological well-being	Health promotion behavior
Perceived health status	1		
Psychological well-being	.617(.000)	1	
Health promotion behavior	.516(.000)	.667(.000)	1

Conclusion

This study is descriptive research aimed at determining the level of association among perceived health status, psychological well-being and health promotion behavior in college students and at providing basic data that could help improve health promotion behavior for college students in early adulthood. This study found that psychological well-being was correlated with perceived health status and health promotion behavior. This is an unstable period during which people can be very passive about the act of health care, have poor awareness of disease and unhealthiness and show a lower level of psychological well-being. It is therefore necessary to provide college students in early adulthood with opportunities to participate continuously in health promotion practice education, taking their characteristics into account and to develop customized programs so that they can have a will to participate in the education.

²Professor, Dept. of Nursing Science, Pai Chai University, South Korea

Abstract

Background/Objectives: With the rapid economic development and changes in living conditions in south Korea, the frequency of chronic diseases has been gradually increasing due to westernized eating habits and decreased physical activities. This study is a descriptive secondary analysis designed to provide basic data necessary to maintain healthy life for patients of osteoarthritis patients by analysing the risk of metabolic syndrome affecting osteoarthritis in Koreans.

Method/Statistical Analysis: Secondary analysis was conducted on the 6th KNHANESraw data provided by the Korean Ministry of Health and Welfare. A total of 4,571 adults aged 19 or older who received both health and medical examinations were selected for analysis.

Findings: 10.8% of total subjects were identified to have osteoarthritis. Logistic regression analyses after adjusting age, sex, education levels, smoking and drinking revealed that the odds ratio of osteoarthritis increased depending on waist circumference of the persons reviewed in the study (OR 1.474, 95% CI=1.121-1.938) in the metabolic syndrome components.

Improvements/Applications: In conclusion, this study showed the waist circumference only of other components of metabolic syndrome was significantly related to osteoarthritis in Korean adults. Therefore, this study suggested that intensive management of obesity including abdominal obesity be useful to prevent risks of osteoarthritis.

Keywords: *Metabolic syndrome, Osteoarthritis, Korean National Health and Nutrition Examination Survey, KNHANES.*

Introduction

Recently, the frequency of chronic diseases in south Korea has been gradually increasing due to rapid economic development and changes in living conditions, as well as westernized eating habits and

decreased physical activities. Accordingly, various chronic diseases are leading the main causes of death, in the order of malignant neoplasms (cancer), heart disease, cerebrovascular disease, diabetes, chronic lower respiratory disease and hypertension^[1]. The concept of metabolic syndrome emerged when it was announced that several risk factors for cardiovascular disease among these chronic diseases could increase the incidence of cardiovascular disease if they existed together in one person. It is known that the major risk factors of cardiovascular disease, such as abdominal obesity, hypertension, hyperglycemia and hyperlipidemia, occur simultaneously in clusters, especially insulin resistance,

University, South Korea

e-mail: whmoon@pcu.ac.kr

which is a common denominator, is known as the major etiology. The mechanism of outbreak of metabolic syndrome has not yet come to light, but it is caused by the interaction of environmental factors, including genetic factors and inappropriate eating habits. Genetic factors are difficult to control, but metabolic syndrome can be prevented by improving environmental factors^[2]. In advanced countries, about a quarter of the population has metabolic syndrome, the overall prevalence rate of metabolic syndrome in south Korea ranged from 20.1% in 1998 to 23.2% in 2012. In addition, the prevalence rate of metabolic syndrome, that is adjusted for age in the population of total adults, has been steadily increasing to 31.3%^[3-4]. It is also known that if the condition is not improved with metabolic syndrome, the risk of developing to cardiovascular disease is 2 times higher and the risk of developing to diabetes is 4 to 6 times higher^[5].

Meanwhile, osteoarthritis is the most general joint disease in adults, accompanied by extreme pain and severely impairing physical and functional disorders and degrading quality of life. In addition, osteoarthritis is a very heavy economic loss and health-related economic burden in that it is the second highest in medical expenses after hypertension^[6]. The prevalence rate of osteoarthritis in Koreans aged 50 and over was 12.5% between 2010 and 2013. By age, the 50s accounted for 4.7% and the 60s accounted for 14%^[4]. The proportion of the elderly population in Korea has been increased from 7.2% in 2000 to 13.1% in 2015 and 14.3% in 2018 due to the development of medical technology and improved living standards and is expected to go into a super-aged society at 2026 with 20% in^[7]. With this aging phenomenon, the prevalence rate of osteoarthritis is expected to continue to increase.

Both osteoarthritis and metabolic syndrome are chronic diseases and due to the characteristics of a rapidly aging society, the prevalence rate has continued to increase, affecting individuals or countries gradually with social and economic ways. In addition, cardiovascular disease and osteoarthritis, which are related to metabolic syndrome, are common risk factors for age and obesity and several epidemiological and biological studies show that similar inflammatory patterns in metabolic syndrome-related cytokine environments as osteoarthritis is no longer only degenerative. Recently, studies on the association of metabolic syndrome and osteoarthritis has been conducted in United Kingdom and the United States, a study conducted in Japan

has been reported that the increase in the number of components of metabolic syndrome and the prevalence rate of knee arthritis have been associated^[8]. In other words, studies on metabolic syndrome and osteoarthritis have been conducted internationally, but there are few studies regarding this subject in Korea.

Therefore, the purpose of this study is to provide basic data for maintaining healthy life of osteoarthritis patients by analysing the risk of metabolic syndrome affecting osteoarthritis in Koreans and identifying the association between metabolic syndrome and osteoarthritis.

Method

Study Design: This study is a secondary analysis study using raw data in 2014, the second year of the 6th KNHANES of the Ministry of Health and Welfare in Korea and is a descriptive research to determine the risk of metabolic syndrome affecting osteoarthritis in Koreans.

Research subject and data collection: The data of this study was analysed by receiving raw data on the KNHANES. Of the 7,550 persons surveyed in the study, 5,979 adults aged 19 or older received both health surveys and medical check-ups. Of these, 4,571 persons (1,927 males and 2,644 females) were subject to analysis, excluding those who had metabolic syndrome components and missing values of osteoarthritis.

Research Variable: The health survey questions in the KNHANES data were used such as monthly average income, education and economic activities, smoking, drinking and physical activities and the examination result was used for the analysis of physical measurements, blood pressure and blood. The demographic characteristics of the subjects were categorized by gender, age, marital status, education level and income level. The classification according to health behaviour was used by smoking, drinking, moderate physical activity days, weekly walking days, body mass index and stress perception rate, etc. The variables of osteoarthritis classified according to the subject's answers in health questionnaire. It is that those who answered with no osteoarthritis in the questionnaire were divided into 'group without osteoarthritis' and those who answered with osteoarthritis in the questionnaire were divided into 'group with osteoarthritis'. The diagnosis of metabolic syndrome was based on the diagnostic criteria of NCEP ATP III. The waist circumference was provided by the

Korean Society for Obesity [9], which is suitable for Koreans. A case of having three or more risk factors of blood pressure, waist circumference, blood sugar, HDL-cholesterol, or triglycerides as a component of metabolic syndrome is defined as metabolic syndrome.

Data analysis method: Statistical analysis was conducted using the IBM SPSS 23 program and statistical significance test level was $p < 0.05$. The risk of osteoarthritis according to metabolic syndrome components and metabolic syndrome was analysed by logistic regression.

Result

General, physical and psychological factors:

In this study, the prevalence rate of osteoarthritis was 10.8% of the total subjects. The prevalence rate of osteoarthritis by gender was 4.5% for male and 15.4% for female, which was higher for female than for male ($p < .001$). The prevalence rate of osteoarthritis by age was 0.4% under 40s, 1.7% in 40s, 9.8% in 50s, 22.1% in 60s and 29.6% in 70s and older ($p < .001$). The prevalence rate of osteoarthritis according to the marital status was 12.7% in married group, which was higher than 0.4% in unmarried group ($p < .001$). The prevalence rate of osteoarthritis according to education level was elementary school undergraduates, 28.9%, elementary school graduates, 13.7%, high school graduates, 5.3%, university graduates, 2.7% that is the higher the educational background was low of the prevalence rate of osteoarthritis ($p < .001$).

The prevalence rate of osteoarthritis according to the classification of the fourth-tier income level was 23.0% for the low class, 10.9% for the middle-low class, 8.2% for the middle-upper class and 5.8% for the upper class, with a lower rate of osteoarthritis as income increases ($p < .001$).

As a result of analysing the difference in osteoarthritis prevalence rate according to health behaviour, the rate of osteoarthritis prevalence was 13.8% in non-smoking groups, 7.4% in the past smoking groups and 3.1% in the current smoking group and lower in current smoking group ($p < .001$). 15.1% in non-drinking groups, 7.7% in moderate drinking groups and 6.2% in severe drinking groups. The higher the frequency of drinking, the lower the prevalence of osteoarthritis ($p < .001$). The prevalence rate of osteoarthritis due to moderate physical activity was higher in the group who did not exercise 6.0%, less than 3 days a week, 5.6% and 11.6% more than 3 days

a week ($p < .001$). The prevalence rate of osteoarthritis according to the number of days of walking per week was in the group who did not walk per week, 12.9%, 8.2% for less than 3 days a week and 10.6% for more than 3 days a week ($p = .013$). The prevalence rate of osteoarthritis according to BMI was 8.8% under 25.0(normal) and 15.1% over 25.0(obesity). The prevalence rate of osteoarthritis according to the stress perception rate was 10.6% with low stress and 10.2% with high stress, so there was no difference between the two groups.

Effects of metabolic syndrome affecting osteoarthritis:

The risk of metabolic syndrome affecting osteoarthritis is as shown in [Table 1]. In metabolic syndrome, the risk of osteoarthritis was 2.318times higher, in fasting glucose was 1.497 times higher, in HDL cholesterol was 1.721 times higher and in triglycerides 1.746 was higher in the abnormal group than in the normal group [Table 2].

Table 1. Odds ratio of osteoarthritis according to metabolic syndrome (N=4571)

Metabolic syndrome	Osteoarthritis	
	Odds ratio	95% CI
Abnormal(Ref. Normal)	2.318	1.913-2.808

Table 2. Odds ratio of osteoarthritis according to components of metabolic syndrome (N=4571)

Variables	Osteoarthritis	
	Odds ratio	95% CI
BP	2.376	1.966-2.871
WC	2.215	1.822-2.692
FPG	1.497	1.237-1.811
HDL-Cholesterol	1.721	1.417-2.089
TG	1.746	1.447-2.108

BP: Blood pressure, WC: Waist circumference, FPG: Fasting plasma glucose, TG: Triglycerides

Risk of osteoarthritis by metabolic syndrome:

The risk factors of osteoarthritis tested by multivariate analysis with statistically significant variables extracted from multivariate analysis are shown in [Table 3]. The risk of osteoarthritis in gender was 5.772 times higher for female (95% CI=3.548-9.392) compared to male. The risk of osteoarthritis in age was 2.792 times in 40s (95% CI=1.019-7.651), 50's 14.869 times (95% CI=6.026-36.687), 60's 37.514 times (95% CI=15.097-93.214), over 70's 45.620 times (95% CI=17.895-116.297), the older the age, the greater the risk of osteoarthritis. At the education level compared to the elementary graduates,

the risk of osteoarthritis was 0.632 times (95% CI=0.442-0.904) for high school graduates and 0.537 times (95% CI=0.334-0.849) for university graduates and 0.747 times (95% CI=0.515-1.086) for middle school graduates but not statistically significant.

The risk of osteoarthritis of metabolic syndrome was 1.167 times higher in the abnormal group than in the normal group, but it was not statistically significant.

Table 3. Risk of osteoarthritis according to metabolic syndrome (N=4571)

Variables	Osteoarthritis	
	Odds ratio	95% CI
Women(Ref. Men)	5.772	3.548-9.392

Heavy drinker	0.864	0.590-1.267
Metabolic syndrome (Ref. Normal)	1.167	0.901-1.513

Discussion

The prevalence rate of osteoarthritis in this study was 10.8%, that female was higher than that of males and increased with age. This is consistent with a study on osteoarthritis in Korea [9], which appears to be higher than that of men as women grow older due to a decrease in female hormones after menopause. The prevalence rate of osteoarthritis caused by health behavioural factors was higher in non-smoking and non-drinking groups and the results were consistent with preceding studies [6,10-11]. This appears to be due to the high number

of osteoarthritis in women who have a high proportion of non-smokers and non-drinkers.

The body mass index showed a higher risk of osteoarthritis in cases higher than 25.0 than BMI below 25.0, which was consistent with preceding studies [2,12] that increased BMI raises the risk of osteoarthritis in the knee [13] and the U.S. NHANES reported that higher BMI increases the risk of knee osteoarthritis [13]. Only the waist circumference showed statistically significant results as an influence variable for osteoarthritis among metabolic syndrome components and these results were consistent with existing studies [13-14]. Previous studies have shown that obesity is associated with the development of osteoarthritis. However, In Korea, there are many cases of light and severe obesity and abdominal obesity compared to Westerners. It means despite low waist circumference and low BMI, risk factors for other chronic diseases as a high aspect seems to be increased [14].

In addition, according to the 5th Annual Report of the KNHANES [15], abdominal obesity was 18.3% in people aged 19 to 64 and 46.1% in people aged 65 or older, while BMI measures 24.1% in adults aged 19 to 64 and 37.8% in people aged 65 or older. In other words, in adults under 64 years of age, obesity by BMI is higher than abdominal obesity, while in people over 65 it is more likely to be abdominal obesity is higher than BMI [14]. The study also found that the prevalence rate of abdominal obesity is 21.2% for those under 65 years old and 34.2% for those over 65 years old, with the prevalence rate of osteoarthritis rising much higher. Therefore, it is necessary to control obesity including abdominal obesity and education should be strengthened to prevent and improve osteoarthritis in the future. In addition, as the number of risk factors of metabolic syndrome components increased, the risk of osteoarthritis increased and common risk variables among upper combinations were blood pressure and waist circumference, which would also be necessary to control the combination for each component.

Conclusion

This study is a descriptive secondary analysis designed to examine the association between metabolic syndrome and osteoarthritis in adults by analysing the raw data of 4,571 adults from the 6th KNHANES in south Korea.

In metabolic syndrome, the risk of osteoarthritis was

2.318 times higher, in fasting glucose was 1.497 times higher, in HDL-cholesterol was 1.721 times higher and in triglycerides 1.746 was higher in the abnormal group than in the normal group.

In conclusion, the importance of abdominal obesity control should be emphasized considering the relation with osteoarthritis of metabolic syndrome. In addition, since metabolic syndrome and osteoarthritis are multifactorial diseases and more risk factors for metabolic syndrome components cause to increase the risk of osteoarthritis, it is necessary to control each component as well.

This study is a secondary study that extracts and re-analyzes part of the master's thesis by Kim ^[16].

The Effects of Critical Thinking Disposition, Perception of Others and Empathy on Communication Competency among Students Majoring in Nursing

Hyea-Kyung Lee¹, Eun-Hee Shin²

¹Professor, Nursing Department, Jungwon University, 185 Munmuro Goesan-eup, Goesan-gun, Chungcheongbuk, Korea, 28024, ²Professor, Nursing Department Munkyeong College, 161, Daehak-gil, Hogyemyeon, Mungyeong-si, Gyeongsangbuk-do, Republic of Korea, 36930

Abstract

Background/Objectives: This study seeks to identify correlations among critical thinking, perception of others and communication competency among nursing school students

Method/Statistical Analysis: Survey respondents were 1st, 2nd, 3rd and 4th year students majoring in nursing at three universities of Chung Nam and Chung Buk who understood the objectives of the study and who gave their consent on participation.

Findings: The critical thinking of subjects scored 3.27(1~5), their perception of others scored 3.35(1~5), empathy scored 3.15(1~5) and communication skills was 3.34(1~5). Variables affecting respondents' communication competency were critical thinking disposition 27.5% ($\beta=0.42$, $p<0.001$), peer relationships 7.8% ($\beta=0.27$, $p<0.001$) and perception of others 6.2% ($\beta=0.27$, $p<0.001$) with a total explanatory power of 41.5%. The study found out that, among those independent variables, critical thinking disposition has the greatest effect on communication competency.

Improvements/Applications: Based on these findings, it seems necessary to develop curriculums and programs that include strategies for smooth communication competency and improved critical thinking among nursing school students.

Keywords: Nursing school students, critical thinking, communication competency, empathy, perception of others.

Introduction

Communication competence is the ability to clearly express one's opinion, or clearly describe one's point of view when the other person's opinion is different from one's own opinion [1]. To nursing school students who have to satisfy nursing demands of

patients in the relationship with patients and people with different professions, it is very important to improve communication competence from college days [2].

Critical thinking is the process where one judges on what to rely on among given contents. As critical thinking ability in nursing process allows nurses to make decisions based on reasons, it is very important in clinical practices [3].

To improve communication competence, the process in which one can correctly perceive the other person and have empathy with the person is needed [4]. The higher one has ability to perceive the other person, the more one can focus on the other person in communication process and the more correctly one can get the information about

the other person [5]. Consequently, perception of others can be considered as an element affecting communication competence of nursing school students.

Empathy is the ability to see the situation with the view of the other person and communicate by understanding the other person's emotion without criticism [6]. Empathy is the ability to communicate with the other person by accurately expressing the internal meaning of emotion the other person cannot express [7]. In nursing, empathy is an important means to form treatment relations with patients and induce cooperation with persons in other professions and strategy to provide effective nursing [8].

Previous researches have suggested variables related with communication competence among nursing school students as follows: one's opinion [9], self respect [9, 10], emotional intelligence, empathic ability [10, 11], grade [11], stress from clinical training [10], perception of oneself and the other person [12] and critical thinking disposition [2]. But, there are not enough researches examining relationship among critical thinking disposition, perception of others and empathic ability. Accordingly, this research intends to examine critical thinking disposition, perception of others and empathic ability and factors affecting communication competence and provide basic sources to develop strategies to improve communication competence.

Materials and Method

- 1. Design:** This research is a descriptive survey research to examine the effect of critical thinking disposition, perception of others and empathic capacity on communication competence among nursing school students.
- 2. Subjects:** This research did a survey to students in nursing departments in 3 universities located in Chungcheongnamdo and Chungcheongbukdo. Those students are from freshmen to senior students. They understood the purpose of this research and agreed to participate in this survey. They signed the agreement on participating in this survey and, they filled out structured questionnaire. The size of samples was calculated with the help of G*Power program. The program demonstrated that the minimum number of respondents needed to do multiple regression analysis using about 7 variables, middle size effect .15, significance level 0.5 and test power .95 is 153. Thus, this research

did survey to 200 respondents and, 197 copies of the questionnaire were used for analysis, excluding 3 copies which were not answered properly.

3. Tools:

Communication Competency: To measure communication competence, this research used Global Interpersonal Communication Competence (GICC) scale developed by Huh Gyeong-ho [13]. The reliability of the tool when Huh developed the scale was Cronbach's $\alpha = 72$. In this research, Cronbach's α was .85.

Critical thinking disposition: To measure critical thinking disposition, this research used the tool developed by Gwon In-soo et al. [13]. The reliability of the tool when they developed the scale was Cronbach's $\alpha = .89$. In this research, Cronbach's α was .88.

Perception of others: To measure perception of others, this research used the tool developed by EunHyeok-gi to test perception of others among Korean adolescents [14]. The reliability of the tool when they developed the scale was Cronbach's $\alpha = .85$ and, in this research, Cronbach's α was .89.

Empathy: To measure empathic capacity, this research used Interpersonal Reactivity Index (IRI) developed by Davis [15] and translated into Korean by Gang Il, et al. The reliability of the tool when Davis developed the scale was Cronbach's $\alpha = .89$. In this research, Cronbach's α was .88.

- 4. Data analysis:** Collected data were analyzed using SPSS 21.0 statistical program. The characteristics of respondents were measured by frequency distributions. Critical thinking disposition, perception of others, empathy and communication competence were analyzed by means and standard deviation. The relationship between general characteristics of nursing school students and their communication skill was analyzed by t-test and ANOVA. Scheffe-test was used for ex-post analysis. The relationships among critical thinking disposition, perception of others and communication competence were analyzed by Pearson's correlation coefficient. To examine variables affecting communication competence of respondents, this study did stepwise multiple regression analysis.

- 5. Ethical Consideration:** To respondents of the survey, this research explained the purpose of the survey and explained that they could stop answering

questions during the survey. The questionnaire was distributed only to students who agreed to and would voluntarily participate in the survey.

Results and Discussion

General characteristics of subjects: The average age of respondents was 21.7 years old and proportion of females was 82.9%. The distribution of students per school year was as follows: Freshmen 30.0%, seniors 25.2%, sophomores 23.3% and juniors 21.4%. To the

questions on motive of choosing nursing as major, 45.2% of respondents answered that they could find jobs easily after graduation, followed by 31.0% who said that their high school scores allowed them to apply for the nursing department and who said their aptitude fit nursing. In satisfaction with major, 41.9% of them said they were “satisfied” and 34.3% said “So so”. In relationship with friends, 48.1% said they had good relationship and 30.0% said “So so”. (See Table 1.)

Table 1. General characteristics of respondents

Characteristics	Classification	N (%)	M±SD
Age			21.73±2.43
Gender	Male	36(17.1)	
	Female	174(82.9)	
Religion	Yes	50(23.8)	
	No	160(76.2)	
Grade	Freshman	63(30.0)	
	Sophomore	49(23.3)	
	Junior	45(21.4)	
	Senior	53(25.2)	
Motive to choose nursing as major	Considering high school scores	9(4.3)	
	Aptitude and hobby fit nursing	65(31.0)	
	Easy to find jobs after graduation	95(45.2)	
	Recommended by parents or teachers	35(16.7)	
	Others	6(2.9)	
Satisfaction with major	Not satisfied at all	6(2.9)	
	Not satisfied	20(9.5)	
	So so	72(34.3)	
	Satisfied	88(41.9)	
	Very satisfied	24(11.4)	
Relationship with riends	Very bad	2(1.0)	
	Bad	2(1.0)	
	So so	6.3(30.0)	
	Good	101(48.1)	
	Very good	42(20.0)	

Differences in communication competency depending on general Characteristics: In the relationship between general characteristics of respondents and communication competency, gender (t=-1.75, p=.081), religion (t=-1.208,p=.205), school year (F=.18, p=.905), motive to choose nursing as major (F=1.06, p=.376) did not have any statistically

meaningful differences. But relationship with friends (F=4.58, p=.001) and satisfaction with major (F=2.87, p=.024) did have statistically meaningful differences. Scheffe ex-post test showed that good and very good relationship with friends significantly boosts communication competency (See Table 2.).

Table 2. Difference in communication competency depending on general Characteristics

Characteristics	Classification	M±SD	t or F	p
sex	Male	3.23±.42	-1.75	.081
	Female	3.36±.41		
Religion	Yes	3.28±.36	-1.20	.228
	No	3.36±.43		
Grade	Freshman	3.35±.38	.18	.905
	Sophomore	3.35±.39		
	Junior	3.36±.52		
	Senior	3.30±.39		
Relationship with friends	Very bad	3.40±.18	4.58 d,e>c	.001
	Bad	3.20±.28		
	So so	3.16±.31		
	Good	3.42±.37		
	Very good	3.43±.58		
Motive to choose nursing as major	Considering high school scores	3.35±.46	1.06	.376
	Aptitude and hobby fit nursing	3.40±.40		
	Easy to find jobs after graduation	3.29±.42		
	Recommended by parents or teachers	3.35±.43		
	Others	3.55±.30		
Satisfaction with major	Not satisfied at all	3.00±.32	2.87	.024
	Not satisfied	3.19±.35		
	So so	3.31±.39		
	Satisfied	3.39±.42		
	Very satisfied	3.48±.47		

Correlations among critical thinking disposition, perception of others, empathy and communication competency: Critical thinking disposition and communication competency are significantly correlated

($r=.528$, $p<.001$) and empathy and communication competency are significantly correlated ($r=.416$, $p<.001$) and perception of others and communication competency are significantly correlated ($r=.452$, $p<.001$)[Table 3].

Table 3. Correlations among critical thinking disposition, perception of others, empathy and communication competency

	Critical thinking disposition	Percept-ion of others	Empathy	Communi-cation Compete-ncy
Critical thinking disposition	1			
Perception of others	.394** ($<.001$)	1		
Empathy	.571** ($<.001$)	.478** ($<.001$)	1	
Communicat-ion Competency	.528** ($<.001$)	.452** ($<.001$)	.416** ($<.001$)	1

Variables affecting communication competency: To examine relative influences of critical thinking disposition, perception of others and empathy on communication competency, this research did multiple

regression analysis using 5 independent variables: 2 general characteristics variables which were found to be statistically significant—relationship with friends and satisfaction with major - and above 3 variables

- critical thinking disposition, perception of others and empathy. The analysis showed that the following three variables had 41.5% explanatory power in total: critical thinking disposition 27.5% ($\beta=.421, p<.001$), relationship with friends 7.8% ($\beta=.272, p<.001$) and perception of others 6.2% ($\beta=.276, p<.001$).

Before conducting multiple regression analysis,

this research did multicollinearity test and found that tolerance limits are .843~.998, above 0.1 and Variance Inflation Factor, (VIF) was 1.002~1.186, below 10. Thus, multicollinearity was not the problem. And independency of standard residuals test showed that Durbin-Watson statistics was 2.057, near 2. Thus, there was no problem [Table 4].

Table 4. Variables affecting communication competency

Variable	B	β	SE	t	p	Adj R2	F	p
Constant	.560		2.45	2.28	.024		50.38	<.001
Critical thinking Dispositi-on	.573	.421	.078	7.30	<.001	27.5		
Relationship with friends	.245	.272	.048	5.14	<.001	35.3		
Perception of others	.221	.276	.046	4.78	<.001	41.5		

Discussion

This research intended to examine critical thinking disposition, perception of others and empathy and variables affecting communication competency among nursing school students and provide basic sources for making and implementing educational programs in the future.

Among general characteristics of respondents, relationship with friends and satisfaction with major make significant differences in communication competency. In the relationship between relationship with friends and communication competency, 'good' and 'very good' relations with friends improve communication competency of respondents compared with 'so so' relations with friends. It means that good relations with friends have positive effect on communication competency. In the same context, satisfaction with major boosts communication competency. Such findings are consistent with findings of Lee & Chung [16], Kwak et al. [10] and Ji [8]. The results seem to be caused by the facts that positive perception on major affects attitudes on professional jobs as well as knowledge area through theoretical education and training education.

There were positive correlations among critical thinking disposition, perception of others, empathy and communication competency. It supports the findings of other researches that the higher critical thinking disposition is [16, 17], the higher empathy is [10, 18], the higher perception of others is [12, 19, 20], the higher communication competency is. Communication

competency is an essential capacity nurses should be equipped with and the basic capacity nursing school students should be equipped with. As it will ultimately improve clinical performance ability of nurses, it is necessary to cultivate communication competency through various learning method in the courses related with communication in the curriculum.

As variables predicting communication competency, critical thinking disposition, relationship with friends and perception of others had explanatory power of 41.5%. While Kwak et al. [10], Jeong et al. [18] found out that empathy affects communication competency, this research did not find such a relationship between the two variables. In the previous research, critical thinking disposition affects communication competency and lets nurses make decisions focusing on foundation basis [21].

If critical thinking disposition is internal to individuals, it is necessary to lead nurses to take care of patients by suggesting rational and reasonable knowledge as basis toward examining the problem of the objects more specifically and minimizing conflicts with the objects [17]. Considering that improvement of critical thinking disposition is the basic premise to improve communication competency, a core capacity of nurses, it is very important to make efforts to cultivate such capacity in nursing education [16]. Consequently, it is necessary to change educational environment or teaching method of nursing education toward improvement of critical thinking disposition [21].

Good relationship with friends was shown to improve communication competency. As there is no previous research dealing with the relationship between the two variables, repetitive researches on it are required. Perception of others means to pay attention to attitudes, action, or feature of others and think of internal thinking and emotion of others [20]. Perception of others is an important element of communication competency. The more attentive one is to others, the higher one is likely to communicate well with others [22]. It seems necessary to do continuous researches on communication competency in the future.

Conclusion

This research is a descriptive survey research to examine the effects of critical thinking disposition, perception of others and empathy on communication competency among nursing school students. The analysis found out that those variables like critical thinking disposition, relationship with friends and perception of others have effects on communication competency. This research is significant in that it suggests a direction in educational programs and implementation of them on communication competency. The findings of this research can be used as basic sources in searching for effective learning strategies to cultivate communication competency and apply and evaluate them. Based on such findings, this research suggests that we need researches on concrete practical ways to improve communication competency among nursing school students.

Changes in the Health-related Quality of Life among Korean Adults: Data Comparison between 2007 and 2017

Myoung-Hee Kim

Professor, Department of Nursing, Semyung University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to analyze and compare changes in Koreans' health-related quality of life between 2007 and 2017.

Method/Statistical Analysis: A secondary analysis was conducted using raw data from 3,854 adults over 20 years old using the Korean National Health and Nutritional Examination Survey (KNHANES) statistics for 2007 and 2017.

Findings: In 2007 the health-related quality of life (EQ-5D) among respondents was 0.97 and it was 0.98 in 2017, which indicated that there were not significant changes in this area. However, among other EQ-5D items, particularly with regard to anxiety and depression, there was a significant decrease noted in 2017 compared to 2007. In addition, socio-economic factors such as level of education and marital status affected health-related quality of life.

Improvements/Applications: It is necessary to develop and manage policies that take into consideration factors affecting people's health-related quality of life.

Keywords: *Quality of life, HR-QoL, EQ-5D, Korean, KNHANE.*

Introduction

As medicine and technology have developed, the world's elderly population has also grown dramatically. This growth in the elderly population has also tended to increase morbidity rates through chronic illness and medical costs. Promoting health-related quality of life (below HR-QoL) is one of the most important tasks of the government, as health and happiness in life is more important than living longer. The Korean government has also tried to establish a fundamental model for various public health and well-being services to improve people's health-related quality of life. HR-QOL is an

individual's or a group's perceived physical and mental health over time. The Korea Centers for Disease Control and Prevention website provides general information about health-related quality of life, such as HR-QOL surveillance and its role in public health practice. The site also lists HR-QOL trend data by state and demographics using our online HR-QOL data application^[1].

HR-QOL is an individual's perceived physical, mental and social health based on their individual's experiences, faith, expectations and level of awareness. The importance of the HR-QoL has gradually increased because it is an independent factor that affects various medical situations such as death and hospitalizations^[2,3].

The survey used the HR-QoL questionnaire from the Korean National Health and Nutritional Examination Survey (KNHANES) and it contained 5 sections, so called Euro QoL-5 dimensions (EQ-5D) asking about current health conditions^[4]. Past research indicated that health related quality of life was closely related to

Corresponding Author:

Myoung-Hee Kim

Professor, Department of Nursing, Semyung University,
Republic of Korea

e-mail: mh1352@semyung.ac.kr

socio-economic factors including education and income. This study focused on Koreans' HR-QoL from 2007 to 2017 with the goal of examining and investigating demographic factors that affect HR-QoL over time and to examine factors that need to be considered when implementing public health and well-being service models.

Method

This study performed a secondary analysis of the Korean National Health and Nutritional Examination Survey (KNHANES) data for 2007 to 2017.

The total number of subjects who participated in the Korean National Health and Nutritional Examination Survey (KNHANES) for 2007 were 4,594 and 8,127 in 2017. Of those subjects, 3,854 were included in the study because they were over 20 year old (1,286 in 2007 and 2,568 in 2017), answered all of the study variables and denied having an illness.

This study used the health related survey questionnaire from the Korean National Health and Nutritional Examination Survey (KNHANES). Demographic variables included sex, age, residential area, education level, marital status, household composition, household income level and occupation. Variables associated with physical and mental health included subjectively perceived health condition, activity confinement, perceived usual stress level, depression (in the past 2 weeks), suicidal ideation (in the past year) and body mass index(BMI).

The EQ-5D was used to measure HR-QoL. The EQ-5D is a standardized instrument that measures HR-

QoL and it is composed of 5 items/areas. The EQ-5D index was obtained by applying a weighted value to the measured score of each question. The score variation was 0 through 1 and higher scores indicated a better quality of life [5].

The study analysis was conducted by following usage guidelines of the Korean National Health and Nutritional Examination Survey (KNHANES) suggested by KNHANES. The raw materials of KNHANES were used for complex sample design.

The differences of EQ-5D index score of Korean adults between 2007 and 2017 were determined by using the complex sample Chi-square test. The socio-economic factors affecting the health-related quality of life of Korean adults in 2007 and 2017 were determined by using the complex sample general linear model (CSGLM) respectively. SPSS version 19.0 (SPSS Inc. Chicago, IL, USA) was used to measure the data and significance level was below 0.05.

Result and Discussion

Changes in Korean Adults' HR-QoL: [Table 1] presents changes in Korean adults' HR-QoL. In the past ten years, there were no significant differences in Korean adults' HR-QoL as the EQ-5D index indicated 0.97 for 2007 and 0.98 for 2017 (Wald F=2.39, p=0.123).

In EQ-5D, the only category to show a significant difference between 2007 and 2017 was anxiety/depression. This data indicates that the category of anxiety and depression had improved in 2017 compared to 2007 ($\chi^2=19.18$, p<0.001).

Value= Estimated value, SE= Standard error, a=Weighted value, EQ-5D: European quality of life-5 dimensions used as a measure of health-related quality of life (HR-QoL)., 1=Performed well, 2=Performed with a few difficulties, 3=Performed badly

HR-QoL comparison in socio-demographic characteristics between 2007 and 2017: According to the study's results regarding the HR-QoL related to socio-demographic characteristics, females, subjects in their 40s and those subjects who lived in urban and countryside areas showed significant differences.

Among women, the HR-QoL was significantly different for females in 2007 and women in 2017 (F=8.27, p=0.004). Significant differences were also noted among subjects in their 40s, where 95% CI of the HR-QoL was 0.97~0.98 in 2007 and 0.98~0.99 in 2017 (F=8.11, p=0.005). Among study subjects who lived in urban areas, 95% CI of their HR-QoL was 0.96~0.98 in 2007 and 0.98~0.98 in 2017, thus indicating that there was a significant difference (F=4.17, p=0.042). That is, compared to 2007, in 2017 the HR-QoL of women in their 40s and who lived in an urban areas had improved.

Factors affecting Korean adults' HR-QoL in 2007:

[Table 2] presents the factors affecting Korean adults' HR-QoL in 2007.

As the subject's age range for 2007 was converted into covariates, sex was the main factor that affected the HR-QoL for Korean adults in 2007. The EQ-5D

index score for Korean men in 2007 was higher than women and this indicated that the HR-QoL of Korean men in 2007 was also higher than that of women (Wald F=17.38, p<0.001). By exploring the HR-QoL according to subjects' educational level, scores for those with an elementary school or below education level were lower than for the subjects who were college students or graduates (95% CI= -0.055~-0.004, p=0.023).

As the study subjects aged, their HR-QoL lowered by 0.001 each year (Wald F =12.09, p=0.001).

The explanation power for socio-demographic variables among the HR-QoL of Korean adults in 2007 was 11.2% (Wald F=4.34, p<0.001).

The Oh's study^[6] about factors affecting the HR-QoL by age group (such as young age group, middle age group and elderly age group,) noted that the women's HR-QoL was low and both genders showed more differences in elderly age group. This study also noted that walking was one of the factors that affected the HR-QoL, thus emphasizing its importance. Factors affecting the HR-QoL played a more influential role for the middle and elderly age groups than young age group. Consequently, it is important to study factors negatively affecting the HR-QoL beginning at a young age.

Factors affecting Korean adults' HRQoL in 2017:

[Table 3] presents the factors affecting Korean adults' HR-QoL in 2017.

As subject's age among Korean adults in 2017 was converted into covariates, educational level (Wald $F=3.02$, $p=0.030$) and marital status (Wald $F=4.82$, $p=0.029$) were the main factors that affected the HR-QoL for Korean adults in 2017.

Those with an elementary school education level had lower quality of life compared to college graduates or those with a higher education level (95% CI= -0.037 ~-0.006, $p=0.007$). Related to marital status, the study subjects who were married indicated having a higher quality of life compared to the group of others (95% CI= 0.001 ~0.016, $p=0.029$).

Household income was not a significant factor affecting the total HR-QoL (Wald $F=2.47$, $p=0.062$),

but it indicated partially significant differences. The study subjects in the low income household group had a lower HR-QoL compared to those in the higher income household group (95% CI= -0.043 ~-0.007, p=0.008). This matched Kraus and Tan’s study results [7], which indicated that socio-economic status influences not only physical and mental health, but also social mobility.

Like the 2007 results, as the study subjects got one year older, their HR-QoL lowered by 0.001 in 2017 (Wald F =14.96, p<0.001).

The explanation power for the socio-demographic variables in the HR-QoL among Korean adults in 2017 was 6.7% (Wald F=3.69, p<0.001).

While numerous studies[8-9] indicated that several factors (younger age, male gender, higher level of education, higher annual household income, status of employment and marital status) affected the HR-QoL individually, this study’s results indicated that education level and socio-economic factors were more closely related to the HR-QoL.

Kim and Park’s research[10] supported this study’s findings that educational attainment was one of variables affecting the subjects’ HR-QoL. Both studies found that higher educational attainment correlated with quality of life and HR-QoL. Socio-economic status and subjective social class affected not only health related quality of life, but also overall quality of life. According to Robert et al.[11], an increased life span and economic growth has improved the HR-QoL in all age groups of subjects, but this change was hidden by an average score among the population and it is therefore important to focus on health differences by economic status for each age group.

Consequently, socio-economic status and level of education are important variables that should be considered when developing a program related to improving the health related quality of life. It is especially important to take into consideration that subjects with a lower socio-economic status might show different results in health related quality of life and overall quality of life.

Conclusion

In 2007 and 2017, the health related quality of life among Korean adults did not show any significant differences. However, a couple of socio-demographic factors affected the HR-QoL in 2007 and 2017. In 2007, men showed a higher HR-QoL compared to women, but there was no significant difference in 2017 and it indicated that sex did not affect the HR-QoL. In 2007, the level of education had some effect on the HR-QoL. In 2017, the level of education and marital status affected the HR-QoL of Korean adults and household income had some effect on the HR-QoL. In 2017, the study results indicated that educational attainment, marital status and economic factors played more significant roles in determining the HR-QoL.

In spite of the government's promotion of health-related policies, social economic status including income, education and assets continues to affect its citizens overall health and quality of life. It is necessary to understand health-related quality of life by considering socio-economic factors by age group when examining fundamental policies. When developing a program, it is equally important to consider the impact of a person's economic status on their health condition in order to improve their health-related quality of life.

Effects of VR-based Rehabilitation Video for Visual Vertigo on Autonomic Nervous System and Subjective Immersion and Interest in the Elderly

Chung-Yoo Kim¹, In-Bae Kim¹, Jong-Ho Kang²

¹Ph.D. Student, ²Professor, Department of Physical Therapy, Catholic University of Pusan, Rep. of Korea

Abstract

Background/Objectives: Many elderly people experience visual vertigo. VR will provide optokinetic stimulation to help reduce visual vertigo. This study is to investigate the rehabilitative effects of VR-based rehabilitation video.

Method/Statistical Analysis: The subjects of this study were 51 elderly people. The rehabilitation video was produced on the basis of traditional visual vertigo rehabilitation video. After watching the rehabilitation video, all subjects were measured for autonomic nervous system activity, heart rate and asked to write a questionnaire on subjective commitment and interest composed of 5 points scale. The collected data were subjected to independent t-test for comparison between groups.

Findings: In subjects who experienced visual vertigo, VR video group showed higher value in sympathetic nervous system activity and parasympathetic nervous system activity after visualization of rehabilitation video than general video group and, subjective immersion and interest showed the same results. In subjects who nonexperienced visual vertigo, on the other hand, VR video group showed higher value than general video group only in subjective immersion and interest after visualization of rehabilitation video. Based on the results of this study, the 360 degree VR rehabilitation video seems to have better therapeutic effect on visual vertigo than the existing video.

Improvements/Applications: Therefore, the convergent use of VR in the vestibular rehabilitation area improved the rehabilitation effect. Future research will increase the participation of active rehabilitation through the development of VR rehabilitation contents and programs.

Keywords: VR, Rehabilitation video, Visual vertigo, Autonomic nervous system, Immersion.

Introduction

Vertigo is one of the common symptoms in life. In particular, it is a high frequency in the elderly population and is a major factor in visiting hospitals^[1]. Vertigo is problematic in itself but has difficulty in performing daily

activities or affects falls^[2]. Data released by the KCDC (Korea Centers for Disease Control & Prevention) reports that falls are a serious threat to the health of the elderly and can result in death or permanent disability^[3]. Therefore, it is necessary to understand and manage the vertigo of the elderly to avoid this problem.

Vertigo can be caused by an imbalance in the vestibular, visual and proprioception systems that are involved in the equilibrium function. In addition, if one of these functions is lost, the other organ system will compensate. However, in older people, degenerative changes occur in all organ systems, making them more

Corresponding Author:

In-Bae Kim

Ph.D. Student, Department of Physical Therapy,
Catholic University of Pusan, Rep. of Korea
e-mail: star10815@hanmail.net

difficult to compensate for in other organ systems^[4]. Among the symptoms of vertigo, elderly people may feel dizzy due to visual stimulation, such as passing between grocery stands or looking at the escalator stairs. This is called visual vertigo^[5]. If people often feel dizzy after seeing moving objects in their daily activities, the elderly will be more likely to be exposed to falls. It is necessary to devise ways to alleviate the symptoms of visual vertigo.

Visual vertigo is deeply related to vestibular-ocular reflex^[6]. The eye is reflexively placed in the optimal position according to the eye movement according to the head movement and further the eye movement according to the body movement or alignment. However, elderly people may have errors in eye movements as their functions decrease as they age. This error causes vestibular problems such as vertigo and we must find ways to deal with these systematic problems.

Figure 1. Schematic diagram of study design

Vestibular rehabilitation is implemented as a way to solve problems in the vestibular system. In general, the mechanism of vestibular rehabilitation is explained by mechanisms through compensation, adaptation and substitution^[7]. Compensation uses a method of inducing habituation as a recovery method through the neuroplasticity of the central nervous system and it seems to have applied this principle to previous studies.

Figure 2. Galaxy Gear360

Recently, with the development of technology, virtual reality (VR) technology is further advanced. Since the first mention of “la realite virtuelle” in the Theatre of Cuelty of French writer Antonin Artaud, virtual reality has evolved to the extent that virtual reality feels as immersed. Previous studies have reported that the application of immersive VR in VR rehabilitation enhances the effect of rehabilitation^[8-9]. From this point of view, in the vestibular rehabilitation for visual vertigo patients, it is thought that VR using 360-degree video will show more effective rehabilitation effect than conventional rehabilitation.

In a recent study, Pavlou^[10] ‘s study, published in 2009, conducted vestibular rehabilitation to stimulate optokinetic in subjects with visual vertigo, suggesting that it would be a new innovation in vestibular rehabilitation. In addition, pavlou suggested the therapeutic potential for the method of kinetic stimulation using high-tech as well as traditional therapies such as low-tech DVD. Pavlou^[11], follow-up study, published in 2012, conducted a pilot study of patients with peripheral vestibular disease using optokinetic stimulation. As a result, dynamic VR reported the results of therapeutic effects as a useful adjunct to vestibular rehabilitation programs.

Motivation in rehabilitation as well as therapeutic effects is an important factor influencing the outcome of rehabilitation. Immersive imaging will be of interest to vestibular patients and have a positive impact on rehabilitation^[12]. From a variety of perspectives, it’s still unknown how VR using 360-degree video will benefit vestibular rehabilitation.

Figure 3. Ubipulse T1

Therefore, the purpose of this study is to investigate the effects of 360-degree VR video on autonomic nervous system, subjective immersion and interest in elderly people who experience visual vertigo and to investigate the rehabilitative effect of 360-degree VR video.

Method

This study was performed on 51 elderly people over 65 years of age living in Guri city, 18 males and 33 females participated in the study. The average age of the subjects was 72.16 ± 1.78 years and the average height and weight were 157.05 ± 5.06 cm and 58.72 ± 5.06 kg. All subjects participated in the experiment after hearing and agreeing with the purpose and method of the study. This study was conducted in compliance with the Helsinki Convention and the Research Ethics Standards. The schematic diagram of the study is shown in Figure 1.

All subjects were randomly assigned to the VR video group and general video group. The rehabilitation video was produced based on the previous visual vertigo rehabilitation video, which was a roadside drive, a street walk and a grocery store corridor. In the case of VR video, images were taken using Galaxy Gear360 (Samsung, ROK) [Figure 2] and the general video was taken using Galaxy Tab 3 (Samsung, ROK). The video was applied by wearing Galaxy Gear (Samsung, ROK) products and watched the Galaxy Tab 3 (Samsung, ROK) at eye level

and placed at a proper distance in view of eyesight. Subjects in each group watched VR and general video for 5 minutes according to their assigned group. After watching the rehabilitation video, all subjects were evaluated for autonomic nervous system activity and heart rate and a questionnaire about subjective immersion and interest composed of five-point scale was prepared. Autonomic nervous system activity and heart rate were measured using the heart rate variability measuring device (ubpulse T1, Laxtha, ROK) [Figure 3]. Collected results were classified into two groups and analyzed: experienced vertigo and non experienced group.

All measured data were independent t test using SPSS 21.0 to test the comparison between groups according to 360 degree VR application. The statistical significance level was set at 0.05.

Result and Discussion

According to the results of this study, In subjects who experienced visual vertigo, VR video group showed higher value in sympathetic nervous system activity (LF, low frequency) and parasympathetic nervous system activity (HF, high frequency) after visualization of rehabilitation video than general video group and, subjective immersion and interest showed the same results [Table 1]. In subjects who nonexperienced visual vertigo, on the other hand, VR video group showed higher value than general video group only in subjective immersion and interest after visualization of rehabilitation video [Table 2]. The results of this study showed that VR video was more immersive and interesting than general video and subjects who experienced visual vertigo were more affected by autonomic nervous system after visualization of rehabilitation video.

Table 1: The changes in subjects who experienced visual vertigo after visualization of rehabilitation video

	VR video	General video
Immersion*	4.07±0.83	2.93±0.44
Interest*	4.29±0.99	2.19±1.17
Heart rate	80.57±7.57	79.94±12.92
Low frequency*	5.44±0.80	4.76±0.97
High frequency*	4.84±0.46	4.19±0.94

*:p<0.05

unit: point, point, bpm, ms², ms²

The change of autonomic nervous system in this study can be regarded as change of vestibular system by visual response. Indeed, according to Kim^[13]'s research, the vestibular system and the autonomic nervous system are closely related as the Vestibulo-Autonomic System. In particular, Kim also showed an increase in the low frequency reflecting the sympathetic nervous system activity and the high frequency reflecting the parasympathetic nervous system activity. Table 2: The changes in subjects who nonexperienced visual vertigo after visualization of rehabilitation video

	VR video	General video
Immersion*	4.07±0.83	2.93±0.44
Interest*	4.29±0.99	2.19±1.17
Heart rate	80.57±7.57	79.94±12.92
Low frequency*	5.44±0.80	4.76±0.97
High frequency*	4.84±0.46	4.19±0.94

*:p<0.05

unit: point, point, bpm, ms², ms²

system activity. The results presented in this study suggest that the visual stimulation by VR video caused the change of autonomic nervous system and that stimulation by visual vestibular reflex can be effectively applied to vestibular rehabilitation.

In addition, according to Kim^[9]'s research, VR increased the immersion, the effect of rehabilitation and thus also affected the balance. Other studies have shown the similar result and it can be seen that the rehabilitation through VR enhances the effect of rehabilitation by increasing the immersion feeling compared to the existing video media^[14-15]. Therefore VR video is expected to show more effective rehabilitation effect than conventional therapeutic general video.

Miled^[16]'s study also provided rehabilitation that provided interesting visual stimuli and reported that interesting stimuli increased the effectiveness of rehabilitation. In this study, the subjective interest score was higher in VR video. Many other studies are also aimed to make interest in using VR games^[17-18]. In this respect, VR video is more interesting, so it will enhance the effect of rehabilitation in vestibular rehabilitation. In a recent Riches^[19]'s study, VR rehabilitation was performed using Computer graphic (CG), patients were evaluated and mediated. In this CG environment, it is expected that the therapeutic effect, immersion and interest will be higher through active participation rather than passive rehabilitation. But we are facing the

limitation of VR content shortage. Future research will verify the effects of VR rehabilitation using CG along with content development.

Conclusion

Based on the results of this study, the 360-degree VR rehabilitation video would be more effective than the previously used rehabilitation video for visual vertigo. Therefore, the converging use of VR in vestibular rehabilitation has enhanced the rehabilitation effect. Future research will increase the participation of active rehabilitation through the development of VR rehabilitation contents and programs.

Factors Affecting Health-related Quality of Life for Subjects with Breast Cancer

Myoung-Hee Kim

Professor, Department of Nursing, Semyung University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to compare the health-related quality of life between subjects in good health and subjects with breast cancer.

Method/Statistical Analysis: A secondary analysis was performed with data from 255 adults using raw data from the Korean National Examination Survey (KNHANES) conducted from 2010 to 2017.

Findings: Subjects with breast cancer displayed a poor level of health awareness and high activity confinement. The EQ-5D index scores between subjects in good health and subjects with breast cancer did not show any significant differences. However, factors affecting health related quality of life for subjects with breast cancer and subjects in good health were different. Household income, perceived health status and activity confinement were the strongest factors affecting the health related quality of life among subjects with breast cancer while residential area, level of education, household composition, perceived health status, activity confinement and BMI were significant for subjects in good health.

Improvements/Applications: The results of the study will be instrumental in giving insights on health-related quality of life for patients with breast cancer and establishing nursing strategies to promote their HR-QoL.

Keywords: *Breast cancer, Quality of life, HR-QoL, EQ-5D, KNHANE*

Introduction

As the frequency of breast cancer occurrences and patients' survival rate have been increasing recently, people are more interested in the quality of life of the patients with breast cancer. It has been necessary to promote the patients' quality of life during their medical treatments in order to receive the best outcomes [1-3].

Most breast cancer patients finish their medical treatments, including chemo therapy and radiation therapy, one year after first being diagnosed [4]. Of particular interest was that 58% of the breast cancer patients were diagnosed before age 49, thus indicating

that Korean breast cancer patients are generally younger than their European counterparts [5]. The growth of young breast cancer patients was primarily related to their family history, but because they are young, they are often better able to survive treatment and thus their life is prolonged. Accordingly, it is important to pay attention to their quality of life. After medical treatments, the majority of breast cancer survivors were still struggling with activities of daily living and their quality of life continued to be decreased [6]. Breast cancer survivors who survived 5 years or more were still afraid of cancer recurrence and continued to experience side effects long after treatments which negatively impacted their quality of life in addition to experiencing long-term psychological barriers and physical discomfort [7].

This study noted that the subjects with breast cancer were in need of not only medical treatments, but also of enhancing their quality of life and for that reason, the quality of life was included as an important index that

Corresponding Author :

Professor, Department of Nursing, Semyung University, Republic of Korea

e-mail: mh1352@semyung.ac.kr

can be used to evaluate the effectiveness of the cancer treatments [8].

This study examined factors that affect health-related quality of life (below HR-QOL) of the subjects with breast cancer by comparing them with the healthy subjects and aims to provide basic materials that can guide the promotion of HR-QoL among breast cancer patients.

Method

This study was a secondary analysis of data collected by the KNHANES from 2010 and 2017. Subjects were selected two groups (subjects with breast cancer and healthy subjects) according to study criteria.

The total number of female participants in the KNHANES from 2010 to 2017 was 35,301. Among them, 113 participants were breast cancer patients with an age range from 31 to 80. An additional 142 healthy subjects aged over 30 were used as a comparison group. Participants who were receiving treatments for other types of cancer were excluded for this study.

This study used the health-related survey questionnaire from the KNHANES. Socio-demographic characteristics included age, residential area, education level, marital status, household composition, household income level and occupation.

Variables associated with physical and mental health included perceived health condition, activity confinement, perceived usual stress level and body mass index (BMI).

The EQ-5D was used to measure HR-QoL. The EQ-5D is a standardized instrument that measures HR-QoL and it is composed of 5 items/areas. The EQ-5D index was obtained by applying a weighted value to the measured score of each question. The score variation was 0 through 1 and higher scores indicated a better quality of life [9].

The study analysis was conducted by following usage guidelines of the Korea Centers for Disease Control and Prevention suggested by the KNHANES. The raw materials of KNHANES were used for complex sample design. Complex sample Chi-square test was to compare the differences of EQ-5D on socio-demographic variables and health related variables between the health subjects and the subjects with breast cancer. The complex sample general linear model (CSGLM) was

used to examine the factors that affect health-related quality of life (HR-QOL) of health participants and participants with breast cancer.

SPSS version 19.0 (SPSS Inc. Chicago, IL, USA) was used to measure the data and significance level was below 0.05.

Result and Discussion

1. Socio-demographic characteristics comparison between healthy female subjects and subjects with breast cancer

Among demographic characteristics [Table 1], significant differences were noted between the healthy subjects and the subjects with breast cancer according to their age ($\chi^2=4.06, p=0.003$) and occupation ($\chi^2=5.50, p<0.001$). The results show a spike in the percentage of subjects with breast cancer in their 40s (compared to those in their 30s) and a drop in the percentage of breast cancer patients in their 60s and 70s. The occupation of the subjects with breast cancer was also significant as it showed that those with breast cancer were more likely to be in clerical positions or be unemployed compared to healthy subjects.

Table 1. Socio-demographic factors of study participants (N=255)

2. Comparison of health-related characteristics between the healthy subjects and the subjects with breast cancer

In health-related characteristics [Table 2], perceived health status ($\chi^2=4.34$, $p=0.015$), activity confinement ($\chi^2=5.99$, $p=0.016$) and BMI ($\chi^2=4.31$, $p=0.015$) showed significant differences between the healthy subjects and the subjects with breast cancer, but not perceived usual stress level.

Beaulac et al. [10] discovered that a year after surgery, breast cancer survivors who had lymphedema and confined shoulder movement had significantly low HR-QOL in physical and functional areas. Accordingly, it is very important for breast cancer patients to make an effort to manage their physical and functional health so their quality of life is not adversely affected.

Table 2. Health related factors of study participants (N=255)

Value= Estimated value, SE= Standard error, a= Weighted value

3. Comparison in HR-QOL between the healthy subjects and the subjects with breast cancer

As shown [Table 3], the EQ-5D index score for the HR-QOL between healthy subjects and the subjects with breast cancer did not show any significant differences (Wald F=0.18, $p=0.672$). The EQ-5D index score for the healthy subjects was 0.92 and the EQ-5D index score for the subjects with breast cancer was 0.91.

In the research done by Matalqah et al. [11] and Wallwiener et al. [12], the EQ-5D index score of breast cancer patients was lower compared to healthy people, which is different from the results of this paper. According to Matalqah et al. [11], the EQ-5D index scores for breast cancer patients and healthy people in Malaysia were 0.71 and 0.87 respectively, which were lower than our EQ-5D index scores, which indicated that Korean breast cancer patients had higher health-related quality of life.

Table 3. EQ-5D index score of healthy women and women with breast cancer

EQ-5D: European quality of life-5 dimensions used as a measure of health-related quality of life (HR-QOL)

4. Factors affecting HR-QOL of women with breast cancer

[Table 4] presents the factors affecting HR-QOL of women with breast cancer.

As a result of examining the socio-economic and health-related factors that affect health-related quality of life of breast cancer patients by controlling age, the factors found to affect the HR-QOL of breast cancer patients were household income (Wald F=3.16, p=0.027), perceived health status (Wald F=4.35, p=0.015) and activity confinement (Wald F=4.81, p=0.030).

When controlling for age, the factors affecting health-related quality of life of healthy women were residential area (Wald F=11.00, p<0.001), education (Wald F=2.67, p=0.050), household composition (Wald F=5.10, p=0.002), perceived health status (Wald F=6.47, p=0.002), activity confinement (Wald F=7.09, p=0.009) and BMI (Wald F=8.08, p<0.001).

Among the subjects with breast cancer receiving medical treatments, those who perceived their health condition positively and those who had less activity confinement had higher health-related quality of life.

According to studies [13, 14], physical activity played an essential role as it reduces the side effects of treatments and disease prognosis. Consequently, it is necessary to examine the factors that affect activity confinement and to develop and apply guidelines to manage overall health. In addition, the breast cancer patients' financial situation is an important indicator of quality of life and this study noted that among subjects with breast cancer, those who had high household incomes had better health-related quality of life. Other research including Edib et al.[15] and Huang et al. [16] had similar findings which support the findings of this study. Economical allowance provides more opportunities for cancer patients to join in social activities and hobbies and minimizes stress levels created by financial struggles such as medical bills or lack of cost of living and accordingly, economical allowance

is closely related to the quality of life of participants. Thus, it is very important to eventually improve public health policies focusing on reducing the medical costs for cancer patients.

Other criteria such as residential area, education, marital status, household composition, occupation, perceived usual stress and BMI did not affect the health-related quality of life of breast cancer patients.

Social support plays a positive role in HR-QOL of cancer patients [17]. Family support is the most primary support in social supports, since as the more family members a person has, the more social support they can receive. However, it did not show any significant difference for cancer patients in this study.

In the studies of Leung et al.[18], social supports including positive and emotional cares, informational consultation and emotional support from spouses or significant others was found to be an important factor in promoting health-related quality of life. Family support is a very important element for breast cancer patients for their health-related quality of life. However, it explained that the emotional support offered by the family unit is the meaningful element rather than the number of people in the household.

Factors influencing HR-QOL of patients with breast cancer in this study were household income, perceived overall health condition and activity confinement and the explanatory power of socioeconomic and health related factors was 41.9%.

It is necessary to develop nursing management plans by considering the each patients' socio-economic and health-related characteristics to maximize their health-related quality of life instead of providing generalized treatment.

Conclusion

Breast cancer patients’ treatment and nursing care are not just survival strategies. The direction of nursing care after the treatment should be aimed at improving the patients’ health-related quality of life.

While there were no significant differences in health-related quality of life between the healthy subjects and the subjects with breast cancer, the factors affecting health-related quality of life were different. It is important to explore alternatives in receiving cancer treatment and promoting health-related quality of life for breast cancer patients since it primarily affects those females aged below 50 in Korea.

Therefore, this study focused on providing fundamental data that can be used to manage the health-related quality of life for subjects with breast cancer by comparing factors that affect the health--related quality of life between the healthy subjects and the subjects with breast cancer.

The Influence of Self-Efficacy, Self-Esteem, Aging Anxiety on Successful Aging in Middle-Aged Women

Jin-Hui Cho

Professor, Department of Nursing, Dongnam Health University, 16328, South Korea.

Abstract

Background/Objectives: The purpose of the study was to identify factors influencing successful aging in middle-aged women.

Method/Statistical Analysis: The subjects of this study were 298 middle-aged women living in 4 cities. The data were collected through structured questionnaire and analyzed using descriptive statistics, t-test, ANOVA, Pearson correlations, Spearman correlations and multiple regression analysis with the SPSS/WIN 21.0 program.

Findings: As a result of regression analysis using self-efficacy, self-achievement and aging anxiety as independent variables, factors affecting successful aging were self-efficacy and aging anxiety. Their explanatory power is 16.8%. Aging anxiety was found to have the most significant influence on the degree of successful aging.

Improvements/Applications: This study shows that self-efficacy and aging anxiety have important effects on successful aging in middle-aged women. In addition, middle aged women learned that nursing knowledge needs to be accumulated and researched to increase self-efficacy or to reduce anxiety about aging.

Keywords: *women, successful aging, self-efficacy, aging anxiety.*

Introduction

Middle age is a transitional period between adolescence and old age, 40-60 years of age, with a decline in biological capacity but social responsibility. As life expectancy increases, the process of aging is prolonged and therefore, we must approach with an integrated concept of successful aging, including the wisdom aspect, rather than focusing only on passive responses to age-related declines ^[1]. In order to have a long and healthy old age, it is necessary to prepare in advance and the middle age in the transition of life into old age will be the most critical point ^[2]. In a study of middle-aged women, they said they were interested in the life of the old age. The higher the awareness of successful aging, the higher the degree of preparation

for retirement^[3]. Therefore, it is necessary to study the factors that influence the successful aging of the middle age. Self-efficacy is a personal belief that they can cope with the various situations they face and that they can influence the progress of things that can happen in their daily life ^[2]. It is also assumed that such factors would have a positive effect on successful aging, but few studies have reported the relevance of these factors in middle-aged women. Self-fulfillment is a personal confirmation, expectation, or belief of one's ability to perform a specific action or activity successfully. It means the satisfaction of achieving or achieving one's purpose. Self-fulfillment is a measure of satisfaction when one achieves their purpose and is used as an index to measure the level of successful aging in a study of the elderly ^[4]. Therefore, it is necessary to study the factors that influence the successful aging of the middle age. Self-efficacy is a personal belief that they can cope with the different situations they face and that they can influence the progress of what can happen in their daily life. 4 and furthermore, it is assumed that it will have a

positive effect on successful aging, but few studies have reported the relevance of these factors in middle-aged women. Self-satisfaction is the satisfaction level when he achieved his purpose and was used as an index to measure the level of successful aging in the study of the elderly [5].

All generations are in a line of life and are expected to be essential factors for successful aging in middle-aged women. Aging anxiety expresses anxiety about an individual's aging, which refers to anxiety caused by physical, mental and social problems derived from aging. Since studies on aging anxiety have negative responses in life satisfaction [6] and self-efficacy [7-8], it is assumed to have similar effects on successful aging in middle-aged women, but few studies have reported the relevance of these factors. We think that research is necessary.

Method

This study is a descriptive research to analyze the effects of self-efficacy, self-fulfillment and aging anxiety on successful aging in middle-aged women.

The study subjects are middle-aged women living in four cities in Seoul, Suwon, Seongnam and Yongin. A total of 310 women aged 40 to 60 were able to understand and respond to the purpose of the study. A total of 298 responses collected after excluding questionnaires with missing responses.

The purpose of this study is to identify the factors affecting successful aging and to provide necessary data for the development of nursing intervention program criteria. The specific purpose is as follows. First, identify differences in successful aging according to the general characteristics of the subject. Second, the effects of self-efficacy, self-fulfillment and aging anxiety on successful aging of the subjects identified.

Rowe & Kahn defined successful aging as "a low chance of developing disease, a low risk for disease and disability, high physical and mental functioning and participation in social and productive activities." [8] Successful aging consists of physical, psychological and social aspects. Physical aging refers to a score measured by Park [9] as a single question. Higher scores on a five-point scale indicate better physical aging. Psychological aging refers to the score of self-acceptance attitude measured by Kim [10]. Their questionnaire has a total of 20 questions and the reliability coefficient in their

study was Cronbach's $\alpha = .81$. Human aging is a score measured using the five questions of Kim [11]. The higher the score, the more successful the aging of the social aspects. In their study, the reliability factor was Cronbach's $\alpha = .72$. The higher the score, the higher the successful aging and the reliability coefficient of the overall successful aging was Cronbach's $\alpha = .72$.

Self-efficacy is Belief that they believe they can successfully do what they need to achieve good results. It is a belief in their ability to cope with different situations. In this study, self-efficacy was measured using the Korean self-efficacy scale developed by Lee et al [12]. It consists of a total of 10 questions and the higher the total score on the 4-point scale, the higher the perceived self-efficacy. In their study, the reliability coefficient was Cronbach's $\alpha = .88$.

Self-fulfillment is a personal confirmation, expectation, or belief of one's ability to perform a specific action or activity successfully. It means the satisfaction of achieving or achieving one's purpose [5]. In their study, the scores were measured using twelve questions about self-fulfillment suggested by Roh [13]. The tool consists of a five-point scale, with higher scores indicating higher levels of self-fulfillment. In their study, the reliability coefficient was Cronbach's $\alpha = .85$.

Aging anxiety is a synthesis of aging and anxiety means fear of their aging process and the aging anxiety scale (AAS) developed by Lastheir and Faulkender [6] used, which Kim et al [14] has revised in Korean and it is a score measured by a tool that verified reliability and validity. In their study, the reliability coefficient was Cronbach's $\alpha = .89$.

Data collection for their study was conducted from August to September 2012, using a self-response method through a structured questionnaire. Participants' anonymity, confidentiality and research content were not used for any purpose other than the study and the survey was conducted to those who signed the written consent. The subjects read and filled out the questionnaire directly. The time required to respond to the questionnaire was about 20 to 30 minutes. Collected data were analyzed using the SPSS / WIN 21.0 program as follows. First, subjects' general characteristics, self-efficacy, self-fulfillment, aging anxiety and successful aging were analyzed using frequency and percentage, mean and standard deviation. Second, t-test and

ANOVA were used to identify the differences in successful aging according to the general characteristics of the subjects. Third, Pearson correlation analysis used for the correlation between variables. Fourth, multiple regression was conducted to understand the effects of self-efficacy, self-fulfillment and aging anxiety on successful aging.

Result and Discussion

1. General Characteristics of Subjects and Differences in Successful Aging

[Table 1] shows the difference of successful aging according to general characteristics.

Frequency analysis was performed to examine the demographic characteristics of the subjects. As for the analysis results, first of all, the total age of 298

respondents was 164 (55.0%) in their 40s, followed by 120 in 50s (40.3%) and 14 in 60s (4.7%). Educational background was 135 high school graduates (45.3%), 113 high school graduates (37.9%). The marriage status was 276 married (92.6%) and 22 (7.4%) divorced or bereaved. The most common occupations were ‘housewives’ 111 (37.2%), 74 (24.8%) ‘others’, 59 (19.8%) ‘professional jobs’, 37 (12.4%). The highest household income was 78 people (26.2%) with ‘more than 5 million won’, followed by 69 people (23.2%) under ‘300-400 million won’, 44 people (14.8%) under ‘200-300 million won’. Expected life expectancy was 183 (61.4%) among ‘80-90 years old’, followed by 58 (19.5%) under 80 ‘and 57 (19.1%)’ over 90 years old. The results of analyzing the differences in the successful aging according to the demographic characteristics of the study subjects show was no statistically significant difference in all items for successful aging.

Table 1. General Characteristics of Subjects and Differences in Successful Aging (N=298)

Variables	Categories	N(%)	Successful Aging		
			M±SD	F/t	p
Age (year)	40~49	164 (55.0)	3.98±.54	.562	.571

	≥500	78 (26.2)	3.96±.50		
Life expectancy	< 80	58 (19.5)	4.01±.58	.480	.619
	80~89	183 (61.4)	3.95±.59		
	≥ 90	57 (19.1)	3.95±.58		

2. Correlations among Successful Aging, Self-Efficacy, Self-Esteem, Aging Anxiety.

The correlation between self-efficacy, self-fulfillment, aging anxiety and successful aging are as follows [Table 2].

increases and the higher the aging anxiety, the more successful aging decreases.

Table 2. Correlations among Successful Aging, Self-Efficacy, Self-Esteem, Aging Anxiety(N=298)

Variables	self-efficacy	self-fulfillment	aging anxiety
	r (p)	r (p)	r (p)
self-fulfillment	.328(<.01)	1	
aging anxiety	-.267(<.01)	.024	1
successful aging	.225(<.01)	.016	-.390(<.01)

3. Influencing Factors on Successful Aging.

The effects of self-efficacy, self-achievement and aging anxiety on successful aging are as follows [Table 3].

To analyze the factors that influence self-efficacy, self-achievement and aging anxiety on successful aging, multiple regression analysis was selected as an independent variable. In the regression analysis has about

Successful aging had the most significant negative correlation with aging anxiety ($r = -.390$) and positive correlation with self-efficacy ($r = .225$). That shows that the higher the self-efficacy, the more successful aging

16.8% explanatory power on the effects of self-efficacy, self-achievement and aging anxiety on successful aging. The significance test of regression coefficient showed that self-efficacy ($t = 2.326, p < .05$) and aging anxiety ($t = -6.345, p < .001$) had a significant effect on successful aging. The coefficient of standardization represents the relative influence of each independent variable on successful aging, with aging anxiety ($= -.353$) being the most influential, followed by self-efficacy ($= .137$). The higher the self-efficacy, the more successful aging

increases and the higher the aging anxiety, the more successful aging decreases.

Table3. Influencing Factors on Successful Aging (N=298)

Variables	B	SE	β	t	p	Tolerance	VIF
(Constant)		.321	4.255	13.245	<.001		
self-efficacy	.137	.090	.209	2.326	.021	.816	1.225
self-fulfillment	-.020	.056	-.020	-.359	.720	.879	1.138
aging anxiety	-.353	.046	-.289	-6.345	<.001	.914	1.094

$R^2 = .168$, Adj. $R^2 = .160$, $F = 19.805$, $p < .001$, Durbin-Watson = 1.929

aged women's self-efficacy. In this study, aging anxiety was the most significant variable for successful aging and self-efficacy was also a significant factor.

Discussion

The purpose of this study was to investigate the self-efficacy, self-satisfaction, aging anxiety and middle-

A middle-aged in previous study reported that elderly life experience had the effect of alleviating aging

anxiety^[15] and the relationship between depression and self-esteem in aging anxiety among middle-aged adults^[16], middle-aged adults. The results were in agreement with the results of some previous studies that reported a significant inverse correlation between aging anxiety and self-efficacy in Koreans^[17]. These results indicate that middle age is a period of loss and a transition to an opportunity for successful aging and it is fearing aging, but it is gradually trying to accept the aging process and future life. In addition, self-efficacy was identified as an important variable affecting the successful aging of middle-aged women. Many previous studies supported the results^[18-19]. This result is in line with the findings of self-efficacy which have positive effects on health promotion behavior, life satisfaction and quality of life. Therefore, self-efficacy was identified as an important variable to successfully adapt to various changes in the new transitional period of middle-aged women's life. Self-efficacy is said to have a significant impact on the choice and continuity of behavior as an expectation of efficacy, which is the belief that an individual can successfully perform the actions necessary to achieve a result. Therefore, strategies for enhancing self-efficacy should be established in health education and nursing interventions for successful aging of middle-aged women.

Conclusion

This study is a descriptive research to identify the factors of successful aging in middle-aged women. As a result of regression analysis using self-efficacy, self-achievement and aging anxiety as independent variables, factors affecting successful aging were self-efficacy and aging anxiety. Their explanatory power is 16.8%. Aging anxiety was found to have the most significant influence on the degree of successful aging. None of the general characteristics affected the successful aging. The results of this study showed that the effects of self-efficacy and aging anxiety were significant for the successful aging of middle-aged women. Through this, it was necessary to understand the aging instability of middle-aged women and to study the accumulation of nursing knowledge and the development of interventions. Therefore, for successful aging of middle-aged women, it is possible to increase self-efficacy, which is a personal belief that they can cope with various situations during their lives and to see the positive effects of adaptation and aging process. We think it is crucial to develop strategies, policies and diversified support programs. Also, it is necessary to repeat research with a broader target in

preparing a successful aging strategy.

The Influence of Social Network and Depression on Successful Aging in the Elderly

Yeon-Sook Kim¹, Jin-Hui Cho¹

¹Professor, Department of Nursing, Dongnam Health University, 16328, South Korea

Abstract

Background/Objectives: The purpose of this study was to investigate the relationship between social network, depression and successful aging of elderly people and to identify the factors influencing successful aging of elderly people.

Method/Statistical Analysis: The subjects of this study were 150 elderly people aged 65 and older who live in three cities. The data were collected through structured questionnaire and analyzed using descriptive statistics, t-test, ANOVA, Pearson correlations, Spearman correlations and multiple regression analysis with the SPSS/WIN 21.0 program.

Findings: The results showed that depression was the most influential factor in successful aging of elderly people, followed by social activities, perform parental grandparent role and 74.1% explained successful aging of elderly people. Based on these results, it concluded that the role of social activities, parents and grandparents is critical and the development of related programs is necessary for the elderly to be successfully aged.

Improvements/Applications: This study showed that depression, social activities and the role of parents and grandparents were significant for the successful aging of the elderly. In particular, depression was more influential than social activities and the role of parents and grandparents. Therefore, it found that research is needed to prevent depression in the elderly.

Keywords: elderly, social network, depression, successful aging.

Introduction

According to the National Statistical Office, the average life expectancy in 2013 was 85.06 years for females and 78.51 years for males^[1]. As life expectancy increases, the process of aging must be prolonged and should be approached with an integrated concept of successful aging, including the wisdom aspect, from focusing only on passive responses to decay with age^[2]. Successful aging is the individual's awareness that he has effectively adapted to the physical and functional changes that have accumulated over a long period of time, while at the same time discovering the meaning or purpose of life^[3-4]. Previous studies have shown that

successful aging is not a final state, but a process of adaptation and that old age is not the end of everything, but the successful completion of a lifelong development process by physically, psychologically or socially developing tasks^[5].

Population aging is a recent phenomenon of social change, which is emerging as a significant cause of social problems in Korea and other countries. On the other hand, older people in 21C have stronger desire to retain resources such as economic power and health and to spend old age comfortably and disease-free than existing older people. Because of these changes and diversity, there is increasing interest in how the elderly's social network can successfully raise the level of successful aging and depression is predicted to impede the quality of life of the elderly^[6]. The purpose of this study is to divide the social network of the elderly into the role of parents and grandparents, economic activities and social

Corresponding Author:

Jin-Hui Cho, Department of Nursing, Dongnam Health University.
jhcho@dongnam.ac.kr.

activities and to investigate the effects of variables and depression on successful aging. A social network is a social unit composed of individual social ties [7]. As the attention of the elderly concentrated on families with frequent contact opportunities, satisfaction with their children's relationships and affection with their grandchildren influenced successful aging [8]. Also, the elderly have been shown to harm their life satisfaction as they become psychologically depressed [9] when they become economically depressed [10]. Accordingly, the study was performed assuming that the role of parents and grandparents, economic activities, social activities and depression, which are the social networks of the elderly, will affect the successful aging.

Method

This study is a descriptive research to analyze the effects of the role of parents and grandparents, economic activity, social activity and depression on the successful aging of the elderly.

The subjects of this study were 150 older people over 65 years old who could understand and respond to the study purpose of the elderly living in three cities. The purpose of this study is to identify success factors of aging and to provide primary data for developing nursing intervention program criteria. The specific purpose is as follows. First, the purpose of the study is to identify the difference in successful aging due to the general characteristics of the subject. Second, the purpose of this study is to investigate the effects of the role of parents and grandparents, economic activities, social activities and depression on successful aging.

Successful aging is a condition that is free from illness or disability, maintains proper physical and mental functioning and spends every day actively [11]. In this study, we used a successful aging scale Kim & Shin [12], which developed a scale based on the characteristics of Korean culture. Reliability factor in this study was Cronbach's $\alpha = .95$. The higher the score, the higher the successful aging. In this study, the average score of the questions used for analysis.

The role activity scale was used to measure the role performance of the elderly Song [13]. In this study, the reliability coefficient of Cronbach's $\alpha = .90$.

The economic activities of old age have positive effects such as securing stable income, contributing to social development and confirming self-use, maintaining

health, suppressing social alienation and loneliness, thus improving the level of satisfaction and success in old age [14]. The measures developed by Park & partially used in Kwak's research used [15]. In this study, the reliability coefficient was Cronbach's $\alpha = .93$

Social activity of Old age was measured based on the research of Cheong & Yi [16], which conceptualizes social activities, consisting of hobbies and volunteer activities, which are longer leisure time than other age groups. In this study, the reliability coefficient was Cronbach's $\alpha = .82$.

Depressed of the questionnaire measuring depression is a Korean-type elderly depression test tool (KGDC), which Han [17] reconstructed a total of 30 questions. The questionnaire consists of 10 questions and each question answered on a 4 level Likert scale. In this study, the Cronbach's α coefficient of .89 was relatively good.

Data collection for this study was conducted for four months from November 2014 to February 2015. The self-response method used through structured questionnaires. Collected data were analyzed using the SPSS / WIN 21.0 program as follows. First, the general characteristics of the subjects analyzed using frequency and percentage, mean and standard deviation. Second, t-test and ANOVA were used to identify the differences in successful aging according to the general characteristics of the subjects. Third, Pearson correlation analysis used for the correlation between variables. Fourth, multiple regression was conducted to investigate the effects of the subjects.

Result and Discussion

1. General Characteristics of Subjects and Differences in Successful Aging

[Table 1] shows the difference of successful aging according to general characteristics.

Frequency analysis was performed to examine the demographic characteristics of the study subjects. According to the analysis results, among the total 150 respondents, the number of women was 100 (66.7%) for women and 50 (33.3%) for men. The most common age group was 70s' with 77 people (51.3%). In the marriage, 87 (58.0%) were married (spouse survived) and 63 (42.0%) were 'married alone due to bereavement or divorce.'

In terms of education level, 52 students (34.7%) graduated from elementary school. 82 (54.7%) had a religion and 68 (45.3%) had no religion. There are 73 positives (48.6%) who answered that they are healthier than their peers. In addition, the results of analyzing

the differences in successful aging according to the demographic characteristics of the study subjects showed age ($F = 8.534, p = .000$), marital relationship ($t = 2.307, p = .022$), an education level ($F = 5.527, p = .000$), religion ($t = 3.163, p = .002$) and health ($F = 2.478, p = .047$).

Table 1. General Characteristics of Subjects and Differences in Successful Aging (N=150)

Variables	Categories	n(%)	Successful aging		
			M±SD	F/t	p
Gender	Male	50 (33.3)	3.28±0.88	1.418	.158
	Female	100 (66.7)	3.07±0.84		
Age (year)	60~69	40 (26.7)	3.37±0.79a	8.534	.000
	70~79	77 (51.3)	3.24±0.86a		
	≥ 80	33 (22.0)	2.63±0.72b		
Marital status	Married (Spouse survival)	87 (58.0)	3.28±0.83	2.307	.022
	Other(Divorce and Bereaved)	63 (42.0)	2.96±0.87		
Education	uneducated	10 (6.7)	2.61±0.91d	5.527	.000
	Elementary school	52 (34.7)	2.82±0.71cd		
	Middle school	18 (12.0)	3.29±0.70bc		
	High school	24 (16.0)	3.13±0.72cd		
	≥ College	46 (30.7)	3.96±0.67a		
Religion	Yes	82 (54.7)	3.34±0.99bc	3.163	.002
	No	68 (45.3)	3.83±0.81ab		
Health perception	Very Dissatisfied	8 (5.3)	3.34±0.88	2.478	.047
	Dissatisfied	30 (20.0)	2.91±0.77		
	Average	39 (26.0)	2.79±1.00b		
	Satisfied	47 (31.3)	3.04±1.02b		
	Very Satisfied	26 (17.3)	2.93±0.76b		

2. Correlations among Successful Aging, Perform parental grandparent role, Economic activity, Social activity, Depression.

The correlation between self-efficacy, self-esteem, depression and successful aging is as follows [Table 2].

Successful aging had the largest negative correlation with depression ($r = -.657, p < .01$), followed by social activities ($r = .556, p < .01$) and parent grandparent roles ($r = .457, p < .01$) and economic activity ($r = .301, p < .01$) were positively correlated. That shows that the higher the depression, the less successful aging and the

more successful aging increases as the role of parents, grandparents, economic and social activities increases.

Table 2. Correlations among Successful Aging, Self-Efficacy, Self-Esteem, Aging Anxiety (N=150)

Variables	Perform parental grandparent role	Economic activity	Social activity	Depression
	r (p)	r (p)	r (p)	r (p)
Economic activity	.464(<.001)	1		
Social activity	.592(<.001)	.468(<.001)	1	
Depression	-.003	-.077	-.072	1
successful aging	.457(<.001)	.301(<.001)	.556(<.001)	-.657(<.001)

3. Influencing Factors on Successful Aging.

The effects of self-efficacy, self-achievement and aging anxiety on successful aging are as follows [Table 4].

The effects of age, marital relationship, education level, religion, health and independent variables of grandparents, economic activity, social activity and depression on the successful aging according to demographic characteristics were analyzed. Multiple regression analysis was performed to confirm. It has about 74.1% accountability for the effects of role performance, economic activity, social activity and depression on successful aging. The significance test of the regression coefficient showed that the aging of the parents grandparents (t = 4.150, p <.001), social activities (t = 6.140, p <.001) and depression (t = -13.918, p <.001) was successful. It was found to have a significant effect on it. The standardization coefficient represents the relative influence of each independent variable on successful aging, which is the dependent variable. Depression (= -.645) was the most influential factor, followed by social activities (= .387) and the role of grandparents (= .243) was the most influential. The higher the depression, the less successful aging and the higher the grandparents' role and social activities, the more successful aging.

Table3. Influencing Factors on Successful Aging (N=150)

Variables	B	SE	β	t	p	Tolerance	VIF
(Constant)		.653	3.426.	5.246	<.001

Discussion

There is increasing interest in how the elderly's social network can raise the level of successful aging and depression is predicted to be a deterrent to the quality of life of the elderly [6]. In addition, the social network reported that the elderly had a significant result on the health status [18]. The purpose of this study was to divide the social network of the elderly into the role of parents and grandparents, economic activities and social activities and to analyze the factors affecting successful aging. In this study, depression was the most significant influence variable for successful aging, followed by social activities and the role of parents grandparents.

Depression was supported by this study because it was predicted as a factor that impeded the quality of life of the elderly, although no previous study found a direct relationship between depression and successful aging [6]. In addition, the study showed that depression affects self-integration as a successful aging partly mediated by the elderly [19]. Social activity is similar to the previous study in which elderly people who participated in social activities of the elderly had higher life satisfaction than those who were not [20]. In other previous studies, the meta-analysis study on factors related to successful aging in Koreans reported that social factors such as family support, social activities, leisure activities and volunteer activities were all significant factors for successful aging [21].

Previous studies have reported that for the emotionally stable retirement life, contact frequency and scope with family and friends who can share fun and difficulty as well as reconciled family are necessary for retirement life [22]. Therefore, the results of this study supported the previous study that parent-grandparent role was a significant influence on successful aging.

Based on the preceding studies, depression, social activities and parent / grandparent roles were analyzed as important factors for the successful aging of the elderly. We need to identify, develop and maintain a social support system that enables this.

Conclusion

This study is a descriptive research to identify the factors of successful aging in the elderly. The results of this study were regression analysis using the role of parents, grandparents, economic activity, social activity and depression as independent variables. As a result,

the factors influencing successful aging were the role of parents and grandparents, social activities and depression, all with 74.1% explanatory power. Depression was the most influential factor for successful aging, followed by social activities and parent/grandparent roles. Among the general characteristics, variables affecting successful aging were age, marital relationship, education level, religion and health. The results of this study showed that depression, social activities and parent/grandparent roles were essential for the successful aging of the elderly. In particular, depression was more influential than social activities and parent/grandparent roles. It found that related studies, such as intervention development, were needed to prevent the depression of the elderly. Also, it found that various opportunities to activate the social activities of the elderly were needed. The more parents and grandparents performed, the higher the level of successful aging. Based on these results, it found that in order to improve the successful aging of the elderly, it is necessary to develop specific educational programs and mediation plans that can lower depression and enhance social activities and role of parents and grandparents.

Abstract

Background/Objectives: This study was conducted to investigate the effectiveness of mobile-based healthcare program on indicators of chronic disease.

Method/Statistical Analysis: This study was conducted on 149 participants from the A company employees who had a Health Check-up at S hospital Health Screening Center (Yong-in, Korea) in 2017 then found to be exceeding the prediabetes standard (Fasting Glucose \geq 100 mg/dL). 109 participants completed the 12 weeks mobile healthcare program. The final data were analyzed from these participants. Participants are divided into two groups; General care group (HbA1c $<$ 6.4%, n=62) and intensive care group (HbA1c \geq 6.5%, n=47).

Findings: After 12 weeks, participants' average HbA1c was decreased to $0.38 \pm 0.65\%$ ($p < 0.001$). HbA1c of the intensive care group was decreased to $0.78 \pm 0.79\%$, which was more effective than the $0.08 \pm 0.25\%$ reduction of HbA1c from the general care group. In addition, with adjustment of the age, body mass index, glucose, the improvement of HbA1c of intensive care group was even more effective than another group (Odds ratio [OR]=4.385, 95% CI 1.043-18.440).

Improvements/Applications: The mobile healthcare program provided to pre-diabetes and diabetes patients was found to be effective in enhancing the indicators of chronic diseases. In particular, the program is more effective to the intensive care group than the general care group.

Keywords: Diabetes, Health Care, Mobile, Health Management Service, Employee

Introduction

Many International Organizations recognized the seriousness of chronic diseases and ask their each nations to make policies to improve it. World Health Organization (WHO) declared WHO Global Action Plan for the 'Prevention and Control of Non-Communicable Diseases (NCDs) 2013-2020 (resolution WHA66.10)' in 66th World Health Assembly then WHO set a goal to decrease the death rate by the chronic disease, such as diabetes, to 25% lower, then to make a realistic goal, WHO advised member countries to establish national

policies^[1]. In addition, during United Nations (UN) 'General Assembly on the Prevention and Control of Non-communicable Diseases' held on September 19-20, 2011, UN addressed a declaration of the high-level meeting that prevention and management of the NCDs are a basic duty of countries^[2].

According to Atlas 8th, the global number of diabetics in 2017 is expected to be 425 million and by 2025 the number is to be 629 million, which is 48% increase. In addition, one of three adults over 20 years of age in the Western Pacific countries (Korea, etc.) has diabetes and one third of deaths were due to diabetes^[3]. International Diabetes Federation (IDF) estimates that health care costs increased to \$ 732.7 billion in 2017, more than three times of \$ 232 billion in 2006^[3]. According to the 2017 Organization for Economic Cooperation

Corresponding Author:

Mi-Joon Lee,
roybrain2@naver.com

and Development (OECD)'s Health Glance, deaths by diabetes are 700,000 people per year in OECD countries. Already 9 million adults which are 7% of the OECD population, has diabetes and the number continues to be increased and they suffer from cardiovascular diseases such as heart attacks, strokes, loss of vision, diabetic foot and kidney diseases^[4].

There needs to be a serious attention to medical situation regarding Korea's diabetes in the OECD's Health Glance^[5]. The rate of hospitalization due to diabetes was decreasing, but Korea still has 281 inpatients per 100,000 people and it is more than the double of the OECD's average, 137, so Korea is No.2, after Mexico of 292^[5]. According to Korea Center of Disease Control (KCDC), the rate of diabetes of the people older than 30 was increased by 1.8%p from 9.5% in 2005 to 11.3% in 2016^[6]. In addition, the treatment rate increased by 18.2%p from 49.0% to 67.2%. However, in 2016, only one third of diabetes patients was able to manage their blood glucose (HbA1c<6.5%)^[6].

There have been national efforts regarding diabetes management. Most of domestic diabetes-related prevention programs are driven by public health centers. In September 2007, Daegu launched a pilot project of high-risk cardiovascular risk groups (hypertension / diabetes) registration. 10 new locations were newly added from 2012^[7]. In addition, according to the general health screening project (Article 5 of Framework ACT On Health Examinations, Article 52 of National Health Insurance ACT, Article 25 of Enforcement Decree of The National Health Insurance ACT, Article 14 of Medical Care Assistance ACT), the screening targets are defined as a law and the targets are expanding^[8]. The subjects of medical examination are beneficiaries of medical benefits and health insurance and as of the end of November 2015, the number of people is about 20.8 million. The goal is to conduct primary and secondary screening for early detection of 13 diseases with a focus on cardiovascular diseases including diabetes^[9, 10].

However, the assessment level of public management was not positive. The given level by the program was high, but each individual's self-management level was low. Health centers currently does not play an effective role in the clinical information system^[11]. The need for improvements shall have many agrees, but there are limitations as a country to manage all chronic diseases^[12].

Therefore, it is necessary to have an alternative solution for efficient management of chronic diseases.

Improving diabetes requires interventions among appropriate exercise, eating habits and blood sugar management. In order to make an effective strategy, the method shall be established through location and tools which are closely connected to daily lives then the method shall be easy of use and cost efficient^[13-15]. Office is the place where the majority of employees stay and it is where they stay for the longest time outside of homes, therefore it is an important place to manage their lifestyles for the prevention and management of chronic diseases^[16]. In addition, previous studies have shown that mobile healthcare program can improve self-management in a cost-effectiveness way^[17]. Especially according to the related regulations and law, Auxiliary medical institution that are built in the workplaces, can be the legally assured institution that can support employees' management and prevention of diseases in the safest way^[18, 19].

Therefore, it is necessary to evaluate and see the effectiveness of mobile diabetes management program, which can manage diabetes anywhere and anytime, provided to the employees by Auxiliary medical institution to manage diabetes.

Method

This study was conducted in the auxiliary medical institution then provided an intervention service between the medical staff and diabetic patients through mobile health care program.

149 participants were the A company employees who received a health Check-up at S Hospital Health Screening Center in 2017 who showed indicators exceeding the prediabetes standard (Fasting glucose \geq 100 mg/dL). Among them, 40 participants were excluded due to any of the following: participants who refused to participate the program (n=33), who did not conduct post-inspection (n=7). Finally, 109 participants were enrolled in this study.

A mobile healthcare program from June to August 2018 was provided. Participants had Check-up before and after the program for measurements such as blood and blood pressure. Eating and physical habits was checked by a Google survey.

There were 4 small group training session for participants. The doctor explained purpose of the mobile healthcare program. The nurse trained blood sugar management method. The nutritionist taught how to manage eating habits. The IT specialist trained how to use mobile healthcare applications.

After the sessions, each portable Bluetooth blood glucose meter and consumables (blood needles, strips and alcohol swabs) was provided to check diabetes for 12 weeks. During the period, 3 mobile messages sent every week which is individualized health information such as participant’s blood records, eating habits and health information. There were a team for writing messages by doctors from family medicine department, nurses and dietitians.

The message provided evidence-based information, including dietary and behavioural recommendations on exercise habits. Notification of users and delivery of disease information is based on the 2019 Diabetes Guidelines of the Korean Diabetes Association^[20]. Participants were trained to check pre-prandial blood sugar, post-prandial blood sugar and fasting blood sugar daily and asked to write their physical activities, diet and medications so they could manage own records by themselves. The results were delivered to participants by the doctor within 7 days of the examination and a report containing an assessment of changes in self-care habits was sent through mobile app within 3 weeks after finishing programs.

Chronic conditions were determined on the basis of HbA1c. More than 6.5% of HbA1c was defined as diabetes^[20]. Participants were assigned into 2 groups, intensive care group (ICG) (HbA1c≥6.5%, n=47) and general care group (GCG) (HbA1c 5.7%-6.4%, n=62) based on the prior HbA1c. To the ICG, additional messages were sent.

Venous blood samples were collected in the morning (AM 8:00-9:00) after an overnight fast of more than 8 hours. Concentrations of HbA1c, fasting plasma glucose (FPG), total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C) and low-density lipoprotein cholesterol (LDL-C) were measured.

Blood sugar level were measured by blood Glucose meter (CareSens N Premier; i-SENS, Seoul, Korea) and obesity were measured by BMI (BSM370; Biospace, Seoul, Korea)

Logistic regression analysis was performed to assess the factors of HbA1c improvement in the GCG and the ICG. The effects on HbA1c between two groups were evaluated using multivariate logistic regression analysis that corrected age and gender. Statistical analysis were performed using SPSS 25.0 (SPSS Inc., Chicago, IL, USA). A p value<0.05 was considered as statistically meaningful.

Prior to this program, participants were aware of their prediabetes status then voluntarily agreed to the program then signed the participation consent. It was informed to participants that they can discontinue the service at any time. After the service closed, the application is disabled within a month and all data will be erased.

Result and Discussion

1. General characteristics of the subjects

The general characteristics of the study subject are given in Table 1.

Table 1. General characteristics of subject (n=109)

Variable	Value
Age	
<40	14 (12.84)
40-49	38 (34.86)
≥50	38 (34.86)
Sex	
Male	105 (96.33)
Female	4 (3.67)
Height	170.31 ± 18.06
Weight	80.241 ± 10.99

Data are presented as n (%) or mean ± standard deviation.

2. Change in forward head posture

Comparisons of parameters before and after using mobile intervention service are given in Table 2. Body mass index (BMI) reduced from 26.92 to 26.47 (p<0.001). HbA1c reduced from 6.53 to 6.15 (p<0.001).

Table 2: Comparison of chronic disease parameters before and after using mobile intervention service (n=109)

Variable	Baseline	After 3 months	t	p value
BMI	26.92 ± 3.28	26.47 ± 3.26	4.281	<0.001
SBP	129.18 ± 12.74	121.68 ± 11.42	5.919	<0.001
DBP	86.07 ± 10.17	77.20 ± 8.97	8.350	<0.001
HbA1c	6.53 ± 0.90	6.15 ± 0.64	6.124	<0.001
TC	176.21 ± 38.64	168.94 ± 36.69	1.945	0.054
HDL-C	49.62 ± 12.02	46.71 ± 10.68	4.940	<0.001
LDL-C	106.13 ± 33.59	102.94 ± 33.11	0.963	0.338

BMI, body mass index; DBP, diastolic blood pressure; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; SBP, systolic blood pressure; TC, total cholesterol.

In both ICG and GCG, HbA1c were declined comparing to the baseline during the 12 weeks participation period. Related to the baseline, ICG's HbA1c change was 0.89%p (p<0.001), GCG's HbA1c reduction was 0.60%p (p<0.001).

For the BMI, ICG decreased significantly from 27 to 26.61 (p<0.001) and for GCG from 26.81 to 26.33 (p<0.001) (Table 3).

Table 3: Comparison of chronic disease parameters between intensive care group (n=47) and general care group (n=62)

		Baseline	After 3 months	t	p value
Intensive care group (n=47, 43.1%)	BMI	27.00 ± 0.57	26.61 ± 3.50	2.154	<0.001
	SBP	128.18 ± 1.79	119.36 ± 12.01	4.729	<0.001
	DBP	87.77 ± 9.35	76.28 ± 9.69	5.341	<0.001
	HbA1c	7.33 ± 0.11	6.55 ± 0.71	6.723	<0.001
	TC	170.91 ± 5.47	161.96 ± 31.39	1.430	0.116
	HDL-C	47.34 ± 1.54	45.74 ± 9.22	1.892	<0.001
	LDL-C	102.13 ± 4.84	99.96 ± 31.46	0.406	0.014
General care group (n=62, 56.9%)	BMI	26.81 ± 0.44	26.33 ± 3.07	3.986	<0.001
	SBP	129.92 ± 1.78	123.18 ± 11.19	3.900	<0.001
	DBP	86.30 ± 10.82	78.18 ± 8.45	6.392	<0.001
	HbA1c	5.93 ± 0.04	5.85 ± 0.36	2.574	<0.001
	TC	180.23 ± 4.99	174.23 ± 39.68	1.307	<0.001
	HDL-C	51.35 ± 1.63	47.44 ± 11.68	4.895	<0.001
	LDL-C	109.16 ± 4.30	105.21 ± 34.38	0.941	<0.001

BMI, body mass index; DBP, diastolic blood pressure; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; SBP, systolic blood pressure; TC, total cholesterol.

3. Logistic regression analysis

Univariate and multivariate logistic regression analyzes were performed to determine whether age and BMI influence HbA1c improvement. The dependent variable is HbA1c improvement and the independent variable is age and BMI. In the crude model, the HbA1c improvement was more effective in the ICG than the GCG (OR=5.676, 95% CI 1.972-16.333). (Table 4).

Table 4: Logistic regression analysis

	Crude	Model 1	Model 2	Model 3
General care group (HbA1c<6.5)	1.000	1.000	1.000	1.000
Intensive care group (HbA1c≥6.5)	5.676 (1.972-16.333)	5.776 (1.954-17.075)	6.501 (1.854-22.803)	4.385 (1.043-18.440)

Model 1: adjusted for age; Model 2: Model 1+body mass index; Model 3: Model 2+glucose.

Discussion

In this study, participants were divided into two groups HbA1c level: ICG (n=47) with the HbA1c level over 6.5% and GCG (n=67) with the HbA1c level below 6.5% and as a result, the ICG showed greater effect on the improvement of the intervention service.

In case of ICG, they received additional customized messages regarding risk of diabetes and its complications so this helped them to have active interests in self-management to make improvements of HbA1c. Participants verified that the effort to improve the HbA1c level was effective for the improvement of BMI and blood pressure.

Conclusion

The study provided mobile intervention service to 149 employees with prediabetes from their health screening and they voluntarily participated in the healthcare program during 12 weeks. As a result, all 109 participants showed a significant statistical decrease in their BMI, SBP, HbA1c after the service.

As result of the study, this is a proposal as follows;

Firstly, this study was during 12 weeks so more

study with longer period to verify the improvement on the indicators of cholesterol is required. This may be the opportunity to identify the improvement of cholesterol through improving HbA1c.

The study was not able to identify the association between HbA1c improvements and characteristic of participants. Therefore, more research is necessary to find which characteristic is effective on improving the HbA1c.

From this study, to satisfy with employees' interests with their health in the workplace, a company shall not stay with just providing health screening to employees but expand to provide an after-service program based on the individual's health examination evaluation result then employees' health condition could contribute to a company's cost effectiveness.

Actor and Partner Effects of Self-Efficacy and Social Support on the Colorectal Cancer Screening Behavior of Husbands and Wives: Based on the Actor-Partner Interdependence Model

Jisun Lee

Professor, Department of Nursing, Honam University, Republic of Korea

Abstract

Background/Objectives: As the healthcare behavior of husbands and wives has effects on their spouse, it would be necessary to examine the dynamic relationship of husband and wife. This study aims to verify the actor and partner effects of self-efficacy and social support of husbands and wives on their colorectal cancer(CRC) screening behavior.

Method/Statistical Analysis: This study surveyed total 249 pairs of husband and wife. The SPSS 24.0 and AMOS 24.0 were used for the data analysis.

Findings: The self-efficacy of husbands and wives showed the actor effects on the CRC screening behavior while the self-efficacy of wives showed the partner effects on the CRC screening behavior of their husbands. The social support of husbands and wives had the actor and partner effects on the CRC screening behavior.

Improvements/Applications: In order to increase the CRC screening rate, it would be necessary to encourage the husbands and wives to participate in the self-efficacy enhancement programs, to understand the level of family support and problems and also to strengthen the family support. The model verified based on the APIM in this study provided the empirical model that could show the dynamic relationship of husband and wife in relation to the CRC screening behavior in the multilateral divisions, which could be used as the theoretical basis

Keywords: *Colorectal Cancer Screening, Health Behavior, Self-Efficacy, Social Support, Actor-Partner Interdependence Model, Spouses*

Introduction

The incidence of colorectal cancer(CRC) in Korea is ranked No.1 in the world^[1]. Emphasizing the necessity of early screening to decrease the incidence of cancer or death by cancer. However, according to the national cancer screening rate in 2019, the CRC screening is about 28%, which is lower than a neighboring country, Japan(41.4%)^[2]. Meanwhile, in case of CRC, the precancerous polyps could be early detected/ treated through the early screening and the incidence of CRC could be remarkably decreased. Thus, it would be

needed to seek for the measures for the improvement of screening rate.As the factors having great effects on the CRC screening behavior, the sociodemographic characteristics, psychological characteristics and partner effects have been reported^[3]. Especially, depending on the marital status, the cases of having a spouse show the higher screening rate than the cases of having no spouse. Based on this, it would be needed to intervene in their partners to improve the cancer screening rate^[4]. Despite the limited researches on the effects of marital relationship on the CRC screening behavior, it has been reported that the healthcare behavior of husbands and wives has effects on their spouse^[5]. Also, the people in the interdependent relationship just like husband and wife, are highly possible to exchange the effects on the mutual health behavior, so that the necessity to analyze

Corresponding Author:

Jisun Lee,

2018091@honam.ac.kr

the data in the unit of husband and wife is emphasized^[6].

As a method to analyze the interrelation of people in the interdependent relationship such as married couple or unmarried couple, Kenny^[7]suggested the Actor-Partner Interdependent Model (APIM). In this model, the effects of actor's independent variables on the actor's dependent variables are called 'actor effects' while the effects of partner's independent variables on the actor's dependent variables are called 'partner effects'. In the marital relationship, the same environment, financial resources and social relationship are shared and this shared environment works as a variable that could be beneficial or harmful to health in accordance with the environment and health behavior of spouse.

Thus, this study aims to verify the actor and partner effects of self-efficacy and social support on the CRC screening behavior of husbands and wives, by applying the APIM to the husbands and wives of CRC screening. The results of this study could provide the empirical model that could examine the dynamic relationship of husband and wife in relation to the CRC screening behavior in the multilateral divisions, which could be also used as the basic data for the improvement of CRC screening rate.

Method

Research Design

This study is a descriptive causality research for verifying the actor and partner effects of self-efficacy and social support on the CRC screening behavior of husbands and wives of CRC screening based on the APIM.

Research Subjects

The concrete standards for the selection of subjects were first, the husbands and wives whose ages were both 50 or more, second, the husbands and wives who understood the objectives of this study and agreed on the participation in this study. As the husband and wife was the unit of analysis in this study, the husbands and wives suitable for the standards of selection were selected through the convenience sampling. After distributing the questionnaires to total 260 pairs, the questionnaires were collected from 249 pairs (249 husbands, 249 wives).

Measurement

Self-Efficacy

The self-efficacy was measured by modifying/complementing the contents of breast cancer of the Champion's Health Belief Model Scale (CHBMS) [8] into the contents of CRC screening. Composed of total ten questions, each question was measured by the 5-point scale. The higher score means the higher self-efficacy. Regarding the reliability of the tool, in the moment of development, the Cronbach's α was .87. In this study, the Cronbach's α was .90.

Social Support

The social support was measured by using the Multi-dimensional Scale of Perceived Social Support (MSPSS) developed by Zimet et al., [9]. As the MSPSS is composed of family support, peer support and special support from meaningful others, it has total 12 questions including four questions in each area, based on the 5-point scale. The higher score means the better social support. Regarding the reliability of the tool, in the moment of development, the Cronbach's α was .83. In this study, the Cronbach's α was .86.

CRC Screening Behavior

According to the Korean National Cancer Screening Guideline, this study verified the matter of conducting the fecal occult blood test at an interval of one year targeting the husbands and wives in their 50 or up and also conducting the colonoscopy or the double contrast barium test in case of abnormal findings.

Data Collection

This study was conducted after approval of the University Research Ethics Committee (2013-0041-1). This study collected data at community service centers located in Seoul and Gyeonggi-do from December 1st 2013 to March 30th 2014. In case when the husbands and wives used the organization together, they were asked to fill out each questionnaire for husband and wife and then the questionnaires were collected on the spot. In case when only one spouse of a married couple used the organization, an envelop including a research explanation and questionnaires was provided and then the spouse was asked to bring it back on the appointed day after filling them out at home. It took about ten minutes to finish the questionnaire. To analyze the couple relationship data in the unit of husband and wife, this study only used the anonymized code that could verify the husbands and wives whose personal information were not exposed.

Data Analysis

The collected data was analyzed by using the SPSS WIN 24.0 and AMOS 24.0 Program. The actor and partner effects of self-efficacy and social support on the CRC screening behavior of husbands and wives were analyzed through the path analysis while the goodness-of-fit of the model was verified through GFI, AGFI, CFI, PGFI, PNF and RMSEA.

Result and Discussion

1. General Characteristics of Husbands and Wives of CRC Screening

In the age of subjects, the husbands were 58.54 years old while the wives were 57.64 years old($t=1.54$, $p=.102$). Regarding the private insurance, the 67% of husbands and the 70% of wives had it($\chi^2=1.56$, $p=.244$). In the family history of cancer, the 55% of husbands and the 53% of wives had no history of it($\chi^2=.10$, $p=.817$).

Regarding the monthly income of family, 3million won or up was 51% while less than 3million won was 49%.

2. Differences in the Self-Efficacy, Social Support and CRC Screening Behavior of Husbands and Wives of CRC Screening

[Table 1] show that the differences in the self-efficacy, social support and CRC screening behavior of husbands and wives of CRC screening. In the self-efficacy of subjects, the husbands were 3.48 ± 0.45 and the wives were 3.74 ± 0.34 , so that the wives were statistically significantly higher than the husbands($t=2.39$, $p=.011$). Regarding the social support, the husbands were 50.36 ± 5.67 and the wives were 52.73 ± 4.58 , so that the wives were statistically significantly higher than the husbands($t=2.43$, $p=.015$). In the matter of CRC screening behavior, the 59% of husbands and the 63% of wives conducted it, which did not show significant differences($\chi^2=0.19$, $p=.186$).

Table 1. Self-Efficacy, Social Support and CRC Screening Behavior of Husbands and Wives

Variables	Husbands (n=249) n(%) or M±SD	Wives (n=249) n(%) or M±SD	t or X2	p
Self-Efficacy	3.48±0.45	3.74±0.34	2.39	.011
Social Support	50.36±5.67	52.73±4.58	2.43	.015
Behavior of CRC Screening	146(59)	158(63)	0.19	.186

CRC= Colorectal cancer.

3. Actor and Partner Effects of Self-Efficacy and Social Support on the CRC Screening Behavior of Husbands and Wives of CRC Screening

The path analysis was conducted to analyze the actor and partner effects[Figure 1].The goodness-of-fit of the model was GFI=.92, AGFI=.88, CFI=.97, PGFI=.67, PNF=.77 and RMSEA=.06, which showed the relatively fine goodness-of-fit. In this study, the actor and partner effects of husbands and wives are as follows. First, even though the self-efficacy of husbands had the actor effects on their own CRC screening behavior($\beta=.66$, $p=.012$), it had no partner effects on the CRC screening behavior of their wives($\beta=.14$, $p=.285$). Second, the social support of husbands had the actor effects on their own CRC screening behavior($\beta=.48$,

$p<.001$)and also the partner effects on the CRC screening behavior of their wives($\beta=.45$, $p=.003$). Third, the self-efficacy of wives had the actor effects on their own CRC screening behavior($\beta=.51$, $p=.021$) and also the partner effects on the CRC screening behavior of their husbands($\beta=.37$, $p=.015$). Fourth, the social support of wives had the actor effects on their own CRC screening behavior($\beta=.41$, $p=.014$) and also the partner effects on the CRC screening behavior of their husbands($\beta=.34$, $p=.005$). The social support of husbands and the self-efficacy($\beta=.36$, $p=.023$) and social support($\beta=.52$, $p<.001$)of wives were influencing each other and this model explained the CRC screening behavior of husbands and wives as 42.1% and 33.4% respectively.

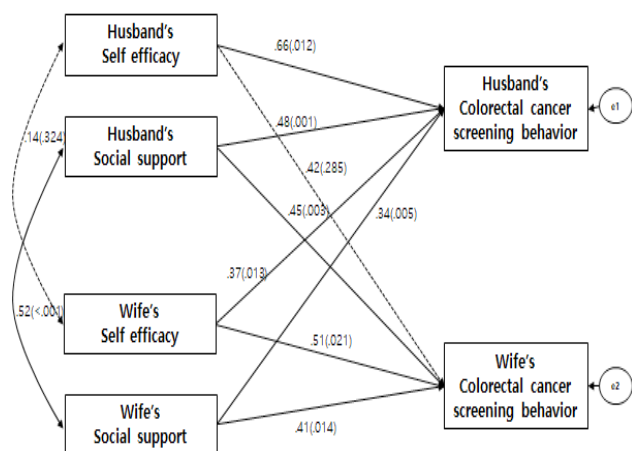

Figure 1. Actor and Partner Effects of Self-Efficacy and Social Support on the CRC Screening Behavior of Husbands and Wives

Discussion

This study aimed to verify the actor and partner effects of self-efficacy and social support on the CRC screening behavior of husbands and wives of CRC screening by applying the analysis on the couple relationship data based on the APIM. The discussions of the results of this study are as follows.

First, in the husbands and wives of CRC screening, the self-efficacy of husbands and wives had the actor effects on their own CRC screening behavior while the self-efficacy of wives had the partner effects on the CRC screening behavior of their husbands. As a belief in his/her own ability to successfully achieve a certain matter when facing a certain matter or situation, the self-efficacy is one of the factors having direct effects on the intention and behavior^[10]. According to a research by Manne et al., ^[6], the attitude and behavior of a spouse had direct effects on the intention of CRC screening behavior of the other spouse and the experience or behavior of the other spouse was considered for the decision-making of CRC screening behavior. Such results accord with the results of this study verifying that the self-efficacy of husbands and wives is interdependently working. Thus, this result supports the hypothesis of APIM explaining that the data should be collected and analyzed together. Meanwhile, in this study, the self-efficacy of wives had the partner effects on the CRC screening behavior of their husbands. This provides the information about who creates the bigger dynamics in the relationship between husband and wife. Especially, based on the study results reporting that wives are playing an important decision-making role in the health behavior of husbands and

wives^[11], women are supporting the decision-making for the health behavior of husbands and wives.

Based on the results of this study, it would be necessary to have the measures for the enhancement of self-efficacy of husbands and wives, in order to improve the CRC screening rate. Especially, the husbands and wives should be encouraged to directly participate in the intervention program helping them to control their own health to increase their self-efficacy. Also, as the self-efficacy of wives has effects on the CRC screening behavior of their husbands, it would be necessary to promote the direct motivation through the relationship adjustment and encouragement from spouse by systematically operating the programs participated by husbands and wives.

Second, in the husbands and wives of CRC screening, the social support of husbands and wives had the actor and partner effects on their own CRC screening behavior. As the important social support resources, the family, colleagues, or friends have positive effects on the early screening and health behavior for the effective prevention of cancer and also work as an element that makes it possible to conduct the behavior for the health enhancement. Especially, verifying the social support in the subjects of cancer screening is helpful for understanding the effects on health condition, health behavior and health-related decision. Moreover, the subjects in a pair based on a close relationship like husband and wife are highly possible to influence each other, so that it is important to verify their relationships. This study verified the important role of social support of husbands and wives in the voluntary preventive behavior. Therefore, when the social support of husbands and wives is high, it could have positive effects on their health behavior, which could be contributing to the decision of screening behavior. Thus, it would be needed to develop the intervention programs that could increase the social support of husbands and wives.

Bandura^[10] explained that sharing the social contexts like marriage would have effects on the mutual motivation, self-efficacy and health behavior. Therefore, in the close interdependent relationship like husband and wife, the self-efficacy and supportive relationship of spouse play an important role in the mutual decision-making. Thus, in order to improve the CRC screening rate, it would be necessary to understand the level of family support and problems through the continuous counseling with a medical team and also to provide the

intervention for strengthening the family support.

Through the discussions above, the effects of self-efficacy and social support on the enhancement of CRC screening rate of husbands and wives were verified. Such results of this study could be used as the basic data for the development of intervention programs for enhancing the CRC screening rate.

Based on the results of this study, the suggestions for the follow-up researches could be made as follows. First, it would be necessary to have the researches on the development of programs including the contents of improving the self-efficacy and social support of husbands and wives of CRC screening and the verification of effects. Second, there should be the researches including diverse variables that could have effects on the CRC screening besides the variables verified in this study.

Conclusion

This study aimed to verify the actor and partner effects of self-efficacy and social support on the CRC screening behavior of husbands and wives of CRC screening. In the results of the analysis, the self-efficacy of husbands and wives had the actor effects on the CRC screening behavior while the self-efficacy of wives had the partner effects on the CRC screening behavior of their husbands. The social support of husbands and wives had the actor and partner effects on the CRC screening behavior. Therefore, to enhance the CRC screening rate, it would be more effective to verify the social support system of husbands and wives and also to plan/carry out the programs that could improve the self-efficacy in the unit of husband and wife. The model verified on the basis of APIM in this study could become the theoretical basis for the development of programs for improving the CRC screening rate by verifying the actor and partner effects of husbands and wives of CRC screening.

The Correlation of the Star Excursion Balance test, Star Excursion Balance Test, Visual Feedback Balance Test

Young-Jin Lim¹, Byoung-Hyoun Moon¹ Ji-Won Kim²

¹Graduate Degree, ²Professor, Dept. of physical therapy, Nambu University 23 CheomdanJungang-ro, KS008, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to evaluate the relationship between Star Excursion Balance Test (SEBT), Y-Balance Test (YBT) and Visual Feedback Balance Test (VFT).

Method/Statistical Analysis: Thirty subjects were recruited for this study. To verify the usefulness of the VFT, we compared the correlation with the existing SEBT and YBT scores. Pearson Correlation Analysis was conducted to determine the difference in each balance test.

Findings: In this study, there were statistically significant correlations between reach distance and composite scores in SEBT, YBT and VFT ($p < 0.01$).

Improvements/Applications: The results suggest that VFT may be able to use dynamic test equipment. The VFT can be used for dynamic balance exercise because it can intuitively visually check balance values.

Keywords: Correlation, Dynamic balance, Star excursion balance test, Visual Feedback, Y-balance test

Introduction

In the human body, balance is the ability to maintain the center of gravity on the base of support during movement^[1]. The ability to maintain balance is an essential part of life because humans have to adjust body's posture and balance with respect to space^[2], such as when humans stand up and sit down in everyday life. A well-balanced posture protects the body from injury and helps maintain its function^[3].

Balance can be divided into static balance and dynamic balance. Static balance is the ability to keep the body's center in base of support without disturbance. Dynamic balance is the ability of the body to maintain balance as it moves and maintain the desired posture by placing the center of gravity within the base of support^[4]. Balance is a complex process that monitors the body's motion through the sensory apparatus, enters the central nervous system and then sends it back to the muscular

skeletal system to perform the response, which is an important element in everyday life. Therefore, balance test has been used in orthopedic, sports medicine^[5] and rehabilitation^[6].

Method of measuring static balance includes Romberg test and one leg standing test^[7,8] and method of measuring dynamic balance includes timed up & go test^[9], star excursion balance Test (SEBT) and Y-Balance Test (YBT)^[10,11]. Especially SEBT and YBT are widely used in clinical practice. The reason is the most common and well-established balanced assessment, because both tests do not require high interventions and techniques. In particular, SEBT and YBT are often performed in clinical practice, because they are the most common and well-established balance assessment and because they do not need to perform high-level arbitration and techniques, they are used most often in clinic^[12-14].

SEBT is a dynamic balance test tool that measures strength, flexibility and the sense of motion of the legs and is measured with eight lines drawn on the ground at intervals of 45 degrees. The test is to measure the distance reached by supporting the ground with the

Corresponding author:

Ji-Won Kim,

rehab@nambu.ac.kr

dominant legs and extending as far as possible with the non-dominant legs in the specified direction^[15,16]. SEBT was studied by many researchers, including changes in muscle activity towards the direction subjects with and without symptom.

YBT performs only three directions: anterior (AN), posterior-medial (PM) and posterior-lateral (PL). It has high inter ratorreliability (intraclass correlation coefficient (ICC) = .88 to .99) compared to the higher repeatability and less test time and is widely used in clinic^[16-18]. However, YBT can be performed when the assessor is present and have to return the box to basic position each time after the test. YBT also has the disadvantage of not receiving visual feedback during the balance test.

Several studies have been reported that visuals have affected balancing when visuals are blocked or limited. Postural fluctuations have been reported to increase by 20-70% in the absence of visual information. Visual feedback is combined with centripetal information from body sensations, contributing to postural coordination and reducing postural movements.

To address these problems, this study developed a VFT using visual feedback sensor system measurement technology. Therefore, the purpose of this study is to investigate the correlation with SEBT and YBT to determine the usability of VFT as an objective tool for the dynamic balance assessment. The purpose of this study was to evaluate the relationship between, YBT, SEBT and VFT.

Method

SEBT is a dynamic balance measurement tool that evaluates muscle strength, flexibility and proprioception. This experiment used three of the eight directions, anterior, posterolecular and posteromedial. In addition, lines in the direction of posterolecular and posteromedial were marked with tape at 135 degree points on both sides of the ground in relation to the forward direction.

Y Balance Test (Functional Movement Systems, Danville, VA, USA) is a modified dynamic balance measurement method by increasing the efficiency of SEBT, which was commonly used to measure the strength, flexibility and proprioception of the lower extremities. Unlike SEBT, YBT consists of only three directions: anterior, posteromedial and posterolateral. The YBT kit consists of a single plate with height and

PVC pipe with three directions: AM and PL PM. The pipes in the PM and PL directions are at an angle of 90 degrees and the pipes in the front and rear directions are at an angle of 135 degrees. Each pipe is marked with a distance in 5 mm so that the distance can be expressed numerically. Each pipe is marked with a distance in 5 mm so that the distance can be expressed numerically.

VFT is performed in the same method as SEBT but the length is measured through the program without the assessor. During dynamic balance test, subjects can receive visual feedback from the screen.

SEBT was measured three times in each direction after sufficient practice until the subject could perform the experiment. The measuring method is to extend the leg as much as possible for 4 seconds and return to the starting position again. The weight was supported by the dominant leg and the distance to the maximum stretched point in cm was recorded while maintaining the balance along the line of the ground with the non-dominant leg^[12]. To prevent muscle fatigue, subjects rested for 30 seconds after each measurement. If the supporting foot falls off the ground, supports the floor with an extended foot for balancing, or fails to return to the starting position after the foot is extended, it was considered a failure and remeasured. YBT was measured three times in each direction after practice until the experiment could be performed as much as possible and it was instructed to return to the starting position in four seconds with the legs stretched out as much as possible for four seconds.

YBT was measured three times in each direction after practice until the experiment could be performed as much as possible and it was instructed to return to the starting position in four seconds with the legs stretched out as much as possible for four seconds. The subject's second toe was placed on the instrument reaching direction line and the experimenters measured the distance from the center of the instrument to the predominant leg and to the maximum point in which the non-dominant leg extends from the center in three directions. To prevent muscle fatigue, subjects rested 30 seconds after each measurement. If the supporting foot falls off the ground, supports the floor with an extended foot for balancing, or fails to return to the starting position after the foot is extended, it was considered a failure and remeasured. It was also considered to be a failure if the end of the body moved while reaching the foot from an unstable support surface when the end device was kicked to reach the maximum reach distance.

VFT is a method of measuring the maximum length reached by extending the legs in each direction on a tape attached to the ground like SEBT. If the leg is extended during the measurement, the ultrasound program on the machine automatically records the distance. After practicing until the experiment could be performed as much as possible, three measurements were taken in each direction and with the hands fixed to the waist, the legs were stretched for 4 seconds as much as possible and the instruction was made to return to the starting position again at 4 seconds. The subject supports the weight with the dominant leg and balances along the line of the ground with the non-dominant leg, stretching the leg as far as possible and recording the distance to the point in cm. If the supporting foot falls off the ground, supports the floor with an extended foot to balance, or fails to return to the starting position after reaching out, it is considered a failure and remeasured.

The Pearson correlation analysis of the reach and composite scores of SEBT, YBT and VFT was performed. And the correlation coefficient (r) was used to determine the reliability between the two variables. The r values were classified as poor reliability below .69, good reliability between .70 ~ .79 fair reliability, good reliability between .80 ~ .89 and high reliability above .90 ~ .99. All statistics were processed by SPSS ver. 22.0 program (SPSS Inc, Chicago, IL, USA) was used.

Result and Discussion

1. Reach distance correlation of SEBT, YBT, VFT

The results of the reach distance correlation of SEBT, YBT and VFT are as follows [Table1-3].

Table 1. Pearson correlation of AN

AN reach distance	PEARSON Correlation Coefficient		significance probability (**p<0.01)		
	YBT	VFT		YBT	VFT
SEBT	.602**	.619**	SEBT	.000	.000
YBT		.485**	YBT		.007

Table 2. Pearson correlation of PM

PM Reach Distance	PEARSON Correlation Coefficient		Significance probability(**p<0.01)		
	YBT	VFT		YBT	VFT
SEBT	.670**	.651**	SEBT	.000	.000
YBT		.621**	YBT		.000

Table 3. Pearson correlation of PM

PL Raach Distance	PEARSON Correlation Coefficient		Significance probability(*p<0.05),(**p<0.01)		
	YBT	VFT		YBT	VFT
SEBT	.416*	.491**	SEBT	.022	.006
YBT		.600**	YBT		.000

2. Composite Score Correlation of SEBT, YBT, VFT

The results of the composite score of SEBT, YBT and VFT are as follows[Table 4-6].

Table 4. Pearson correlation of AN

AN Composite Score	PEARSON Correlation Coefficient		Significance probability (**p<0.01)		
	YBT	VFT		YBT	VFT
SEBT	.578**	.760**	SEBT	.001	.000

SEBT	.669**	.787**	SEBT	.000	.000
YBT		.684**	YBT		.000

Result and Discussion

The purpose of this study is to identify the correlation between the reach distance and the composite score of the dynamic balancing test, SEBT, YBT and VFT. Dynamic balance testing is the ability of the body to maintain balance during the performance of the movement. During the movement, the body center is placed on the support surface to evaluate the performance of the movement. SEBT and YBT are dynamic balance tests performed frequently in clinical use and VFT is an instrument that can provide visual information to users during dynamic balance tests. The purpose of this study is to examine the correlation between the range of distance and composite scores of the existing clinical evaluation tools SEBT, YBT and VFT and whether the test tool can be used as an objective tool for balance evaluation.

In this study, there were statistically significant correlations between AN, PM, PL reach distance and composite scores during SEBT, YBT and VFT (p <0.01). SEBT has traditionally been widely used in clinical practice to assess dynamic balance. YBT is an instrument that is made by modifying and improving SEBT and it is measured using only three directions (AN, PM, PL) unlike SEBT that extends in eight directions. YBT consists of three pipes and a plate with height. The PVC pipe of PM and PL are located at 135° each in the AN direction and the angle between the two pipes of PM and PL is 90°. According to the study of Coughlan et al. (2012), when the reach of SEBT and YBT in each direction is compared, the reach distance of anteior directions is correlated because the reach of SEBT is longer than that of YBT^[16]. Plisky et al. (2009) reported higher in Inter-rater reliability in YBT compared to SEBT, which he claimed was because the use of standardized kits in YBT reduced errors^[18]. However, YBT has the hassle of having the tester check each record, record it on the test sheet and inform the subjects.

Our findings showed statistically significant correlation results in the reach distance and composite score reached not only in SEBT and YBT, but also in VFT. Visual information can be integrated with afferent information coming from vestibular and somatosensory to contribute to postural agitation, improving dynamic balance. Uchiyama and Demura(2008) showed that when providing visual information, pre- and post-pressure center point shifts were reduced compared to when no visual biofeedback was given^[19].

The VFT applied in this study was applied to the evaluation of dynamic balance by integrating visual feedback which is essential for the motor control factor. This is because the ability to control motion is essential for dynamic balancing capabilities and visual biofeedback is necessary for proper motor control, which changes the control of motion. VFT is a functional test performed on the ground that does not require three pipes and plates and does not change in height, unlike the YBT, which is performed on a high plate, the same conditions as in everyday life. VFT is an automated system using ultrasonic sensor system measurement technology with visual feedback, allowing the experimenter to return the boxed plate to its original position and eliminate visual errors between the subject and each time during the balance measurement. Therefore, VFT is not only suitable as testunobtrusiveequipment for dynamic balance ability, but also as a tool for balance exercise. The limitation of this study is that the VFT did not confirm inter-rater reliability. In future studies, it will be necessary to examine the inter-rater reliability during VFT.

Conclusion

This study was conducted to investigate the correlation between SEBT, YBT and VFT and to find out whether VFT can be used as a balance assessment. As arsulsts, VFT is not only suitable as testequipment for dynamic balance ability, but also as a tool for balance exercise. Further research will require study of motion analysis during VFT.

Study the Association between the Thyroid Autoimmunity Markers and Polycystic Ovary Syndrome in Euthyroid Women

Nassrin Malik Aubead

Lecturer Department of Obs. & Gyn., College of Medicine/University of Babylon-Hilla-Iraq

Abstract

Polycystic ovary syndrome during childbearing age is considered as one of the commonest endocrine disease in reproductive age females, with a prevalence of 4% to 15%. The clinical expression of PCOS is variable, but mostly includes anovulation or oligo-ovulation, clinical or biochemical hyperandrogenism and ovarian polycystic picture in U\S. **Objective:** To determine the levels and prevalence of thyroid antibodies in euthyroid women has PCOS.

Patients and method: A case control study carried in the Infertility clinic of the Babylon Teaching Hospital for maternity and children in Al-Hila city, Babylon governorate, /Iraq in the period from October 1, 2018 to the end of Nov. 2019. **Results:** the current study found a highly statistically significant association between the studied group among the BMI ($P<0.001$), while no significant association between the studied groups regarding the age ($P>0.05$). Eighty percent of the patients (PCOS) group, and 20% in control group presented with family history with thyroid disease. Anti-TG were negative in (85.72%) of the PCOS group patients, 8.57% of the patients with borderline positive and only (5.71%) were positive (>110 IU/ml). TSH level in PCOS group (2.3 ± 0.5) were increase with significant association than that in control group (2.1 ± 0.8), highly significant increase were found in Anti-TPO, Anti-TG, free testosterone and LH in PCOS group than that in control group ($P<0.001$).

Conclusion: There is increased risk of thyroid disease with increase in thyroid Autoimmunity Markers in PCOS patients.

Keyword: PCOS, Anti-TPO, Anti-TG, Thyroid Autoimmunity Markers,

Introduction

Polycystic ovary syndrome during childbearing age is considered as one of the commonest endocrine disease in ladies, with a prevalence of 4% to 15% of the female population of childbearing age being estimated ⁽¹⁾.

The clinical expression of PCOS is variable, but mostly includes absence of ovulation or oligo-ovulation, clinical or biochemical hyperandrogenism and ovarian polycystic picture in U\S ⁽²⁾. Variability in phenotypic expression continues to be a reason for investigation and

should be considered at the time of the clinical approach ⁽³⁾.

The prevalence of thyroid pathology in patients who has PCOS remains a matter of debate. Several studies have shown a relationship between PCOS and the existence of hypothyroidism and autoimmune thyroid disease AITD ⁽⁴⁾. The AITD in PCOS is proposed to be related to genetic factors that also contribute to the pathophysiology of this syndrome, suggesting that autoimmune mechanisms are involved in the pathogenesis of PCOS ⁽⁵⁾.

While insulin resistance (IR) seems to be a fundamental event to initiate or perpetuate the most important pathological conditions of this syndrome, it is associated in obese patients with an increase in adipokines - cytokines and other inflammatory markers

such as, tumor necrosis factor α (TNF α) and IL-6^(6,7). Moreover, its related to a defect in auto phosphorylation receptor, and phosphorylation of signaling molecules coupled to the insulin receptor independently of obesity and body mass index (BMI))⁽⁸⁾. Structural changes of the thyroid gland have been determined in different states of insulin resistance in relation to thyroid nodular disease⁽⁹⁾.

The effects described for insulin resistance establish phenomena of selectivity, maintaining the mitogenic pathways that involve this hormone as a vital factor of cellular growth and generation. The effect of insulin resistant on the thyroid gland recently has been evaluated, and demonstrating that patients with this condition have a greater thyroid mass, as well as a higher prevalence of thyroid nodules, and even recently has been related to early stages of thyroid carcinogenesis. In view of the overexpression of insulin receptors and insulin-like growth factors type 1 and 2 (IGF-1 and 2), with high structural homology and the existence of hybrid tetramers, in cell cultures of thyroid tumors, which They have also been isolated in granulosa and ovarian cells from PCOS patients^(9,10).

One of the common autoimmune disorders in childbearing women (5% to 20%) is the autoimmune thyroid diseases (AITD)⁽¹¹⁾. Previous studies have stated a relation between thyroid autoimmunity in pregnant women and adverse gestational outcomes like preterm labor and recurrent miscarriages⁽¹²⁾; moreover, recently many studies have described that there is an association with PCOS⁽¹³⁾.

Aim of the study: To determine the levels and prevalence of thyroid antibodies in euthyroid ladies with PCOS.

Patients and method:

A case control study carried in the in the Infertility clinic of the Babylon Teaching Hospital for maternity and children in Al-Hila city, Babylon governorate, / Iraq in the period from October 1, 2018 to the end of Nov. 2019. For this study, each patient presented with hypertrichosis and menstrual disturbance with in the age in between 18-40 years who visited the infertility clinic at same period. For determining of PCOS we depend on The Rotterdam Classification in the case of: (1) menstrual disorders such as amenorrhea (no menses for the last six months), oligomenorrhea (cycles of >35 days), (2) clinical and / or biochemical hyperandrogenism, (3) U\ S

pictures show PCO (more than 12 follicles, 2-9 mm in size).

The presence of 2 of these 3 criteria was necessary to determine poly cystic ovarian syndrome when all other diagnoses, such as congenital adrenal hyperplasia, androgen secreting tumors, Cushing's syndrome, and hyperprolactinemia, were excluded⁽¹⁴⁾. Clinical hyper-androgenism (hypertrichosis) with Ferriman-Galway score more than (7) and / or acne and/or androgenic(male) pattern of alopecia⁽¹⁵⁾. Biochemical hyperandrogenemia was determined by increased testosterone. The proportion of luteinizing hormone to follicle stimulating hormone more than two found to be high. To detect the presence of cystic ovaries, ultrasound performed on the transabdominal pelvis. Other causes of hyperandrogenism excluded by 17-OH progesterone stimulated with adrenocorticotropin, a test for dexamethasone suppression, and / or urinary cortisol excretion for 24 hours. Ladies with similar age group who visited the infertility clinics with complains not related to poly cystic ovarian syndrome or thyroid problems, with normal menstruation enrolled as controls (N=35).

Medical history taken in detail, developed physical examination, Age, BMI were recorded.

Laboratory parameters measurement:

Five cc of venous blood samples were collected in the morning from each participants using clot activator tube during menstrual cycle (2-5th days of MC). By using centrifuge the separation of serum were done after standardized time needed and then put in a special refrigerator to frozen at temperature below -80°C to do further analysis. The following serum measurements were achieved: TSH, free thyroxin level (FT4 and FT3), anti-thyroid peroxidase antibody (anti-TPO), anti-thyroglobulin antibody (anti-TG), fasting blood glucose, fasting insulin, LH, FSH, free testosterone.

As we measured the blood glucose in mg/dL so we use can calculate the HOMA-IR (mIU/L) as follow:

Fasting insulin mIU/L multiply by fasting glucose mg/dL divided by (405).

Insulin resistance readings range:

- Normal (less than 3)
- Borderline (3-5)

- Severe IR (more than 5)

Statistical Analysis

Data entered by the researcher by use of computerized statistical software; Statistical Package of the Social Sciences (SPSS) version 23. Descriptive statistics are presented in the form (mean ± standard deviation). One-way ANOVA analysis was used to compare more than two means. In all statistical analyzes,

the significance level (p-value) was set at ≤ 0.05 and the result was presented in tables and / or graphs.

Results

Seventy participants enrolled in the current study with response rate of 100%. Table 1 show that the BMI in PCOS group were highly significant than BMI in healthy control group (P<0.001). The age in case group were less than that in control group but with no statistically difference were found (P>0.05)

Domains	PCOS group (No=35)	Control group (No=35)	P value
Age (year)	27.2±6.7	28.3±7.2	NS
BMI	29.4±3.1	27.7±3.6	<0.001

As shown in figure 1, 80% of the patients in case group (PCOS) and 20% in control group presented with family history with thyroid disease.

Figure 1: family history of thyroid disease in the studied group (case and control)

Anti-TG-IgG were negative in (85.72%) of the PCOS group patients, 8.57% of the patients with borderline positive and only (5.71%) were positive (>110 IU/ml)

Domain	No.	%	
Anti-TG IgG	Positive (> 110 IU/ml)	2	5.71
	Borderline positive (90 - 110 IU/ml)	3	8.57
	Negative (< 90 IU/ml)	30	85.72
	No.	%	
Anti-TPO IgG	Positive (> 55 IU/ml)	4	11.42
	Borderline positive (45 - 55 IU/ml)	4	11.42
	Negative (< 45 IU/ml)	27	77.16

Table 3 revealed that TSH level in PCOS group (2.3 ± 0.5) were increase with significant association than that in control group (2.1 ± 0.8), highly significant increase were found in FBG, Fasting insulin, HOMA-IR, Anti-TPO, Anti-TG, free testosterone and LH in poly cystic ovary group than that in healthy group (P<0.001), while difference between FT4, and FSH was not significant.

Table 3: The relation of many domains and the studied groups

Domain	PCOS group	Control healthy group	P-value
FBG(mg/dL)	108.57±11.27	98.68±15.1	<0.001
Insulin(IU/ml)	22.7±3.4	17.20±5.3	<0.001
HOMA-IR (mIU/L)	6.08±2.51	4.19±1.81	<0.001
TSH µIU/ml	2.3 ± 0.5	2.1 ± 0.8	0.03
FT4 nmol/L	78.23± 21.4	76.9 ± 22.2	NS
Anti-TPO IU/ml	46.5 ± 16.9	32.9 ± 10.2	<0.001
Anti-TG IU/ml	92.3±23.4	34.8±6.20	<0.001
Free testosterone	0.98 ± 0.44	0.36 ± 0.14	<0.001
LH	9.7 ± 6.5	5.4 ± 2.8	<0.001
FSH	6.4 ± 4.2	6.8 ± 1.5	NS

Discussion

One of the most common connection between PCOS and thyroid disease is the increase level of insulin resistance and BMI⁽¹⁶⁾. The current study revealed that there is increase in BMI of the PCOS group, which is very common in women with this disease. As mentioned by Lim S et al, this prevalence was between 54–68% of cases⁽¹⁷⁾. Moreover, many studies were in agreement with current study. Nevertheless, it is not in agreement with Duntas L et al, and with Harpsoe M et al, when they concludes that there is no association between thyroid autoimmunity and BMI^(18,19).

Prevalence of thyroid disorders (Td) in women With the PCOS, this is still a matter of debate. Different studies demonstrated a link between PCOS and attendance hypothyroidism and antithyroid antibodies⁽²⁰⁾.

In a retrospective study of 197 women With PCOS, reported a high prevalence of subclinical hypothyroidism and thyroid autoimmunity, with frequencies of 26.3 and 20.3%, respectively

Ganie and colleagues reported a significantly higher prevalence of PCOS in euthyroid adolescents with

chronic lymphocytic thyroiditis (CLT) compared to healthy controls (46.8 vs. 4.3%)⁽²¹⁾.

In addition, a recent meta-analysis study indicates that the occurrence of autoimmune thyroiditis and Plasma TSH levels in patients with poly cystic ovarian syndrome was significantly higher than those of healthy group⁽¹⁵⁾.

While in the current study we found that positive anti TPO were found in 11.42% of the patients with PCOS, this is less than (37.8%) that found in a study carried by Ozdemir D et al, in Turkey⁽²²⁾. Moreover, it is less than that found by Indian study done by Sinah U et al, when positive anti-TPO were found in 22.5% of the PCOS patients included his study⁽¹⁵⁾. This may be due to differences in sample size collection and different in cutoff value of the markers used in the studies.

The current study show that LH/FSH were increase >2 times in 24% of the PCOS patients and < 2 times in 76%, while in Banaszewska B et al, study they revealed that the raised was in 45.4% in LH/FSH ratio and the raised was 64% in Anlakash A et al^(23,24).

The mean serum of anti TPO in PCOS group was significantly elevated than that in healthy group ($p < 0.001$), also the anti-TG serum levels were higher increase in PCOS group than that in control group. In agreement with Syrian study regarding the anti-TPO but this study that carried by Al-Saab R et al, mentioned that serum level of anti-TG were more elevated in PCOS group than that in control healthy group but with no significant association ⁽²⁵⁾. In addition to that, Kachuei et al, in Iranian study were in agreement with Al-Saab R et al finding ⁽¹³⁾.

Conclusion

There is increased risk of thyroid disease with increase in thyroid Autoimmunity Markers in PCOS patients.

No Conflicts of Interest

The Effect of Slow Stroke Back Massage, Cold-compress and Warm-compress on Superokside Dismutase and Malondialdehyde Levels in Primary Dysmenorrhoea

Mukhoirotin¹, Kurniawati¹, Zuliani¹

¹Nursing Science Program, Faculty of Health Science, Unipdu Jombang, Indonesia

Abstract

During dysmenorrhea occurred inflammation and endothelial dysfunction with lipid peroxidation sign and it was an indication of oxidative stress. Several previous studies have showed in dysmenorrhoea there was an increase of MDA levels and a decrease of SOD plasma. The aim of this study was to determine the effect of Slow Stroke Back Massage (SSBM), cold-compress and warm-compress on Superokside Dismutase and Malondialdehyde levels in Primary Dysmenorrhoea. This study used a Quasy Experiment design with approach a Post Test Only Control Group Design. The population in this study was all female students in Health Science Faculty of Unipdu Jombang who experienced dysmenorrhoea, a total sample in this study was 50 respondents and they were divided into 4 groups. The instruments in this study were included: thermometer for measured the temperature, and a Spectrophotometer which consists of NBT (Nitro Blue Tetrazolium) method for measured SOD level, Thiobarbituric Acid (TBA) method for measured MDA level. The data were analyzed by using the Kruskal-Wallis test and Post Hoc Test with $\alpha \leq 0.05$. The results of this study showed that there were disfferences of SOD level in SSBM, warm-compress compared to control and there were no differences in SOD levels between cold-compress with the control. There were significant differences of MDA levels in all treatment groups and control.

Keywords: *Slow Stroke Back Massage, Cold-compress, Warm-compress, Superokside Dismutase Malondialdehyd*

Introduction

Primary dysmenorrhea is a complaint of lower abdominal pain during menstruation among young women without pelvic pathology⁽¹⁻³⁾. Cramping pain of menstruation occur ≥ 2 days and accompanied some symptoms such as nausea, diarrhea, headaches and bloating⁽⁴⁻⁷⁾.

The incidence of primary dysmenorrhea was estimated at 60%-88% occurred young women⁽⁷⁻⁸⁾. Dysmenorrhoea give an impacts for personal health and social. A study mentioned that about 600 million of work hours and the economic losses of around 2 billion dollars per year in the United States⁽⁹⁾. Studies in

Korea showed that about 83%-94% of female students complained of cramps during menstruation⁽¹⁰⁻¹¹⁾. The menstrual cramps defined as colic pain before or during menstruation in the pelvis, lower back, or upper legs that last for 48-72 hours⁽¹²⁾.

In primary dysmenorrhea has an increase of endometrial secretion, PGF2 α and leukotriene levels during menstruation so it makes an increasing of uterine tone and pain⁽¹³⁾. Also occurred an inflammation and endothel dysfunction characterized by lipid peroxidation which is an indication of oxidative stress⁽¹⁴⁻¹⁵⁾. Lipid peroxidation can be identified by an increasing of malondialdehyde (MDA) levels⁽¹⁶⁾. On healthy conditions, oxidative stress and free radical are balanced in the cellular system. Oxidative stress occurs because of an imbalance between pro-oxidants and antioxidants⁽¹⁷⁾. It men has an increase on concentration of reactive oxygen species (ROS) and or reactive nitrogen species (RNS) and has a decrease in defense of

Address: Campus of UNIPDU, Peterongan, Jombang, Indonesia

antioxidant mechanisms⁽¹⁸⁻²²⁾. Some of ROS are needed for the development of normal cell function with the condition on the oxidation of each molecule returning to the reduced status⁽²³⁾. Excessive ROS can defeat the body's natural antioxidant defending system⁽¹⁷⁾, induce lipid peroxidation and the damage of DNA and cell membranes^(18,24-25). One of endogenous antioxidant is superoxide dismutase (SOD). Several previous studies said that in dysmenorrhoea process will increases MDA⁽²⁶⁻²⁸⁾ and decreases in plasma SOD⁽²⁹⁾.

Nonsteroidal anti-inflammatory drugs (NSAIDs) consumption can reduce menstrual pain by inhibiting the cyclooxygenation enzyme especially in acute phase and reducing prostaglandin F2 levels in menstrual fluids⁽³⁰⁻³¹⁾. Eventhough this drug is beneficial but it also has side effect such as dyspepsia, nausea, breast tension, bleeding between two menstrual cycles, visual and hearing disorders and abnormal results of kidney and liver function⁽³²⁻³⁷⁾, so effective and efficient interventions are needed for patients who experienced primary disminorhea. These efforts can be giving a SSBM, cold-compresses and warm-compress. Massage can reduce the production of NF- κ B, inflammatory cytokines and TNF- α ⁽³⁸⁾. Cold-compress can reduce prostaglandins and it maked strengthen the sensitivity of pain and other subcutaneous at the site of injury by inhibiting the inflammatory process by reducing blood flow and giving analgesic effects by slowing the speed of nerve delivery so the pain impulses are late or less to reach the brain⁽³⁹⁾. Warm-compress can increase the circulation on pelvic area. Previous studies said that local heat intervention was effectives as ibuprofen⁽⁴⁰⁾ and paracetamol⁽⁴¹⁾. However, the study about the impact of SSBM, cold-compresses and warm-compresses on SOD and MDA level are limited so the researchers are interested to conduct this research with the aim of this study was to determined the effect of SSBM, cold-compresses and warm-compresses on SOD and MDA in Primary Dysmenorrhoea.

Method

This research used Post-Test Only with Control Group Design. The population were all female students in Faculty of Health Sciences Unipdu who experienced dysmenorrhoea. Sample size was 50 respondents, divided into 4 groups, it were SSBM (n=13), cold-compress (n=12), warm-compress (n=13), control (n=12). The sampling technique was purposive sampling. Inclusion criteria were 1) primary dysmenorrhoea; 2) pain

intensity: moderate to severe, 3) have not received anti-pain medicine; 3) Cooperative. Exclusion criteria were 1) experienced secondary dysmenorrhoea; 2) refused in the middle of intervention. The instruments were: thermometer and a Spectrophotometer which consists of NBT for measured SOD level, TBA for measured MDA level. The data were analyzed by using the Kruskal-Wallis test.

Findings

Table 1. The differences of SOD level after giving intervention

Group	Median (Min-Max) pg/ml	p
SSBM	1099 (1069.2-1190.8)	0.001
Cold-compress	1061 (1029.2-1187.5)	
Warm-compress	1081 (1035.8-1215.8)	
Control	1034 (900.8-1135.8)	

Kruskal-Wallis test

Table 2. The differences of SOD level after giving intervention

Group	p
SSBM vs Cold-compress	0.005
SSBM vs Warm-compress	0.068
SSBM vs Control-group	0.001
Cold-compress vs warm-compress	0.205
Cold-compress vs control	0.106
Warm-compress vs control	0.007

Post Hoc Mann-Whitney test

The Kruskal-Wallis test obtained p=0.001 (there was significant differences of SOD levels between the two groups). The Mann-Whitney Post Hoc Test showed that there were significant differences of SOD in SSBM vs. Cold-compress, SSBM vs. Control and Warm-compress vs control.

Table 3. The differences of MDA level after giving intervention

Group	Median (Min-Max) pg/ml	p
SSBM	164.17 (142.5-194.2)	0.000
Cold-compress	100.83 (52.5-127.5)	
Warm-compress	72.5 (40.8-114.2)	
Control	286.67 (234.2-347.5)	

Kruskal-Wallis test

Table 4. The differences of MDA level after giving intervention

Group	P
SSBM vs Cold-compress	0.000
SSBM vs Warm-compress	0.000
SSBM vs Control	0.000
Cold-compress vs Warm-compress	0.014
Cold-compress vs control	0.000
Warm-compress vs control	0.000

Post Hoc Mann-Whitney test

The Kruskal-Wallis test showed there were significant differences in MDA between each the 2-groups.

Discussion

The pain of primary dysmenorrhea can spread to the lower back and thighs and occurred 2-3 days⁽⁴²⁾. Primary dysmenorrhea occurs due to an increasing of endometrial prostaglandin production so it makes uterine hypercontractility and increasing uterine basal pressure followed by the decreasing of blood flow in large or small blood vessels in uterus and in the end giving impacts like ischemia and pain⁽⁴³⁻⁴⁴⁾. Endometrial ischaemia can activates phospholipase A2 so it will hydrolyze acylgliserolipids and producing free fatty acids, especially arachidonic acid which is metabolized by the enzyme lipoxigenase, cyclooxygenase, and cytochrome P450 to eicosanoid formation and activated the release of ROS⁽⁴⁵⁻⁴⁶⁾. Excessive ROS can defeat the defense of body's natural antioxidant system⁽¹⁷⁾ so in primary dysmenorrhoea there is an increase of MDA levels and a decrease of SOD levels.

The results of this study showed that SOD level among intervention group was higher than control group. SSBM and warm-compress were effected the increases of SOD level in primary dysmenorrhoea and statistically there is no differences of SOD level between cold-compress group and control group, however the maximum value of SOD levels in cold-compress group was higher than control group. SSBM, cold-compress and warm-compress were effected to reducing MDA level in primary dysmenorrhea.

SSBM give impact on an increase of SOD level and a decrease of MDA level, this occurs because the mechanical pressure of the massage will encourages on increasing blood circulation by increasing arteriolar

pressure⁽⁴⁷⁻⁴⁸⁾. The massage on the neck and shoulders are increase peripheral blood flow and it can detected by using infrared thermography⁽⁴⁹⁾. The increasing of blood circulation can improve the oxygenation in tissues and also improves ischemia and reduce the production of free radicals and the uptake of the antioxidant SOD. Ischemia in uterine endometrial cells and muscles is a condition of reperfusion ischemia which generates a lot of oxygen free radicals which is it gives an impact on the uptake of SOD⁽²⁹⁾.

The results showed that there were no differences of SOD level in cold-compress and control, and there were differences of MDA level in cold-compress and control. Although, there was no differences of SOD level in cold-compress and control, the maximum of SOD was higher than control. Cold-compress works by reducing the inflammatory process, reducing edema and reducing local pain⁽⁵⁰⁾. The decreasing of MDA, possibly due in cold-compress work by reducing the inflammatory process so the prostaglandin products also decrease, and in the end also decreasing uterine contractility, and oxygenation in endometrial tissue will improves.

SOD and MDA after given a warm-compress also given an impacts where there was an increase of SOD and a decrease of MDA. A warm-compress given an impacts on blood flow of pelvic region increases because the effects of vasodilation⁽⁵¹⁾. The changes mechanism in SOD and MDA levels after given of warm-compress intervention was same as the SSBM intervention. Hot hip-bath intervention for 10 minutes every day in 7 days before menstruation was effected to reducing menstruation pain among women with primary dysmenorrhea. This happens because the hot hip bath can increase blood flow in myometrium, which is it can clear prostaglandins and in the end it will reducing cramps and pain⁽⁵²⁾.

Conclusion

1. The SSBM, warm-compress were effected to increasing of SOD levels in primary dysmenorrhoea
2. The SSBM, cold-compress and warm-compress are effective to reducing MDA levels in primary dysmenorrhoea

Ethical Clearance-obtained from the ethics commission of Nursing Faculty, Airlangga University.

Modification of Chicken Egg Shell and Lime Extract (*Citrus amblycarpa*) for Minimizing Lead (Pb) Level on Blood Cockles (*Anadara granosa*)

Narwati¹, Hadi Suryono¹, Setiawan¹

¹Researcher & Lecturer at Department of Environmental Health, Poltekkes Kemenkes Surabaya

Abstract

Heavy metal in human body generally is from food consumed by the human either through fish or other aquatic animals in fresh water or seawater which are polluted by heavy metal. The presence of heavy metal in human body in certain level can cause several diseases, such as kidney disease, liver, nerve, and brain disease. Moreover, this research aimed at analyzing the decrease of lead (Pb) level on blood cockles (*A. granosa*) through engineering of stirring time, adsorption temperature, and variation of lime extract (*C. amblycarpa*) concentration by using Stirring Chamber tools through using chicken egg shell adsorbent. The research design used simple experiment in posttest only control group design. Meanwhile, the subject in this research was divided by two groups randomly in which a treatment was given to one group as control group and experiment group. Sample of blood cockles that was used was in 72 samples. Lime extract concentration in 1%, 1.5%, and 2% in stirring time of 5 minutes, 10 minutes, and 15 minutes before and after heating in 35°C utilized stirring speed in 150 rpm. Meanwhile, the chicken egg shell adsorbent was in 50 gram for each treatment. The sampling technique in this research utilized purposive sampling and data was analyzed by utilizing Statistic test of Two-Way Anova. Result showed that Pb level in fresh cockles before heating was 0.223 ppm and after heating, it reduced to be 0.062 ppm. Result of hypothesis test was obtained p-value <0.05, which was 0.000, and it indicated that there was a significant enhancement of chicken egg shell adsorption capacity in minimizing Pb level on blood cockles after being conducted the addition of lime extract with temperature variation and stirring time in certain stirring speed through engineering tool of Stirring Chamber. All in all, conclusion of this research was there was a significant enhancement of modified chicken egg shell adsorption capacity and lime extract in minimizing Pb level on blood cockles. Moreover, it was expected that this research could give contribution to food technology in reducing heavy metal of Pb level in pre-treatment of blood cockles (*Anadara granosa*) with modifying lime extract and chicken egg shell through Stirring chamber tool.

Keywords: pH of a solution; adsorption temperature; lime extract

Introduction

Sea environment in the world has been discovered that it is contaminated by heavy metal. Concentration of heavy metal in environment varies partially or totally as

an impact of environmental condition and human activity.

⁽¹⁾ Condition of aquatic environment that is polluted by heavy metal can impact on biota that lives in it. Pereira, *et al* conducted a research against aquatic biota and it was known that the fish that was tested contained chromium metal, which was 1.5 mg kg⁻¹.⁽²⁾ In the water, through food chain process, first heavy metal is absorbed by phytoplankton, bacteria, fungi and low-level organisms which then, they are eaten by higher-level organisms until they enter into human body if the human consumes them.⁽³⁾ Referring to this statement, it can be meant that one of causes the human can be contaminated by heavy

Indonesia

metal is from food consumption pattern that is gotten from the waters which are contaminated by heavy metal.

Kenjeran beach Surabaya, East Java Province, Indonesia is one of water areas which has been contaminated by heavy metal. Indication of heavy metal contamination in Kenjeran beach Surabaya has been proven by conducted research by Suryono, *et al* and they stated that the presence of Hg level in 0.582 ppm in blood cockles was taken from Kenjeran beach Surabaya.

⁽⁴⁾ Result of laboratory test that had been conducted by researchers showed that Cd level and Pb level on blood cockles were in the average of 0.93 ppm and 1.92 ppm. Water biota, particularly blood cockles, can be become one indicator of pollution level which is occurred in the water. The blood cockle's body contained heavy metal level which exceeded normal limit that had been determined. Therefore, it could be used as bio indicator of pollution in the environment.⁽⁵⁾ Conducted research in first stage by Suryono, *et al* had proven that potency for chicken egg shell waste in reducing Hg metal on blood cockles (*Anadara granosa*) was through stirring chamber tools without controlling stirring speed, adsorption temperature, or pH of a solution. This research was studied further in second research in same year edition in research report that analyzed intervention of temperature and stirring speed of Stirrer chamber in improving potency of egg shell as adsorbent for reducing Cd metal and Pb metal on blood cockles.⁽⁴⁾

Result of the research showed that the decrease of Cd metal and Pb metal level was not occurred optimally. Effort in improving chicken egg shell capacity in adsorption process was conducted continuously and one of them was manipulation of pH of a solution. pH in a solution was known that it could influence the presence of metal. Meanwhile, the metal characteristic in low pH generally was as free cation. Whether, on basic pH, metal tended to precipitate as hydroxide, oxide, carbonate or insoluble phosphate.⁽⁶⁾ This explained that in acidic condition, metal ions could bind easily to the surface of adsorbent. According to conducted research by Abdel-Khalek *et al*, they explained that there was a significant enhancement of capacity of bio-composite chicken egg shell waste in pH 5,23 and contact time in 5 minutes with room temperature. Research result showed that there was maximum adsorption capacity in higher pH 5.23, which was 94,9 mg/g rather than pH 7,09 in which the adsorption capacity was only occurred in 49.5 mg/g.⁽⁷⁾ Besides, this research explained that pH of a solution which was acidic had potency in influencing the

enhancement process of metal adsorption. This research strengthened researcher's argumentation that model in manipulation of solution by adding acid could increase egg shell potency in binding heavy metal. One of substances that could make acidic solution was by using lime extract (*Citrus amblycarpa*).

Lime (*C.amblycarpa*) is one of orange types that can reduce pH value because it contains acid. Acid in orange mostly is citric acid. Kordial in his research evaluated pH value by adding several types of orange extract and one of them was lime extract. Adding lime extract in 1.3% of solution had pH 4.6, meanwhile, concentration of lime extract in 1.5% of solution had pH 3,97. Furthermore, this research aimed at analyzing the decrease of lead (Pb) on blood cockles (*A. granosa*) through manipulation of stirring time, adsorption temperature, and variation of lime extract concentration (*C. amblycarpa*) by using Stirring Chamber tools which used adsorbent of chicken egg shell.

Research Method

This research was simple experiment research by Posttest Only Control Group Design in order to investigate the influence of stirring time, adsorption temperature, and concentration of lime extract against Pb metal level, either in control group or experiment group. In simple experiment, the subject was divided by two groups (or more) randomly. A treatment was given to one (or more) group(s) as treatment group and another group (without any treatment/ giving other treatments) as control group. Furthermore, pattern of this design could be seen as followed:

Pretest	Treatment	Posttest
Treatment group	X1	O2
Control group)2

Figure 1. The research design

Findings and Discussion

This research used chicken egg shell as adsorbent that had been through activation process chemically and it used HCL solution. Besides, blood cockles (*A. granosa*) that was become sample in this research was taken from Kenjeran beach Surabaya. Moreover, model development in this research was Stirrer chamber tool which was rearranged its component of stirring speed

settings and adsorption temperature. The setting of stirring speed included: 150 rpm and could be conducted a stirring either in temperature of 35°C or before heating. Besides, it had been conducted laboratory test against Pb level on blood cockles as the sample and the result of the laboratory test was showed in table 1.

Table 1. Recapitulation of Average of Pb level on Blood Cockles (*Anadara granosa*) before Heating based on Lime Extract Concentration in 2019

Sample Code	Concentration of	Stirring Time	Average of
	Lime Extract		Pb Level (ppm)
KW1T0	0%	5	0.197
KW2T0		10	0.19
KW3T0		15	0.18
AW1T0	1%	5	0.10
AW2T0		10	0.07
AW3T0		15	0.05
BW1T0	1.5%	5	0.077
BW2T0		10	0.053
BW3T0		15	0.04
CW1T0	2%	5	0.047
CW2T0		10	0.03
CW3T0		15	0.027
Total			1.061
Average			0.088

Table 1 showed that total of Pb level in the average from each treatment before heating was 1.061 ppm with average totally in 0.088 ppm. Data in table above showed that there was a significant enhancement of lime extract concentration and the Pb level on blood cockles reduced significantly. The lowest Pb level was in lime extract concentration of 2% with stirring time in 15 minutes, which was in 0.027 ppm.

Table 2. Recapitulation of Average of Pb Level on Blood Cockles (*Anadara granosa*) based on Lime Extract Concentration after Heating in 2019

Sample Code	Lime Extract	Stirring Time	Average of
	Concentration		Pb Level (ppm)
KW1T1	0%	5	0.17
KW2T1		10	0.16
KW3T1		15	0.14
AW1T1	1%	5	0.07
AW2T1		10	0.03
AW3T1		15	0.02
BW1T1	1.5%	5	0.06
BW2T1		10	0.027
BW3T1		15	0.017
CW1T1	2%	5	0.037
CW2T1		10	0.013
CW3T1		15	0.01
Total			0.754
Average			0.063

Table above showed that Pb level on blood cockles for total average of all treatments was 0.754 ppm with average totally in 0.06 ppm. Besides, based on the table, it could be known that a tendency of Pb level on blood cockles reduced more in 3 variations of stirring time and variation of lime extract concentration after being conducted heating. The highest reduction on the treatment of adding 2% of lime extract concentration in 15 minutes of stirring time was 0.01 ppm.

Figure 1. Pb Level (ppm) on Blood Cockles Based on Concentration and Stirring Time Before and After Heating

That graphic showed a tendency of difference of Pb Level on Blood Cockles before and after heating. Pb level after heating was lower than Pb level before heating, which was 0,01 ppm.

According to concentration of adding lime extract before and after heating could be seen the average of difference of Pb level on blood cockles from control group (KW), which was 0.047 ppm, group of AW sample code by giving lime extract in 1% was 0.033 ppm, group of BW sample code by giving lime extract in 1.5% was 0.022 ppm, and group of CW sample code by giving lime extract in 2% had average of difference in 0,017 ppm.

In other words, it could be stated that the higher the lime extract concentration, the bigger the differences of Pb level on Blood Cockles rather than blood cockles that was not added by lime extract anymore.

Figure 2. The Difference of Average of Pb Level (ppm) on Blood Cockles Before and After Heating Based on Lime Extract Concentration

That graphic showed that sample which was a control had a tendency of higher Pb level rather than in treatment group which was given lime extract. It was seen that concentration of lime extract in 2% had difference of lower Pb level rather than in sample group of lime extract concentration in 1% and in 1.5%. Hence, it indicated that there was a significant difference of Pb level on blood cockles based on variation of lime extract concentration before and after heating.

Analysis of Difference of Pb Level on Blood Cockles (*A.granosa*) among several treatments

In order to investigate the influence of lime extract and stirring time against Pb level on blood cockles (*A. granosa*) in twice observations, which were before and after heating, the researchers utilized Anova test. Requirements of Two-Way Anova test was conducted if it was completed the homogeneity test. According to the homogeneity test, it showed that all p-value Lavene test >0.05 (p-value before being heated up was 0.690 and after being heated up was 0.348), which meant that the variation of between groups was not significant different either before or after being heated up, thus, data was homogeneous and qualified the homogeneity assumption. Besides homogeneity test, normality test was also conducted in order to fulfill Anova test, which was through Kolmogorv Smirnov normality test with lilliefors correction which showed that anova residuals before and after heating was 0.200 (>0.05) for each, thus, the data contributed normally and it fulfilled the normality assumption.

Moreover, there was a significant influence between lime extract and stirring time against Pb level on twice

observations, which were before and after heating. Besides, it could be showed on table of Anova test and the result showed that there was a significant influence between lime extract and stirring time separately against the average of Pb level before and after heating. This could be proven from p-value of 0.000, and it indicated that there was a significant influence between lime extract and the average of Pb level on blood cockles before and after heating. Besides, there was a significant influence between stirring time and Pb level on blood cockles before and after heating, which was showed by p-value <0.05. In the other hand, there was an addition of lime extract and stirring time together and it was obtained p-value of 0.010. Thus, it indicated that there was a significant influence of lime extract concentration and stirring time together against the average of Pb level on blood cockles.

Furthermore, in order to investigate the difference of average in Pb level between each treatment of lime extract concentration, it could be showed in Post Hoc test by utilizing Tukey test. In Post Hoc test, it showed a significant difference of Pb level average between lime extract concentration that had p value 0,000, which meant that both lime concentrations which were compared with it had significant difference of Pb level value. The difference of the highest Pb level on blood cockles was showed between lime extract concentration of 0% and lime extract concentration of 15%, which was in 0,1461 rather than lime extract concentration of 5% (0.1144) and 10% (0.1278). This indicated that there was a significant influence between lime extract concentration and the decrease of Pb level on blood cockles. Furthermore, data from the table above showed that the higher the lime extract concentration, the bigger the difference of Pb level on blood cockles rather than on blood cockles which was not added by lime extract anymore.

The Post Hoc test (Tukey) in order to assess the difference of Pb level based on stirring time that was obtained data from all variations of stirring time which had significant difference against Pb level on blood cockles. The difference of the highest Pb level on blood cockles was showed on the comparison of stirring time in 5 minutes against stirring time in 15 minutes, which was 0,0346 rather than stirring time in 10 minutes, which was 0,0229. In other words, this data showed that the longer the stirring time in this research, the higher the difference of Pb level.

Conclusion

It could be concluded that manipulation of stirring time, adsorption temperature, and variation of lime extract concentration (*C. amblycarpa*) was through Stirring Chamber tools by utilizing adsorbent of chicken egg shell, which could reduce Pb level on blood cockles.

Illnesses as an Excuse for Corrupt Indonesian Officials to be Free From Legal Liabilities

Yogi Prasetyo¹, Fery Irawan¹, Sugeng Wibowo¹, Arief Budiono¹, Indiantoro¹

¹Lecturer at Faculty of Law, Universitas Muhammadiyah Ponorogo, Indonesia

Abstract

This research aims to explain the phenomena of illnesses used by corrupt Indonesian leaders to be free from legal liabilities. Illnesses in the law enforcement of corruption cases became a problem which may inhibit the legal processes. The research method used is the sociolegal method, which analyzes the society's social behavior related to the constitutional regulations. The research data is obtained from the various examples of the cases of officials with corruption cases who use the excuse of being sick in order to be free from legal liabilities. The data also includes constitutional regulations which are related to the theme's problem. The research results show the phenomenon of sicknesses used by the corrupt Indonesian officials to be free from legal liabilities. With the basis of humanity, thus the legal process is paused for some time, and they receive special treatment which gives more comfort just as that for sick people. This is also related to the constitutional regulations in Indonesia which give protection towards the health rights for the Defendant. Yet, this is usually misused by the defendants to lie or to pretend to be sick.

Keywords: *illness, excuse, officials, corrupt, law.*

Introduction

Indonesia is a country which is currently occupied in eradicating corruption cases conducted by its officials, both in the central and regional scales.¹ Numerous corruption cases had occurred and attracted public attention,² particularly the ones related to the attitude and behavior of the suspects of corruption in order to be free from legal liabilities. They use various ways to avoid being sentenced, from bribery, fleeing, to the classic excuse of being sick. However, amongst many recent corruption cases, there were tendencies in misusing illnesses to avoid being legally punished. The majority of corruption cases involve most suspects claiming to be ill during the process. It might be perceived as an easier and less-risky alternative for the case they face. By being sick, the suspects are treated in a special, different way. It may allow the suspects to be free from the legal liabilities of corruption.

The large number of suspect corrupt officials who use the excuse of being sick turn this into an ironic public phenomenon, as prior the said occurrence, they seemed to be in good health. By using illnesses as an excuse, the corrupt suspects gain special treatment which will advantage them compared to the healthy suspects to the point that they might obtain certain permit to leave prison to seek for treatment or to be treated in hospital. For corrupt suspects who claim to be sick, naturally, the treatment given is of the standards of those who actually suffer illnesses. They are treated by medical personnel instead of prison guards most of the time. They also gain another advantage in a form of a proper and comfortable room for medical patients or in one of hospital rooms—which is, obviously, located outside of the prison. By being in those places, they obtain certain facilities which allow them to enjoy said facilities and their freedom, by not experiencing the inconvenience they might have around the prison cells and its surroundings.

Illnesses then become a condition abused by the corrupt individuals to inhibit or even to escape from legal liabilities – despite whether the said illness are deemed to be the actual condition or was staged to make a healthy individual seem to be ill. In proceeding their

operation, the corrupt cases who use the excuse of being sick also involve medical personnel such as doctors, nurses, and health institutions such as hospitals. These perpetrators have usually worked together to make this condition as an appropriate reason or basis to be treated differently which may inhibit or hinder the legal processes. A doctor's note from the doctor or from the hospital may be used as a material for consideration in proceeding legal liabilities on corrupt suspects. They might gain permit to seek for treatment for their illness prior resuming the current legal processes. They often manage to make themselves seem to be sick to avoid being legally sentenced as they are sick. Therefore, this state of illness may affect the legal processes towards corruption cases in Indonesia.

Method

This study used Sociological method.³ Research data may be the phenomenon of illnesses being an excuse for corrupt officials to escape from legal liabilities and also legal data in the form of laws and regulations related to the research problems⁴ therefore, it may result in providing further comprehension of the law.

Findings and Discussion

Phenomena of Illnesses within Corruption Cases in Indonesia

Illnesses have become an ironic yet amusing phenomenon in proceeding legal actions related to corruption in Indonesia. The majority of corruption cases conducted by the Indonesian officials are mostly followed by the classic excuse of being sick. The said condition shows how one's disability might be used to disrupt the humanity of law in the context of social life in society. It is both inappropriate, unethical, and may even be considered as violating the law itself to demand ill corruption suspects to follow the legal processes. Various conditions can be described to indicate illnesses, such as: dizziness, short of breath, abdominal pain, unwell, depression, severe stress, and even mental disorders. They are the reasons used by corrupt suspects to avoid legal processes.⁵ However, the said condition is often misused by the corrupt suspects to be able to benefit themselves in doing activities outside of the prison comfortably and also be used to inhibit or hinder the legal processes. Therefore, illness is often used as an excuse by corrupt suspects to escape from legal liabilities.

By witnessing the corrupt suspects being ill, the humanist side may emerge which then might affect the legal processes. It may be reasonable as being ill is such an inconvenience for anyone and has to be treated immediately. The humanitarian reasons in such circumstances are most preferred, which explains the special and specific treatment for them in order to make them more comfortable for their speed recovery. This leniency given for their recovery to the point providing health facilities outside of Correctional Institution. This matter is considered as a peculiar phenomenon which then emerges public questions as to this being a fact or a mere farce.

Indonesian Officials who Use Illnesses as An Excuse to Be Free from The Legal Liabilities

Illness is considered as the most effective way used by Indonesian officials who got entangled in corruption which doesn't have legal risk amid the State's incessant fight against corruption, these can be seen from many legal processes in corruption that full of sicknesses drama. It can be seen from several cases below:

1) Setya Novanto (ex-chief of People's Representative Council for the 2014-2019 period) who got entangled in the case of E-KTP corruption, complained to have hypertension and complication illness when he was investigated by Corruption Eradication Commission (KPK) and even fabricated the car accident's case that he experienced, so he must be treated specifically and intensively with various medical equipment at the Hospital. Hence, the legal investigation process against him was interrupted.

2) Miryam S. Haryani (ex-member of People's Representative Council for the 2014-2019 period) who also got entangled in the case of E-KTP corruption, complained to be sick when she was about to be investigated by KPK. She gave fake information to the Hospital Doctor Team and was faking her illness to escape from the KPK's investigation. Hence, the legal process against her was delayed for a long time.

3) Irman Gusman (ex-chief of Regional Representative Council for the 2014-2019 period) who got entangled in the corruption and bribery case of imported sugar, complained to have a heart issue when he was about to be investigated by KPK. Hence, the legal case investigation process against him was delayed for several days.

4) Romahurmuzyi (ex-member of People's Representative Council for the 2014-2019 period) who was captured red-handed by KPK in the bribery case for the Chief election of East Java Province's Department of Religion and Gresik Regency's Department of Religion. He claimed to have abdominal pain and bleeding when defecating. Therefore, the legal case investigation process against him was delayed for several days.

5) Idrus Marham (ex-member of People's Representative Council for the 2014-2019 period) who got entangled in the corruption of Riau 1 Electric Steam Power Plant (PLTU) project, claimed to be sick when he was about to be investigated by KPK. Therefore, the legal case investigation process against him was postponed.

6) Zumi Zola (ex-Governor of Riau for the 2017-2022 period) who got entangled in the corruption and bribery case of the ratification of Riau Province's Local Government Budget, claimed to have shortness of breath when KPK was investigating him. Thus, the legal case investigation process against him was stopped and postponed for several days until he regained his health.

Analysis on Positive Law in the Constitutional Regulations Which May Be Used as the Excuse of Illness in Order to Be Free from Legal Liabilities

There are several constitutional regulations in Indonesia which may be used as the basis for the corrupt officials as excuses of illnesses in order to defend themselves from the snares of law.⁶ Below are several the referred regulations:

1) The 1945 Constitution of the Indonesia's Republic CHAPTER XA Human Rights, Article 28H paragraph (1) Everyone has the right to live in physical and spiritual prosperity, to live, and to have a good and healthy living environment and the right to obtain health services. Paragraph (2) Everyone has the right to get special treatment and facilities to obtain equal opportunities and benefits in order to achieve equality and justice. Article 28J paragraph (1) Everyone must respect the human rights of others in the orderly life of the community, nation and state.⁷

2) The Constitution of the Indonesian Republic Number 39 of 1999 regarding Human Rights CHAPTER I General Provisions, Article 1 Humans Rights are a set of rights inherent to the nature and the existence of humans as a creature of the God Almighty and are His

gifts that must be respected, upheld and protected by the State law, the Government, and everyone for the honor and protection of human dignity.⁸

3) The Constitution of the Indonesia's Republic Number 36 of 2009 Regarding Health CHAPTER I General Provisions, Article 1 Health is a healthy condition, both physically, mentally, spiritually, and socially that enables everyone to live productively both socially and economically. CHAPTER III Rights and Obligations, Article 4 Everyone has the right to health. Article 5 paragraph (1) Everyone has the same right in obtaining access to resources in the health sector. Paragraph (3) Everyone has the right to determine independently and responsibly the health services required for themselves.⁹

4) The Constitution of the Indonesia's Republic Number 31 of 1999 Regarding Eradication of Corruption CHAPTER IV Investigation, Prosecution and Examination at the Trial Court. Article 26 Investigation, prosecution and examination at the Trial Court for a criminal act of corruption shall be carried out based on the applicable criminal procedure code, unless stipulated otherwise in this Constitution.¹⁰

5) The Indonesian Criminal Code (KUHP) CHAPTER VIII Lapse of the Right to Prosecute and of the Punishment, Article 78 Paragraph (1) The right to prosecute shall lapse by lapse of time.¹¹

6) The Indonesian Criminal Procedure Code (KUHAP) CHAPTER VI Suspects and Defendants, Article 58 Suspects or defendants who are subject to detention shall have the right to contact and receive a visit from their private doctor for the interest of their health whether it has any connection or not to the case process.¹²

7) The Constitution of the Indonesia's Republic Number 12 of 1995 Regarding Corrections CHAPTER III Corrections' Inmates, Article 14 paragraph (1) point d Inmate has the right to receive proper health services and food.¹³

8) The Government Regulation of the Indonesia's Republic Number 31 of 1999 Regarding Development and Guidance of Corrections' Inmates CHAPTER I General Provisions, Article 1 point 1 Development is an activity to improve the quality of devotion to God Almighty, intellectual, attitude and behavior, professional, physical, and spiritual health of the inmates

9) The Government Regulation of the Indonesia's Republic Number 32 of 1999 Regarding Requirements and Procedures for the Implementation of Inmates Rights CHAPTER I General Provisions, Article 1 paragraph 4 Health services are promotive, preventive, curative, and rehabilitative efforts in health for Inmates and Correctional students in the Correctional Facility. Article 17 paragraph (1) In the case that the patient as referred to in Article 16 paragraph (3) requires further treatment, the Correctional Facility's doctor provides recommendations to the Head of the Correctional Facility so that the health services are carried out at the Government public hospitals outside of the Correctional Facility.¹⁵

10) The Republic of Indonesian Government's Decree No. 58 year 1999 regarding the Conditions and Procedures for the Implementation of the Authority, Duties, and Responsibilities for the care of the Prisoners, Chapter I Basic Conditions, Article 1 states that the prisoner service process is done starting from the admission until the release of the prisoners from the National Prison.¹⁶

11) Decree of the Correctional General Director No. E.03.PP.02.10 year 2003 has determined the minimum standard of health services for the inmates in Correctional Centers, which are; a) Institutionally, the health services provided are still in the basic level, which is first-aid doctors and clinics; b) Referral health treatments for the ill inmates are given based on the condition of each Correctional Centers. C) The forms of promotive, preventive, curative, and rehabilitative services are given systematically.¹⁷

Conclusion

Illnesses become a mode of condition used by many Indonesian officials who are detained for corruption to be free from legal liabilities. With the excuse of being ill, they receive special treatments which are more comfortable, like not being placed in prison cells like healthy inmates. They may even be placed in hospitals outside of the Correctional Center area with minimum surveillance. The receive services from health workers and family members who take care of them. The important matter regarding this issue is the fact that the legal processes are paused until their condition is stated healthy again. This may inhibit or hinder the enforcement of the corruption laws. The constitutional

regulations in Indonesia has actually regulated the things which regards the health rights protection of Defendants or inmates. Yet, these regulations seem to be misused by the inmates to make illnesses as an excuse to create a condition or a situation which brings them favorable conditions.

Model of Social Support for Adolescent Mental Health with Disabilities

Tri Riana Lestari¹, Atikah Adyas¹, Agusni Karma¹, Elsy Rachmawaty², Yopi Harwinanda Ardesa³, Ester Syeffty Pasaribu⁴, Mayke Ruth Loyali⁵

¹Associate Professor, Department of Orthotics-Prosthetics, Poltekkes Kemenkes Jakarta I, ²Assistant Professor, Department of Nursing, Poltekkes Kemenkes Jakarta I, ³Assistant Professor, Department of Orthotics-Prosthetics, Poltekkes Kemenkes Surakarta, ⁴Laboratory Assistant, Department of Orthotics-Prosthetics, Poltekkes Kemenkes Jakarta I, ⁵Student, Faculty of Cultural Studies, Universitas Indonesia

Abstract

For adolescents, disability is more than a physical limitation. Discrimination, social stigma, and pressure from the environment can induce a social limitation that excludes them from social. The lack of support causes them to suffer from physical limitations that will affect their mental health, and worse will create not only physically disabled but also impact their life. This study aims to find an appropriate social support model for maintaining the mental health of adolescents with disabilities from examining the factors of adolescents' characteristics, family, peers, health workers, and community leaders. This research method used cross sectional study, a total of 100 adolescents with disabilities from Cerebral Palsy Center Jakarta and Surakarta special schools were involved in this observation. This research consisted of collecting data, conducting FGD with teachers, health workers, family, and processing data with Smart-PLS. The results was that the adolescent mental health with disabilities were formed by individual characteristics (such as age, gender, education), the role of family, friends and teachers. Support from family, friends, teachers, community leaders in their roles are needed in stabilizing emotions and maintaining mental health of adolescents with disabilities.

Keywords: adolescents; disabilities; support; social support model; mental health

Introduction

Children with special needs have physical disabilities, or intellectual disabilities: Autism, Down-Syndrome, low intelligence quotient deficiencies associated. This may be due to genetic errors, problems during pregnancy and birth or social conditions of living.¹ Young persons with disabilities are like young people everywhere: they have dreams and ambitions, interests and desires, also hopes for their futures.² Disabilities categorized into four health conditions, developmental disabilities (DD), mental health conditions (MH), physical disorders (PD)

and the fourth condition is a combination of the three.³

Worldwide, as many as more than 1 billion humans live in various form of disability.⁴ The number of people with disabilities live in our environment sometimes makes us feel that we 'know' them. However, understanding the meaning and impact of the disabilities they have in relation to their ability to be actively involved in social, political, cultural and economic matters is a challenge that can distort. Not only have physical challenges, millions of people with disabilities across the world still have to struggle with social and legal challenges that limit them in accessing education, physical and sexual health care, employment, recreational activities, and harmony in family life.⁵ Such obstacles are a serious challenge for persons with disabilities who are still adolescents.² In fact, adolescents with DD and MH cannot access health care facilities freely. A large proportion of children with DD have unmet preventive health and therapy services.⁶

Corresponding author:

Tri Riana

Lestari (tririanaestari@yahoo.co.id)

Address: Jl. Wijayakusuma Raya 47-48

Cilandak-Jakarta

Krauss et al. found children with mental retardation and autism to have greater problems in specialty medical accessing care than children with other special needs.⁷ A growing body of research indicating that children with MH have poor health care access and extensive unmet needs.^{8,9} Kataoka et al. found that 80 percent of children who needed mental health services, did not receive those services.¹⁰

The most difficult constraints are social challenges stemming from discrimination, stigma, prejudice, and routine failure to include persons with disabilities in development policies and various designs on civil programs.² Physical, socio-economic, socio-cultural, and legal barriers continue to limit access to education, health care including SRH, employment, leisure activities, and family life for millions persons with disabilities worldwide, and violence against young persons with disabilities is widespread.¹¹ Persons with disabilities, including young persons with disabilities, are at greater risk of living in poverty than are their peers without disabilities.¹² They are more vulnerable to violence, including gender-based violence (GBV), and are less likely to attend school.² This also includes how children with special needs have the right access and support from their environment regarding information and adequate use of health services. Hence there are differences difficulties using health care services for Children with Special Health Care Needs (CSHCN) with different health conditions.¹³

Negative attitudes, a lack of understanding about disability, and stigma can have profound consequences for all persons with disabilities but especially for young persons with disabilities. These attitudes represent one of the greatest impediments of young persons with disabilities face in achieving inclusion. Children with disabilities are among the most marginalized and excluded groups of children.¹⁴ According to one report in Canada, 53 percent of children with disability reported having no or one close friend, and significant percentages said they were shunned or avoided at school.¹⁵ Children with disabilities are also facing risk of bullying, which can have long-term consequences for their social development and mental health.² In many cases, stigma against children with disabilities extends to family members and caregivers, as a result, this matter causes parents and families allow teenagers with disabilities to continue to stay at home with reasons to protect them from prejudice and violence.¹⁶ Discrimination is felt not only in form of limited restrictions of

facilities or infrastructure in various fields for children with disabilities. Today, peer pressure is in the form of *bullying* against children with disabilities is a thing that is rife. *Bullying* is a form of aggression in which there is an imbalance of power between the bully and the victim^{17,18} that occurs largely in the context of the peer group.^{19,20} Bullying, which may be indirect (eg, name-calling) or indirect (eg, gossip), covers a wide range of behaviors, from social exclusion to physical assault.^{21,22}

This research aims to analyze the influence of adolescent characteristics, parental characteristics, adolescent health status, family support, peer support, health worker support, teacher support, and support from community leaders on adolescent mental health with disability.

Method

This research used method uses cross sectional study in three stages. The first stage was named identification stage, begins with collecting data on the condition of young people with disabilities as exploration material. The next stage was conducting interviews with questionnaires as quantitative data collection followed by Focus Group Discussion (FGD) with teachers, health workers (Community Health Center) and family. Data was collected by mental health screening through Strength and Difficulties Questionnaire (SDQ). Data analysis was carried out with the help of Smart Partial Least Square (Smart-PLS) software. Data from the FGD results were analysed from a review of strategic issues and the concept of the solution to producing a model. The third stage was conducted by testing the model obtained through analysis of the appropriate model and continued by interpreting it.

Population in this research was adolescent with disabilities in Extraordinary School (SLB) for Disabled Children Education Foundation / Cerebral Palsy Center (CP Center) in Jakarta and Surakarta. The sample criteria were: 11-18 years old), teenagers were physically disabled or blind, willing to be a respondent. The sample size were 100. The sampling technique was multistage random sampling technique, with the stages of location determination, groups determination, sample determination, data collection, model formation. Data were analysed by Structural Equation Modeling .

Findings

The majority of adolescent were in 15-16 years old,

male, elementary school and have a normal condition. The majority of adolescents with disabilities have fathers with professions involved in the world of entrepreneurship and mothers as a house wife.

Table 1. The Path Coefficients in The Structural Model

No	Relationship Path	Path-Coefficient	T
1	Effect of adolescent characteristics on adolescent mental health	0.409677	5.788648
2	Effect of parental characteristics on adolescent mental health	0.375323	4.255468
3	Effect of health status on adolescent mental health	0.099224	1.518259
4	Effect of family support on adolescent mental health	- 0.027197	0.368035
5	Effect of peer support on adolescent mental health	- 0.142037	2.060303
6	Effect of health worker on adolescent mental health	0.027049	0.305939
7	Effect of teacher support on adolescent mental health	0.252390	3.455639
8	The influence of community leader support on adolescent mental health	0.049226	0.488571

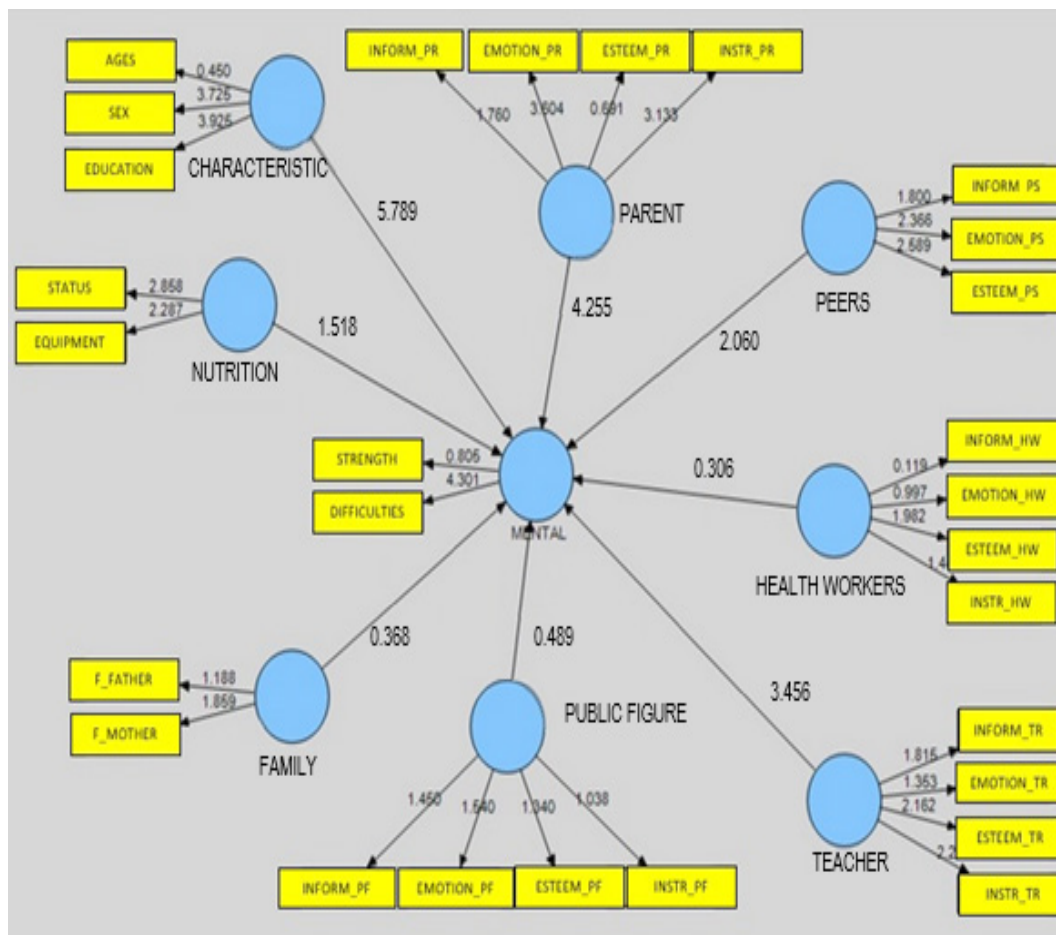

Figure 1. Social Support Model Analysis

There was a significant effect of adolescent characteristics, parental characteristics, health status, family support, peer support, health worker, teacher support, public figure on adolescent mental health (Table 1 and Figure 1).

Discussions

This can align with previous studies correlate that the result was the finding that family and school support are protective factors underscores the need to target the environment.^{28,29} Coordination is needed among school, home, and community because adults must intervene on behalf of children and youth with disabilities, in this context of children with Learning Disabilities (LD) who are bullied.^{22,30} School climate and community attitudes that tolerate bullying and promote negative attitudes toward students with LD must change. As the main source of difficulty is attributed to the student, an increased awareness of the impact of labels is needed.³¹ Therefore, more systemic interventions, such as changing schools and community orders to help children with friends and friends,^{32,33} are recommended and implemented. Effective strategies to include positive contact with children who have disabilities, along with indirect experience offered through information in books and discussions guided by adults. Such approaches should be incorporated into the curriculum to foster understanding of LD.

A mental health problem can be seen as a 'disturbance in functioning' in an area such as relationships, mood, behaviour or development. When a problem is particularly severe or persistent over time, or when a number of children are often described as having mental health disorders. Serious mental illness can lead to significant distress and disability that undermines quality of life.³⁴ This study is aligned with the statement that family and a close friend could decrease depression of adolescent with disabilities.^{35,36} Therefore, love and appreciate have a really significant value for them.^{37,38,39} Accordingly, there is a framework to resist mental illness for adolescent with special needs. Based on the results of hypothesis testing, there is a significant trajectory or path that describes the results of this study: (1)-Characteristics of adolescents (age, gender, and education) influence adolescents mental health (strength and difficulties); (2)-Support of friends (providing information, emotional support, esteem) influence adolescents mental health; (3)-Support parents (providing information, emotional support, appreciation, and instruments) influence

adolescents mental health; (4)-The support of friends (providing information, emotional support, respect) influence adolescents mental health.

Conclusion

This research study adds a new result in the world of science in the field of improving the emotional quality of adolescents with special needs or disabilities through a model framework that illustrates the need for fundamental and intense support from family, friends, teachers, community leaders in their role in stabilizing emotions and maintaining health mental adolescents with disabilities. Characteristics of adolescents also influence this condition, so a good emotional understanding of adolescents with disabilities is needed to convince them that they are matter and valuable.

Caring for a child with disability, depending on the type of disability, can result in physical health problems, mentally health problems, and time or financial burdens on parents.²⁴ Therefore, it is important for health professionals to focus on the mental health of a child with a disability in different family structures, and to assess their needs for psychological support. In particular, maternal mental health is important for both parents and children because poor maternal mental health is related to unfavourable parenting practices, child health problems, and poor school performance.

Many situations have proven, poor families provide inadequate nutritional support for their children with disabilities, and children with disabilities do not get the care and special care in accordance with their special needs from parents/family, and must feel miserable condition due to various limitations of the ability of poor families. Parent orientation is ultimately more priority on efforts to meet family survival, and ignoring the need for children with disabilities due to limited financial resources. Environmental support is a support system that can reduce the risk of depression and pressure on persons with physical disabilities.

The Implication of the Indonesian Local Regulations Revocation towards the Local Economy and Out of Pocket Healthcare

Hartiwingsih Hartiwingsih¹, Isharyanto Isharyanto², Asri Agustiwi³

¹Professor, ²Doctor, at Sebelas Maret University, Surakarta, Indonesia, ³Student of Law Doctoral Program, University of Surakarta, Surakarta, Indonesia

Abstract

This research discusses the implication of the local regulation revocation towards the economic and health condition in a number of regions in Indonesia. And also, some of the cases which resulted in the implication conditions. This article was the result of a doctrinal study with literature review study and secondary data. The result of the research shows that (i) there is a government's authority in revoking Perdas; (ii) the revocation of the local regulations in certain regions exerts adverse effect on the economy and healthcare. This article suggests that there is a need for the development of Perda with high-quality substances so that it can cope with the implication of legal regulations.

Keywords: Local, Regulations, Revocation, Healthcare

Introduction

The revocation of 3,143 local regulations (Perda) on June 13th, 2016 generates various reactions from many parties, including those from the media. The Chairperson of the Republic of Indonesia's House of Representatives, Hasan¹ for example, agrees very much with the revocation of the Perda. It is because it is unnecessary to maintain the Perda which inhibits investment and gets the people into trouble, according to Hasan¹. However, most people gave negative response towards the revocation of the Perda. For example, Aulianshah² in *Beritagarid* news web wrote, that the revocation of these Perdas are aimed to eliminate obstacles for the sake of economic development from investment including healthcare investment.

The revocation is conducted on Perdas inhibiting investment deregulation program because many Perdas are still in contradiction with the higher regulations and lengthen the investment licensing bureaucracy. This decision exerts serious effect on the government. The revocation of the Perda becomes the government's instrument in implementing deregulation to remove the problematic Perdas inhibiting investment, as argued by Sholikin² and Utami³.

Those Perdas are related to retribution, tax, and investment in regions in Indonesia, because they are not consistent with the vision of development led by the government with *Nawacita* (ten ideals) through a variety of economic policy packages. The impacts include the more complicated process of health services as these Perdas are also partly related to tax or retributions of healthcare workers or healthcare facilities. A study conducted mentioned that 21,7% of the population seeks medical care to doctors, whereas only 3-4% seeks medication from hospitals, thus extra financial regulations may burden it.

In the attempt of improving the nation's competitiveness, legal politics in Indonesia directs the law development to support the manifestation of sustainable economic growth, to govern economy relevant to the problem particularly in business world and industrial world, and to create investment certainty, particularly in the law enforcement and protection, as explained by Agustiwi⁴. The guarantee cannot be nationalized. In addition, it is also easy to manage the license by developing one-stop service policy. The facilities provided do not only include the regulation to get law certainty but also tax exemption or deduction or postponement and no nationalization, and if any the

corresponding investor will be given compensation approved government and investor as argued by Budiarta⁵. Aulianshah also have Statement that many of the perda gave extra burdens for the people because in the end, the extra tax, retributions and others would become production cost.

Therefore, it is expected that local agency organizations would be slimmer according to the spirit of government reinvention in order to achieve good governance, as argued by Simangunsong and Hutaso⁷. The local government's action in making regulation which burdens the medical workers or doctors' health facilities may not give healthcare services thus may hinder the patients' care as there is a limitation of facilities or human resources, which are caused by inconsiderate regulations.

Parallel to that, it was reported by Susanti in *Kompasiana*⁸ that the Perdas are against the constitutional regulations. They inhibit licensing and gives various tariff burdens to the society. Surely, those problematic Perdas are also against the spirit of decentralization and regional autonomy, which are believed to be able to increase the quality of regional service, competitiveness, work effectivity, and the people's welfare. The reality which happens is that the Perda actually increase the financial burdens of the patients (out of pocket) in obtaining healthcare.

Constitutional Economics as a scholarly direction, the subject of which constitutional-legal regulation and economic development are directly interrelated; the impact of the constitutional rules and principles on the process of adoption and implementation of economic decisions as well as the inverse correlation to the healthcare system, as mentioned by Budiarta⁶.

The results of the conducted research allow identifying the following features of investment activity. According to Kuwado in *Kompas media*⁹, the annulation or the eradication of those Perdas create a significant domino effect towards the increase of investment in Indonesia. The first domino effect which happen is the increase of the society's burden in the economic sector as it increases the society's expenditures in accessing healthcare.

The investment activities of foreign investors including in the health sector, in their territory are generally governed by national laws, regulations and administrative procedures, as well as bilateral investment

agreements. According to Sagynbekova, Allanina, and Babaeva¹⁰, the main provisions of these legislative acts are, as a rule, identical in developed countries as a whole. In almost all states, foreign investors are unable to carry out their investment activities in key sectors of the host. To invest abroad, there are declarative orders and authorization-based procedures, as argued by Sagynbekova et al¹⁰.

Materials and Method

This study employed normative juridical approach and qualitative normative analysis technique based on secondary data supported with primary data to sharpen the analysis in discussion as argued by Soekanto and Mamudji¹¹. Therefore, the library study conducted in this study provided in-depth information relevant to the problem studied.

Data analysis was conducted using qualitative approach. Qualitative approach, according to Soekanto¹², is the method of research resulting in descriptive analysis in which what is stated by respondents in written form or orally and also their behavior is investigated and studied as a whole¹³.

Results and Discussion

Hundreds of Perdas have been revoked by Ministry of Internal Affairs in Java and Bali islands, most of which are related to natural resource management. In 6 provinces in Java Island, the Ministry of Internal Affairs has revoked more than 400 Perdas. The majority of the regulations regards regional retribution, tax, and tariffs in various sectors, including the health sector.

This has impacts towards the fact that the tariffs will be burdened to the patients, which results to out of pocket healthcare. More perdas were revoked in regions in Indonesia and it occurs because those regulations were in contradiction with the higher constitutions or Law – thus certainly breaking the *lex superiori derogate legi inferiori* principle, meaning that when there are different regulations, the provision of the higher legislation disables the lower legislation. In addition, according to Fitra¹⁴ in the online media *katadata.id*, the government expects that the reduction of Perdas. The aim is so that the existing healthcare and health infrastructures can grow, thereby advancing the Indonesian and it is in line with the ideals of development.

The investment developed in Indonesia is intended to create development in regions by giving the foreigners

the opportunity of investing through international cooperation, to make the development of the regions run smoothly. Although the private sector is progressing more rapidly, but the law, the financial institutions, the growth goes very well. The legal system, as well as the financial system are well developed and they are sustainable with the private sector, as argued by Allen et al¹⁵.

In the Federation of Russia, to attract foreign investment, the development of the rule of law is necessary. The investments are done through a mechanism of a statutory law in Russia in line with the norms of international law. This law will create a supportive environment for attracting foreign investment in Russia, as explained by Skvortsova et al¹⁶.

In Indonesia, many legal products are developed, particularly related to the investment, are revoked due to some factors. To rebuild the medium-class economy and to give the foreign investors the opportunity of investing in Indonesia toward the free trade, some factors still need improvement. In the online media, *finance.detik*, Damarjati¹⁷ reported an interview with the Indonesian president, who stated that Perdas made should not complicate and make investment difficult. This statement was reported in the media as the government's explanation regarding the eradication of some Perdas.

Viewed from human resource aspect, it can be said that the quality and the quantity of the legislative drafters are still very worrying. It is not only related to their skill and knowledge, but also to their career levels and incentives. According to Abdullah¹⁸, the number of legislative drafters in Indonesia is still small and this profession has not been a functional post until today.

The development of the Perda substance is of course adjusted with individual regions' need, meaning that the development of Perda should obligatorily contain the following principles: objective clarity, institutional or organizational, compatibility of content type to material, and effectivity or effectiveness, as mentioned by Amir¹⁸. The Perda intended to facilitate regional investment also requires the local government's high-quality contribution, either formally or materially, by considering domestic local values in order to promoting Indonesian economy in general and local economy in particular.

Perdas which collect tax, retribution, contribution, and other forms of tariffs to health facilities actually

results to negative impacts to the facilities and to the people. The hospitals are obligated by the government to provide services for the poor, yet the hospitals are expected to survive and take care of the organization's condition by obtaining profit. It may cause cost recovery which happens if the total cost may be recovered by the total revenue of the services provided. The loss or the out of pocket services experienced by the people are because of the tariff burdens based on the Perdas, to increase the regional income, which is burdened to the people.

The Chairperson of Governmental Law Agency for South Sulawesi Province, Nasir¹⁹, stated that thousands Perdas have been revoked, 143 of which are products of South Sulawesi Province. South Sulawesi Province Government states that they will not make lawsuits against the revocation of Perdas. Out of those regulations revoked, 31 Perdas are products of the regency and the city governments. They include Perdas about telecommunication tower, public service, businesses, procurement retribution and liquor circulation and control. These taxes and retributions are also burdened to health instances of facilities, as they are regarded as businesses. "These 31 Perdas come from 19 out of 24 regencies/cities existing in South Sulawesi".

Surakarta City is also threatened to be poor due to the revocation of Local Tax Perda. Rudy, the Mayor of Surakarta,²⁰ said that the revocation of Local Tax Perda will affect the potential of the Local economy. It also affected on the out of pocket of Solo City healthcare significantly. It is because more than 80 percent of Local Original Income comes from local tax post. He said that Surakarta City government will be at loss with the lost potential local tax income of IDR 227 billion.

In addition to Solo, Depok City government reacts directly to the revocation of thousands Perda conducted by central government. Depok City government coordinates immediately with the West Java Province Government to confirm the Perda revocation plan. If there will be revocation, it will not be done entirely. The West Java Governor, Ahmad Heryawan²¹ stated that he would ask the Indonesian Ministry of Internal Affairs for an explanation about the revocation of some Perdas, because it would impact the local development. If the Perdas contain inappropriate articles considered as inhibiting, it should not be revoked entirely. If revision can be made, the revocation would not be needed. Most Perdas revoked are those which can inhibit investment. So far, there is no constraint with investment in West

Java²¹.

In Ternate area, there are five Perdas revoked that will putatively result in the loss of IDR 11 billion to Ternate City Government. The loss results from Local Original Income. Those five Perdas come from Ternate City and these will affect significantly. But the Ternate City Government (2016) does not know which Perdas will be revoked, because the local government and Local Legislative Council have not received the confirmation yet until today, as argued by Ariefana²².

A similar report has been written by Kresna, which stated that the Ministry of Internal Affairs has officially announced the revocation of 3.143 Perdas and Decrees of the Regional Government which are considered as problematic. Some of the 391 revoked Perdas are regarding local tax or retribution for healthcare and education and this became a burden for the people. From the start, the government has stated that the aim of revoking the Perdas are to increase investment dan to decrease the burdens of the people, as explained by Kresna²³.

The Perda is the law which regulates the local needs of the people who is indeed at that time is needed, therefore it becomes illogical if the cancellation is done because it conflicts with the rules above, although it is against the principle, as argued by Posner²⁴. the revocation of the perdas actually have the tendency to be similar with the government's opinion, in which the aim of the revocation is to decrease the burdens of the people. It may have effect in the decrease of the out of pocket healthcare system. According to the media reports, the revoked Perdas are those which may decrease the society's burden in the healthcare service payment from personal funds, thus impacts the public welfare. The Indonesian media stated that such annulment is crucial to develop the public welfare.

Conclusion

According to the media report, the revocation of many Perdas by the local government is actually problematic; the substance and material of the Perda regards the financial burdens of business workers, the healthcare and the education sectors, which includes licenses requirements and other factors such as tax, retributions, and financial burdens which will have impacts to the economy, to the out of pocket healthcare services, and the public welfare.

The Patient Safety Model within Decubitus Ulcer Patients in Hospital: Based on the Organizational Citizenship Behavior and Knowledge Management

Tri Johan Agus Yuswanto¹, Naya Ernawati¹

¹Lecturer, Health Polytechnic of Malang, Indonesia

Abstract

Decubitus ulcer event is an indicator of patient safety in nursing care at the clinic, so a method is needed to reduce the incidence of decubitus ulcer in the patient in hospital. The research aims to create a model for increasing patient safety based on Organizational Citizenship Behavior (OCB) and knowledge management on unexpected events (decubitus ulcer) in achieving the target of patient safety program in Hospital, using cross-sectional design. The subjects were 100 nurses who work in the inpatient room of Surabaya Haji Hospital, selected by purposive sampling. Data collection was done by questionnaire, then analyzed using Partial Least Square (PLS). The model of increasing patient safety based on OCB and knowledge management has proven effective in reducing the incidence of decubitus ulcer in the patient ward. This model is recommended to implement in the hospital to enhance the quality of nursing care.

Keywords: patient safety, organizational citizenship behavior, knowledge management, decubitus ulcer

Introduction

Patient safety has become a global issue since the IOM (Institute of Medicine) report, the United States in 2000 which stated that “to err is human”⁽¹⁾. Patient safety is a top priority in providing services to patients related to the issue of quality and image of the hospital. Safety is a fundamental principle of patient care and a critical component of quality management⁽²⁾.

Patient safety in hospital includes managing risks, identifying and managing risks to patients, analyzing incidents, learning abilities and following up incidents, and implementing solutions to reduce risk. Nurses are the key to development quality through patient safety⁽³⁾. The incidence of decubitus ulcer patients is an indicator of patient safety in clinical nursing care. If the patient safety indicator has not reached the specified standard, it will affect the quality of services. As a result of the frequent occurrence of decubitus ulcer patients are at risk

of increasing unexpected events or at risk of occurrence of adverse events.

Basically, the performance of individuals or groups is what ultimately affects the progress of the organization as a whole. Other factors that affect individual performance which ultimately lead to organizational performance are OCB. OCB can be defined as extra behavior related to work outside of routine tasks determined by job descriptions or measured in formal evaluations⁽⁴⁾.

OCB is implemented for a long time and by many people it will result in organizational effectiveness⁽⁵⁾. The components of OCB are: altruism, conscientiousness, sportsmanship, civic virtue, courtesy.

Knowledge management is used as an effort to maintain, analyze, organize, improve, and share understanding and experience. Such understanding and experience is built on knowledge, both manifested in individuals or inherent in the processes and real applications of an organization. Knowledge management is used by organizations as a new innovation to channel raw data into information and knowledge. Unexpected events occur because nurses commit negligence or errors in handling decubitus ulcer due to various factors

including burden high work and inpatient room has a high complexity and risk.

Knowledge management according⁽⁶⁾ is a knowledge management development from the concept of Nonaka and Takeuchi Knowledge management has 7 stages including knowledge identification, knowledge acquisition, knowledge creation, knowledge application, knowledge transfer, knowledge sharing, knowledge documentation. The advantages of the model are that data becomes information processed through collecting, classifying and grouping, processing data so that it changes shape and properties according to its uses, interprets data, stores data, delivers data to users, and uses in supporting the interests of the organization⁽⁶⁾.

Efforts to prevent decubitus ulcers based on OCB which is an extra role are expected to make nurses more capable, responsive, alert, empathetic, and responsible in handling decubitus ulcers. Knowledge management approach is a technique to create knowledge harmony so as to achieve optimal performance. The approach of OCB and knowledge management is a combination of two concepts to maximize the role of extra-role and intra nurse roles in managing knowledge that has been obtained to be applied to practice in accordance with the knowledge gained and reflected in the performance of a nurse so decubitus ulcer can be minimized.

Method

This research used a quasy-experimental pre post test design with the complete sampling 100 nurses in Haji Hospital Surabaya. Their mean age was 28 years (26-30), and 78 (70.9%) were female, and 22 (20.1%) were male, 40 (40%) had experience of work more than

five years. Path analysis with PLS was used to test the effect of patient safety model based on organizational citizenship behavior and knowledge management toward nurses performance in decrease ulcus decubitus in hospital. The data collection was done by the way the questionnaire and observation. The population to bring up this strategic issue is by giving a survey to evaluate the patient safety implementation that modified factors that influence service quality from Donabedian, which include individual factors, organizational factors, management factors, applying the OCB from Organ and Bateman and knowledge management theory from Nonaka and developed into a modified questionnaire from Kuntarti's previous research on the stages of knowledge management.

FINDINGS

It is essential establish the reliability and validity off the latent variables to complete the examination of the structural model. subvariable knowledge, commitment, decision making, culture, monitoring, assessment, intervention, implementation, evaluation, unexpected incidence of decubitus ulcer, the incidence is almost an decubitus ulcer injury is declared valid where the outer loading value is in accordance with the expected criteria >0.5. This shows that indicators in the structure have met the validity test. Whereas for the attitude and leadership type sub variables it is declared invalid where the value of outer loading >0.5.

The composite reliability was >0.7. The cronbach alpha was >0.5. Thus it can be concluded that each variable has fulfilled the reliability test.

Table 1. The result summary for reflective outer models

Variables	Indicators	Outer-Loading	Composite-reliability	Cronbach-Alpha
Individual	Knowledge	0.894	0.870	0.702
	Attitude	-0.322		
	Commitment	0.640		
Organization	Decision making	0.965	0.716	0.680
	Leadership	-0.461		
Management	Culture	0.823	0.889	0.757
	Monitoring	0.843		

Cont... Table 1. The result summary for reflective outer models

Decubitus Ulcer prevention	Assesment decubitus ulcer prevention	0.724	0.758	0.515
	Intervention decubitus ulcer prevention	0.665		
	Implementation decubitus ulcer prevention	0.670		
	Evaluation decubitus ulcer prevention	0.668		
The incidence of decubitus ulcer	Unexpected incidence of decubitus ulcer	0.905	0.853	0.808
	The incidence is almost an decubitus ulcer injury	0.899		

Table 2. The path coefficient and t-statistic of inner model

Variables	Path Coefficient	T Statistic	Remark
Effect of individual factors on the implementation of decubitus ulcer prevention	0.383	2.798	Significant
Effect of organizational factors on the implementation of decubitus ulcer prevention	0.230	2.171	Significant
Effect management factors on implementation of decubitus ulcer prevention.	0.522	3.668	Significant
The effect of implementing ulcus decubitus prevention on events is not expected	0.490	2.735	Significant

The results of the PLS analysis of the influence of individual factors on the implementation of ulcus decubitus prevention obtained path coefficient values of 0.383 and t statistics of 2.798 ($t > 1.96$). These results indicate that there is a significant influence between individual factor variables on the implementation of decubitus ulcer prevention. The positive sign of the coefficient indicates a unidirectional relationship. The same direction can be interpreted that the higher the individual factor, the more the implementation of decubitus ulcer prevention will increase.

The results of PLS analysis of the influence of organizational factors on the implementation of decubitus ulcer prevention obtained path coefficient values 0.230 and t statistics 2.171 ($t > 1.96$). These results indicate that there is a significant influence between organizational

factor variables on the implementation of decubitus ulcer prevention. The positive sign of the coefficient indicates a unidirectional relationship. This unidirectional relationship can be interpreted that the higher the organizational factors, the more the implementation of decubitus ulcer prevention will increase

The PLS analysis of the effect of factor management on the implementation of decubitus ulcer prevention is obtained path coefficient value 0.522 and t statistic 3.668 ($t > 1.96$). This result shows that there is a significant influence between factor management variables on the implementation of ulcus decubitus prevention. in the same direction. This unidirectional relationship can be interpreted that the higher the factor management, the more the implementation of ulcus decubitus prevention will increase. Strategic issues obtained from PLS

analysis are individual factors, organizational factors, and management factors.

The results of the PLS analysis influence the implementation of ulcus decubitus prevention on unexpected events obtained path coefficient value 0.490 and t statistic 2.735 ($t > 1.96$). This result indicates that there is a significant influence between the variables of implementation of ulcus decubitus prevention on unexpected events. show a unidirectional relationship. The same direction can be interpreted that the higher the implementation of ulcus decubitus prevention, the event is not expected to decrease.

The quality of the structural model using R-square of the dependent variables is measured with the stone-Geisser Q-square test for predictive relevance. Based on these figures, the Q-square predictive relevance is calculated as follows:

Q Square predictive relevance

$$Q^2 = 1 - (1 - R1^2)(1 - R2^2) = 1 - (1 - 0.763)(1 - 0.504) = 0.88 \text{ (88\%)}$$

Since $Q > 0$, so the model is stable, and the predictive relevance requirement is satisfied.

Discussion

Sub variables on individual factors include demographics which consist of age, years of service, and level of education, knowledge, attitude. The ability and affordability sub variables are the main factors that influence are the main factors that influence behavior and individuals⁽⁸⁾, sub-demographic variables have indirect effects on individual behavior and performance. Demographic characteristics it is also an important thing known by the leader or someone inside motivate and improve its performance.

According to Anvari there are 5 supporting areas for knowledge management, namely human resources, leadership, organization, internal processes and vision. Human resources in this case are nurses which include age, years of service, level of education⁽⁹⁾. Age is related to maturity and maturation level, in the sense that increasing age will also increase technical/psychological maturity/maturity, as well as increasingly able to carry out their duties⁽¹⁰⁾. Davis & Newstorm argue that the more age increases the more job satisfaction and achievement. Age can affect one's physical, mental, work ability and responsibility, so that it can be interpreted that the more

mature a person is, the better his performance in safe nursing care⁽¹¹⁾. Older nurses have maturity in thinking and acting and have the ability to recognize and prevent the danger they get along with the development of age and maturity. This fact will make him more careful and pay close attention. Increasing age and technical and psychological will increase, the more able to make decisions, the more wise and think rationally, so the better performance⁽¹⁰⁾.

Higher the level of education, the greater the desire to use their knowledge and skills. Higher nurse education is easier to understand the task⁽¹²⁾. Nurses who have higher education have higher work ability⁽¹³⁾. Behavior is based on knowledge will be more lasting than behavior that is not based on knowledge⁽¹⁴⁾.

Knowledge is part of cognitive process which can be improved through education. This is confirmed by Winslow et al in CHSRF and FCRSS which explain that there is a relationship between nursing education and patient needs. Nurses must improve education and training opportunities for all aspects of nursing that have an impact on patient safety and can reduce unexpected events. Knowledge is the main capital to obtain good skills and attitudes, with good knowledge individuals will be motivated to do ulcus decubitus prevention⁽¹⁴⁾. Knowledge is information that has been organized and analyzed to make it understandable and applicable to problem solving or decision making⁽¹⁵⁾. Competency is ability and characteristics possessed by someone with knowledge, skills and attitude behavior required in carrying out his job duties, so that can carry out their duties in a professional, effective and efficient manner and in accordance with the performance standards carried out⁽¹⁶⁾.

Knowledge is a basic element for every employee to change his behavior in implementing something⁽¹⁷⁾. Knowledge can not only be seen as a useful investment at any given time but how knowledge influences nurse performance is important in managing HR. The results of this study support Yulia's research that within the framework of facilitating knowledge transfer, patient safety training programs need to be carried out on an ongoing basis⁽¹⁸⁾.

Nurses have a positive attitude and commitment in preventing ulcus decubitus. Individual needs will arise if the individual feels there is an imbalance between hope and reality, so that an impulse will emerge to meet

expectations.

Organizations are consciously coordinated social units, which are composed of two or more people who function on a relatively continuous basis to achieve a common goal or set of goals⁽¹⁹⁾. Organizational variables that influence a person's behavior and performance, namely resources, leadership, reward, structure and job design⁽⁸⁾. According to Swanborg in Molina, one of the functions of management is to lead the process of delegation, supervision, coordination, and control of the implementation of organizational plans. The focus is to guide and increase motivation with the efforts made, namely by creating a reward system, providing positive feedback, integrating organizational goals with staff/individuals, reducing job dissatisfaction, supporting resources. Nurse performance is influenced by various factors including individual factors and the environment/organization. Organizations have a large role to plan, move and evaluate the goals to be achieved. The organizational structure shows a way group assignments, lines of communication and authority relations and manufacture decision⁽²⁰⁾.

On the subvariables of organizational factors: leadership, leadership is one of the main factors that influence staff performance because leadership is a driver for all existing resources within an organization. The success of human resources in achieving organizational goals is also inseparable from the influence and behavior of leaders in developing their employees. The effectiveness of employees in carrying out their work depends on the influence received from their leaders. Leadership in nursing is the ability and skill of a nurse leader in influencing other nurses under his supervision to carry out their duties and responsibilities in providing care and nursing care so that the goals of nursing are achieved. Leadership influences organisational citizenship behaviour⁽²¹⁾, particularly through trust⁽²²⁾.

Organizational structure is the way a group is formed, communication lines and authority relations and decision making⁽²⁰⁾. This means that with a good organizational structure, staff will be more obedient in carrying out their work, especially in implementing prevention of ulcus decubitus. The intended organizational structure contains a command line and a good communication system to provide information to each other regarding the task fields of each section. Organizational structure is a factor that is closely related to nurse compliance in implementing patient safety. Quality and safety of

nurses associated with various factors in the system, organization and work environment are things that affect patient quality and safety⁽³⁾.

OCB in health care are encouraged, employees and organisations are more likely to be more productive and flourish⁽²³⁾. The final results of the implementation of knowledge management will be reflected in someone's performance⁽²⁴⁾. Knowledge management consists of knowledge identification (acquisition and creation), knowledge application, knowledge sharing and transfer, the knowledge repository is a way or tool for an organization to build a knowledge, where knowledge will later be used by organization to develop itself⁽⁷⁾. A knowledge-sharing culture and organisational learning were found to be core factors affecting nursing performance⁽²⁵⁾.

Conclusion

Prevention of decubitus ulcer based on OCB and knowledge management is an approach method as an effort to prevent the occurrence of decubitus ulcer.

Call for Papers / Article Submission

Medico-Legal Update invites articles, case reports, newspaper clippings, report medico legal activities to update the knowledge of readers in scientific disciplines such as Forensic Medicine, Forensic Sciences, Environmental Hazards, Toxicology, odontology, Anatomy and law etc.

The following guidelines should be noted:

- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Discussion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: **medicolegalupdate@gmail.com**

About The Journal

Print-ISSN:0971-720X, Electronic - ISSN:0974-1283, Frequency: Quarterly (4 issues in a year)

Medico Legal Update is a journal which brings latest knowledge regarding changing medico legal scenario to its readers. The journal caters to specialties of Forensic Medicine, Forensic Science, D. N. A. fingerprinting, Toxicology, Environmental hazards, Sexual Medicine etc. The journal has been assigned international standard serial number (ISSN) 0971-720X. The journal is registered with Registrar of Newspapers for India vide registration numbers 63757/96 under Press and Registration of Books act, 1867. The journal is also covered by EMBASE (Excerpta Medica Database) from 1997 and by INDEX COPERNICUS, POLAND.

Medico-Legal Update is a quarterly peer reviewed journal. The journal has also been assigned E- ISSN 0974-1283 (Electronic version). The first issue of the journal was published in 1996.
