Table (1) Demographical characteristics of the study sample

Sex	No.	%
Male	53	53%
female	47	47%
Age	No.	%
Less than 25	5	5%
25-29	44	44%
30-34	19	19%
35-39	13	13%
More than 40	19	19%
Place of work	No.	%
I.C.U	20	20%
Pediatric	20	20%
Surgical	20	20%
Emergency	20	20%
Operation room	20	20%
Years of experiences	No.	%
Less than 5	38	38%
5-10	32	32%
More than 10	30	30%
Graduate of	No.	%
Nursing school	4	4%
preparatory nursing	18	18%
Institute	38	38%
College	40	40%

Table-1- reveals that (53%) of the sample were males, (44%) of the sample were between (25-29) years of age, (38%) of them had experiences less than (5 years), and (40%) of them had bachelor degree in nursing science

Table (2) checklist scores for personal hygiene practices among nurses

Practice	Frequency	
	Yes	No
Use uniform according to hospital policy	96	4
Uniforms are clean	78	22
Use proper shoes (not slippers)	96	4
Have short fingernails	80	20
Do not wear jewellery (rings/bracelets)	78	22
Use needle-cutter or specific container to discard used syringes, needles and other sharp items	100	0
Wash hands before contact with patients	40	60
Wash hands after each step of working	80	20
Wash hands after contact with patients	40	60
Wear gloves when needed	40	60
Use protective devices (gown, mask, gloves and goggles) when in contact with infectious patients or if there is possibility of splashing blood or other drainages	40	60
Use protective measures if drawing blood (gloves, masks and goggles)	22	78
Hepatitis B vaccination complete (3 times)	50	50

Table -2- shows that 96% of the sample wear uniform according to hospital policy, 78% from them own uniform are clean, 96% use proper shoes, 80% of keep short fingernails, 78% not wear jewellery, 100% from the sample uses specific container to discard used syringes, 60% from them didn't wash their hand before contact the patients, 80% from them wash hands after contact the patients, 60% didn't wear gloves and never use protective devices when contact with infectious patients, 78% of nurses didn't use protective measures when drawing blood, Finally 50% from the sample didn't take Hepatitis B vaccine.

Table (3) Comparison of the differences between nurse's practice regarding hand hygiene rate and their gender.

Practice	sex	No	X	SD	DF	T.obs	P.value

Discussion

Since the era of Islamic message, Islam religion encouraged people to maintain personal hygiene especially hand washing before and after eating, before and after use of toilet to prevent transmission of disease from one person to others. ⁽²⁾, Florence Nightingale in 1854 was stated the relationship between nursing performance and infection control that was first identified during the Crimean war, when she worked at a military hospital in Scutari/ Italy, the services in that hospital was too bad . Nightingale's notes and her believes in this health facility led her to believe the enhancing hygienic conditions would decrease the number of deaths. "championed the cause of improved hygiene, food, and living conditions for the hospitalized soldiers she attacked the hospital conditions and called for basic public health, infection control measures, cleanliness, hygiene and education about the importance of the issue" . The confirmation was come from Jean Lawrence, which is chairman of the Infection Control Nurses Association (ICNA) he also said that Florence Nightingale was maybe the first nurse mentioned to infection control without recognized it ⁽⁸⁾. Now the nursing staff are the key which are players the important role during health care to ensure the survival of infection control. ⁽⁷⁾. Nosocomial infection control is conceder important for three main cusses : the first one to avoiding transmission of infections from patients to health care provider staff and from them to patients ,second one to development the bacterial support and resistance, finally to limitation of financial consuming resources ^[9,10]. in 3 ways could be Transmission of nosocomial infections in hospitals, from patient to patient, patient to health staff and health caregivers to patients ^[11]. A huge reason for transporting of microorganisms is because forgetting hand washing, protective devices such as gloves and masks and a weak of personal hygiene in HCWs, in particularly improper disposal of sharp tools, ^[12]. The major findings of this study were as follows: hand washing compliance was significantly higher among female nurses ($p=0.04$) than male nurse (see Table-3).This finding is supported by the study of (Askarian, 2014) which concluded" that the Female nursing staff in CCU unit pay attention to hand washing significantly more than males after patient care contact.⁽⁴⁾ [Malekzadeh, 2015], said that inter gender behaviours differences with regard hand washing may be as a result of basic differences in the education of parents on hand hygiene for girls and boys. However females were more look after. Which also add more support to this result. Similar findings have been

stated, that led us to think females were more likely to wash their hands than male in HCWs ^[5]. The study also revealed slightly significant relationship between the level of education and hand washing ($p=0.04$), majority of the staff (%40) were staff nurses which had bachelor degree (see Table-4). This results is a similar with the study did in Italy ^[6] which stated that "nurses how are graduated from a higher level of education and with a higher knowledge of risk a transmitting and infectious disease as well as during working were more focusing to doing appropriate antisepsis of the surgical wound with hand washing pre and post medication care ^[13]. [Health centre, 2016] suggested that to be careful a high level of hand cleanses adherence, HCWs need education, clear guide notes, and some understanding to infection complications. This study reveals also that there were statistically significant difference between years of experience and hand washing practice (see Table-6). While the exact reasons for these observed patterns are not clear, several possibilities exist. The first, are that of all health care settings put a lot of effort to make sure that all staff should compliance with WHO Quid lines of hand washing whenever contact with the patients., the second is that the dramatically increase in the number of high educated nursing staff.

Conclusion

Hand washing is important. This study has shown that there was negligence in some personal hygiene practices among nurses such as (hand washing, use protective devices, use protective measures, and hepatitis B vaccination).

Molecular Detection for Nosocomial *Pseudomonas aeruginosa* and its Relationship with multidrug Resistance, Isolated from Hospitals Environment

Wathiq Abbas Hatite Al-Daraghi¹, Mohammed Sattar Abdulkadhim Al-Badrwi²

¹Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Iraq.

Abstract

Pseudomonas aeruginosa is an important pathogen in hospitalized patient's causative to their morbidity and mortality due to its multiple resistance mechanisms. Therefore, as a therapeutic option becomes restricted, the search for a new agent is a priority. So *Pseudomonas aeruginosa* is an extremely versatile Gram-negative bacterium capable of thriving in a broad spectrum of environments, and this performs main problems to workers in the field of doctors and nurses. One hundred and fifty samples were collected from different sources from Al-Kut hospitals, divided into two main groups: clinical (80) samples and (70) samples as a Nosocomial, collected from October to the December of the year 2018. All of these samples were cultured by specific and differential media, Forty (40) isolates of *P.aeruginosa* bacteria were identified by using microscopic examination, biochemical tests. The identification of (40) isolates of *P.aeruginosa* confirmed VITEK-2 system. The antibiotic sensitivity test recognized for all bacterial isolates and the results showed high sensitivity to amikacin, gentamicin, ciprofloxacin and Chloramphenicol, and high resistant to oxacillin and Cefoxitin. A molecular diagnosis is recognized by conventional PCR technique to detect the specified gene amplification products of the *bla*OXA-1 gene for *Pseudomonas aeruginosa*.

Keywords: Hospitals ; *Pseudomonas aeruginosa* ; multidrug Resistance.

Introduction

Pseudomonas aeruginosa is a Gram-negative bacillus, straight or slightly curved rods, non-spore forming, capsulate; it is usually motile by one polar flagellum (monotrichous), measuring about 1-5 µm long and 0.5-1.0 µm wide. It occurs as single bacteria, in pairs and occasionally in short chains possess mucous layer due to material alginate slime layer as well as, multi-layers of extracellular polysaccharide⁽¹⁾. The bacterium is ubiquitous in soil, a variety of aqueous solutions, including disinfectants, soaps, eye drops, as well as sinks and respiratory equipment, some strains hemolysis blood completely (β-hemolysis) by producing hemolysis toxin. *P. aeruginosa* forms smooth round colonies and irregular edge with a fluorescent greenish to yellow pigment pyoverdine. It also produces the non-fluorescent bluish pigment pyocyanin, which diffuses into the agar. Many types of media may be used for selective isolation of *P. aeruginosa* like cetrимide agar which promotes pyocyanin, pyoverdine, and pyourubin red colour and pyomelanin black colour production⁽²⁾.

Pseudomonas aeruginosa is one of the most important secondaries of the hospital-acquired infection in burnt patients⁽³⁾, and it is leading to the nosocomial pathogen, causing infections that usually accrue late during hospital stay⁽⁴⁾. *P. aeruginosa* groups have a tendency to form biofilms, which are compound bacterial groups that stick to a variety of surfaces together with plastics, medical transplant materials, and tissue. They are very difficult to destroy^(5, 6). *P. aeruginosa* produces the resource of virulence factors, as well as pili, flagella exopolysaccharides, proteases, elastase, lipases, iron chelators and a variety of various toxins, including pyocyanin, chemical compound, exotoxin A, and the Type III Secretion System (T3SS) toxins ExoS, ExoT, ExoU, and ExoY⁽⁷⁾.

Materials and Method

Specimens' Collection:

Through the period prolonged from October to December of the year 2018, One hundred and fifty specimens were collected from some hospitals including

80 clinical samples from hospitalized patients and 70 samples from Nosocomial sources. The clinical samples included four main clinical sources: Urine samples, exudate samples from wounds of the burn units patients, stool samples, Sputum samples from Cystic Fibrosis(CF) patients and Ear Swabs. The nosocomial samples included many hospital nosocomial sources: ICU, Operations Hall, Birth Hall, burning gowns, Devices and medical equipment, hand wash and hospital bed rooms.

Bacterial Isolation

Both of the clinical and Nosocomial samples were cultured on MacConkey agar, Nutrient agar, Blood agar, and Cetrimide agar, incubated for 24 hours at 37°C. this isolates may belong to *Pseudomonas aeruginosa* growth on Cetrimide agar for characterization of *Pseudomonas aeruginosa* such as blue-greenish colour, mucoid colony, smooth in shape, and have a fruity odour. colonies were picked and re-cultured on another MacConkey agar plates in order to be appeared as pale greenish and lactose non-fermenter colonies, while on Blood agar they appeared as large, opaque irregular colonies with butyrous consistency(shiny) give fruity odour and *B*-hemolytic colonies. and on Nutrient agar appeared as yellowish green, smooth in shape with flat edges and elevated center. Further identification tests included the morphological characteristics and biochemical tests were carried out depending on Forbes *et al.* (8).

Bacterial Identification:

Colonial morphology on MacConkey agar, Nutrient agar, blood agar, and Cetrimide agar was depended initially to identify bacterial isolates, colony shape, texture, colour and edges were examined. In addition to macroscopic characteristics; microscopic examination of a gram-stained slide was examined under a light microscope with special regard towards cell shape and arrangement. Biochemical tests and VITEK 2 system were depended to complete the identification of *P. aeruginosa* isolates.

PCR amplification:

DNA template of all bacterial isolates was prepared by boiling method (30 min in 100°C). The DNA of isolates was targeted only for the *bla*_{OXA-1} gene using the primer (Z. Tavajjohi, *et al* Iran (9) listed in Table 1. A reaction mixture (25 µl) contained 2 µl of DNA, 1 µl of each primer, 12.5 µl of Master Mix 2X (Z.Tavajjohi, *et al* ., 2011), and 8.5 µl of nuclease free water. The experiment was sustained according to the following program: initial denaturation at 95°C for 5 minutes, followed by 30 cycles at 95°C for 30 Sec. , 55°C for 30 Sec. , 72°C for 30 Sec. and a final extension at 72°C for 7 minutes. The PCR products were analyzed using gel electrophoresis (1% agarose) and stained with safe dye and visualized by Gel Doc apparatus (BioRad, USA) (Table 2).

Table (1): Primers used in this study.

Gene	Primer Sequence		Product size (bp)	References
bla OXA-1	F	5'-AGCCGTTAAAATTAAGCCC-3'	908	Z.Tavajjohi, et al ., 2011

Steps	Temperature	Time	Number of Cycle
Initial Denaturation	95°C	5 min.	1
Denaturation	95°C	30 Sec.	30
Annealing	55°C	30Sec.	
Extension	72 °C	30Sec.	
Final extension	72 °C	7 min.	1
Hold	10 °C	10 min.	1

Results and Discussion

Isolation and Identification of *Pseudomonas aeruginosa*:

Out of One hundred and fifty samples, clinical and Nosocomial specimens were analyzed for the presence of *Pseudomonas aeruginosa*, the results of bacterial isolation and identification revealed the detection of forty (40) isolates of *Pseudomonas aeruginosa*.

Biochemical Tests:

Some biochemical tests were performed for more validation. showed 40 isolates of *P. aeruginosa* provided by some biochemical tests, results showed positive results for oxidase test, catalase test, motility test, , and production of β -hemolysis while (40) isolations negative results to citrate utilization tests, indole production and urease production tests negative to Gram's stain and capable of growing on cetrimide agar as blue greenish colonies (at 37°C for 24 hrs.). (figure 1, table 3).

Figure (1): *Pseudomonas aeruginosa* colonies on (A) Blood agar r and (B) Cetrimide agar and (C)Nutrient agar, after 24 hours of incubation at 37°C.

Table (3): The biochemical tests of *Pseudomonas aeruginosa*

Biochemical test	Result
Gram stain	G- rods
Kligler's iron agar	K/K
Growth at 42°C	+
Motility	+
Oxidase production	+
Catalase production	+
Hemolysis(β -hemolysis)	+
Indole production	-
Urease production	-
Methyl-red	-
Voges-Proskauer	-
Lactose fermentation	-
Simmon's citrate	+

(+) Positive result, (-) Negative result

P. aeruginosa has a wide growth temperature range, optimum growth at 37°C. Slower growth rates are seen at 4°C. *P. aeruginosa* is distinguishable from other clinically *Pseudomonas* spp. by its capability for growth at 42°C. They also grow well at pH range 6.6-7.0. It was tolerant of a wide variety of physical conditions, including temperature and pH. Also, it was resistant to high concentrations of salts and dyes. It is typically given a positive result to the oxidase test and catalase. It does not ferment carbohydrates, but many strains oxidize glucose⁽¹⁰⁾. The identification was performed with the automated VITEK-2 system using the GN-ID cards which contains 64 biochemical tests, from (40) isolate of *P. aeruginosa* (40) positive result of the *P. aeruginosa* demonstrated.

Distribution of *P. aeruginosa* according to Type of Specimens :

A percentage of about 50% (40) isolates belonged to *P.aeruginosa* from total 80 isolates, 28(70%) isolates were positive to clinical *P. aeruginosa* and 12(30%) isolates were positive for Nosocomial sources. The percentage of the positive results from burns, ears and wounds were 5 %, 27.5% and 12.5% respectively (table 4).

Table (4): Distribution of *Pseudomonas aeruginosa* isolates in Nosocomial samples

Site of samples	Numbers of sample and Percentage
ICU	2 (5%)
Operations Hall	4 (10%)
Birth Hall	2 (5%)
Burn Hall	2 (5%)
Devices and medical equipment	2 (5%)
Total	12 (30%)

The low percentage was found in burn specimens which accomplished 5%. Results obtained reported that the highest percentage of *Pseudomonas aeruginosa* from ear swab (27.5%). In comparison with Nosocomial isolates of *Pseudomonas aeruginosa* the highest percentage isolation of Operations Hall (4%) where are the isolates reported low present in burn hall, birth hall

and Devices and medical equipment (2%) in comparison with clinical findings.

P. aeruginosa is well-adapted to the respiratory tract environment, especially in patients with the chronic obstructive bronchopulmonary disease, who are hospitalized in intensive care units or immunocompromised,⁽¹¹⁾ *Pseudomonas aeruginosa* is very hard to kill because of its ability to build resistance to many cleaners and medicines. *Pseudomonas aeruginosa* is accountable for 16% of healthcare facility respiratory disease cases, 12% of hospital-acquired UTI, 8% of surgical wound contaminations, and 10% of blood stream infections.⁽¹²⁾ Vandealet al. (2005)⁽¹³⁾ studied the epidemiology of *P. aeruginosa* in cystic fibrosis rehabilitation centre, sixty-seven isolates of *P. aeruginosa* were isolated from patient's sputum, the infection by patient-to-patient-transmission could have happened in the past, the risk of patient-to-patient transmission during the study period (63day) was relatively (10%) and the risk of persisting colonization with a newly acquired strain during the study period was (4%).

Antibiotics Resistance in *P. aeruginosa*

In the present study the in vitro antibiotic sensitivity test of isolated

P. aeruginosa strains examined revealed Amikacin and Gentamicin to be the most effective antibiotic followed by Ceftriaxone, Ciprofloxacin & Cefotaxime-clavulanic acid in decreasing order as reported in the table(5).

Table (5): Antibiotic resistance and sensitivity of *Pseudomonas aeruginosa* to antibiotics

Antimicrobial Agent	Pseudomonas aeruginosa (40 isolates)			
	S		R	
	No.	%	No.	%
Amikacin(AK)	40	100%	0	0%
Gentamicin(GN)	40	100%	0	0%
Cefotaxime-clavulanic acid (CEC)	30	75%	10	25%
Aztreonam(AT)	20	50%	20	50%
Cefoxitin(CX)	3	7.5%	37	92.5%
Ceftriaxone(CTR)	35	87.5%	5	12.5%
Oxacillin(OX)	0	0%	40	100%
Ciprofloxacin(CIP)	35	87.5%	5	12.5%

Antibiotic sensitivity testing is an essential tool for treatment. *P. aeruginosa* is considered as one of UTI infection, burn, CF, otitis ear and wound infection is resistant to a range of antibiotics due to the permeability barrier provided by its outer membrane for hydrophilic substances, although using sometimes surfactant as a permeabilizing agent to enhance the interaction of hydrophilic material with the hydrophobic cell wall did not enhance the antibacterial activity of some agent against *P. aeruginosa*⁽¹⁴⁾. Malla *et al*⁽¹⁵⁾ reported that *P. aeruginosa* were susceptible 100% to Amikacin and Gentamycin which are similar to our study.

Another study by V. Saegeman *et al.*, (2010)⁽¹⁶⁾ stated that *P. aeruginosa* had shown high sensitivity to a β -lactamase antibiotic with 100% for Amikacin(AK), 95% to Gentamicin(GN) and 87.5% to Ciprofloxacin(CIP). Osazuwa *et al.*, (2011)⁽¹⁷⁾ in Nigeria recorded 100% resistance for both oxacillin and Cefoxitin(CX). These results agree with the percentages in this study.

Resistance to some antibiotics such as cefotaxime, neomycin and kanamycin showed an increase in comparison with previous studies, this might be due to the variation in the usage of antibiotics⁽¹⁸⁾.

Genomic DNA Extraction:

Using a genomic DNA purification kit (Promega), Genomic DNA was extracted from *Pseudomonas aeruginosa* isolates. Extraction genomic DNA from 40 isolates that were confirmed as bands by gel electrophoresis. The DNA concentration and purity were measured by Nanodrop spectrophotometer, all the isolates had DNA concentration between (50-100 ng/ μ l) and purity of the DNA.

Molecular Detection of *Pseudomonas aeruginosa* by *bla_{oxa1}* like gene:

The result of PCR analysis concerning of the found the *bla_{oxa1}*, showed that studies *P. aeruginosa* possess the gene *bla_{oxa1}* like gene from 40 isolates, 10(25%) isolates positive *bla_{oxa1}* like gene showed 4 (40%) from clinical isolates and 6 (60%) from nosocomial (figures not shown).

From 10 positive isolates, 4 strains of clinical isolates; urine and ear isolates were multi-drug resistant. The prevalence of *bla_{oxa1}*-1 positive isolates of ESBL *P. aeruginosa* occurred in 40% of isolates and MDR phenotype was common in *P. aeruginosa*. The most

prevalent gene among ESBL producers were *bla_{OXa}*-1 which compromises the efficacy of MDR bacteria especially in clinical(urine, ear, and stool samples) and nosocomial samples (operation hall, burning gown, and ICU) according to the results in this study and tend to be geographically limited.

The *bla_{OXa}*-1 ESBLs provide *P. aeruginosa* with an additional powerful resistance mechanism with potentially serious clinical implications, including limitation of the therapeutic options. ESBLs manufacturing organisms create distinctive challenges to clinical microbiologists, clinicians, infection control professionals and scientists engaged in finding new antibacterial agents⁽¹⁹⁾. In this study, the prevalence of *bla_{oxa}*-1 of *P. aeruginosa* isolates was 25% that less than values reported in different studies like in Iran; Malaysia; and Pakistan

This study reported 10 isolates (25%) of *bla_{OXa}*-1 ESBL of *P. aeruginosa* in clinical and nosocomial isolates from 40 isolates. The studies conducted by others depicted low rates, 7.7% (J Jacoby GA)⁽²⁰⁾, 3.7% (Neil Woodford *et al*)⁽²¹⁾, 4.2% (Lim *et al.*,⁽²²⁾ respectively, of ESBL production of *P. aeruginosa*.

Knowledge Assessment of Working Women Regarding Breast Cancer / Control and Prevention in Kirkuk Technical Institute

Wafa Mahmood Jasim

Assist Prof / Community Health Dept/ Kirkuk Technical Institute-Northern Technical University / Iraq

Abstract

Breast cancer is the most common cancer in women both in the developed and less developed world In Iraq, it is the commonest type of female malignancy, accounting for approximately one-third of the registered female cancers according to the latest Iraqi Cancer Registry.

A descriptive cross-sectional study was conducted on working women in Kirkuk Technical Institute during the period from 1st April till 30th June / 2016 to assess their knowledge regarding breast cancer prevention and control methods.

The total number of included studied women was 71 from different scientific departments after distributing a special questionnaire form and face to face interview was done after receiving the written agreements to participating in the study.

Majority of working women are technical (52.2%), married (74.7%) aging above 40 years (47.8%) with employment years above 15 years (50.0%).

Both electrical and survey dept. go with the establishing of breast cancer prevention at adulthood after fully matured (44%, 45%) respectively in comparison to 57.7% of study women from electronic dept. go with the starting of cancer prevention at the birth of a first child .

The main recommendation of the study is that further researches should be done because there is a need for increased efforts towards developing and widely available cancer educational program that focuses on the main preventive measures and encouraging the women with breast disease, not only providing them with information but also for the ability to make her decision to control the disease

Key words : *Knowledge, breast cancer, assessment, control and prevention.*

Introduction

Women play a critical role in maintaining the health and well being of their communities because families and communities health is tied to the health of women. Woman illness or death has serious and far-reaching consequences for their children, families, and communities ⁽¹⁾.

Among women, breast cancer is the most common cause of cancer mortality accounting for 16% of cancer deaths in adult women ⁽²⁾. Breast cancer is a serious life-threatening public health problem of great concern. Increases in the incidence of breast cancer are

being observed in both industrialized and developing world ⁽³⁾.

WHO promotes breast cancer control methods within the national cancer control program which is directed for both non- communicable diseases and other related health consequences his program includes (prevention, **early detection of the disease, diagnosis, treatment, rehabilitation with the assistance of palliative care**) ^(3, 4).

The key strategies for population-based breast cancer control are :

1- Increasing the awareness of the general public about this health problem.

2- Appropriate policies and health programs ⁽⁵⁾.

Nowadays countries with low and middle income facing a double burden of breast cancer which is regarded as a top killer in women aging over 30 years old. These countries need further specific strategic methods that concentrated for effective ways of disease prevention ⁽⁵⁾.

A study was done by Nada *etal* during 2014 mentioned that breast cancer constitutes about one fourth of the reported cancer cases among Iraqi population which is regarded the main cause of death and each year many women are exposed to the vicious ramifications of breast cancer which include death if left untreated or the negative outcomes that would experience, cosmetically and psychologically, after exposure to surgical intervention ⁽⁶⁾.

Another study was done in Iraq about the breast cancer incidence trends from 2000- 2009 which reported that the disease incidence of all female breast cancer in Iraq (all ages) has risen and there is a rapid increase in the age-specific incidence rate among the age group 60-69. However, this disease among Iraqi women still affects younger age groups than their counterparts in developed countries ⁽⁷⁾.

Reduction in the incidence of breast cancer needs control of both modifiable risk factors with the effective integrated preventive measures that promote (intake of the healthy diet, daily physical activity, alcohol, and weight control) which eventually have a direct impact for the future outcomes. ^(8,9).

In more recent years, many studies have indicated the effect of diet and other behaviors on the occurrence of breast cancer. These additional risk factors are environmental factors such as tobacco use, radiation, endocrine disturbance and shift work ⁽¹⁰⁾.

The main three important screening tests usually considered for controlling and preventing the disease which is 1- clinical breast examination (CBE) 2-X-ray mammography 3- breast self-examination (BSE). In industrial countries, breast cancer mortality is declining where screening mammography is the standard for care. BSE is appealing as a patient-centered, non-invasive screening procedure which allows women to become more comfortable with their own bodies ^(11, 12).

The aim of the study: to assess the knowledge of working women regarding breast cancer control and prevention methods

Methodology-

1- Ethical issues

Official agreements were taken from Kirkuk Technical Institute before establishing the study

2- Study design and setting:-

A descriptive cross-sectional study was carried out in Kirkuk Technical Institute on three scientific departments (Electronic, Electrical, and Survey).

3- Study sample and sampling method:-

A randomly selected sample from 71 working women (25 from the electronic department and 26 from the Electrical department and 20 from the Survey Department).

A specific special questionnaire form was distributed to them after receiving their written consent and the data was collected by interviewing with the study women after complete explanation of the main objectives of the study.

4- Study period :

The study was conducted during the period from 1st April till 30th June / 2016.

5- Data collection tool:-

Certain designed prepared questionnaire form has been conducted by the investigator utilizing a recent updated related literature to the study subject included three main parts:-

Part-1- Demographic characteristics like (age, employment year, type of work, and martial status).

Part-2- Information about their knowledge regarding disease control and preventive measures with the main risk factors). Part -3- Their knowledge about the specific time for starting the prevention of breast cancer.

6- Reliability of the questionnaire form:-

The data was presented to (4) experts in different fields, they were (2) Clinical physicians, (1) Community physicians and (1) statistical experts.

Inclusion criteria: Any married woman

Exclusion criteria: History with chronic diseases such as hypertension, Diabetes’s mellitus, or renal disease.

7- Statistical analysis of data:-

The information regarding each participant was transferred into a code sheet and the data entry was done

using a computer Pentium IV and the statistical analysis was calculated by mine tab program /2016⁽¹³⁾.

All the statements with Yes and No answer, number and percent will be calculated.

Chi-square test was used to detect the relation between the studied variables and the level of significance is taken at level 5% (P < 0.05).

Results

The total number of working women are 89 distributed among three scientific departments.

The number of women responded to study was 71 and the response rate was (79.7%).

Table (1): Socio- demographic characteristics of the study women

Socio- demographic parameter		Number(N=71)	Percent
Age group in year	<20	8	11.2
	20-25	10	14.3
	25-30	19	26.7
	35-40	24	33.8
	>40	10	14.0
Employment years	5- 10 years	9	12.6
	11- 15 years	23	32.4
	> 15 years	39	55.0
Type of work	Official	12	16.9
	Technical	37	52.2
	Teacher	22	30.9
Marital status	Single	18	25.3
	Married	53	74.7

Table 1 shows that most of the study women are technical (52.2%) aging between 35-40 years (33.8 %) with employment years above 15 years (55.0%), married (74.7%).

Table (2): Frequency distribution of study women according to family history and type of relationship

No.	Items	Yes		No		Total	
		No.	%	No.	%	No.	%
7	1-Family history of breast cancer	9.8	64	90.2	71	100.0	
4	2- Relation of breast cancer with the relatives	Mother	Sister		Aunt		Grand mother
		3	0		0		

Table 2 indicated that 90.2 % of study women had a negative family history of breast cancer and only 9.8 % of them had a positive history of breast cancer with a first degree (mother and sister).

Table (3): Study women distribution according to their knowledge about the risk factors, preventive and control measures for breast cancer.

Knowledge parameter	Number of working women (=71)				*P value
	yes	%	No.	%	
Risk factors of breast cancer					0.000
a- Aging factor	12	26.1	11	44.0	
b- Contraceptives pills	21	45.6	7	28.0	
c- Life style	10	21.8	5	20.0	
d- Family history	3	6.5	2	8.0	
Total	46	100.0	25	100.0	
Control measures :					0.240
a- Advanced educational program	19	48.7	12	37.5	
b- Raised general public awareness	10	25.6	8	25.0	
c- Control risk factors like contraception	8	20.6	5	15.6	
d- Regular cheek up	2	5.1	7	21.8	
Total	39	100.0	32	100.0	
Preventive guidelines :					0.000
a- Screening by mammography	18	29.4	6	30.0	
b- Modifying healthy life style	20	39.2	3	15.0	
c- Regular breast self exam	13	25.5	4	20.0	
d- Breast clinical exam	3	5.8	7	35.0	
Total	51	100.0	20	100.0	

Table 3 shows that there was a statistically significant agreement among study women knowledge regarding risk factors was for contraceptive pills (45.6%), (48.7%) for the advanced educational program as a control measures and (39.2%) for modifying healthy life style as a preventive measure for breast cancer prevention with a P value = 0.000 .

Table 4: Frequency distribution of study women according to their knowledge about the specific time for starting the prevention of breast cancer

Specific time for starting the prevention of breast cancer	Study women N=71						Total	P* value
	Electronic dept. N= 26		Electric dept. N= 25		Survey dept . N=20			
	No.	%	No.	%	No.	%		
1- Child hood before and during breast development	2	7.7%	7	28%	4	20%	13 (18.3%)	0.166

Cont... Table 4: Frequency distribution of study women according to their knowledge about the specific time for starting the prevention of breast cancer

2- Young adult hood before fully maturation of the breast	5	19.3%	1	4%	5	25%	11 (15.5%)	0.124
3- Adult hood after the breast fully mature	4	15.3%	11	44%	9	45%	24 (33.9%)	0.045
4- The birth of a women first child	15	57.7%	6	24%	2	10%	23 (32.3%)	0.015

* χ^2 – test was used

Table 4 shows that both electrical and survey dept. go with the establishing of breast cancer prevention at adulthood after fully matured (44%, 45%) respectively in comparison to 57.7% of study women from electronic dept. go with the starting of cancer prevention at the birth of a first child with a P value = 0.015

Discussion

Regarding the family history of breast cancer, the study shows that most of the working women had a negative family history of breast cancer. This result goes with the American cancer society (ACS) report about the disease / 2007⁽¹⁴⁾ The report stated that any women who had a history of breast cancer in her family is more prone to be a risk factor for it and this will lead gradually to increase the level of education about the disease occurrence

Shambhavi *etal* conducted a study in Mangalore, Karnataka / India to assess the teacher's knowledge regarding breast cancer and to find the association between the level of knowledge and some selected demographic variables. They found that the highest number of school teachers (60%) were in the age group between 25 -35 years and least were about > 55 years of age (6%)⁽¹⁵⁾.

Concerning the general knowledge of the breast cancer , the current study show the about half of study women knowledge regarding risk factors was for contraceptive pills and for the advanced educational program as a control measures. This result may be explained because of better information sources from the scientific references and the declaration of the Ministry of health on the television about the danger and risk factors of the disease.

Samir /2011⁽¹⁶⁾ conducted a study in the college of nursing / University of Sulaimani who found that the general informative background of study students regarding breast cancer, clinical manifestation, risk factors and control measures were ranged between highly significant and moderate. He explained that because of the student scientific study and general information in their college.

Another study was prepared by Alkhasawneh /2007⁽¹⁷⁾ at Pamukkale University Denizli hospital / Jordan among nurses. He found that 74 (57.6%) of them were correctly knew at least four risk factors of the disease and the increasing age 72%, familial history 94.4%, childlessness 85.6%, absence of breastfeeding 82.4%, and taking birth control pill or hormone replacement therapy 50.4% were well-known risk factors. However, a small percentage of them believed that early menarche 23.2% and late menopause 28.8% were the risk factors of breast cancer. He discussed these results because of breast cancer is being considered as a disease of the developed countries and much efforts with strong emphasis had been given to this issue in addition to that further preventive and control measures was conducted against breast cancer.

A similar study was conducted by Nada *et al.* / 2012⁽¹⁸⁾ in Kirkuk University about knowledge, attitude and practice towards breast cancer and breast self-examination as the most effective preventive measure towards breast cancer.

They found that the general knowledge about breast cancer and the practice of breast -self-examination was relatively well in Kirkuk yet the positive attitude towards learning the screening techniques and the intention to teach others were fairly encouraging they recommended

for promoting public health awareness campaigns through various media.

Dr. Golditiz *et al* / 2015⁽¹⁹⁾ published a study about the prevention of breast cancer mentioned that control and prevention should start early in life because nearly 25% of breast cancer patient is diagnosed in women younger than age 50 years in developed countries and 22% of it is diagnosed in premenstrual women and is often aggressive than cancer diagnosed in postmenopausal women . They recommended for adaptation of a specific strategy to decrease cancer risk by calculated how much the differences would occur in a sample of women .

A study was done by Coleman / 2008 ⁽²⁰⁾ to assess the survival rate of breast cancer. He found that the disease range was from 80% or more in North America, Sweden, and Japan to reach up to 60% in Middle income- countries and very low in low income-countries which reach to 40% and they explained these differences because of lack of preventive measures like early detection health programs which later on lead to increase the proportion of women complaining of late and advanced stage of the disease with the lack of adequate specific diagnosis of the disease .

Conclusion

Informative background for studied women was good but still, there is a defect in disease prevention and time for early detection.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors declare that they have no conflict of interest.

Funding: Self-funding

The Effect of Esomeprazole on Cell Line Human Cervical Cancer

Azal H. Jumaa¹, Ahmed Sami Jarad², Wissam Sajid Hashim Al Uboody³

¹AL-Yarmouk University College, Department Of Dentistry, Baghdad, Iraq, ²College of Veterinary Medicine, University of Fallujah, Iraq, ³Department of physiology, College of medicine, Al Muthanna University/Iraq.

Abstract

Esomeprazole is an inhibitor of the proton pump that reduces gastric acidity and is used in indigestion treatment; Esomeprazole is a promising treatment for tumors, such as melanoma and B cell leukemia, through several mechanisms, including rapid cellular acidification and activation of many types of caspase enzymes, which in turn lead to the activation of cellular apoptosis

This work was designed to assess the toxicity of the (Esomeprazole) on (HeLa cell line) in vitro at concentrations starting from one - ten thousand µg/ milliliter and compared with cytotoxicity of vincristine and methotrexate at concentrations between one - ten thousand µg/ milliliter In 3 incubation periods

The results showed that the cellular toxicity of one µg / milliliter was a lot of more than the cellular toxicity of ten and a hundred µg / milliliter. The results additionally showed that toxicity of esomeprazole was considerably more than vincristine and methotrexate on HLA cells at seventy two hours.

Key word: *esomeprazole, vincristine, Hela cancer cell line.*

Introduction

Cervical malignant tumor is a common categories of cancer between female, lead to women's sexual ability and fertility ⁽¹⁾. Chemotherapy is that the backbone strategy for cancer treatment especially in the early stage in case of cervical cancer, is treated by surgery or irradiation with chemotherapy ⁽²⁻⁵⁾. Chemotherapy kills both cancer cells and normal cells with a high split rate ⁽⁶⁻¹⁴⁾, Common side effects of chemotherapy are nephrotoxicity, which usually associated with vincristine and methotrexate therapy

Several approaches to solve the toxicity of conventional cancer treatments have been developed, like using of natural agents as plant extract that may show a promising anticancer activity ⁽¹⁵⁻²³⁾.

Investigation about the efficacy of some drugs that already used to treat diseases other than cancer. it show a hopeful role in the handling of malignancy, such as aspirin, which acts as a protective agent for various types of Cancer (colorectal cancer), through a mechanism like suppress platelets aggregation ⁽¹⁹⁾, also acetaminophen at the therapeutic dose was capable of killing liver

cancer cells by turn activate apoptosis ⁽²⁴⁾. On the other hand, Omeprazole has the ability to rise the sympathy of the immune B-cell leukemia cell line to the vinblastine by several mechanisms, including an increase in cellular acidity ⁽⁴⁾.

Omeprazole have been shown to have potential to reduce resistance of tumor cell to chemotherapy by altering the pathway of the transfer of lysosomes contains and autophagy that activate programmed cell death mechanism ⁽³⁾. A mixture of esomeprazole and amygdalin reveled ability to suppress the growth of cervical cancer cells in vitro ^(5; 23).

Martial and Method

Proton pump inhibitor: Esomeprazole (nexium) ® 40 mg (AstraZeneca) was used in different concentrations ranging from one to 10000 µg / mL. These concentrations were set by thinning of the medication with bovine serum unrestricted medium.

Chemotherapeutics agent; a) Vincristine sulphate 1 mg/ml vial (hospira UK.) was used at different concentration ranged between (1-10000) µg/ml, after

dilution with bovine serum free medium

Methotrexate vial (50 mg/5cc - kocak / turkey) was used at different concentration ranged between (1-10000) µg/ml, after diluted with bovine serum free medium

$$\text{Inhibitor rate \%} = \frac{\text{The optical density of control} - \text{The optical density of test.}}{\text{The optical density of control}} \times 100$$

Cell line culture:

The human cervical cell line cancer gotten from the unit of tissue culture in the Iraqi Center for Cancer and Medical Genetics Research . It were planting in tissue culture flasks with size 75 cm 2 and with controlled conditions involving 5% of humidified, carbon dioxide on 37 ° C in RPMI-1640 media (Kigma Chemical, England) with fetal bovine serum at 10% (FBS), with add some anti biotic include pen.-strep. With concentration 1% ⁽¹⁰⁾.

Cytotoxicity Assay:

Human cervical cancer cells grown in microtiter plate (96wells) have been handled with a range of concentrations of each (esomeprazole, vincristine and methotrexate), cell density increases throughout the development period and also the cytotoxic effect of analytical agents strongminded once many incubation periods, ⁽¹⁰⁾ each milliliter contains 1X10⁵ cells / ml, serum calf medium (10 percent) Used for seeding, plates were then incubated at 37CO for 24 hours to achieve cell attachment, followed by various serial dilution (1-10000 µg / ml) for esomeprazole, vincristine and methotrexate by victimization maintenance medium.

After twenty-four hours of incubation, cells were exposed (for each concentration tested, six replicates at 200µl), two hundred µl of maintenance medium in

addition to each control group well, the days of exposure were twenty-four, forty-eight, and seventy-two hours. The cultures were wrapped with self-adhesive paper, then transferred to incubators and then colored cells with MTT stain. Each well’s optical density was scanned via a micro-ELISA at a wavelength of 550 nm (17 ; 10) ; the measurement of the substance frequency by using the subsequent equation⁽¹¹⁾

Statistical Analysis

The Statistical Analysis System (SAS) ⁽¹⁸⁾ used it to determine the outcome of varying parameter factors in the study.

Results and Discussion

Esomeprazole cytotoxic effect:

The findings of esomeprazole productivity inhibition of Hela cancer cells show an increase in productivity inhibition with an increase in the concentration of esomeprazole ranging from (10-10000) µg / ml, for every 3 incubation periods, except (1 µg / ml) wherever growth inhibition was significantly higher than 10 µg / ml to all incubation cycles, whereas there was no significant variation between the development reserve of (1 µg/ml) with (1000 µg/ml) for 24hr. and (1 µg/ml) with (100 µg/ml) for 48hr. and 72hr. incubation periods table (1).

Table (1) Effect of concentration and time in growth inhibition rate for Esomeprazole on Hela cancer cell line

Hormesis will explain the fluctuated growth inhibition of esomeprazole; hormetic result may be a common biological development in pharmacological medicine characterized by a reverse action of low concentrations compared with high concentration ⁽¹⁶⁾. The carbon-based biochemical pathway by hormesis action aren't well clear, it's imagined that low amounts of poisonous ingredient might start the healing process in the body ⁽⁶⁾. This compound might increase the activity of anticancer agent whereas others may forestall the carcinogenic effect of some genotoxic compound ⁽⁹⁾

Several recommended mechanisms will explain the toxicity of esomeprazole on Hela cancer cells, because the ability of esomeprazole to induce a lysosomes membrane permeabilization, inflicting increase outflow of lysosomes contains to the cytoplasm, inflicting lysis of cellular elements then death, additionally to hydrolytic activity, the lysosomal enzymes also can offer acidic atmosphere that encompasses a role in killing tumor cells ^(8 ; 13 ; 15). Another mechanism in vitro via a fast intracellular acidification and activation of many caspase enzyme ⁽⁵⁾, esomeprazole has ability to produce ROS in B cells neoplasm by many ways ⁽⁴⁾.

Comparison among the cytotoxic effect of Esomeprazole, Vincristine and Methotrexate:

As shown in table (2) the manner of vincristine growth inhibition is dose and time dependent reflecting the fact of increase in vincristine cytotoxicity occurred with increase in time of its persistence inside cancer cells which occurred by several mechanisms including

mitosis blocking in metaphase, and blocks the ability of tubulin to polymerize to form microtubules binding by binding of microtubule protein, (tubulin) with esomeprazole then. Consist of Tubulin dimers

that resulting from paracrystalline aggregates, leading to Spindle apparatus dysfunction, frozen in metaphase, impaired chromosomal segregation and cellular proliferation.

Permeabilization of lysosomal membrane is one of the vincristine anticancer mechanisms which Causing increase of lysosomes contains leakage to the cytoplasm and occurrence of cell death by the Degenerative activity of lysosomes contains and acidic conditions which equip by lysosomes acidic ambience.

When comparing between the growth inhibition of vincristine with esomeprazole as shown in table (4,5,6), the results establish the development reserve of esomeprazole was more than vincristine growth inhibition on Hela cancer cells, especially at 24 hr. and 72hr. incubation periods . reflecting the ability of esomeprazole to enhance permeabilization of lysosome membrane was more than the vincristine ability , that may related to the development of resistance toward vincristine action by efflux of vincristine through the special transport system P-glycoprotein ⁽²⁰⁾ leading to less in persistence time of vincristine inside cancer cells , producing less in antineoplastic activity of vincristine which including inhibition in microtubules formation , with less ability to induce lysosomes membrane permeabilization as compared with the inducing ability of esomeprazole , where esomeprazole has a superiorities on vincristine to induce lysosomes membrane permeabilization which mainly related to the less resistance development toward esomeprazole activity.

While the result of methotrexate. Growth inhibition as shown in table (3) the growth inhibition at 72hr. was less than the growth inhibition at 24 hr. especially at 10,100 and 1000 µg/ml, this result reflecting the developments of resistance toward methotrexate Cytotoxicity ,where there is several mechanism by

which cancer cells follow to resistance the cytotoxicity of MTX included (weakening in methotrexate moving into cells, making of altered form of DHFR that have a fewer affinity for the dysfunction, intracellular height of intracellular DHFR, by quality enhancement or modified quality guideline and diminished capacity to combine methotrexate polyglutamate) ⁽⁷⁾.

when comparing between the cytotoxicity of esomeprazole and methotrexate as shown in table (4,5,6) and, the result of comparison demonstrated the growth inhibition of esomeprazole was more than the growth inhibition of methotrexate, that may relate to less resistance development toward esomeprazole.

Abstract

Background: Type 2 Diabetes mellitus is a group of metabolic disease characterized by increase blood glucose level (hyperglycemia) resulting from either defect in insulin production by pancreas or increase insulin resistance that lead to decrease insulin effect in the body. prediabetes It is stage before diabetes mellitus including impaired fasting glucose (IFG) where the fasting glucose level (6.1-7.0 mmol/L) and impaired glucose tolerance (IGT after glucose load) glucose level (7.8-11 mmol/L). (**salusin- β**) It is a newly glass of peptide it is synthesized in many body tissues, like (skeletal muscle, human vascular smooth muscle cells, and endothelial muscle) it have important role in Diabetes pathogenesis it has been reported to involve in vascular inflammation and the relation between salusin β and diabetes through endothelial injury, salusin β increase inflammation in diabetes. It have essential role in pathological endothelial dysfunction. **Method:** by using ELISA kit, we measured serum level of salusin β in 30 patients with prediabetes and 30 patients with type 2 DM compare with 30 healthy volunteers enlisted as normal controls. **Result:** serum salusin β level in patient with type 2 DM were significantly higher than prediabetes group and normal subjects. Salusin β in prediabetes group no significant higher than in healthy control subjects. **Conclusion:** Serum Salusin β level in patients with type 2 DM are expressed at significantly high levels were no difference in Salusin β level of prediabetes group and normal control subjects.

Keywords: Salusin β , diabetes mellitus, prediabetes, ELISA.

Introduction

Diabetes mellitus is a group of metabolic disease characterized by increase blood glucose level (hyperglycemia) resulting from either defect in insulin production by pancreas or increase insulin resistance that lead to decrease insulin effect in the body. Feature of hyperglycemia include polyuria, weight loss, polyphagia, polydipsia, unclear .

Prediabetes It is stage before diabetes mellitus including impaired fasting glucose (IFG) where the fasting glucose level (6.1-7.0 mmol/L) and impaired glucose tolerance (IGT after glucose load) glucose level (7.8-11 mmol/L), to forms of prediabetes in which increase glucose level more than normal range but below the renal threshold of diabetes level, the HbA1c range in the two. state . The presence of prediabetes is associated with the presence of β cell dysfunction and insulin resistance and about 5-10% of population are

development to. Salusin β It is a newly glass of . salusin- β have special physicochemical properties, It is present in biological fluids such as human plasma , urine and vascular .the bioactive peptide (salusin- β) is synthesized in many body tissues, stomach, bone marrow, small intestine, thymus, lymph, salivary glands, adrenal medulla, adrenal cortex, spleen, liver, brain, skeletal muscle, testes, human vascular smooth muscle cells, and endothelial muscle. salusin β it have important role in the diabetes. it has been reported to involve in vascular inflammation and the relation between salusin β and diabetes through endothelial injury, salusin β increase oxidative stress, cardiac dysfunction and inflammation in diabetes. It have essential role in pathological endothelial.

The aim of the present study was to evaluate serum level of Salusin β in patients with type 2 DM , Prediabetes, and compare this group with control healthy group as well as to investigate whether it can be used as

a biomarkers for detection of diabetes.

Materials and Method

Study design case control study

The present study include 90 Iraqi participants (30 with type 2 DM, 30 with prediabetes, 30 normal healthy control group) the Age range (30-65)years, the age and gender matched to the patients and control group. Blood sample collected between September 2018 and april 2019. The following biochemical parameters have been studied. Salusin β , hs- CRP by ELISA method, fasting blood sugar (FBS), HbA1c, blood urea, serum creatinine, Lipid profile by colorimetric method by (cobas C111). Measure body mass index (BMI), and measure (WC). Fasting serum Samples were collected from patients and control by taking eight (8) ml of venous blood will be collected in plane tube (without anticoagulant). Blood are stand for 30 minutes then centrifuged in 1800 RPM for 15 minutes. Serums are transferred to new tube and keep in -20 C until assay.

Salusin ELISA

A total 100 μ l serum was analyzed using a commercially available ELISA kit Salusin β (melsin) according to manufactures recommendations. Prepare all reagents before starting assay procedure. It is recommended that all Standards and Samples be added in duplicate to the Microelisa Stripplate. Add standard: Set Standard wells, testing sample wells. Add standards 50 μ l to standard wells. Add 10 μ l of testing sample of sample wall .Then add 40 μ l of sample diluent to testing sample well, doesn't add anything to the Blank well. Add HRP-conjugate reagent 100 μ l to each well, covering with an adhesive strip , incubate for 60 minutes

at 37°C. Aspirate each well and wash, repeating the wash 4 times for a total of 5 washes. Wash by filling each well with Wash Solution (400 μ l) using a squirt bottle, manifold dispenser or auto washer. Removal of liquid completely at each step is essential to good results. After the last wash, remove any remaining Wash Solution by decanting or aspirating. Invert the plate and blot it on a clean paper towels. Add 50 μ l of chromogen solution (A) and added 50 μ l of chromogen solution B to each well. mix Gently and incubate for fifty minutes (15) minutes at 37°C. and Protect from light. Add 50 μ l from Stop Solution to each well. The color should change from blue to yellow of the walls. If the color in the wells is green or the color change does not appear uniform, gently tap the plate to ensure thorough mixing. Read the Optical Density (O.D.) at wave lengths 450 nm and using a microtiter plate reader within 15 minutes.

Statistical Analysis

Statistical analysis was carried out by using SPSS version 20 and Microsoft excel 2013.the numerical data expressed as mean \pm SD. Comparison between mean serum Salusin β concentration and (IFG, DM) groups were performed. Receiver Operating Characteristics (ROC) Curve was calculated to estimate the sensitivity and specificity of the used Salusin β .

Result

There was highly significant difference in mean Salusin- β among study groups ($P < 0.001$); the level was highest in diabetic patients with highly significant difference ($P < 0.001$) in comparison with that of both prediabetics and control subjects; however, there was insignificant difference between control and prediabetic groups ($P = 0.736$),

Table 1. Salusin- β in patients and control groups

Characteristic	Control		Prediabetic		Diabetic		P	P1	P2	P3
	Mean	SD	Mean	SD	Mean	SD				
Salusin- β (pg/ml)	5.12	1.15	5.27	0.83	7.80	2.47	<0.001 † HS	0.736 ¥ NS	<0.001 ¥ HS	<0.001 ¥ HS

n: number of cases; data were presented as either mean and standard deviation; †: One way ANOVA; ¥: post hoc LSD test; HS: highly significant at $P \leq 0.01$; NS: not significant at $P \leq 0.05$; S: significant at $P \leq 0.05$; P1: Control vs prediabetic; P2: Control vs DM; P3: Prediabetic vs DM

Result

Figure 1. Bar chart showing the mean serum salusin beta in diabetics, prediabetics and control subjects

Because of the highly significant difference in the level of salusin-β in diabetic patients when compared to prediabetics and control groups, the authors of the current study suggested the presence of a cutoff value that can predict a diagnosis of diabetes with certain level of accuracy. For that reason, receiver operator characteristic (ROC) curve analysis was carried out and the results are shown in figure 3.1 and table 3.6. The cutoff value was > 6.5 with an accuracy level of 88.2 %, a sensitivity level of 80 % and specificity level of 93.3 %, table 3.6.

Figure 2. Receiver operator characteristic (ROC) curve to predict the Salusin β cutoff value with a diagnosis of diabetes mellitus

Table 2. Cutoff value , sensitivity and specificity of Salusin- β.

Characteristic	Salusin-β
Cutoff value	> 6.5
AUC (95 % CI)	0.882 (0.796 - 0.940)
Accuracy	88.2 %
P	<0.001
Sensitivity	80.00
Specificity	93.33

Discussion

It is a peptide that present in endothelium tissue and in cell membrane it is play important role in endothelial function and pathogenesis of diabetes the increase level of salusin β in patients with type -2 diabetes mellitus related with the complication of diabetes due to endothelial injury (7). In the present study found increase in Salusin β concentration in diabetes group and high significant deference between diabetes group and another two groups at p value (<0.001) and normal level of prediabetes and control group . And this agreement with study done by (7) salusin β was higher in level with high glucose (diabetes group). Salusin beta was positively correlated to female gender There was no significant correlation among markers in all three study groups, as shown in table (3.3) Because of the highly significant difference in the level of salusin-β in diabetic patients when compared to prediabetics and control groups, the authors of the current study suggested the presence of a cutoff value that can predict a diagnosis of diabetes with certain level of accuracy. For that reason, receiver operator characteristic (ROC) curve analysis was carried out and The cute off value was > 6.5 with an accuracy level of 88.2 %, sensitivity level of 80 % and specificity level of 93.3 %, result show in table (3.6). Salusin beta was negatively correlated to age, positively correlated to FBS, positively correlated to HBA1c, negatively correlated to cholesterol and negatively correlated to LDL, in the present study the result show there was positive correlation between salusin-β and FBS. And no correlation between salusin-β and adiponectin, no correlation with lipid bound sialic acid and no correlation with lipid profile.

Table 3. Correlations of biochemical markers to demographic, disease characteristic lipid profile and renal function in prediabetic group

Characteristic	salusin (pg/ml)	
	<i>r</i>	<i>P</i>
Age	0.312	0.094
Gender	0.449	0.013*

Vitamin D and its Association with the Severity and / or the Control of Asthma among Adult Iraqi Asthmatics

Haider Abdulhameed Alqaraghuli¹, Hashim Mahdi Hashim²,

¹FICMS med FICMS Respiratory, College of Medicine, Al-Nahraine University/Iraq,

²MRCP, College of Medicine, al-Nahraine University/Iraq

Abstract

Background: asthma is one of the common chronic diseases with variable presentations and pathogenetic mechanisms. Vitamin D is thought to influence the expression as well as the severity, control and treatment responses in some asthmatic patients. Aim of study: to examine the possible association between asthma severity and level of control with vitamin D level in a sample of Iraqi adult asthmatics. **Method:** randomly selected 50 patients with asthma diagnosis were evaluated for medical factors of asthma harshness and control with measurement of 25-hydroxyvitamin D serum level (mean age \pm SD: 48.5 \pm 14.05 years, 30% males, FEV1: 1.44 \pm 0.63 L, 60 % severe, 60% poorly controlled). **Results:** most of asthmatic patients (96%) were found to have vitamin D level of less than 30 ng/ml (17.66 \pm 7.06 ng/ml) and this was related to severity of airway obstruction (mild: 28.71 \pm 5.52 ng/ml, moderate: 19.9 \pm 4.56 ng/ml, severe: 13.81 \pm 4.22 ng/ml, $p < 0.001$) as well as control of asthma (controlled: 27.13 \pm 6.12 ng/ml, partly controlled: 20.62 \pm 4.21 ng/ml, uncontrolled: 17.66 \pm 7.06 ng/ml, $p < 0.001$). In addition, the 25(OH)D level was significantly associated with history of ER visits and hospitalizations. No significant association between the gender, age, BMI, the presence of allergic rhinitis and the status of vitamin D level. **Conclusions:** low levels of 25(OH)D were common in this sample of Iraqi adult asthmatics and was most prevalent and severe in those with severe and/ or uncontrolled asthma. This finding supports the hypothesis of possible vitamin D role in asthma.

Key words: vitamin D, severity and / or the control, asthma, Iraqi asthmatics.

Introduction

asthma is a common chronic illness with growing prevalence in many parts of the world for many years. More than 300 million persons from all ages, and different ethnics, grieve from asthma and its burden on patients, the families, and economy of the health authorities and is increasing internationally. It is defined by “a history of symptoms including wheeze, shortness of breath, chest tightness and cough that vary over time and in intensity, together with variable expiratory airflow limitation”.⁽¹⁾

It has been suggested that there is heterogeneity in asthma expression and phenotypes and these respond differently to treatment options which suggests different pathogenetic mechanisms. In most asthmatics, i.e. the classical type, the symptoms are well controlled by beta 2 agonists and inhaled corticosteroids. However, some phenotypes of asthma do not exhibit similar response to corticosteroids and those patients are labelled as steroid – refractory and are challenging to manage clinically.⁽²⁻⁶⁾

Vitamin D affects the pathophysiology of asthma by effect on several mechanisms. It may help in maintaining the immune homeostasis especially the innate immunity by the direct stimulation of the expression of the gene responsible for the production of the antimicrobial peptide cathelicidin, which is known to be active against viruses, bacteria and fungi, and its deficiency may predispose to infections and consequent asthma exacerbations.⁽⁷⁾

In addition, vitamin D can reduce inflammation and smooth muscle proliferation by inhibiting the synthesis and release of cytokines related to the Th1 immune response and it may decrease the expression of TNF- α which lead to enhanced inflammatory response in asthmatics. In addition, it has been suggested that the level of 25(OH)D may facilitate steroid response in asthmatics.⁽⁸⁾ The purpose of study is to find any link between vitamin D level and the severity and / or the control of asthma in a sample of adult Iraqi asthmatics.

Method

This is a cross sectional study of randomly selected 50 patients (35 females and 15 males) with asthma who regularly attend the respiratory medicine outpatient clinic at Al-Imamein Kadhimein Medical City. Patient interviewing and testing period was from the first of December 2014 till 31st of December 2015. **Inclusion criteria:** confirmed asthma diagnosis, age 18 years and above

Exclusion criteria: presence of smoking history, use of supplemental vitamin D, presence of co-morbid chronic condition like chronic renal failure, diabetes mellitus, heart failure and use of prolonged daily systemic steroids in the last year.

Asthma severity and control: the level of control and asthma severity were assessed via the simple questions suggested by Global Initiative for Asthma (GINA)¹ by asking about the frequency of daytime symptoms, night symptoms, use of rescue inhalers and limitation of activity. Patients were grouped as well controlled, partly controlled and poorly controlled. Patients were grouped according to the forced expiratory volume in one second (FEV₁) percentage of predicted into mild intermittent/persistent ($\geq 80\%$ predicted), moderate persistent ($\geq 60\%$ but $<80\%$ predicted) and severe ($<60\%$ predicted).⁽¹³⁾

Spirometry: according to the American Thoracic Society guidelines⁽¹⁴⁾, by a practiced operator using Masterscreen system (Jaeger Co., Höchberg, Germany) at the pulmonary function test laboratory in Al-Imamein Kadhimein Medical City. FEV₁ and forced vital capacity (FVC) were recorded. For those with FEV₁ of less than 70% predicted, reversibility testing using nebulized salbutamol 2.5 mg for 5 minutes and repeating the spirometry testing after 5 minutes was done. Reversibility was documented with both 200 ml increase in FEV₁ and 12% increase in FEV₁.

Vit D level assessment: vitamin D level was determined using Vidas[®] 25 OH Vitamin D Total test (bioMérieux SA, USA) according to the manufacturer recommendation. Levels of < 20 ng/ml considered deficiency, 20 – 29.9 ng/ml considered insufficiency and ≥ 30 ng/ml were considered as sufficient according to the previous recommendations.⁽¹⁴⁾

Other measurements: height and weight were recorded by a trained personnel during spirometry and

the body mass index was calculated using the standard equation weight (kg)/height (m)².

Statistical Analysis : done by SPSS 22 , data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values). Chi square test was used for categorical variables and Pearson's Correlation two tailed test was used for parametric variables. P value was equal or less than 0.05 mean significant results.

Results

50 patients involved in the study, mean age was 48.5 ± 14.05 years (range 19 – 72). There were 35 (70%) females and 15 males (35%). Body mass index (BMI) was 30.72 ± 7.86 (range 15.79 - 53.69). The mean level of vitamin D was (17.66 ± 7.06) ng/ml and range from 8.1 – 39.80 ng/ml. The FEV₁ mean was 1.44 ± 0.63 L with a range from 0.53 to 3.7 L. as in table (1).

Table 1: Age, BMI, FEV₁, FVC and 25 (OH) D level in relation to gender (mean \pm SD)

Variable	Female	Male
Age (mean \pm SD) years	48.17 \pm 14.56	49.27 \pm 14.83
BMI (mean \pm SD)	32.76 \pm 7.90	25.94 \pm 5.4
FEV ₁ (mean \pm SD) L	1.33 \pm 0.46	1.69 \pm 0.88
FVC (mean \pm SD) L	2.07 \pm 1.72	2.34 \pm 0.98
25(OH) level(mean \pm SD) ng/ml	17.01 \pm 6.75	19.16 \pm 7.77

In this study, only 8 patients (16%) had mild persistent asthma, and only 9 patients (18%) had well controlled asthma. Figures 2 and 3 display the control and severity of asthma among this study sample respectively. Regarding treatments used for patients, 34 patients (68%) were using beta agonist inhalers, 19 (38%) were on inhaled corticosteroids (ICS) and 17(34%) on combination ICS and long acting beta agonist (LABA). There was no significant association between the treatment use and the level of 25(OH)D. There is a significant positive correlation between the level of 25(OH)D and FEV₁, $r(50) = 0.772$, $p < 0.001$. There was negative significant correlation between the level of vit D and the number of emergency visits, $r(50) = -0.749$, $p < 0.001$. Other correlations are shown in table 2.

Table 2 - Correlations of parametric variables with 25(OH)D level

25(OH)D correlations		
Variables	Pearson's Correlation (r)	Significance (p)
Age	-0.109	0.452
BMI	0.195	0.174
FEV1	0.772	<0.001
FVC	0.224	0.118
FEV1/FVC	0.557	<0.001
Emergency Visits	-0.749	<0.001
Hospitalizations	-0.465	0.001

The level of asthma control was found to be significantly related to the severity of asthma ($p < 0.001$) with 60 % ($n=30$) of patients having poorly controlled asthma, of whom 86.7% ($n=26$) having severe persistent asthma (Figure 1). In addition, the severity of asthma was significantly related to the status of vitamin D ($p < 0.001$) with 81.8% ($n=27$) of patients with severe asthma having deficiency of 25(OH) (level < 20 ng/ml) (Figure 2). Moreover, the level of control was also significantly related to the status of vitamin D ($p < 0.001$) with 96.7% ($n= 29$) of poorly controlled asthmatics having deficiency of vitamin D (Figure 3).

Figure 1: Level of asthma control and its severity

Figure 2: Level of asthma severity and Vitamin D status

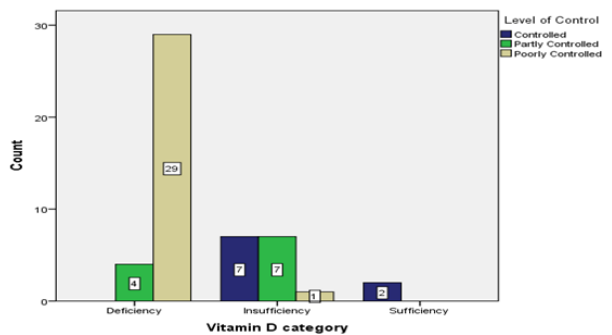

Figure 3: Level of asthma control and Vitamin D status

Mean and SD of levels of 25(OH)D, FEV1, FVC, FEV1/FVC according to the level of asthma severity and control are presented in tables 3 and 4.

Table 3 - means, standard deviations of 25 (OH) D level, FEV1, FVC, FEV1/FVC and patient numbers in relation to the level of asthma control.

Asthma Control Level	25 (OH) level (ng/ml)	FEV1(L)	FVC (L)	FEV1/FVC
Controlled (n=9)	Mean ± SD			
	27.13±6.12	2.1±0.68	2.51±1.01	85.57±10.63
Partly controlled (n=11)	Mean ± SD			
	20.62±4.21	1.67±0.55	2.12±0.59	74.69±8.72
Poorly Controlled (n=30)	Mean ± SD			
	17.66±7.06	1.15±0.45	2.02±1.87	67.00±13.63

Table 4 - means, standard deviations of 25 (OH) D level, FEV1, FVC, FEV1/FVC and patient numbers in relation to asthma severity

Asthma Severity	25(OH)D(ng/ml)	FEV1 (L)	FVC (L)	FEV1/FVC
Intermittent / Mild Persistent	28.71± 5.52	2.2 ± 0.68	2.5 ± 1.06	89.72 ± 9.77
Moderate Persistent	19.9 ± 4.56	1.7 ± 0.54	2.4 ± 0.66	72.97 ± 7.87
Severe Persistent	13.81 ± 4.22	1.1 ± 0.36	1.9 ± 1.85	66.94 ± 13.0

There was no significant association between the age, gender, BMI, the presence of allergic rhinitis and the status of vitamin D level.

Discussion

In this study, high prevalence of vitamin D deficiency and inadequacy among this sample of Iraqi adult asthmatics (96%, n=48). This high ratio is similar to that stated in Chinese (90%) and Costa Rican (90%) adult asthmatics but is higher than that recorded in German adult asthmatics (64%).⁽¹²⁻¹⁴⁾ However, this percentage is much higher than that seen in childhood asthma reported in previous studies; 20% in Iranian, 28% in Costa Rican, 38% in Egyptian, and 44% in Puerto Rican childhood asthmatics.⁽¹⁵⁻¹⁸⁾ These discrepancies between adults and children asthmatics may be related to behavioral variables seen in areas with plenty of sunny days as by avoiding sunlight, dress habits and racial difference in skin color. Importantly, in Iraq the cultural and religious background may play a role in limited sun exposure. Other variables for low vitamin D level like being overweight or female gender can also play a role but there was no significant association. In this study, the level of vitamin D was not associated with markers of allergy; namely the presence of allergic rhinitis used in our study. This lack of association of vitamin D level and markers of allergy has been described in some studies.^(9,12,13) However, such associations have been reported in other studies^(10,14,15,18) These contradicting results may be related to the different populations studied, the difference in allergen exposure between regions and the variability in outdoor exposure to sun in different parts of the world. These findings need cautious interpretation since the sample size is small and the other parameters of allergic response (like IgE level, sputum eosinophilia, allergen specific IgE antibodies, IL-4, and IL-5) have not been studied in this study. The major result of this study was the presence of significant correlation between the levels of vitamin D and the FEV1, FEV1 percent of predicted (as a marker of asthma severity), and FEV1/

FVC ratio (as a marker of airway obstruction), $p < 0.001$ for all parameters. This finding has been recorded in most of the studies in both adults and children.⁽¹¹⁻¹⁹⁾ Moreover, vitamin D level was significantly associated with the level of asthma control, patients with higher level of vitamin D tend to have better asthma control (27.13±6.12 in controlled, 20.62±4.21 in partly controlled and 17.66±7.06 in uncontrolled, $p < 0.05$). This finding was also observed in a cross-sectional studies in Italian children and German adults.^(11,14)

In this study, the risk of emergency department visits and hospitalizations were found to be significantly associated with vitamin D level, $p < 0.001$ for both. These findings are consistent with the results obtained from other studies, both in adults and children.^(9,10, 12-14, 16-18)

However, a causal relationship between asthma and vitamin D deficiency cannot be established due to the sample size and cross-sectional project. In specific, the possibility of reverse causation cannot be eliminated as the patients with severe, poorly controlled asthma are more likely to be home bound with less exposure to sun and may be exposed to frequent steroid rescue courses that might have induced the deficiency state in vitamin D. Additional issue is the selection bias as there was unbalanced male to female ratio (30% males vs. 70% females). However, comparable gender inequality in asthma have been recorded in previous studies conducted on Iraqi adult asthmatics.^(19, 20) Also This study was conducted in a tertiary center and in a specialized respiratory unit, which may not reflect the overall population of asthmatics in Iraq. Additional limitation of this study is the absence of control group of well persons to regulate that the level of vitamin D has a solid association with asthma or this observation of low vitamin D level is just a coincidence.

Conclusion

this study demonstrates that a low level of vit D is related with clinical parameters of poor asthma control plus severe asthma as predicted FEV1.

Determination *Enterococcus faecalis* in Asymptomatic Urinary Tract Infection Associated with Diabetes Type 2 Patients in Suwayrah General Hospital-Iraq

Ibtisam H. Al-Azawi¹, Mohammed H. Abbas²

¹Prof. Dr. /College of Medicine , University of Al-Qadisiyah , Iraq,

²Post Graduate Student/ College of Medicine, University of Al-Qadisiyah, Iraq

Abstract

Background: Asymptomatic Urinary Tract Infection is common in diabetes type-2 patient and predisposes these patients to more severe urinary tract infections (UTIs). Enterococci have been documented to cause infection of the urinary tract and other sites. Although several species of *Enterococcus* have been recognized, *Enterococcus faecalis* has been considered one of the major agents of urinary tract infections.

Objectives: To determine the percentage *Enterococcus faecalis* of ASB , antimicrobial resistance in diabetics and non-diabetics in urine sample and detection of enterococcal surface protein (*esp*) gene .

Method: The study involved a total of 611 participants including 197 diabetes mellitus patients and 414 non-diabetics in Suwayrah-Wasit-Iraq. Mid-stream urine was collected from consented subjects and dipstick , general urine examination and bacterial culture were conducted for each sample. Isolates were identified using standard biochemical tests and VITEK-2 system .

Results: All collected samples are asymptomatic bacteriuria. There was a significant difference in the percentage of asymptomatic bacteriuria (ASB) between diabetics and non-diabetics ($P = 0.010$). There was no significant difference in resistance between diabetics and non-diabetics ($P > 0.05$). *Enterococcus faecalis* isolates showed (50%) resistance to Erythromycin and Levofloxacin. The *esp* gene was observed in all *Enterococcus faecalis* isolates .

Conclusion: The females of age more than 60 years old have the higher percentage of asymptomatic UTI. Erythromycin and Levofloxacin were more resistance in Enterococci isolated .

Keywords: Diabetes mellitus, percentage, asymptomatic bacteriuria, antimicrobial resistance.

Introduction

Diabetes type-2 has been recently associated with urinary tract infections. The mechanism of pathogenesis for this association is not fully elucidated , however, it is suggested that high glucose concentration in urine may favor the growth of pathogenic microorganisms and stimulate urinary tract infection⁽¹⁾ . Asymptomatic bacteriuria is a form of UTI characterized by the presence of significant amount ($>10^5$ cfu/ml) of bacteria in urine ⁽²⁾.

Several studies have documented the association of asymptomatic UTIs with diabetes; however, reports on the prevalence of ASB appear contradictory ⁽³⁾.

Most studies reported the percentage to be higher in people with diabetes than people without diabetes (4). On the contrary, another study reported no significant difference in the percentage of ASB between diabetic and non-diabetic ($P > 0.05$) ⁽⁵⁾, others report that *Enterococcus spp.* are more often associated with UTI among diabetics and cause 13% of asymptomatic bacteriuria in diabetics compared to 4.9% in non-diabetics ⁽⁶⁾.

The incidence of urinary tract infections due to *Enterococcus faecalis* has risen steadily over the years and *Enterococcus faecalis* urinary tract infection now outnumbers *Enterococcus faecium* urinary tract infection 5:1 ⁽⁷⁾.

Recent results indicate that *Enterococcus faecalis* can not only adhere to epithelial cells in the urinary tract, but also invade cells, leading to formation of intracellular bacterial communities in the bladder. The combination of these multiple virulence mechanisms, the ability to survive in harsh conditions, and both intrinsic and acquired resistance to many antibiotics explains the high frequency of infection by *Enterococcus faecalis* ⁽⁸⁾.

The enterococcal surface protein (Esp) is a high-molecular-weight surface protein of unknown function whose frequency is significantly increased among infection-derived *Enterococcus faecalis* isolates. Esp is another surface protein and has been shown to promote colonization and persistence in bladder (but not kidneys) Esp also influences, at least in some strains, biofilm formation in vitro ⁽⁹⁾.

Method

This work has applied on 611 asymptomatic UTI patients (197 of them had diabetes mellitus and 414 were non-diabetic), 208 males and 403 females, their ages ranged from 20 – 70 years old attended to emergency and consulting unite in the Suwayrah general hospital in Wasit province during the period from November 2018 to October 2019. Out of 197 asymptomatic UTI diabetic patients, seven showed *Enterococcus faecalis* culture results. And five out of 414 asymptomatic non-diabetic patients showed *Enterococcus faecalis* culture results which considered as a control group.

The study participants were educated on how to collect a “clean-catch” midstream urine specimen and the importance to avoid contamination. They were advised on washing of hands prior to collection and labia separation, especially in females. Participants who had difficulties collecting their specimens were assisted by trained personnel. Urine samples were collected into sterile containers, placed in a cool box (0 °C) and transported to the laboratory within 2 hours. The samples were then stored in a refrigerator and analysed within 8

hours of collection. Each sample was separated into two parts under sterile conditions; one part for urinalysis and the other for culture. The dip stick test was performed using urine test strips as described by the manufacturer (Condor-Teco, Beijing, China). Wet preparation of centrifuged urine was observed using 40 times objective lens to detect blood, pus and other cells. A calibrated 10µl wire loop was used to inoculate uncentrifuged urine into MacConkey, blood and plates incubated aerobically at 37°C for 24 hours. Significant ASB was defined as urine culture of > 10⁵ cfu/ml without symptoms of cystitis. Isolates were identified using standard biochemical techniques and VITEK-2 System .

Antimicrobial susceptibility testing was performed with the automated VITEK-2 compact system by using AST-P580 cards. These included; Levofloxacin ,Erythromycin , Linezolid ,Teicoplanin ,Vancomycin ,Tetracycline ,Tigecycline and Nitrofurantoin (BioMérieux , France).

The PCR technique was also used detection virulence gene of *Enterococcus faecalis* after DNA Extraction from all bacterial isolates.

Results

Of the 611 participants enrolled into the study 208 were males while 403 were females. Majority of participants were in the age group more than 60 years , while the least age range was less than 40 years as showed in Table (1). The overall percentage of ASB in this study was (1.96 %). There was a significant difference in the percentage of ASB between diabetics and non-diabetics (P = 0.010) .

Table 1 shows the distribution of ASB with respect to age and sex. There was no significant difference in the distribution of ASB with age (P = 0.357) among the study participants. However, women demonstrated a higher percentage than men in both diabetic and non-diabetic groups.

Table 1: Distribution of *Enterococcus faecalis* asymptomatic UTIS with respect to age and sex .

Age	No.	Diabetics with ASB No. (%)	Non-diabetics with ASB No. (%)	Total with ASB No. (%)
Sex				
20-30 year	102	0(0 %)	0(0 %)	0(0 %)
30-40 year	130	1(0.77 %)	1(0.77 %)	2(1.54 %)
40-50 year	121	1(0.82 %)	1(0.82 %)	2(1.64 %)
50-60 year	120	2(1.66 %)	1(0.84 %)	3(2.5 %)

enterococcal surface protein (*esp*) virulence gene of *Enterococcus faecalis* was detected in all 12 *Enterococcus faecalis* isolates showed in Figure (1).

Figure (1) : Agarose gel electrophoresis (1.5%) showing PCR product of a partial fragment of *esp* gene under U.V. light after staining with ethidium bromide. M: 100 bp marker; lane 1-12: *Enterococcus faecalis* isolates. The size of product is 887 bp.

Discussion

The association of diabetes mellitus and urinary tract infections is increasingly being reported. Especially, infection by *Enterococcus* bacteria. Asymptomatic bacteriuria is common among diabetic patients and may lead to serious complications if not properly managed⁽¹⁰⁾. ASB has been identified as a risk factor for acquiring symptomatic UTIs especially in diabetic women⁽¹¹⁾. UTIs are more severe in diabetic patients involving life-threatening complications such as emphysematous pyelonephritis and renal papillary necrosis. The present study revealed an overall percentage of ASB of 1.96%; 4.06% in diabetics and 0.96% in non-diabetics (table 1).

This result is concurrent with that of earlier reports which recorded prevalence of high percentage in diabetics and low percentage in non-diabetics⁽¹³⁾. In other earlier reports which recorded percentage low percentage in diabetic and high non-diabetic⁽¹⁴⁾. Consequently, the issue of prevalence of ASB remains debatable. This

inconsistency has been attributed to variations in sample size, geographical location, culture or screening method. In the present study, ASB was significantly higher in diabetics than non-diabetics ($P = 0.010$). This is in line with majority of previous reports⁽¹²⁾. However, it is suggested that high glucose concentration in urine may favor the growth of pathogenic microorganisms and stimulate urinary tract infection⁽¹⁵⁾. The females are more susceptible to UTI than males, because their urethra is shorter and closer to anus more than in males, so that the intestinal flora which may ascend to urinary tract and cause UTI⁽¹⁷⁾. The most affected age group in females were these of more than 60 years, it may be due to Estrogen deficiency, diabetes mellitus, gynaecological diseases (cystocele) and operations, urological diseases (incontinence, residual urine, cystopathy), operations, immunological changes and diabetic cystopathy⁽¹⁸⁾.

Results of the antibiotic susceptibility test revealed no significant difference ($P > 0.05$) in the resistant

pattern between diabetics and non-diabetics (Table 2). Resistance to Levofloxacin and Erythromycin may be due its frequent use in our study area to treat UTIs and other infectious diseases ⁽¹⁶⁾.

In figure (1) , shows all isolated have *esp* gene , the ability of enterococci to adhere the epithelial cells of urinary tract is a key initial step in UTI pathogenesis due to encoded by the *esp* gene facilities colonization and persistence of *Enterococcus faecalis* in urinary tract infections ⁽¹⁹⁾.

Conclusion

The study revealed diabetic patient have a higher percentage of asymptomatic UTI than non-diabetic patients. Females of age more than 60 years old have the higher percentage of asymptomatic UTI. Erythromycin and Levofloxacin were more resistance in *Enterococcus* isolated . Therefore the need to speed up sensitization against antibiotic abuse in Suwayra -Wasit – Iraq.

Acknowledgement: We would like to thank all the diabetic patients and healthy volunteers who consented to take part in this study. Our sincere gratitude also goes to the management and Staff of all the Suwayrah general hospital especially Microbiology laboratory where samples were collected. We also acknowledge the material and technical support of the Department of Microbiology and Parasitology, College of Medicine - University of Al-Qadisiyah -Iraq.

Oral Desmopressin as an Add-on Therapy for Men with Benign Prostate Hyperplasia they Suffering from Persistent Nocturia

Firas Alquraishi¹ Saif H. Mohammed¹, Yasser Al-Hakeem¹

¹Lecturer, PhD. surgery Department, Al-Nahrain University/College of Medicine/Iraq

Abstract

Background: men with benign prostate hyperplasia suffer from urinary tract infection especially in lower part of the tract and common manifestation of this infection is nocturia. Treatment of nocturia depends mainly on α -blockers; however, these drugs have limited success in relieving this symptom. **Aims:** This study aims to assess the efficacy of desmopressin (0.2mg) as an add-on therapy with α -blockers in relieving refractory nocturia for men with BPH. **Patients and Methods:** Inclusion criteria for this prospective, non-randomized, open-label trial included men ≥ 60 years old with LUTS due to BPH; a total IPSS of ≥ 14 points; and persistent nocturia with ≥ 2 voids/night despite using α -blockers for at least 10 weeks prior to inclusion. Patients with diabetes mellitus, known neurogenic bladder dysfunction, uncontrolled hypertension, congestive heart failure, and those using diuretics were excluded from the study. Fifty one patients were included and categorized into two groups; those who continued on α -blocker treatment (n=22), and those for whom oral desmopressin (0.2 mg) was used as an add-on therapy (n=29). After four weeks of treatment, the International Prostate Symptom Score (IPSS), storage and voiding subs-scores, nocturia episodes, maximal flow rate (Q_{max}) and bother score were measured and compared with their respective baseline values. **Results:** there were no difference significantly between the two groups in all measured demographic and clinical parameters (all p -values > 0.05). After four weeks of treatment, the total IPSS, storage sub-score, nocturia episodes, and bother score were all significantly better in the group were desmopressin add-on (P-values ≤ 0.05). No significant differences were observed in the voiding sub-score and Q_{max} value between the two groups (both p -value > 0.05). **Conclusion:** adding desmopressin to α -blockers is active therapy for men with BPH and suffering nocturia and no initial response to α -blockers.

Keywords: nocturia, desmopressin, benign prostate hyperplasia, lower urinary tract infection

Introduction

Benign prostatic hyperplasia is one of the most common causes of lower urinary tract symptoms (LUTS) in ageing men. BPH can cause nocturia via different mechanisms including detrusor overactivity and a high post void residual (PVR), both of which can result in decreased voiding volume and frequent voiding ⁽¹⁾. However, LUTS is not the sole cause of nocturia. Rather, nocturia is considered as a multifactorial condition and five main causes have been identified including nighttime polyuria, worldwide polyuria, decrease bladder volume, sleep problems and circadian clock illnesses ⁽²⁾. It is very common to find a patient with more than one of these factors involved ⁽³⁾. Nocturia is a critical condition that

necessitates clinical attention. Persistent nocturia can result in chronically disturbed sleep, with a negative effect on patient's class of life (QoL) and general health. In elderly, frequent voiding during night can particularly expose the patients to slipping and fractures ⁽⁴⁾. Moreover, the impact of nocturia extends beyond being a medical issue. For example, the annual direct cost of managing nocturia in Germany, including the costs of medical consultations, investigations, medicines and treatments of falls and fractures, is about 2.32 billion euros and the annual indirect costs, by loss of labor due to diminished efficiency or absence at the workplace, is about 20.76 billion euros ⁽⁵⁾. The treatment approaches for nocturia usually depends on pharmacological therapy

that is assigned principally for BPH, namely α -blockers, 5α -reductase inhibitors, and anticholinergics. However, in most cases with BPH, using these drugs is not associated with satisfactory results in reducing voiding frequency⁽⁶⁾. Thus, this study aims to assess the efficacy of desmopressin (0.2mg) as an add-on therapy with α -blockers in relieving refractory nocturia for men with BPH.

Patients and Method

A prospective study for four weeks single center, open-label, non-blinded comparative study. Inclusion criteria were men ≥ 60 years old with LUTS due to BPH; a total IPSS of ≥ 14 points; and persistent nocturia with ≥ 2 voids/night despite using α -blockers for at least 10 weeks prior to inclusion. Patients with diabetes mellitus, known uncontrolled hypertension, neurogenic bladder dysfunction, congestive heart failure and those using diuretics were excluded from the study. From February 2018 to February 2019, patients who attended the Urosurgery department at Al-Imamain Al-Kadhumain Medical City in Baghdad were assessed for inclusion. After excluding ineligible cases, a total of 51 patients were included and assigned into two groups, those who remained on an α -blocker (n=22), and those who received oral desmopressin 0.2 mg add-on therapy with an α -blocker (n=29). All included patients were assessed

at baseline and after four weeks for IPSS, including storage and voiding sub-scores, as well as bother scores and Q_{max} levels. A consent form explaining the aims of the study was obtained from all patients. The study was approved by the ethical committee of Al-Imamain Al-Kadhumain Medical City. **Statistical Analysis:** Statistical Package for Social Sciences (SPSS) was used for data analysis. Paired student t-test was used to compare means of total IPSS, voiding and storage sub-scores, and Q_{max} at baseline and 4 weeks after the onset of treatment within the same group, while independent t-test was used to compare the means between the two groups. A p-value of ≤ 0.05 was considered as significant.

Results

Baseline Characteristics of the Patients: continuous data were subjected for normality test (Shapiro Wilk test) and were found to be normally distributed. The mean age and stander deviation of the patients on α -blockers alone is (63.95 \pm 10.15) years compared to (62.43 \pm 10.72) years for those patients using desmopressin add-on with no significant difference (P-value = 0.607). Likewise, no significant differences between the two groups in IPSS total score, storage and voiding sub-scores, nocturia episodes, bother score, PSA level, prostate size and Q_{max} (all P-values >0.05) (Table 1).

Table 1: Baseline characteristics of patients

Variables	α -blocker alone (n=22)	Desmopressin add-on (n=29)	p-value*
Age (years)	63.95 \pm 10.15	62.43 \pm 10.72	0.607
IPSS total score	24.18 \pm 3.69	25.75 \pm 4.94	0.221
IPSS voiding sub-score	11.8 \pm 1.8	12.1 \pm 2.4	0.306
IPSS storage sub-score	13.1 \pm 1.9	13.65 \pm 2.6	0.903
Nocturia episodes	3.95 \pm 0.78	4.0 \pm 0.75	0.835
Bother score	4.64 \pm 1.0	4.52 \pm 1.05	0.685
PSA (ng/ml)	1.7 \pm 1.0	1.66 \pm 0.98	0.874
Prostate size (cm ³)	52.5 \pm 13.86	54.11 \pm 12.97	0.675
Q _{max} (ml/s)	17.68 \pm 5.54	15.59 \pm 4.32	0.135

Data presented as mean \pm SD; IPSS: international prostatic symptom score;

PSA: prostate specific antigen; Q_{max}: maximum urine flow rate

*Using independent sample t-test.

Effect of desmopressin add-on on IPSS scores, bother score, and Q_{max}:

As seen in table (2), when each treatment group was assessed separately before and after treatment, the total IPSS, storage sub-score, voiding sub-score, bother score, and nocturia episodes were significantly lower following treatment in both groups (all p-values ≤0.05). However, Q_{max} values were significantly higher only in the desmopressin add-on group (p-value=0.025). In a head-to-head comparison for the same parameters following four weeks of treatment (table 2), the mean IPSS

score for the desmopressin add-on group (14.07±3.66) was significantly lower than that of α-blocker alone group (17.09±4.5), with P-value of (0.012). Similarly, desmopressin add on-treated group had a better IPSS storage sub-score compared to α-blocker alone group (6.92±1.71 vs. 7.98±2.87, P-value 0.018), with a significantly lower bother score (2.83±0.96 vs. 3.91±1.19, P-value 0.001) and a significantly less nocturia episodes (1.59±0.82 vs. 3.32±0.99, p-value 0.0001). On the other hand, there was no significant difference between the two groups in the voiding sub-score (P-value 0.366) and Q_{max} (P-value 0.074).

Table (2): Effects of desmopressin add-on on IPSS scores, sub-scores, and Q_{max}

Variables	Status	α-blocker alone	Desmopressin add-on	p ^(a) -value
IPSS total score	Baseline	24.18±3.69	25.75±4.94	0.012
	After treatment	17.09±4.5	14.07±3.66	
P^(b)-value		< 0.001	< 0.001	
IPSS voiding sub-score	Baseline	11.8± 1.8	12.1±2.4	0.336
	After treatment	9.12±2.7	7.15±2.2	
P^(b)-value		<0.001	<0.001	
IPSS storage sub-score	Baseline	13.1± 1.9	13.65±2.6	0.018
	After treatment	7.98±2.87	6.92±1.71	
P^(b)-value		<0.001	<0.001	
Nocturia episodes	Baseline	3.95±0.78	4.0±0.75	0.0001
	After treatment	3.32±0.99	1.59±0.82	
P^(b)-value		0.001	0.0001

Discussion

For greatest knowledge, this study is the first study that show usage of desmopressin in management of patients with benign prostate hyperplasia and suffering from nocturia. The current results confirms the efficiency of desmopressin as an add-on therapy in the alleviation of nocturia through reducing the total IPSS, storage sub-score, nocturia episodes, and bother score after four weeks of treatment compared to those treated with an α -blocker alone. Several previous studies have reported similar findings.

Shin et al. (2014) enrolled 405 men with persistent nocturia due to BPH in a large prospective randomized trial to investigate the role of desmopressin (0.2 mg) as add-on therapy in reducing LUTS in those patients. It was found that the number of episodes of nocturia, nocturnal urine volume, and nocturnal index were significantly decreased using an α -blocker plus an antidiuretic agent (7). In a cross sectional study including 136 patients, Chen et al. (2016) reported that long-term treatment with low dose desmopressin, 0.05 mg increased to 0.2 mg as required, was effective in the treatment of nocturia in Chinese patients with LUTS/BPH with or without nocturnal polyuria (6). In another study, Kim et al. (2017) divided a total of 86 men with persistent nocturia in spite of the usage of α -blocker therapy for 8 weeks into two collections, one of this collection of patients treated with desmopressin (0.2 mg) and another collection of patients take placebo. The desmopressin added group was significantly improved when compared with placebo group in the no. of nocturnal occurrences, nighttime urine volume, entire IPSS, nocturnal polyuria index, and International Consultation on Incontinence Questionnaire score. Furthermore, the authors found that the adverse events in desmopressin add-on group were not different from that in the placebo group. Regarding QoL, no significantly differences between 2 groups in the variation of IPSS QoL score, so the International Consultation on Incontinence Questionnaire-Nocturia Module (ICIQ-N) agreed with this results that there was significant improved when used desmopressin add-on compared to the group not used it (8). More recently, Taha et al. (2018) published a systematic review that included 3072 patients with BPH/LUTS and persistent nocturia. The study demonstrated that a combination of α -blockers and desmopressin add-on resulted in a 64.3% reduced in the occurrence of nocturnal voids compared to 44.6% of patients used α -blockers a lone (9). On the other hand, a Turkish study by Koca et al

(2012), which is similar to our study, found that there was no significant difference in terms of IPSS, Q_{max} , and QoL between alfuzosin-alone and desmopressin add-on treatment after a treatment duration of three months, although both groups had a significant improvement in these parameters when compared to their baseline measurements (10). The effect of desmopressin can be explained by the fact that in most cases nocturia is considered as an associated condition within LUTS, and accordingly treated with drugs allocated for BPH or overactive bladder. Usually, these drugs include α -blockers and (or) 5 α -reductase inhibitors. However, the response to such treatment was not satisfactory in most cases which could be due to the multifactorial nature of nocturia (6). Furthermore, nocturia can be improved by some behavioral performs such as decreasing fluid intake at bedtime, thus several non-pharmacological factors can interfere with the drug activity (Km et al., 2017). Desmopressin acetate (Minirin®) is an artificial equivalent of arginine vasopressin, alike antidiuretic action but have no vasopressor actions. Have active effects in the management of conditions with polyuria: such as primary nighttime enuresis and essential diabetes insipidus. Therefore, it can be expected to possess a dual activity when it is used as an add-on therapy beside α -blockers in reducing nocturia as well as other LUTS (11). Collectively, these data support the use of oral desmopressin (0.2 mg) as an add-on treatment to α -blockers for the management of men with BPH/LUTS they suffering from refractory nocturia. The present study has limitations including: absence of blinding and randomization, small sample size, the lack of input from a bladder diary or from a nocturia-specific questionnaire and not addressing the side effects of desmopressin. Further studies that include women with LUTS are required to popularize the use of desmopressin as essential element for treatment of this disorder.

Conclusions

Adding desmopressin to α -blockers is active therapy for men with BPH and suffering nocturia and no initial response to α -blockers.

The Practicing and Attitude of Some Medical Students at Al-Nahrain College of Medicine Towards Cosmetic Rhinoplasty

Nibras Alaa Hussain¹ Qais Ismaeel Kadhem², Ashraf MA Hussain³

¹FIBMS, MBChB; Al-Nahrain University/College of Medicine/ Family & Community Medicine Department/Iraq, ²Family and Community Department, College of Medicine , University of Babylon/Iraq, ³PhD Community, Family and Community Department, College of Medicine, University of Babylon/ Iraq

Abstract

Background: Rhinoplasty in universal is connected with cosmetic surgery carried out to produce alterations in the interior and exterior components on the nose for merely cosmetics good reasons to get better look. It was common cosmetic procedures around the world because the nasal deformities effect on the psychology of the person as a negative impact on their self-confidence and social interaction with others.

Objectives: The study is an attempt to display the practicing and attitude of some medical students towards cosmetic rhinoplasty and its relation to some studied variables.

Methods: A cross-sectional study was conducted at Al-Nahrain medical college, during March 2016. A total of 200 undergraduate students were given a semi constructed questionnaire .The sample selected randomly by systematic random sampling.

Results: The practicing of rhinoplasty among this sample was 10.5%. Most of them happy with their nose appearance. 56.5% of the sample see this surgery socially accepted in Iraq. There was significant relation between person undergoing rhinoplasty and presence of family history of it.

Conclusion: More than half of the medical student found cosmetic rhinoplasty is socially accepted in Iraq. Despite the majority of them had no family history of undergoing rhinoplasty but there was significant difference between doing such surgery and the presence of family history. More than two third of the students included in this study like more awareness program on cosmetic surgery.

Recommendation: Encouragement for more studies to be done for this subject, and developing an educational program to increase awareness about rhinoplasty.

Keywords: *rhinoplasty, attitude, cosmetic.*

Introduction

Among males and females the nose aesthetic is become occupied, the nose due to it's central prominent part of the face, so when the nose is taller than other facial part of face or not complement the face, it can affect self-perception and confidence.⁽¹⁾

Rhinoplasty in universal is connected with cosmetic surgery carried out to produce alterations in the interior and exterior components on the nose for merely cosmetics good reasons to get better look.⁽²⁾

Currently there is always a developed picture attention among a variety of racial and ethnic communities around the world. Possibly because individuals living longer, a larger feeling of self-stem driven by way a person's looks are suffering from, ⁽³⁾ and the nasal deformities effect on the psychology of the person as a bad effect on their self-confidence and public communication with others ⁽⁴⁾. Rhinoplasty presently increasing everywhere in the world, particularly in the Gulf countries, according to the statistics done worldwide; it is become the fifth most usually done plastic technique international.⁽⁵⁾ While

in Saudi Arabia it is the second most common plastic surgery.⁽⁶⁾

Plastic rhinoplasty customized to repair, reconstruct or replace any physical defect due to: (Birth disorders, Trauma, Burns, Developmental abnormalities, Infections, Tumors, Preference and self-choice).⁽⁷⁾

Complications of Rhinoplasty include: (Complications of anesthesia. Epistaxis, Septal perforation and hematoma, Unsatisfactory appearance and deformity, Infection, Worsening rather than improvement in shape or in the nasal functions).⁽⁸⁾

In Iraq despite their lifestyle was largely dedicated by costumes, traditions and some religious interpretation, there has been growing interest in the past few years in cosmetics procedures, especially in rhinoplasty. And their plastic surgeons have gained huge experiences and skills in reconstructive and cosmetic surgery to help rehabilitate many thousands of people wounded by bombs or bullets.⁽⁹⁾

Subjects and Method

A cross-sectional study was adopted at Al-Nahrain College of medicine. The sample selected randomly by systematic random sampling and choose 200 students, during March and April 2016, were given a semi constructed questionnaire especially prepared for this study and collected by the fourth year students, which include **Demographic information** e.g. age in years, gender, stage order, father and mother education in years and **attitude questions like:**

(How do you feel about your nose?, In the past , Have you had cosmetic Rhinoplasty ?, Do you think cosmetic Rhinoplasty are necessary ?, Family history of having cosmetic procedures?....)

Data was translated into a computerized data base structure .Statistical analysis was done by using SPSS Version (20) computer software and Microsoft Excel 2010 used to draw figures present in this study .

Table(1):- Attitudes of the sample of Al-Nahrain medical students towards cosmetic rhinoplasty .

Questions	Attitude	Numbers (%)
1- feeling about Your nose	Happy	96 (48%)
	Not happy	37 (18.5%)
	Don't care	67 (33.5%)

Verbal consent was taken from all participants before they answered the questionnaire.

Result

Among 200 students there were 86 (43%) males and 114 (57%) females. The percent of students whom practicing rhinoplasty among this sample was 10.5%. See figure 1

Figure-1- The percent of students whom practicing rhinoplasty among the sample from Al-Nahrain medical students,2016.

-All college stages were included in this study according to their total numbers, first stage= 33(16.5%), second stage 37(18.5%), third stage 39(19.5%), fourth stage 34(17%), fifth stage 30(15%) and sixth stage 27(13.5%). See figure -2-

Figure-2- Distribution of the sample according to the student's stages in Al-Nahrain medical college, 2016.

-The age of the study group ranged (17 – 25) years with mean ± SD (21.2 ± 1.76)years.

-Concerning the questions about the attitudes of AL-Nahrain Medical Students towards cosmetic rhinoplasty. See table 1

Cont... Table(1):- Attitudes of the sample of Al-Nahrain medical students towards cosmetic rhinoplasty .

2- any previous cosmetic Rhinoplasty?	Yes No	21 (10.5%) 179 (89.5%)
3-are rhinoplasty necessary?	Yes No Not sure	57 (28.5%) 76 (38%) 67 (33.5)
4-any family history of cosmetic intervention?	Yes No	30 (15%) 170 (85%)
5-your friend has previous cosmetic surgery?	Yes No	102 (51%) 98 (49%)
6- you embarrassed from cosmetic procedures if anybody identified about it?	Yes No	59 (29.5%) 141 (70.5%)
7- You support your friends experiencing cosmetic procedures if they told you?	Yes No Uncertain	96 (48%) 51 (25.5%) 53 (26.5%)
8-If cosmetic surgeries were done free, would you go for any cosmetic operation ?	Yes No Not sure	55 (27.5%) 94 (47%) 51 (25.5%)
9-If you were cognizant that somebody did cosmetic surgery, this effect on relationship with him?	Yes No Not sure	16 (8%) 141 (70.5%) 43 (21.5%)
10-it is socially accepted in Iraq?	Yes No Not sure	113 (56.5%) 29 (14.5%) 58 (29%)
11-If (10) yes, to how much it is acceptable?	Widely Averagely Not acceptable	29 (14.5%) 135 (67.5%) 36 (18%)
12-any awareness program on cosmetic operation ?	Yes No Not sure	142 (71%) 32 (16%) 26 (13%)

Comparing students, who had rhinoplasty and those had not:-

There was no significant association regarding the gender of the students and the history of doing rhinoplasty (P=0.36). See table (2).

-Table (2) Rhinoplasty according to the gender of Al-Nahrain medical students.

Gender	Do rhinoplasty	Don't do rhinolasty	Total	Significance
Male	11 (12.8%)	75 (87.2%)	86(100%)	X ² = 0.842 P=0.36
Female	10 (8.8%)	104 (91.2%)	114(100%)	

-While there was significant difference between gender of students and the attitude of their relation with a person who undergo rhinoplasty (P=0.002). See table (3).

Table (3) Negatively effect of operation on the student relation according the gender.

Gender	Yes	No	Not sure	Total	Significance
Male	13 (15.1%)	60 (69.8%)	13 (15.1%)	86(100%)	X ² = 12.422 P= 0.002 2
Female	3 (3.6%)	81 (71.1%)	30 (26.3%)	114(100%)	

-Finally there was significant relation between undergoing rhinoplasty and the presence of family history of doing such surgery at (P= 0.002). See table (4).

Table (4) Family history association of undergoing rhinoplasty and doing such surgery.

	Family history	No family history	Total	Significance
Had rhinoplasty	8 (38.1%)	13 (61.9%)	21 (100%)	X ² = 9.816 P= 0.002 Df= 1
Had not rhinoplasty	22 (12.3%)	157 (87.7%)	179 (100%)	

Discussion

The concerning about the appearance is progressively increase both in the developed and the developing countries, so this lead to increase in cosmetic surgeries done yearly⁽¹⁰⁾. The mean age of student involved in our study was similar to study done by Ahmed M... et al in Pakistan⁽¹¹⁾ and by Tanthry D...et al in India⁽¹²⁾, this is due to the sample take in our study and samples of them is taken from the college whom their age closely in the same variety.

The prevalence of rhinoplasty was 10.5% in this study and this more than the global percentage 8.2%⁽⁵⁾ and this may be due to selection of the sample from medical students whom more aware about this surgery, also the age of them which had tendency to do such procedure.

Regarding their satisfaction about their nose appearance, it was found that less than half of the sample were happy about their nose appearance like what was found in Iran Aliasghar M...et al.⁽⁸⁾

Most of the students included in this study see rhinoplasty surgery as not necessary like what Rozin... et al found, as they preferred the natural things over unnatural things.⁽¹³⁾

The majority of this sample 70.5% were not embarrassed about undergoing cosmetic procedures and this like what was found in London by Swami V ...et al.⁽¹⁴⁾.

Regarding socially acceptance of rhinoplasty more than half found it socially accepted in Iraq and this like what found by Swami V.et al.⁽¹⁴⁾This may represent the opinion of medical students and not all Iraqi's people. Concerning the students relationship with a person undergoing rhinoplasty, about two third of them their relation were not affected negatively ,and this like what found by Swami V...et al in London,⁽¹⁴⁾ while Delinsky in United States found there was a negatively affect on relationship with such person.⁽¹⁵⁾

Less than third of the included students in this study like to do cosmetic surgery if it was done free in Iraq, and this nearly like what found by AL Mohanna Sh. ... et al in Saudia Arabia.⁽¹⁶⁾

2/3 of the defendants suggested the need for more consciousness of beautifying operation in the culture like what was originate in Nigeria by Opeyemi A.... et al in 2014.⁽¹⁷⁾

Regarding the gender there was no significant difference in doing rhinoplasty and this like what found in Nigeria,⁽¹⁷⁾ while in other study done in Saudia found significant relation between both gender⁽¹⁶⁾ and this may be due to take the sample whom had nearly same socio-demographic and educational levels.

Also there was significant relation between male and female according to their relationship with a person who undergo rhinoplasty, this like what Swami V. ... et al.⁽¹⁴⁾

Finally this study found a significant relation between doing rhinoplasty and the presence of the family history of rhinoplasty and this like what was found in Iran ⁽⁸⁾ and in Saudia. ⁽¹⁶⁾ And this means friends and relatives influence a major motive for undergoing cosmetic rhinoplasty.

Conclusion

As the number of rhinoplasty operations are increase, so further research concerning the reason of this increase. It also recommend doing more movements to increase consciousness toward rhinoplasty problems.

The Level of Serum Progesterone on the day of HCG Administration in Assisted Reproduction Cycles

Adnan A.H. Albdairi¹, Hanan Khudheir Hussein²

¹Teeba IVF Center/Ministry of Health/Iraq, ²College of Medicine, University of Babylon/Iraq

Abstract

Introduction: During stimulated IVF- ET cycle spontaneous LH surge occur in about 20 – 50 % of cycle stimulated with gonadotropin without the pituitary suppression of GnRH agonist. This has been related to maturation and recovery of oocyte together decrease fertilization and implantation rate, this spontaneous LH surge is associated with increase in serum progesterone , so without pituitary suppression with GnRH , the rise of serum progesterone in the per ovulatory period may indicate the occurrence of spontaneous of LH surge, the aim of study is to indicate cutoff point of progesterone in the day of HCG administration. **Method:** This was a retrospective, non-interventional cohort study of patients undergoing ICSI at Tiba infertility center in Babylon, from period 2015 - 2019, all patient age from 20 – 45 years old under long protocol, had at least one grade I embryo transferred, total amount of patients was 1457. At second day of menstrual cycle we stimulate by used recombinant FSH, measured on second day of menstruation serum FSH, LH and estrogen levels, transvaginal ultrasound used to monitored the follicles. when follicle became 14 mm in size we used antagonist. 3 or more follicles gotten 18 mm in diameter. Activation gave either hCG alone or mixture of hCG and agonist. After 14 days from embryo transfer we checked HCG and after that after 10 days transvaginal ultrasound was done. **Results:** In our study showed the significant association between positive pregnancy outcome and progesterone level at day of HCG trigger were 79.2 % of female with positive pregnancy at progesterone level < 1.5, while 9.3 % of female with positive pregnancy at progesterone level > 2.5, There is a significant differences of LH at day of HCG activate rendering to progesterone level day of HCG activate, progesterone level (< 1.5) had more chief level at day of HCG activate with mean and SD (5.38 ± 2.52), and reduction when the level progesterone rise. **Conclusion:** pregnancy cannot depend on progesterone level at day when HCG administration for assisted reproduction cycles treated with GnRH agonists and gonadotrophins. So cutoff point of progesterone can reach to above 1.5 ng/ ml and expected of pregnancy at this level.

Key word: *serum progesterone , HCG , IVF, estrogen, HCG trigger.*

Introduction:

During stimulated IVF- ET cycle spontaneous LH surge occur in about 20 – 50 % of cycle stimulated with gonadotropin without the pituitary suppression of GnRH agonist (1,2). This has been related to maturation and recovery of oocyte together decrease fertilization and implantation rate (3–5), this spontaneous LH surge is associated with increase in serum progesterone , so without pituitary suppression with GnRH , the rise of serum progesterone in the per ovulatory period may indicate the occurrence of spontaneous of LH surge (6), with the use of GnRH agonist to suppress pituitary gonadotropin increase in serum progesterone in the day of HCG administration has been reported sporadic cases (7), in such cases the usage of plasma progesterone as a conception predictor is controversial with some studies reported that peri- ovulatory rise in progesterone has negative outcome, some studies reported that peri-ovulatory rise in progesterone has negative outcome in pregnancy rate during assisted reproductive cycle (8,9), while other studies disagree and consider the rise in progesterone in the daytime of HCG management as unconnected to the proportion of pregnancies in assistant reproductive cycles(7), premature progesterone elevation during IVF cycles and its effect of endometrium respectively (10–12), the exact mechanism of peri-ovulatory plasma progesterone increase during stimulation IVF cycle is not fully clear as the rise proceeds the HCG administration for the final maturation of

oocyte and is not associated with LH surge during IVF cycles relatively high dose of exogenous FSH require to achieve multiple follicular maturation (13), some study contribute the premature progesterone elevation FSH stimulation (14,15). Recently publish study on sample of humen ovary cortices shows that FSH stimulate the enzymatic activity of 3B- HSD which are salting increase conversion of progesterone to progesterone (16). Different cutoff points have been used to difine the progesterone elevation during stimulation IVF cycle that is range from 0.8 – 2 ng / ml (10,17), significant decrease in pregnancy rate with 1.5 ng/ ml or above progesterone level at the day of HCG administration (18,19). The aim of study is to indicate cutoff point of progesterone in the day of HCG administration.

Materials and Method

This was a retrospective, non-interventional cohort study of patients undergoing ICSI at Tiba infertility center in Babylon, from period 2015 - 2019, all patient age from 20 – 45 years old under long protocol, had at least one grade I embryo transferred, total amount of patients was 1457. At second day of menstrual cycle we stimulate by used recombinant FSH, measured on second

day of menstruation serum FSH, LH and estrogen levels, transvaginal ultrasound used to monitored the follicles. when follicle became 14 mm in size we used antagonist. 3 or more follicles gotten 18 mm in diameter. Activation gave either hCG alone or mixture of hCG and agonist. After 14 days from embryo transfer we checked HCG and after that after 10 days transvaginal ultrasound was done, pregnancy occur when at least one gestational sac and detectable cardiac pulse. Progesterone measurement on the day of hCG administration. Samples were tested with electrochemiluminescence immunoassay. Statistical analysis: Progesterone 1.5 ng/ ml; this cut-off on the day of hCG administration. Comparisons were made by Student's t test and Chi square analysis where applicable. P <0.05 was considered statistically significant

Results:

In our study showed the significant association between positive pregnancy outcome and progesterone level at day of HCG trigger were 79.2 % of female with positive pregnancy at progesterone level < 1.5, while 9.3 % of female with positive pregnancy at progesterone level > 2.5 as show in table 1.

Table 1: Association between progesterone level at day of HCG trigger and pregnancy outcome (age 20-45)

Study variables	Pregnancy		Total	X2	P-value
	Positive	Negative			
Progesterone level at day of HCG trigger					
Less than 1.5	570 (79.2)	537 (72.9)	1107 (76.0)	8.226	0.042 *
1.5- 2	52 (7.2)	75 (10.1)	127 (8.7)		
> 2- 2.5	31 (4.3)	39 (5.3)	70 (4.8)		
More than 2.5	67 (9.3)	86 (11.7)	153 (10.5)		
Total	720 (100.0)	737 (100.0)	1457 (100.0)		

*p value ≤ 0.05 was significant.

In our study the distribution of patients with infertility according to pregnancy outcome. Those patients those get pregnant represent (49.4%) of study sample. (age 20-45).

Figure 1: Show distribution of patients with infertility according to pregnancy outcome

The mean differences of age (years) according to pregnancy outcome including (positive and negative). There were significant differences between means of age between these two groups (N= 1457, t= -7.316, and P=<0.001*). Were 30.9% get pregnant at age 20-40 years as show in fig (2)

Figure 2: The mean differences of age according to pregnancy outcome.

The mean significant differences of estrogen at day of HCG activate rendering to progesterone level day of HCG activate, progesterone level (>2 - 2.5) had more predominant level at day of HCG trigger with mean and SD (2625.73 ± 65.62), as show in table 2.

Table 2: The mean differences of estrogen at day of HCG trigger according to progesterone level day of HCG trigger.

Progesterone level at day of HCG trigger	N	Mean	SE	P-value
Less than 1.5	1107	1870.16	23.20	<0.001*
1.5 - 2	127	2231.16	72.35	
>2 - 2.5	70	2625.73	65.62	
> 2.5	153	1849.71	72.50	
Total	1457	1935.78	21.00	

There is a significant differences of LH at day of HCG activate rendering to progesterone level day of HCG activate, progesterone level (< 1.5) had more main level at day of HCG activate with mean and SD (5.38 ± 2.52), and decrease when the level progesterone increase as show in table 3. while in table 4; There is no significant differences of LH at day of HCG activate rendering to progesterone level day of HCG activate, progesterone level (< 0.9) .

Table 3: The mean differences of LH level at day of HCG trigger according to progesterone level day of HCG trigger.

Progesterone level at day of HCG trigger	N	Mean	SE	P-value
Less than 1.5	1107	5.38	2.52	<0.001*

> 2- 2.5	31 (4.3)	39 (5.3)	70 (4.8)		
More than 2.5	65 (9.0)	86 (11.7)	151 (10.4)		
Total	720 (100.0)	737 (100.0)	1457 (100.0)		

*p value ≤ 0.05 was significant.

Discussion

During IVF/ICSI and embryo transfer, the rise of progesterone in late follicular parts of cycles has controversial affect (7,8,10,12), in our study significant association between positive pregnancy outcome and progesterone level at day of HCG trigger were 79.2 % of female with positive pregnancy at progesterone level < 1.5, while 9.3 % of female with positive pregnancy at progesterone level > 2.5, similar to study done by Jawa Ashmita and similar the study done by Ze Wu in China (20,21). In our study the distribution of patients with infertility according to pregnancy outcome. Those patients those get pregnant represent (49.4%) of study sample. (age 20-45), The pregnancy rate in 45% (65/143) in study done by Kinnari Vilaschandra Amin (22). The mean differences of age (years) according to pregnancy outcome including (positive and negative). There were significant differences between means of age between these two groups (N= 1457, t= -7.316, and P=<0.001*). Were 30.9% get pregnant at age 20-40 years, similar to study done by Jawa and study done by Ze Wu in China (20,21). In our study mean significant differences of estrogen at day of HCG trigger according to progesterone level day of HCG trigger, progesterone level (>2 - 2.5) had more predominant level at day of HCG trigger with mean and SD (2625.73 ± 65.62) , in difference to study done by Francisca Martínez; no significant differences in progesterone /estrogen ratio between conception and no conception cycles (23). Un obvious mechanism responsible for increasing plasma progesterone, exposure to FSH lead to increase sensitivity of granulosa cells (GCs) to LH this occur after hMG treatment this lead to premature Latinization even low plasma LH (24). IVF-ET have been lesser during the existence of pre-hCG rise in plasma P, lead to decrease embryo and oocyte quality, when increase in plasma progesterone the oocyte got from follicular have this rising lead to pregnancy rate decrease (24,25). So in our study 1107 women get pregnancy when level of progesterone < 1.5 ng/mL, 127 get pregnant in level of 1.5- 2 ng/mL, 70 get pregnant in level of >2 - 2.5 ng/mL, and the no. increase in level > 2.5 ng/mL to 153 women get pregnant. a premature elevation of progesterone 0.9 ng/mL was observed in 62% of 166 IVF cycles pretreated with GnRH-a. We do not see an obvious explanation for the discrepancy between Loughlin's results and hose reported by other investigators (24).

Conclusion

Pregnancy cannot depend on progesterone level at day when HCG administration for assisted reproduction cycles treated with GnRH agonists and gonadotrophins. So cutoff point of progesterone can reach to above 1.5 ng/ ml and expected of pregnancy at this level.

Abstract

This study was performed on fifty adult male laboratory rats (*Rattus norvegicus*) of 175 – 200 grams weights. The animals were randomly allocated into five equal groups of ten rats each. The groups of rats were: First, control group where the animals were fed on a standard diet along the experiment period; the Second and Fourth groups, where also maintained on a standard diet while the Third and Fifth groups were also maintained on a standard diet and they were orally dosed with Quercetin (20 mg) and vitamin C (500 mg) daily. Suspension in phosphate buffer solution (PBS) was made for the bacteria and colony forming unit (CFU) count was done after making 10-folds serial dilutions. The rats of the second and third groups were intramuscularly injected with 16×10^6 (CFU) of *Klebsiella pneumoniae* while those of fourth and fifth groups were intramuscularly injected with 20×10^5 (CFU) of *Pseudomonas aeruginosa*. After 48 hours of challenge with bacteria, all the rats of the second group and 4 rats of the third group died. On the other hand, all the rats of fourth group and 3 rats of the fifth group died. The organs of died animals of all groups like the stomach, spleen, liver, and thigh muscle were immediately picked up and weighed after death and well homogenized with (PBS) to obtain counting of (CFU) in the organs mentioned. Passing 3 days later, the survived 6 rats of third group and the survived 5 rats of fifth group were euthanized and their organs were treated as the same as the process mentioned before to gain the organs (CFU) count. The results in this study clarify that the use of Quercetin plus vitamin C has led to increase the survival of rats challenged with bacterial infection and the organs bacterial count of them was significantly less than those rats maintained without supplementation with Quercetin and vitamin C at ($P \leq 0.05$).

Keywords; Quercetin, Vitamin C, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*.

Introduction

Opportunistic microbial pathogens are serious challenging obstacle in fields of human or veterinary medicines and *Pseudomonas aeruginosa* comes in the queue of these pathogens ⁽¹⁾. The other paramount pathogen is *Klebsiella pneumoniae* which is considered as a major problem in patients who suffer from malignancies and who are dwelling in hospitals ⁽²⁾. Vitamin C is well proved for its fantastic features in defending against diseases, protecting and promoting all bodily functions. Of these effects relating to vitamin C are its role as an antioxidant agent, collagen and bone formation assistant, and assistant in enzymes and coenzymes models ⁽³⁾. In addition, vitamin C was approved to be protective in different ways and in different systems of the body and it can be gained

naturally by consuming different vegetables and fruits especially citrus fruits, berries, tomatoes and others ⁽⁴⁾. Furthermore, vitamin C was clearly reported to cause healing, repairing and protection against heavy metals intoxication in the vital organs like liver and kidney of laboratory animals ⁽⁵⁾.

Polyphenolic compounds are a vast family spreading in the world of plant kingdom and comprise flavonoids as a member of them ⁽⁶⁾. Quercetin belongs to the family of flavonoids and it is of highly antioxidant capacity ⁽⁷⁾ and it is fluently found in apples, beans, broccoli and onions in particular ⁽⁸⁾. The antioxidant potency of quercetin was found to be as four times as that of tocopherol ⁽⁹⁾. The effects of quercetin were linked to its antioxidant potency and its modulating effects on antioxidant enzymes beside its genomic stability effect

(10). Vast range of beneficial features of quercetin were reported like anticancer, anti-inflammatory, antiulcer, antibacterial, antiviral, cataract preventing role, cardiovascular system protector and other (11). Quercetin also has a protective role against lipid peroxidation and prevent cellular injury (12). Besides, quercetin was reported to be protective against poisonous compounds and has ameliorating and protective role for the hematological and reproductive aspects of laboratory animals (13, 14).

Materials and Method

- Animals and Diets

Fifty adult laboratory male rats (*Rattus norvegicus*) of weights 175 – 200 grams were purchased from a local licensed laboratory medical centre and they were housed in a suitable cages in a very typical laboratory conditions and allocated randomly into five groups of ten rats each. The rats were fed and treated as:

1- Control group, fed and maintained on a standard diet (AIN-93) referenced by (15).

2- Second group, fed and maintained on a standard diet.

3- Third group, fed and maintained on a standard diet and they were orally dosed with Quercetin (20 mg) and vitamin C (500 mg) daily. The doses of quercetin and vitamin C were chosen depending upon LD50 (161mg/kg for quercetin, and 11,900 mg/kg for vitamin C) as referenced by (16, 17) respectively.

4- Fourth group, fed and maintained on a standard diet.

5- Fifth group, fed and maintained on a standard diet and they were orally dosed with Quercetin (20 mg) and vitamin C (500 mg) daily.

- Experimental Challenges

The protocol of the experiment was continued for one month during which the rats were maintained on standard diets and the treatment with quercetin and vitamin C was done as mentioned before. After that, the rats of the second and third groups where intramuscularly injected with 16×10^6 (CFU) of *Klebsiella pneumoniae*. Organs of these animals including spleen, liver, kidney, lung and thigh muscle were homogenized in sterile PBS after being removed and weighed. Viable

bacteria number in the organs was obtained by plating on specific agar; BHI agar and the expression of results was the number of CFU/g – tissue. The rats of the fourth and fifth groups were intramuscularly injected with 20×10^5 (CFU) of *Pseudomonas aeruginosa*. Organs of these animals were processed as before mentioned and viable bacteria number in these organs determined by plating on specific agar plates; cetrinide agar and the expression of results was the number of CFU/g – tissue. All plates where incubated for 24 hours at 37 C° and the scoring of CFU was done. The bacteria isolates used in this experiment where obtained from Basrah general hospital. Cetrinide agar was prepared according to the manner described by (18).

- Statistical analysis

At ($P \leq 0.05$), (t) test was used to find out the significant differences among groups by using SPSS program version 20.

Results and Discussion

It is obvious from the results shown in tables below that the use of quercetin and vitamin C was very effective against the experimental infection of rats with *Klebsiella pneumonia* and *Pseudomonas aeruginosa* bacteria where it causes a significant increase in the survival numbers and ratios of rats (table 1) and a significant decrease in the numbers of bacteria isolated from different rats organs (tables 2 and 3).

Quercetin has been reported and documented by vast numbers of researches to be a very potent against viral, fungal, and bacterial infections beside its beneficial effects on all bodily systems and immunity. One of these studies (19) who mentioned that quercetin has a wide range of antiviral, antibacterial, antioxidant properties. As anti-inflammatory agent in animals, quercetin was found to be very potent against inflammation and has a modulatory effect on the immune system beside boosting immunity as a whole (20). It was found to decrease TNF- α of adipose tissue and nitric oxide generation in obese rats (21). The mechanism of quercetin effects against bacterial infection might be related to its anti-inflammatory role where it has a very strong antioxidant potency and cause increase the secretion of cytokines (22, 23).

Vitamin C on the other hand, is well known for its drastic effects against infections such as protozoal, viral and bacterial infections (24). Infections with microbial agents in humans or animal lead to oxidative stress and

then activation of phagocytes which in turn will cause elevation in reactive oxygen species ROS production^(25, 26). These ROS are known to cause damages to the cells and it was found in many cases of infection that vitamin C contents in macrophages or leukocytes declines severely

in cases of infection^(27, 28). One can exclude that vitamin C is required as antioxidant in case of infection and it can exert its action throughout its antioxidant effects against ROS beside its boosting role to other immune system compartments^(29, 30, 31, 32).

Table (1). Role of quercetin and vitamin C on rats' survival after being challenged with *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*.

Groups	Total rats number	Number of died rats	Number of survived rats	Ratio of survived rats %
Control	10	0	10	100

Study The Role of Selenium in The P-Selectin and E-Cadherin Serum Levels in Women with Preeclampsia

Aysel A. Ahmed¹, Raid J. Al-Timimi,² Enas Adnan Abdulrasol³

¹Department of Chemistry and Biochemistry, Collage of Medicine, Al-Nahrin university. Baghdad Iraq

Abstract

Preeclampsia (PE) is characterized by endothelial dysfunction with vasoconstriction due to cell adhesion molecules or mediators released by defective placentation. Platelet selectin (P-selectin) and epithelial cadherin (E-cadherin) are the cell adhesion molecules, is elevated in many inflammatory conditions including PE.

Objective: To investigate if P-selectin and E-cadherin levels can be used as a marker for adverse outcomes in pregnancy complicated with PE.

Patients and Method: This study involved 90 pregnant women in their third trimester of pregnancy divided into 2 group:

Group A: involves 45 pregnant women with PE.

Group B: involve 45 healthy pregnant women and normal fetal growth (Control group).

Result: The results show there were a high significant increase in the mean values of P-selectin with high increase in the mean values of E-cadherin in PE group when compared to control group.

ROC curve shows sensitivity and specificity and false positive rate for predication of PE by P-selectin and E-cadherin in control and patients groups, and the maximum accuracy for the P-selectin and E-cadherin in discrimination between control and PE patients groups.

Conclusions: There is an inverse relationship between cell adhesion molecules and selenium in PE compared with normal pregnancy.

High level of serum P-selectin and E-cadherin are associated with the presence PE, which provide additional information for predicting of PE and preventing its complications and for better understanding pathogenesis of PE.

Key words: *platelet-selectin and epithelial-cadherin, with preeclampsia & with normal pregnancy.*

Introduction

Preeclampsia (PE) is a disorder of pregnancy, is a multisystem syndrome that is primarily, characterized by the onset of high blood pressure (HBP) (hypertension) and often a significant amount of protein in the urine (proteinuria). When it arises, the condition can appear any time from the twenty weeks of pregnancy ⁽¹⁾. The exact causes of PE and eclampsia - a result of a placenta that doesn't function properly, insufficient blood flow to the uterus could be associated. Genetics plays a role as well, and have many risk factor for PE is most often seen

in first-time pregnancies, in pregnant teens, and in women over 40 years old While it is defined as occurring in women have never had high blood pressure before, other risk factors include:

- A history of high blood pressure prior to pregnancy.
- A history of preeclampsia.
- Having a mother or sister who had preeclampsia.
- A history of obesity.

History of diabetes, kidney disease, lupus, or rheumatoid arthritis.

P-selectin functions as a cell adhesion molecule (CAM) on the surfaces of activated endothelial cells, which line the inner surface of blood vessels, and activated platelets. In inactivated endothelial cells, it is stored in granules called Weibel-Palade bodies. In inactivated platelets P-selectin is stored in α -granules of platelets, have been shown to correlate with the level of oxidative stress in pregnancy (2).

Other names for P-selectin include CD62P, Granule Membrane Protein 140 (GMP-140) and Platelet Activation-Dependent Granule to External Membrane Protein (PADGEM) (3).

Cadherin (named for “calcium-dependent adhesion”) are a type of cell adhesion molecule (CAM) that is important in the formation of adherence junctions to bind cells with each other (4). E- Cadherin is a class of type-1 transmembrane proteins. It is dependent on calcium (Ca^{2+}) ions to function.

Cell-to-cell adhesion mediated by E- Cadherin plays an important role in tissue differentiation, holding the tissues together as they form during embryonic development.

Role of Adhesion in Preeclampsia:

Increase expression of adhesion molecule interfere with homeostasis. For example adhesion molecules can activate platelets through their contact with exposed epithelial wall (5,6). Abnormal active platelet are involved

in the pathogenesis of several pathologies including PE.

Patients and Methods

A case control study was conducted on 90 pregnant women (aged 18-45 years old) from the obstetrics and gynecology department of Al- Immamain Al-Kadhmain Hospital and Baghdad Teaching Hospital, after taking an approval from institutional review board (I.R.B.) of the Medical Collage / Al-Nahrain university and taking a written informed consent from all women in the study.

The subject in the study were 45 pregnant women with PE patient and 45 health pregnant women with gestational age matching to the cases at sampling, which remain normotensive and deliver a healthy baby. Blood pressure for each pregnant women was measured twice in four-hour intervals while resting, at third trimester as well as protenuria detected in urine sample by a simple dip-stick test.

The blood sample were taken from each women that participate in the study and used to measure P-selectin and E-cadherin by using enzyme linked immunosorbent assay (ELISA) method.

Result

Serum Levels of Adhesive Molecules

Mean serum level of P-selectin in PE patients was 261.69 ± 101.64 ng/mL which was higher than that of controls (204.13 ± 85.68 ng/mL) with a significant difference (Figure 1).

Figure 1: Mean serum level of P-selecting in PE patients and healthy controls

Similarly, mean serum level of E-cadherin in patients (69.45 ± 15.26 ng/mL) was higher than that of controls (58.6 ± 21.69 ng/mL) with a significant difference (Figure 2).

Figure 2: Mean serum level of E-cadherin in PE patients and healthy controls

Diagnostic Value of Adhesive Molecules

Receiver operating characteristic curve was used to explore the diagnostic value of adhesive molecule in the context of discrimination between PE patients and healthy controls (Figure 3).

For P-selectin, the AUC was 0.586, 95% CI= 0.469-

0.704, $p = 0.159$. The sensitivity and specificity of the test at cut off values of P-selectin= 211.0 ng/mL were 0.60 and 0.556 respectively.

For E-cadherin, the AUC was 0.617, 95% CI= 0.495-0.739, $p = 0.056$. The sensitivity and specificity of the test at cut off values of E-cadherin= 64.87 ng/mL were 0.622 for both.

Figure 3: Receiver operating curve for P-selectin and E-cadherin in the context of discrimination between PE patients and healthy controls

The combination of the two markers did not improve the discriminative value (Figure 4). The AUC was 0.613, 95% CI= 0.496-0.729, $p= 0.056$. The sensitivity and specificity of the test at the corresponding cut off values were 0.60 and 0.51 respectively.

Figure 4: Receiver operating curve for a combination of P-selectin and E-cadherin in the context of discrimination between PE patients and healthy controls

Discussion

In the present study, markers were chosen to reflect inflammation, endothelial dysfunction and poor placentation which are the hallmark of PE. Previous studies which have done on the these markers in other similar clinical situations such as CVD, had shown great association of the markers with the disease processes.

Nevertheless, these clinical condition are known to share more than one physiological and vascular factors. So that this study aimed to investigate the role of current markers with PE development.

Serum Levels of Adhesive Molecules

In the current work, the mean level of P-selectin was found to be significantly higher in women with PE compared with the control group. Presented a significantly higher expression of P-selectin in PE than in apparently healthy pregnant women.

Same results of increased levels of sP-selectin in preeclamptic pregnancies were obtained by ⁽⁷⁾. The authors proposed that their findings support an inflammatory model for PE, while the endothelial cell activation might be a secondary to a primary inflammatory response. However, ⁽⁸⁾ observed significantly increased levels of both P-selectin and sP-selectin form in women with PE in comparison with normal pregnant women and came to the result that normal pregnancy is connected with increased platelet activation followed by further alteration in these parameters in pregnancies complicated by hypertension.

Also, the present findings are in accordance with the results reported by ⁽⁹⁾, who suggested that the elevated level of the P-selectin is associated with PE (Figure 1), sP-selectin acts as a marker for platelet and endothelial activation and as an initiator of the pro-coagulant state as well as playing an important role in atherosclerosis. The current results of elevated sP-selectin in PE seem

to confirm that these processes occur in preeclamptic pregnant women and the excess circulating sP-selectin aid to the pathogenesis of this pregnancy-specific disorder.

There are two sources of sP-selectin. A minor proportion of this marker is produced through alternative splicing of mRNA which removes the exon that codes for the transmembrane domain.

However, the main proportion of sP-selectin is primarily derived from proteolytic cleavage of the ectoderm part of membranous P-selectin.

Interestingly, shedding of sP-selectin requires leukocyte adhesion to activate platelets or endothelial cells through interaction of PSGL-1 on leukocyte⁽¹⁰⁾.

PE involves an endothelial cell activation to coagulation hyperactivity and inflammation, which implies the availability of PSGL-1 for activation of platelets and endothelial cells with eventual increase in sP-selectin shedding.

The circulating platelet count is reduced reflecting a decreased platelet lifespan⁽¹¹⁾. Features of platelet activation in PE include an increased expression of platelet surface P-selectin (CD62P)⁽⁶⁾. As can be observed from receiver operating characteristic curve (ROC) (Figure 3). Analyses of P-selectin demonstrated the low discriminative value of this marker to diagnose PE both in terms of sensitivity and specificity. The sensitivity was 0.60 and specificity 0.556 respectively. And the AUC was 0.586, 95% CI=0.469-0.704, P=0.159. This is because sP-selectin can be elevated in many pathologies. For example in a case-control study, including women with polycystic ovary syndrome (PCOs) and healthy control women, found that sP-selectin levels were significantly higher in PCOs women than controls.

The current study revealed a significant elevation in serum level of E-cadherin in PE compared with control. This result is in accordance with during human placental development, cytotrophoblast (CTB) differentiates and fuses with the syncytiotrophoblast cell layer (STB), allowing for growth of the syncytium and for re-epithelization of aged or damaged regions of villi. This process of trophoblast turnover is regulated to ensure normal fetal development. Localization and expression of cadherins are highly relevant to the morphology of trophoblasts at different stages of placental development. E-cadherin, a classical cell-cell adhesion molecule, is expressed

in villous CTB, but is lost when they differentiate and syncytialise, resulting in the absence of E-cadherin expression in the STB of both healthy 1 and 2 trimester placentae⁽¹²⁾. The reduction of E-cadherin expression from 1 trimester to 3 trimester is reported in normal term placenta⁽¹³⁾. A number of studies have shown that the expression of E-cadherin was increased in PE resulting in CTB proliferation⁽¹⁴⁾, although more recent studies have shown the reduced expression of E-cadherin in PE, or no changes in E-cadherin expression in TNF- α induced reduction of trophoblast invasion⁽¹⁵⁾. Elevated expression of E-cadherin raises the proliferation of CTB and inhibits their differentiation into STB in PE, which suggests the alterations of E-cadherin levels are potentially important to the pathogenesis of PE⁽¹⁶⁾. Consistent with other studies, this data showed that E-cadherin was expressed in a higher level in the preeclamptic patient women compared with normotensive pregnant women. Studies have shown the villous trophoblast undergoes increased apoptosis in preeclampsia and the increased apoptosis was observed in STB⁽¹⁷⁾.

As can be observed from receiver operating characteristic curve (ROC) (Figure 3), analyses of E-cadherin demonstrated poor diagnostic value of this marker to diagnose PE. The sensitivity and specificity was 0.622 for both.

The combination of the two markers did not improve the discriminative value (Figure 4). The AUC was 0.613, 95% CI= 0.496-0.729, p= 0.056. The sensitivity and specificity of the test at the corresponding cut off values were 0.60 and 0.51 respectively.

Conclusions

There is an inverse relationship between cell adhesion molecules and selenium in PE compared with normal pregnancy.

High level of serum P-selectin and E-cadherin are associated with the presence of PE, which provides additional information for predicting of PE and preventing its complications and for better understanding pathogenesis of PE.

Abstract

Zinc Oxide Nanoparticles have been prepared using a simple green synthesis method by green tea extract (*Camellia sinensis*) as a reducing and capping agent, XRD measurement of Nano powder stated that Zinc Oxide had a hexagonal wurtzite structure, UV-Vis. The maximum absorption peak was approximately 318 nm and the energy gap was nearly 3.8eV calculated using Planck's equation, blood serum sugar levels, liver function after ZnO NPs injection for rats was recorded. Forty-eight adult male rats were used and separated randomly into six groups of eight (n=8) rats in each group. Results stated that blood glucose levels, liver enzymes were increased in groups that injected by dexamethasone while considerably modified in rats administered by the first dose (100 mg/kg) of ZnO Nanoparticles while the other dose (300 mg/kg) hadn't any significant effects.

Keywords: *Dexamethasone, XRD, Zinc Oxide NPs, AST, HDL-C*

Introduction

recently, a strategic development has been frequently implemented in the context of a novel green synthesis technique that forms biocompatible nanoparticles because of the possibility of developing bio-nanomaterials with particular biological functionalities⁽¹⁾. Today, non-toxic, environmentally friendly techniques have gained more importance because of their ability to generate a wide variety of nanomaterials to cover better suite biomedical applications⁽²⁾ most of these apps are due to the fact that the Nanometer scale has considerably unique characteristics compared to the bulk. Nanoparticles have good surface bonding, The large surface-volume ratio in nanoparticles is the primary reason for a structural deformation that can influence the physical characteristics of nanoparticles⁽³⁾ In particular, the synthesis of zinc oxide nanoparticles has gained considerable interest due to the fact that it has excellent characteristics for biomedical apps, zinc⁽⁴⁾ plays a significant part in the preservation of blood sugar and activate more than three hundred of body enzymes.⁽⁵⁾, it is also known to maintain the structure of insulin and has an important roles in insulin biosynthesis, storage

and secretion⁽⁶⁾. There are several zinc transporters in pancreatic β - cells⁽⁷⁾. This report intended to investigate the ability of prepared Zinc Oxide by green synthesis to recover blood glucose, liver enzymes and lipids in rat's body after dexamethasone administration.

Materials and Method

Zinc Acetate Dehydrate ($\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$) (0.2 M) is mixed with 70ml of Deionized Water using a magnetic stirrer, stirring 1500 rpm a few minutes. Then 20 ml of the previously prepared green tea leaf extract was obtained from the stock solution (stored in the refrigerator) and gradually added. Now the blend was stirred continuously for 2 hours at 40°C. The solution was then cooled at room temperature and centrifuged twice at 4000 rpm for 15 min after a thorough washing and then dried at 60°C for 3 hours, lastly the produced ZnO nano-powder pale white colored using for further studies.

Experimental Protocols and Grouping

(Forty-eight) Male adult Wister albino rats weighing (175-225 g) and (10-14) weeks old housed in cages

made of polypropylene under controlled conditions (25 ± 5) ° C and 12/12 hrs light / dark cycles, drinking water and diet food were provided ad libitum, animals were grown and housed at the University of Baghdad / animal house in the college of science. The experimental animals were randomly grouped into six groups, each of which consisted of eight rats ($n=8$) treated for 30 days and designed as follows: G1 the first group was served as negative control, G2 the second group was injected intraperitoneally with (0.5 mg/kg) dexamethasone sodium phosphate, G3 and G4 were injected intraperitoneally with (100 and 300) mg/kg ZnO NPs⁽⁸⁾ and (0.5 mg/kg) of dexamethasone respectively, G5 was injected with 100 mg/kg ZnO NPs and G6 injected with 300 mg/kg ZnO NPs. The Laboratory animals were fasted 24 hrs before dexamethasone injection; they were weighed and anesthetized by inhalation in a glass dome.

Biochemical assessment & Statistical Analysis

When the experiment period end; blood samples collected from animals by heart puncture, the blood centrifuged at 4000 rpm for 10 min, serum was separated for test of several biochemical parameters such as blood glucose level (BGL) measured by commercially kit (Biosystem, Germany), cholesterol (TC), High Density Lipoprotein Cholesterol (HDL-C), Triglyceride (TG) and Low Density Lipoprotein Cholesterol (LDL-C) estimated using an available kit (Linear kit, Spain), serum levels Alanine Amino transferase (ALT), Aspartate Amino transferase (AST), Alkaline Phosphate (ALP) and Total Bilirubin (TB) were assessed using commercially available kit (Reflotron kit, Germany). Results were stated as means \pm standard Errors. The

Statistical Analysis System applied one way (ANOVA) analysis of variance to verify (LSD) using statistical package of Prism software 8.1.2 (Version 8.1.2, GraphPad, San Diego, CA, USA). The Probability (P) value ≤ 0.05 has been considered to be of statistical significance. When pancreatic samples collected from animals after organs separation and fixed in 10% buffered neutral formalin solution, dehydrated in gradual ethanol (70%), cleared in xylene, and embedded in paraffin. 5 micron thick paraffin sections were prepared and then regularly stained with Hematoxylin and Eosin (H&E)⁽⁹⁾ and examined microscopically.

Results and Discussion

Structural characterization of Nano-powder was recorded by Pro Penalty CAL with Cu-K α radiation (1.5406 Å). X-ray diffraction was indicating the structure and crystalline nature of as synthesized ZnO Nanoparticles. Results show all diffraction peaks are in good agreement with the international crystallographic data table; JCPDS card No. 01-075-0576. No impurities peaks can associate to the XRD spectrum of the gotten powder, showing high purity of ZnO products and the peaks intense of the samples proof to good crystallinity. The broadening of the diffraction peaks clearly indicates the presence of Nano-size, large broadening in X-ray diffraction lines occur when particle size is less than 100 nm, The peak width at half height using the Debye-Scherrer formula⁽¹⁰⁾ gives indication for average crystallite size of green synthesized ZnO NPs, The calculated average crystallite size was 9.27 nm, result of X ray pattern agreed with⁽¹¹⁾⁽¹²⁾.

Table (1): The structural parameters of as synthesized ZnO Nanoparticles

2 θ (Deg.)	G.S (nm)	FWHM (Deg.)	dhkl Exp.(Å)	dhkl standard (Å)	(hkl)
30.81	14.7	0.539	2.877	2.902	(100)
34.32	8.4	0.941	2.593	2.613	(002)

76.5	15.7	0.510	1.243	1.268	(202)

The optical behavior recorded by VARIAN spectrophotometer (Cary 5000 Scan), to explain the optical properties and energy gap value of ZnO NPs; UV-Vis absorption spectrum has been studied. Fig. (1) Shows the exciton maximum absorption is about 318 nm. Actually, energy absorbed in UV or visible region causes a change in the electronic excitation of the molecule, and hence results in corresponding change in its ability to absorb light in the UV-visible region of the electromagnetic radiation. The optical energy band gap for ZnO NPs was 3.8 eV has been calculated using Planck's relationship⁽¹³⁾.

Figure (1): Absorption Spectrum of ZnO nanoparticles

Table (2) shows blood glucose of the study groups, mean blood glucose level (BGL) of G2 after 30 day administration of dexamethasone showed a significant

increasing compared with control group, the reasons behind increasing glucose is generated oxidative stress by sugar causes the generation of free radicals that attack and damage beta cells, thus inhibiting the formation and secretion of insulin, and then stops glucose metabolism and glycogen decomposition, Oxidative stress is involved in creation of ROS that damage cellular membranes, proteins and nucleic acids, the auto oxidation of glucose that produces hydrogen peroxide (H_2O_2), a strong ROS⁽¹⁴⁾, these results similar to previous study⁽¹⁵⁾ that reported the dexamethasone cause tissue damage in pancreas.

Treatment with 100 mg/kg of ZnO NPs were responsible of significant reduction to BGL ($P \leq 0.05$) may be due to that Zinc has been elucidated to be a potent metal that Improves glucose utilization and metabolism through its potent influence on enhancement of hepatic glycogenesis through actions on the insulin signalling pathway⁽¹⁶⁾, interestingly, on the basis of Umrani and Paknikar⁽¹⁷⁾; ZnO did not possess the risk of hypoglycemia in living organisms so it can act as an insulin secretion, more researches have the same results revealed that ZnO NPs could increase serum insulin level in diabetic animals⁽¹⁸⁾.

Table (2): Changes of Serum biochemical parameters in treated rats with CeO₂ Nanoparticles after 30 days, Each value represents the mean± standard error of (n=8), The values were found to be statistically significant at $P \leq 0.05$, (* $P < 0.01$, ** $P < 0.001$, *** $P < 0.0008$, **** $P < 0.0001$)

Groups Parameters	Means± SE					
	G1	G2	G3	G4	G5	G6

HDL-C(mg/dL)	45±1.6	26±3	46.2±2.3*	29±1.4	40.2±2.2	35±1.7
LDL-C(mg/dL)	91.2±8.1	172±13.1	115.2±3.9*	163.5±5.1	101.7±2.4	113.7±2.4

ALT and AST are very sensitive enzymes and have been closely connected with hepatic damage these levels enzymes will rise when liver is in dysfunction^{(19) (20)}, Maiti et al.⁽²¹⁾ have suggested that increases in the actions of ALT, AST, and ALP in the serum of diabetic rats as a consequence of hepatic damage, ALT and AST levels increased is associated with insulin deficiency has been interrelated to increased gluconeogenesis during hyperglycemia⁽²²⁾.

The results showed there was a significant increase in liver functions parameters such as ALT, AST and ALP in experimental animals compared with negative control group (**G1**) table (2), increases of liver functions parameters levels possibly due to hepatic damage and increase synthesis of these enzymes in the liver⁽²³⁾, and a significant decrease ($P \leq 0.05$) with liver enzymes when animals treated with (100 mg/kg) of ZnO NPs while there was no statistically significant effect of 300 mg/kg dose for infected rats respect to **G2**. Increases of Bilirubin levels may be attributed to the changes in cell membrane permeability with change of effective stress of the membrane under the oxidative stress⁽²⁴⁾, ZnO nanoparticles have reduced Bilirubin levels in **G3**; **G5** and **G6** were nearly the normal ranges.

G2 had a significant increase in cholesterol; this increasing attributed to high exposure of free radicals which stimulate the rate limiting enzyme hydroxyl-methyl glutaryl which is responsible for liver synthesis⁽²⁵⁾. When these animals treated with 100 mg/kg of ZnO NPs, a significant recovery in cholesterol levels occurred. Higher levels of Triglycerides (TG), LDL-C and reduction in HDL-C levels in **G2** is possibly due to a direct consequences of conversion white adipocytes to

brown adipocytes⁽²⁶⁾, or may be attributed to decrease the activity of lipoprotein lipase which is responsible for TG removal. However, triglyceride and LDL-C levels ($P \leq 0.05$) decreased was evident. With the exception of raises of serum HDL level.

Histological section in (Fig. 2a) shows pancreatic lobules containing acini (*), islets of Langerhans (***) and unstained connective tissue septa (***) for control group. Fig. (2b and c) showed damage and necrosis of endocrine cells of islet (*), Langerhans with shrinkage of islet (**), degenerated acini cells and islet of Langerhans (***) and presented different alterations of rat's pancreas and many histological changes were detected in pancreas section of (**G2**) that administrated by dexamethasone, such as necrosis and damage of endocrine cells of islet Langerhans with shrinkage of islets, Dexamethasone induced necrosis is mediated by reactive oxygen species mediated lipid peroxidation which causes bursting of plasma membrane of the cell and disturbance of osmotic balance this osmotic alteration ultimately leads the cell towards necrosis. The histological sections showed several modified in rats pancreas of rats in groups that treated with 50 mg/kg of ZnO Nanoparticles (**G3**), whereas group that treated with (100 mg/kg) (**G4**) had no clear changes after dexamethasone and nanoparticles injection, in fig. (3a) the section shows animal from **G3** had a normal histological structure of islets of Langerhans of pancreas which consist of α and β cells, in between capillaries blood vessels, while fig. (3b) section shows no effects of Nanoparticles on pancreatic cells, abundant necrosis, degenerated acini and damage of endocrine cells, **G5** and **G6** in fig. (3c and d) appears look like normal pancreatic structure.

Figure (2): Cross sections of pancreas (a) Control group G1, (b and c) G2 X400 (H&E)

Figure (3): Cross section of pancreas (a) G3 (b) G4 (c) G5 (d) G6 X400 (H&E).

Conclusions

Biocompatible nanoparticle synthesis was produced by using green tea extract (*Camellia Sinensis*) method for the preparation of Zinc Oxide nanoparticles. Successful formation of nanoparticles by examining its structural and optical properties was investigated. Results indicated that blood glucose concentrations, liver enzymes and lipids were enhanced in dexamethasone-injected groups, while significantly altered in rats administered 100 mg / kg dose of ZnO NPs and the other dose (300 mg / kg) did not significantly improve BGL, liver enzymes and lipids.

Study the Role of Trichomoniasis in In Vitro Fertilization (IVF) Failure

Huda Dhaher Al-Marsomy¹, Faten Ahmed Hassan²

¹Department of Microbiology, College of Medicine, Al-Nahrain University, Iraq,

²Children Welfare hospital, Medical City, Baghdad, Iraq

Abstract

Trichomoniasis is a sexual transmitted disease that affects human fertility. In women, trichomoniasis has been related to infertility due to pelvic inflammatory disease that compromises tubal patency, while in men, trichomoniasis may contributed to infertility by deficit of sperm cell quality and function due to physical damage. In this article, asymptomatic fifty couples with unexplained infertility, undergoing In Vitro Fertilization (IVF) were examined for *Trichomonas vaginalis* (T.V.) infection. In 70% of couples, embryo implantation failed and pregnancy was not achieved, probably as a consequence of trichomoniasis. The result indicates that *T. vaginalis* pathogenicity, adverse reproductive health outcomes, in time diagnosis, and treatment may improve implantation rate in patients with unexplained infertility undergoing Assisted reproductive technology (ART).

Key word : *Trichomonas vaginalis* , (IVF) Failure, infertility; sexual transmitted disease

Introduction

Trichomonas vaginalis is a globally occurring anaerobic/ microaerophilic protist parasite which colonizes the epithelium of the human urogenital tract⁽¹⁾. Aside from human papillomavirus, trichomoniasis is the most common sexually transmitted infection worldwide, based on estimates of the World Health Organization (WHO) from 2016⁽²⁾, *T. vaginalis* infection , affect approximately 156 million people every year. Medical opinion has traditionally held that it plays little role in health complications in women, and it is rarely seen in men, the Centers for Disease Control and Prevention (CDC), reports that only 30 percent of people with trichomoniasis report any symptoms at all⁽³⁾. However, evidence has recently accumulated implicating *T. vaginalis* as a contributor to a variety of adverse outcomes among both sexes. Among both women and men, the association of *T vaginalis* with human immunodeficiency acquisition and transmission has been shown in multiple studies^(4,5). Among women, trichomoniasis may play a

role in development of cervical neoplasia, postoperative infections, and adverse pregnancy outcomes and as a factor in atypical pelvic inflammatory disease and infertility^(6,7). Among men, trichomoniasis has emerged as a cause of nongonococcal urethritis and contributes to male factor infertility⁽⁸⁾. Published reports clearly show that the rate of trichomonas infections among infertile couples is higher than that among fertile ones⁽⁹⁾.

The interaction of vaginal pathogens with epithelium and mucosa of the reproductive tract affects the immunological harmony needed for the success of embryo implantation. Nowadays, *T. vaginalis* is a latent pathogen in the reproductive tract, in this way is responsible of the adverse reproductive health outcomes in humans. Trichomoniasis proves the way for several bacterial intruders of the inflammation processes, thereby increasing the risk of failure in reproductive capacity and increasing the risk by 1.5-3 times of HIV and VPH acquisition^(10,11). *T. vaginalis* evades host immunity by the presence of adhesion proteins, cysteine proteases, and lipophosphoglycan molecules, all of which increase the pathogenicity of this intruder. The parasite adheres to the vaginal and cervical epithelial cells and triggers an immunosuppressive response from monocytes, macrophages, and dendritic cells. Also, *T. vaginalis* carries viruses and other parasites, such as mycoplasma

Corresponding author:

Huda Dhaher Al-Marsomy

hudaalmarsome@yahoo.com

and gardenella, causing chronic mucosal damage and an inflammatory reaction which gives rise to severe consequences in reproductive outcomes⁽¹²⁻¹⁵⁾. Goodman *et al.*⁽¹⁵⁾ reported the presence of a Totiviridae viral family, which is a virus with a doubled stranded RNA that concurrently, is infecting the *T. vaginalis* parasite⁽¹⁵⁻¹⁷⁾. Infection of *T. vaginalis* by such a virus increases severely the immunological genesis of trichomona virulent factors by changes in its genome organization, protein coding, and replication signals. Trichomona virus increases the recurrence of the parasite infection and resistance to the metronidazole treatment^(15,18,19-21).

Materials and Method

Ethics Statement: All human participants were enrolled in conformity with informed consent, privacy and confidentiality of patients who were sampled and analyzed anonymously during study (No. 53.2017).

Sampling:

From August 2017 through to August 2019, a prospective and case-control study at Dr. Khawer center for infertility and In vitro fertilization (IVF) in Erbil province of Kurdistan region of Iraq, were conducted. For research purpose only, fifty women under the age of 35 years, had normal body index, and nonsmokers and their spouses (normal seminal fluid analysis according to the world health organization parameters (WHO) at 2010),⁽²²⁾ with unexplained infertility, were enrolled in this study. High vaginal swab and semen sample had been collected from the participate couples.

DNA extraction and PCR:

The genomic DNA was extracted by the extraction kit gSYNCTM (Geneaid England) directly from high vaginal swab, following the manufacturer's instructions.

PCR steps

The primer set targeting beta tubulin gene 9/2 which is a conserved region found in all of *T. vaginalis* (gene bank accession No. L05470) were used to amplify a 112 bp piece of the gene, the sequence of the primers.

Forward primer sequences (5'-3'): CAT TGA TAA CGA AGC TCT TTA CGA T

Reverse primer sequences (5'-3'): GCA TGT TGT GCC GGA CAT AAC CAT

PCR protocol:

The PCR master mixture prepared at final volume of 20 µl in 0.2 mL PCR tubes. Component and their volume are explained in Table (1).

Table (1): the PCR construct master mixture for amplification of (BTUB) gene:

Reagents	Volume for 1X
Master mix(Prime taq Primemix)	10.0 µl
Forward primer	1.0 µl
Reverse primer	1.0 µl
Nuclease free water	4.0 µl
DNA	4.0 µl
Total	20 µl

The PCR amplifications were performed on a program according to the cycle

The construct reaction conditions for (BTUB) as shown in table (2):

Table (2): the construct reaction conditions for (BTUB):

Stage	Temperature	Time	Cycles
Initial Denaturation	95	5 minutes	1 cycle
Subsequent denaturation	95	30 second	10 cycles
Annealing	(64-55)	30 second	
Extension	72	1.0 minute	40 cycles
Subsequent denaturation	95	30 second	
Annealing	55	30 second	
Extension	72	1.0 minute	1 cycle
Final Extension	72	10 minutes	
	4	To time end	

A 3 µl volume of each reaction was subjected to electrophoresis on 3.0 % agarose gel in Tris-acetate-EDTA buffer pH 8.5 (45 min at 10 V/cm) and staining

with safe dye. The DNA bands were visualized under UV light (transilluminator). The size of the amplified products was assessed by comparison with a commercial weight marker, Smart Ladder (50 bp) GeneDix|Korea and photographed by digital camera.

PCR products sequencing:

To reconfirm the PCR results, 10 amplified PCR products were directly sequenced by targeting Beta tubulin gene in both directions using, the Big Dye Terminator method. Sequencing was performed bi-

directionally using the same primers used in PCR amplification of the beta tubulin genes (Macrogen /South Korea). The obtained sequences were aligned (by using Bio edit software) with normal sequence from GenBank.

Results and Discussion

Unfortunately, all the examined women for trichomoniasis were positive by detection of BTUB gene and 40% of their spouses also. Only 30% of these women successfully achieve pregnancy, as shown in table 3.

Table (3): the percentage of trichomoniasis in males and females and the successful percentage of IVF.

Gender	T.V. infection percentage	IVF percentage	IVF success percentage	IVF failure percentage
Female	100%	100%	30%	70%
Male	40%			

Although, couples that enrolled in this study were chosen very carefully, to overcome the IVF failure causes and to insure getting good eggs quality (eggs without chromosomal changes) and quantity, not defective embryo (that can implanted successfully in the uterus), yet it has long been regarded as a sexually transmitted infection of minor importance, trichomoniasis is not routinely screened in asymptomatic patients and the infection can persist for 3-12 months in the genital tract. (23-26). Patients with trichomomiasis are asymptomatic in 70-100% of male cases *versus* 35-85% of female cases (23), however, the asymptomatic women may also experience, at least part of pathological signs, could be due to the genetic diversity of the parasite strains to express virulence factors, which increase cytoadherence, cytolysis and cell detachment (27).

Additionally, previous studies have reported that trichomoniasis has high rates of reinfection due to resistance of the parasite to metronidazole treatment (18, 26) making this microorganism a serious reproductive tract pathogen.

The *T. vaginalis* protozoan attaches to vaginal epithelial cells through its barbed tail, membrane expression of surface protein p270, secretion of proteases and a cell-detaching factor, leading to an intense host inflammatory response, inducing local

cytotoxic effects, genital tract damage, and reproductive effects (28,29). Because, trichomonas has been been isolated from fallopian tubes, peritoneal fluid, and the pouch Douglas, scientists suggesting that motile trichomonas may be able to invade the whole genital tract (30,31). There are several studies that conclude that *T. vaginalis* causes urogenital damage to different types of cells and tissues, such as connective and muscular tissues, due to an excessive cytotoxic local effect suggesting high risk of reproductive failure (31-37). Trichomonas bind to the cells inducing membrane retraction, cell blebbing, and apoptosis. These changes of cell architecture can be evidenced under microscopy and characterized by condensed chromatin and intense cytoplasm vacuolization (37). In this study, the female partners did not report any infectious symptom and, therefore, they were not tested for *T. vaginalis*, but they might have been affected with latent trichomoniasis. They are an examples of asymptomatic patient who obtained a negative outcome of implantation failure after ART. More than 20% of women with trichomoniasis have a chronic inflammatory process in the reproductive tract and that may explain the embryo implantation failure after ART procedure. Consequently, the clinical implication of embryo implantation failure depends on both the quality of the embryo and the receptivity of endometrium mainly marked by the correct and exact immune environment needed for a successful pregnancy.

On the other hand, men infected with *T. vaginalis* display abnormal motility of the spermatozoa and high semen agglutination. A relevant tropism from *T. vaginalis* microorganism to the head or flagella of the human spermatozoa has been reported. The adhesion of *T. vaginalis* and sperm affects sperm motility followed by phagocytosis, lysis, and digestion of sperm cell^(38, 39). In 2008, Benchimol *et al.*

⁽⁴⁰⁾ report that, after one hour of interaction between *T. vaginalis* and sperm cells in an *in-vitro* environment, 75% of the sperm cells were immotile or dead. Additionally, cyto-adhesion and phagocytic activity of trichomonas to ingest and digest spermatozoa in an *in-vitro* environment suggest a similar behavior in an *in-vivo* environment as a cause for decreasing numbers of motile sperm directly affecting reproductive success. Latent trichomoniasis infection could be the cause of the unexplained infertility in men, since sperm damage evidenced by severe asthenozoospermia.

This search showed that, Couples with unexplained infertility must be widely screened and tested for sexually transmitted pathogens to ensure adequate conditions of the female reproductive tract needed to achieve pregnancy. Further studies are required to accurately fill the gap of knowledge between trichomoniasis, unexplained infertility, and implantation failure.

In conclusion: The result indicates that *T. vaginalis* pathogenicity, adverse reproductive health outcomes, in time diagnosis, and treatment may improve implantation rate in patients with unexplained infertility undergoing Assisted reproductive technology (ART).

³Professor, Al-Mustaqbal University College, Babylon/Iraq

Abstract

Background: Caesarean section was first introduced to reduce the risks of normal delivery, and is recommended only when the lives of the mother and fetus are compromised, as it is associated with certain risks. However, some women's perceptions may be influenced by local culture. According to international statistics, the rate of C-section is increasing globally, and in Iraq it is 2-3 times higher than other nations. More than 1/3 of women in Babylon choose C-section voluntarily, believing it is safer, healthier, and less painful.

Aim of the Study: Identify the unexpected medical and surgical conditions of newborns by elective cesarean delivery in Al-Hillah city, and assess the association between the actual gestational age at birth and decision by which elective caesarean sections were done as influenced by local socio-demographic factors and perceptions; that resulted in those conditions.

Methodology: This study is a cross sectional study conducted in Al-Hilla General Teaching Hospital from the beginning of March 2018 until the end on August 2018, and included a total of 150 neonates born via elective cesarean section who had unexpected medical and surgical conditions.

Results: Mean maternal age was (26.27±9.56) year ranging from (16-43). Seventy percent of them had timing of < 39 weeks of gestation, and 36.7% had actual gestational age at birth of < 37 weeks. Almost half of them chose C-section for being safe. Respiratory compromise was the commonest medical complication among mothers. There was significant relationship between decision basis and actual gestational age at birth, as well as between maternal age and medical and surgical complications (P-value<0.05).

Conclusion: Neonates born after elective cesarean delivery in Al-Hillah city have significantly higher rates of respiratory morbidity and longer length of hospital stay, with increased risk of certain medical and surgical complications. The unexpected medical complications are inversely related to gestational age at which elective cesarean section is timed.

Keywords: cesarean section; medical complications; surgical complications.

Introduction

Child delivery in Babylon is associated with a multitude of physical, emotional, social, physiological, ethnocultural, and psychological dimensions. Cesarean

section rates are increasing in Babylon Province. Given the steady rise of C-sections carried out, the unexpected adverse health outcomes in neonates born via this mode of delivery it seems necessary to investigate and forge out sufficient information about this area of obstetric practice and the factors that attract women's decision of choosing this mode of delivery given that few scholarly articles in Iraq are available currently[1].

In an ethnographic based study carried out by Latifnejad-Roudsari et al. in 2014, non medical factors including dread of mesmerizing normal vaginal delivery related pain, local Iraqi social attitudes and values, and social network were blamed as the reasons affecting the choice of opting for elective cesarean delivery and act partly for a proportion of the observed increase [2].

Caesarean sections are either planned electively or emergent. Planned sections are done before delivery commences, as compared to emergency sections, which are undertaken before or after labour has commenced [3]. The reasonable gestational age for scheduled sections has become a matter of heated debate among professionals dealing with maternal and child health care [4].

Over nearly a half century, maternal and child health care professionals have defined “term pregnancy” based on the assumption that fetal maturity is completed at the end of 37th week [5]. However, it recently became clear that neonatal respiratory complications are reduced when increasing the gestational age to 39 weeks. There is evidence that babies born by planned C-section at 37 weeks have more occurrences of certain complications than those at 39 weeks [6]. Therefore, experts recommend that elective C-section be conducted from 39 weeks onwards to achieve fetal maturity [7].

Although pregnancy is a physiological process, its end is a painful experience for mothers and associated with fear, dread and anxiety [8]. Local culture in Babylon province has a major impact on women’s beliefs and attitudes towards labor pain, coping mechanisms, and observed behaviors. This attitude can influence women’s decisions about her mode of delivery [9].

Safe delivery is the target of every medical team dealing with childbirth. C-section was introduced primarily to reduce the risks maternal child complications. Unfortunately there is a false assumption nowadays that scheduled C-section provides a safe and healthier means of escaping vaginal delivery pain. That is why it is estimated that more than half of women voluntarily choose C-section as the preferred mode of delivering their babies [10].

C-section rate is an important health insurance index. According to WHO, C-section rate was 15% in 1985, significantly increasing in 2009 worldwide [11]. In

North America notably the United States of America, C-section accounted for 26.1% of all deliveries in 2002. In Europe, this rate was one quarter of births in some EU states. In addition, in Latin America this rate is also quite high reaching up to 40% [12].

According to regional health records and statistics, the prevalence of C-section in Iraq is up to three times higher than the international rate [13]. Although scheduled operations should be decided when the health of the mother or baby are compromised; this mode of delivery has become a way of avoiding distress of labor pain, due to a common notion that its less painful, safer, and healthier than vaginal delivery [14].

Aim of the Study

Identify the unexpected medical and surgical conditions of newborns by elective cesarean delivery in Al-Hillah city, and assess the association between the actual gestational age at birth and decision by which elective caesarean sections were done as influenced by local sociodemographic factors and perceptions; that resulted in those conditions.

Patients and Methods

This is a cross-sectional study conducted in Al-Hilla General Teaching Hospital from the beginning of March 2018 until the end on August 2018, and included a total of 150 neonates born via elective cesarean section who had unexpected medical and surgical conditions following the procedure, who were born at various gestational ages. Excluded cases were those who did not develop unexpected outcomes, as well as those born via emergency C-section or normal vaginal delivery.

Results

Timing of caesarean section was less than 39 weeks in 70.0%, while it was equal or more than 39 weeks in the remaining 30.0% (Figure 1).

Figure 1: Distribution of the timing of elective caesarean section

Figure 2 shows the primary basis for decision to time elective caesarean section, which is clinical in 26.75% and by ultrasound in 73.3%.

Figure 2: The primary basis for decision to time elective caesarean section

Figure 3 represents the reasons for opting for elective C section cited by women.

Figure 3: Reasons for opting for elective C-section cited by women

Table 1 shows that the higher percentage of unexpected medical complication of pregnant women who underwent elective caesarean section was respiratory compromised which represented 23.3%, followed by nosocomial infection and neonatal sepsis, prematurity, congenital heart disease which represented 16.7%, 14.7%, and 12.7% respectively.

Table 1: Distribution of unexpected medical complication of pregnant women who underwent elective caesarean section.

Medical complication	Number	Percentage(%)
Respiratory compromised	35	23.3%
Prematurity	22	14.7%
Postmaturity	5	3.3%
Birth asphyxia	10	6.7%
Nosocomial infection & neonatal sepsis	25	16.7%
Reluctant to feed, artificial feeding & GERD	9	6.0%
Seizure and electrolyte disturbance	15	10.0%
Hypothermia and hypoglycemia	5	3.3%
Congenital heart disease & other anomalies	19	12.7%
Stillbirth	5	3.3%
Total	150	100.0%

Table 2 shows that the higher percentage of surgical complication was injury followed by intestinal obstruction, pneumothorax and trachea esophageal fistula in a percentage of 40.0%, 30.0%, 20.0% and 10.0% respectively.

Table 2: Distribution of unexpected surgical complication of pregnant women who underwent elective caesarean section.

Surgical complication	Number	Percentage(%)
Pneumothorax	10	20.0%%
Intestinal obstruction	15	30.0%
Tracheo esophageal fistula	5	10.0%
Others (injury)	20	40.0%
Total	50	100.0%

Table 3 shows that chi-square test was conducted to find an association between variables (decision by which caesarean section was conducted and actual gestational age at birth) and timing of caesarean section (less than 39 weeks and equal or more than 39 weeks).

Table 3: Association between variables and timing of caesarean section

Variables	Timing of caesarean section		Total	X2	P-value
	<39 weeks	≥39 weeks			
Decision					
Clinically	20(19.0%)	20(44.4%)	40(26.7%)	10.39	0.001*
Ultrasound	85(81.0%)	25(55.6%)	110(73.3%)		
Total	105(100.0%)	45(100.0%)	150(100.0%)		
Actual GA at birth(week)					
< 37	55(52.4%)	0(0.0%)	55(36.7%)	44.99	<0.001*
37 – 42	40(38.1%)	25(55.6%)	65(43.3%)		
≥ 42	10(9.5%)	20(44.4%)	30(20.0%)		
Total	105(100.0%)	45(100.0%)	150(100.0%)		

*P-value≤0.05 was significant

Discussion

Depending on the results of this cross sectional study, vaginal birth should be highly encouraged to avoid unexpected negative maternal child health outcomes . The results are highlighted by the findings of Knoblauch H.^[15]. In similar international studies, participants assumed that vaginal delivery was necessary for baby's lungs functional maturation, propping up of mother-child emotional attachment, reduction of unnecessary drug usage and other interventions. Overall, they assumed that vaginal delivery was less risky than C-section as it eliminates maternal child adverse outcomes^[16].

The highest percentage of unexpected medical complications of pregnant women who underwent elective C-section was respiratory compromise in 23.3%, followed by nosocomial infection and neonatal sepsis in 16.7%, prematurity in 14.7%, and congenital heart disease in 12.7%. This study is in line with international studies that indicate lung complications are the commonest cause of neonatal morbidity following elective C-sections^[17].

These are in part attributed to the absence of hormonal and physiological cascade of changes associated with birth which are vital for lung function

in newborns, which do partially occur in neonates delivered as preterm^[18]. Term neonatal respiratory distress syndrome is also associated with higher need for oxygen and assisted pulmonary ventilation, lengthy hospital stays and higher mortality than other causes of respiratory morbidity in term counterparts^[19].

Infants delivered by planned C-sections in Babylon have an increased risk of adverse respiratory morbidity. The relative risk increased with decreasing gestational age. Nearly one quarter (23.3%) of unexpected neonatal medical conditions following elective C-sections were neonatal respiratory compromise that required SCBU or RCU admission, including (respiratory distress syndrome, transient tachypnea of newborn and assisted ventilation in respiratory care units). These complications are similar to international studies and surpassed other medical conditions.

As shown by this current research paper elective C-section can elicit some unexpected negative outcomes in neonates. The findings are in agreement with those of Fenwick and associates, who concluded maternal and fetal health, mother-child bonding and attachment, and transition to motherhood as the main positive benefits of vaginal delivery^[20]. An outstanding issue pointed out by those with scheduled cesarean experience was mothers' "paralysis" literally and helplessness to care for the child with unexpected negative outcomes and meet the maternal role; the results were in harmony with those of Cranley and colleagues.^[21]

Thus results of the present study demonstrate that vaginal delivery remains and should remain a symbol of well being and health as it is a defining point in life. Since childbirth pain is usually ends with positive outcomes, this distinguishes it from other types of painful experiences. The study of Manthata also explicitly emphasized this fact^[22]. Selecting C-section electively in Babylon according to this paper was mainly out of fear of labor pain. The study of Poikkeus likewise concluded that women's preference for elective C-section is due to their unfound anxiety of pain during vaginal delivery and unrealistic thoughts about their inability to withstand vaginal birth^[23].

Almost all participants had positive attitude towards scheduled C-section despite its adverse outcomes. They also attributed many advantages to it. The most important conceptions were that it is harmless, painless and maintain beauty of reproductive organs, with

no negative impact on intimacy and sex life^[24]. Gungor and associates, in a study in 2008, also documented similar social beliefs. They also found that the frequency and mode of delivery are greatly influenced by cultural beliefs^[25].

Conclusions

Neonates born after elective cesarean delivery in Al-Hillah city have significantly higher rates of respiratory morbidity and longer length of hospital stay, with increased risk of certain medical and surgical complications. The unexpected medical complications are inversely related to gestational age at which elective cesarean section is timed. The recommended gestational age at which elective cesarean section should be timed is at 39 weeks.

Isolation of MRSA from Drinking water Supplies in Al-Anbar Province, Iraq

Shirin Yasin Bdewi¹, Mohammad Hamid Kareem², Mohammed Mosleh Shwaish², Mustafa Salah Hasan²

¹Ministry of Education, Alanbar Education Directorate, Iraq. ²College of Vet. Med., University of Fallujah, Iraq

Abstract

This study was aimed to isolate MRSA from water supplies from different places in alanbar province, fifty water samples were cultured on nutrient, macConkey and blood agars then subcultured on MSA and Staph 110, then gram stain and biochemical test done to confirm this bacteria. Then antibiotic susceptibility test were done on *S. aureus* by using different antibiotics including Methicillin, erythromycin, Doxycycline, Sulfa-trimethoprim, penicillin, chloramphenicol, ciprofloxacin.

The results showed that 12 (24%) samples were diagnose as *S. aureus*, these were showed complete resistance to methicillin, erythromycin, Doxycycline and showed different percent for resistance to other antimicrobials that used.

In conclusion, the MRSA were isolated from drinking water in significant percentage and this strain of bacteria were showed higher resistance to antibiotics.

Key words: MRSA, drinking water, Antibiotic.

Introduction

The WHO reported that MRSA was an important pathogenic bacteria causing high infections that was initially detected in 1961 & became a main threats to the public health (1).

In a study of Chen et al. (2), they reported that above two million of MRSA infection cases around the different countries in the world producing human death. As described in the UK, above five thousands deaths each year were showed to be linked with MRSA, although in Netherlands, MRSA has been found to be causes for in excess of twenty percent of all infections for MRSA (3). In Europe, it has been reported that MRSA was responsible for above 170,000 infections each year, consistent to forty four percent from all infections linked to the health care (4).

Staphylococcus aureus is an environmentally widespread but it is found chiefly on the skin as well as mucous membranes of human and animals. *Staphylococci* are sometimes identified in the GIT and has been discovered in a sewage. *S. aureus* can become free by human direct contact with the water environments for example the pools for swimming as well as fun waters. It has been also identified in a drinking water supplies (5), there is an indication of spread through the drinking of such water. While *Staph. Spp.* are somewhat resist to residuals chlorine than the *E. coli*, their occurrence in water is restricted by conventional therapy as well as disinfection procedures (6).

This study aimed to isolate MRSA from human water supplies and detection of resistance to different antimicrobials by using antimicrobials sensitivity test.

Materials and Method

A Fifty drinking water specimens were taken from a different places found in Al-anbar province (Fallujah, Heet, Ramadi, Ana, Rawa, Al-qaim, Saqlawya, Garma), these were cultured on primary media (nutrient, macConkey, blood agars), then were subcultured on other media such as mannitol salt agar and Staph 110, then gram stain as well as biochemical tests were done including catalase, oxidase as well as coagulase (7).

The antibiotics sensitivity test were done according to Bauer et al. (8) by using different antibiotics including Methicillin, erythromycin, Doxycycline, Sulfa-trimethoprim, penicillin, chloramphenicol, ciprofloxacin.

Results and Discussion

The current results were showed detection of 12 isolates of MRSA from water specimens (Table 1, Fig. 1&2).

Table 1- Number and percentages of MRSA from different location

Location	Number of MRSA	Percentage (%)
Fallujah	1	8.33
Ramadi	2	16.66
Heet	1	8.33
Ana	1	8.33
Rawa	0	0
Al-qaim	1	8.33
Saqlawya	4	33.33
Garma	2	16.66
Total	12	24%

**Figure -1- S. aureus on MSA (left)****Figure -2- Gram positive cocci**

The WHO reported that above 80% of all illness as well as the diseases on the world is made by insufficient hygiene, contaminated water or unreachability of water & at least five million deaths occur in each year which attributed to the water-borne illnesses (9). These results were in agreement with results of (10) who isolated *S. aureus* from the water provisions. Also, these similar to results of another study in Ghana that showed *S. aureus* was detected from about 64% of the specimens, with about 34.38% from well water supplies, 32.81% from hole supply & 31.25% from the tap water (11).

A study of Salim et al. (12) in Iraq found that *Staphylococcus aureus* were isolated from bottled drinking water during storage for one year at 18°C. Also, in Nigeria (13) isolated *S. aureus* from a drinking water. Moreover the bacteria that resist antibiotic were upper in the tap water than in treated water (14). Additional studies have also recognized *S. aureus* that are MDR in seaside societies in their tap water as well as fresh water (15).

The results were disagree with a results of Hillo (16) who reported that *S. aureus* not detected in drinking water in Albasrah city.

The present results of antimicrobial sensitivity test for presumptive *S. aureus* (12 isolates) showed complete resistance to methicillin, erythromycin, Doxycycline and showed different percent for resistance to other antimicrobials that used (Table 2, Figure 3).

Table 2 Antimicrobial susceptibility test for S. aureus

Antimicrobials	Resistance (%)	Sensitive (%)
Methicillin	12 (100)	0
erythromycin	12 (100)	0
Doxycycline	12 (100)	0
Sulfa-trimethoprim	5 (41.7)	7 (58.3)
penicillin	10 (83.3)	2 (16.7)
chloroamphenicol	3 (25)	9 (75)
ciprofloxacin	4 (33.3)	8 (66.7)

Figure 3- showing MRSA on Muller hinton agar

The current results were in agreement with results of many studies, Younis et al. (17) reported that 96.6% of *S. aureus* isolates were resistant to penicillin. Shi et al. (18) reported that 87.6% of isolates were resistant to penicillin. Abera et al. (19) recorded that 94.4% of isolates were resistant to the penicillin. Vanderhaeghen et al. (20) reported that all isolates (118 *S. aureus* isolates) in their study were resistant to tetracycline. Tiao (21) found that none of the 20 *S. aureus* isolates tested in her study carried the *mecA* gene and one showed methicillin resistance phenotypically. Turutoglu et al. (22) stated that out of 18 *S. aureus* isolates, 15 were typically resistant to the methicillin but didn't carry the *mecA* gene.

Also, these strains presented greater amounts of resistance to the family of macrolides especially erythromycin as reported by (23).

The incidence of genes that are responsible for antibiotic resistance in drinking water is of special concern because of the amount of persons as well as animals who are possibly affected by consuming contaminated water that contains bacteria which are antibiotic resistant and can transmit antibiotic resistance to the usual bacterial flora in the bowels of humans as well as animals.

The presence of resistance for most antibiotics that are used may be due to random usage of antibiotics and usage of drugs by incomplete course, these may lead to what is called multi drug resistance bacteria.

It has been concluded that MRSA isolated from water suppliers in a significant number and this has been resistant to multiple antibiotics.

The Predictive Value of Red Cell Distribution (RDW) in Patients with Type 1 and Type 2 Diabetes Mellitus

Huda Jabbar Dibby¹, Radhi Farhod Shlash²

¹Assistant professor of Physiology/Department of Physiology/ College Of Medicine/ University of Al-Qadisiyah/ Al-Diwaniyah province (58001) / Iraq, ²Professor and Physician / Department of Internal Medicine / College of medicine/ University of Al-Qadisiyah/ Iraq

Abstract

Background: Epidemiologically speaking the diabetes mellitus is one of the common leading causes of mortality and morbidity worldwide. Prognosis of the disease is variable and depends on the development of macrovascular and microvascular complications. Researchers are nowadays spending plenty of time trying to identify prognostic factors in order to make treatment approach be tailored according to the predictive value of such prognostic factors. One of these newly introduced factors is red cell distribution width (RDW).

Aim of the study: The current study was aiming at shedding light of the possible prognostic role of RDW in patients with type 1 and 2 diabetes mellitus.

Patients and methods: The present case control study was carried out at diabetes center in Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Province, Iraq. The study started on January 2019 and ended on August 2019. The study included 30 patients with established diagnosis of type 2 diabetes mellitus, 30 patients with type 1 diabetes mellitus and 30 apparently healthy control subjects. Diabetic patients were selected randomly from the pool of patients already registered in that center.

Results: We grouped diabetic patients into two groups according to HbA1c level, $\leq 7\%$ and $> 7\%$ and contrasted hematological levels between those new groups. The results showed no significant difference in mean hematological values between the two groups in diabetic type 1 and type 2 patients ($P > 0.05$).

Conclusion: There was no significant role for RDW in predicting poor glycemic control of patients with type 1 or type 2 diabetes mellitus.

Key words: RDW, diabetes mellitus type 1 and 2

Introduction

Diabetes mellitus is represented by a heterogenous group of metabolic disorders sharing in common the criterion of chronically elevated blood sugar level ^(1, 2). The disease is heterogenous because of variation in the etiology associated with raised blood sugar. The most common form is type 2 diabetes mellitus in which the etiology is shared by resistant to insulin action and some degree of defective insulin secretion;

even though, early in the disease there may transient period of hyperinsulinemia ⁽³⁾. Type 2 diabetes was previously called non insulin dependent diabetes mellitus and adult onset disease; however, and because of insulin requirement to control the blood sugar level in significant proportion of patients late in the disease, in addition to the identification of children with type 2 diabetes mellitus, the preferred name nowadays becomes the “type 2 diabetes mellitus” ⁽³⁾.

Type 1 diabetes mellitus, on the other hand, is often recognized in patients younger than 40 and is principally caused by profound insulin deficiency ⁽⁴⁾. From etiologic perspective, the disease is autoimmune in approximately 70-90 % of cases and the rest of cases are

Corresponding author:

Huda Jabbar Dibby

huda.budairy@qu.edu.iq

labeled idiopathic as no cause can identified ⁽⁵⁾. Other forms of diabetes mellitus included gestational diabetes, endocrine abnormality, drug induced and exocrine disease of the pancreas such as pancreatic tumors and resection ⁽⁶⁾.

Epidemiologically speaking the disease is one of the common leading causes of mortality and morbidity worldwide ^(7, 8). Prognosis of the disease is variable and depends on the development of macrovascular and microvascular complications ⁽⁹⁾. Researchers are nowadays spending plenty of time trying to identify prognostic factors in order to make treatment approach be tailored according to the predictive value of such prognostic factors ⁽¹⁰⁾. One of these newly introduced factors is red cell distribution width (RDW) ⁽¹¹⁾. Red cell distribution width (RDW) is a quantitative hematological parameter which can indicate the degree of variation in size of RBC (anisocytosis); initially was considered in the differentiation of cause of anemia ⁽¹²⁾.

The data obtained from published articles dealing with the predictive role of RDW in diabetes mellitus are conflicting and no clear consensus can be inferred from these data. Besides, data from Iraqi literatures dealing with this subject are extremely rare; therefore, we were encouraged to plan and conduct the current study aiming at shedding light of the possible prognostic role of RDW in patients with type 1 and 2 diabetes mellitus.

Patients and Methods

The present case control study was carried out at diabetes center in Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Province, Iraq. The study started on January 2019 and ended on August 2019. The study included 30 patients with established diagnosis of type 2 diabetes mellitus, 30 patients with type 1 diabetes mellitus and 30 apparently healthy control subjects. Diabetic patients were selected randomly from the pool of patients already registered in that center.

Variables included in the questionnaire form included: duration of illness, age, body mass index, systolic and diastolic blood pressures, a number of hematological parameters, namely (MCV, RDW, WBC and platelet count), serum lipid profile (triglyceride, HDL and LDL) and glycated hemoglobin (HbA1c %). Patients were considered type 2 diabetes bases one positive protein c results.

The study was approved by institutional ethical approval committee and verbal consent was obtained from all participants.

Data were then transformed into an SPSS (version 23) spread sheet for statistical analysis. Quantitative data were expressed as mean and standard deviation. Independent samples t-test was used to compare mean values between two groups, whereas, one way ANOVA was used to compare mean values among more than two groups. The level of significance was considered at $P \leq 0.05$.

Results

The current study included 30 patients with diabetes mellitus type 1, 30 patients with type 2 diabetes mellitus and 30 control subjects. The characteristics of subjects enrolled in the current study are shown in table 1. There was no significant difference in mean duration of diabetes mellitus between type 1 and type 2 DM patients ($P > 0.05$); however, patients with type 1 DM were significantly younger than type 2 DM patients ($P < 0.05$). There was also, no significant difference in mean BMI among study groups ($P > 0.05$).

In addition, there was no significant difference in mean systolic blood pressure (SBP) and diastolic blood pressure (DBP) among groups ($P > 0.05$). WBC count was significantly higher in diabetic patients in comparison with control group ($P < 0.05$); however, the count was comparable in both diabetic groups ($P > 0.05$). Besides, there was no significant difference in other hematological parameters and serum lipid profile among study groups ($P > 0.05$), as shown in table 1. We grouped diabetic patients into two groups according to HbA1c level, $\leq 7\%$ and $> 7\%$ and contrasted hematological levels between those new groups. The results showed no significant difference in mean hematological values between the two groups in diabetic type 1 and type 2 patients, as shown in table 2 and 3.

Discussion

Diabetes mellitus is a heterogenous disorder with wide spectrum of outcomes and complications that vary from to patient. These outcomes are determined by macrovascular and microvascular complications. Microvascular complications include nephropathy, retinopathy and neuropathy; whereas macrovascular complications included ischemic heart disease and cerebrovascular accidents. The development of these complications can be delayed and their effects can be minimized if patients were able to control their blood sugar strictly. For that reason, the quality of life of patients with type 1 and type 2 diabetes mellitus can be improved if treatment is directed toward strict glycemic control. Indeed, glycemic control can be determined by measuring HbA1c every 90 days in average. Recent studies have shown that the red cell distribution width (RDW) can be used as a prognostic factor since it has a correlation to HbA1c and diabetic complications and can be used as a predictive marker for diabetic control (11, 13); however, some authors have denied such role for RDW in diabetes mellitus (14, 15).

The evidence connecting red cell distribution width (RDW) with an increasing risk of mortality has been grown since the early report of its predictive value in patients with heart failure. It has also been described to independently anticipate cardiovascular and overall mortality in various high-risk populations and in the general population (16, 17). Besides, it has been shown to be a significant predictor of mortality in number situations such as malignancies, obesity and renal disorders (18). For that reason, some authors suggested that linking RDW to diabetes prognosis is justified (11).

In the current study it was shown that RDW is not sufficiently affected by type of diabetes or even by degree of glycemic control indicated by HbA1c. These results are in agreement with a number of authors (14, 15) and disagree with other authors (13, 11), thus we believe that it is very early to judge the role of RDW in diabetic prognosis and that a lot of research work is needed in order to reach clear consensus about such role.

In one study, it was found that Red cell distribution width (RDW) was significantly higher in diabetic patients than in control subjects ($P=0.008$). It was also higher in patients with uncontrolled glycemia (HbA_{1c} $>$ 7%) than those with good control (HbA_{1c} \leq 7%; $P=0.035$) (11).

Actually, these findings are not consistent with the present study findings; however, the author of the later study agreed with us that other hematological characteristics were not affected by diabetes or its degree of glycemic control.

It is worth to mention that WBC was significantly higher in both diabetic groups when compared to non diabetic group. This finding is similar to the findings of several other authors (19-21); however, it contradicts other authors (11). Several explanations have been suggested to explain the high WBC in association with diabetes such as increased insulin resistance, development of complications and high rate of infections (19-21).

In conclusion, there was no significant role for RDW in predicting poor glycemic control of patients with type 1 or type 2 diabetes mellitus.

Histopathological Changes Associated with Cutaneous Leishmaniasis in Patients with Baghdad Boil/South of Iraq

Amal Khudair Khalaf

Dept. Microbiology \ college of Medicine \ University of Thi-Qar

Abstract

Cutaneous leishmaniasis is an endemic disease in Iraq and it is become epidemic in Nassirriyah city recently/ South of Iraq.

The following histopathological study were achieved in microbiology dept. at college of Medicine in University of Thi-Qar, targeting Nassirriyah city in south of Iraq where Baghdad boil is highly distributed during a period of time at end of April 2016. several of tissue (skin) biopsies were obtained by dermatologist under sterilizing condition and at Al-Hussain teaching hospital where the patients have entered for treatment . the result explain the following changing :

- marked epidermal hyperplasia with hyperkeratosis .
- two small granulomas of macrophages some with vaculation in the dermis .
- sever dermal hyperplasia and folliculitis also hyperkeratosis and scab formation.
- marked hyperplasia of epidermis , hyperkeratosis and scab formation .

Key words : *coetaneous leishmaniasis , Baghdad boil , histopathology*

Introduction

The parasitic disease of Leishmaniasis caused by haemoflagellate *Leishmania tropica* . It is widespread and may cause serious health problems in communities throughout the Mediterranean regions and the Middle East, including Iraq [1-3]. There are an estimated 12 million cases worldwide, and there are about 1.5 million new cases of cutaneous leishmaniasis each year, of which over 90% occur in Afghanistan, Algeria, Iran, Iraq, Saudi Arabia, Syria, Brazil and Peru [4]. Old World disease primarily is caused by *Leishmania tropica minor* in urban areas and *Leishmania tropica major* in dry desert areas [3].

In Iraq, two species are present: *L. tropica*, the agent of anthroponotic cutaneous leishmaniasis (ACL), and

L. major, the agent of zoonotic cutaneous leishmaniasis (ZCL). Both ACL and ZCL were reported as causative agents of leishmaniasis in Iraq, but ACL is found mainly in suburban areas [5]. The disease is epidemiologically unstable, with large and unpredictable fluctuations in the number of cases. The total incidence rate of cutaneous leishmaniasis in Iraq varies from 2.3 / 100000 to 45.5 / 100000 [5]. Cutaneous leishmaniasis is characterized by one or more cutaneous lesions on areas where sandflies have fed. Persons who have cutaneous leishmaniasis have one or more sores on their skin. The sores can change in size and appearance over time. They often end up looking somewhat like a volcano, with a raised edge and central crater. A scab covers some sores. The sores can be painless or painful. Some people have swollen glands near the sores (for example, in the armpit if the sores are on the arm or hand).[6]

Materials and Method

- **Skin biopsy** : Biopsies were taken from patients by the dermatologist and placed in 10% of formalin to prepare it for tissue processing .⁽⁹⁾

- **Histology** : Tissues biopsy were processed according to ⁽⁹⁾, briefly the tissue from the skin collected and placed in 10% formalin for histopathological studies and dehydrated by several dilutions of ethanol alcohol dealcoholization with xylol, then embedded with paraffin wax blocked (3-5) mm thickness sections were obtained by microtome. The sections were put on glass slides deparaffinised with xylol, rehydrated by alcohol and stained by hematoxyline and eosin.

Fig(1) : explain the presence of Baghdad boil or cutaneous leishmaniasis

Results

The following histopathological changing has associated with Baghdad boil , the clinical infection with cutaneous leishmaniasis caused by the protozoan *Leishmania tropica* , as illustrated in the following figures;

Fig (2) : marked epidermal hyperplasia with hyperkeratosis (10X)

Fig(3): small granuloma in the dermis consist of macrophages and fibroblast at the periphery (40X)

Fig (4) marked hyperplasia of epidermis , hyperkeratosis and scab formation (10X)

Fig (5) : marked hyperplasia of epidermis , hyperkeratosis and scab formation , keratin nest in the dermis (10X)

Fig (6): two small granulomas of macrophages some with vacuolation in the dermis (40X)

Discussion

The skin covers the human body and is constantly exposed to the environment. As a barrier against infection, the skin not only forms a physical hindrance but also serves as a very important immunological organ.

cutaneous leishmaniasis appears in variable patterns clinico-pathologically, and sometimes a simple erythemic lesion, shows (LD) bodies and in few cases has been diagnosed clinically malignant and remained untreated for years. The CL clinically presents according

to the stage of infection and the clinical type of disease basically an ulcer appearing at the site which heals slowly, takes months to years depends upon the host immunity.

Cutaneous leishmaniasis, a wide clinical and histological spectrum. The histological picture in CL differs according to the stage of infection and the clinical type and host immunity. There is evolution of the lesion as it progresses from a papule and nodule into a soft boggy, crusted plaque or nodule⁽¹²⁾. The lesion breaks up after 3-4 months into a well circumscribed ulcer, which heals slowly over a period of 3 to 12 months. The histological spectrum in CL has wide range with a great variation in morphology. The appearances may range from predominance of leishmanial granuloma with macrophages showing epithelioid. Granuloma formation results from macrophages activation into epithelioid cells, considering clinicopathological relationship⁽¹¹⁾. The histological picture in CL differs according to the stage of infection and the clinical type. A consistent finding is a moderate to heavy dermal infiltrate of lymphocytes, plasma cells, and macrophages. In approximately 80% of cases, epithelioid cell granulomas with giant cells and a rim of lymphocytes are present. It is important to search for amastigotes, which are diagnostic^(13,14). Histopathological changing of skin during cutaneous leishmaniasis explain the granulomatous reaction in the site of infection together with presence of amastigote stage or LD bodies in the lesion based on the current study. The essential feature of CL pathology is the colonization by amastigotes of cells of the mononuclear phagocytic system and the resulting granulomatous inflammatory response. A granuloma is defined as a compact collection of mature mononuclear phagocytes, not necessarily accompanied by accessory features such as necrosis. Conceptually granuloma evolves in three stages: 1) the development of an infiltrate of young mononuclear phagocytes; 2) the maturation and aggregation of these cells into an unorganized granuloma; and 3) the potential maturation of these cells into an epithelioid or organized granuloma⁽⁷⁻¹⁰⁾

Cutaneous Leishmaniasis presents a spectrum of manifestations both clinically and histologically. Lesions can present as nodule, plaque or ulcer mostly present on exposed sites^(8,9). Histopathological findings in acute CL include dermal infiltrate predominantly consisting of macrophages containing large number of leishmania organism called LD bodies^(5,6) In addition plasma cells and dense mixed inflammatory cell infiltrate are also

present in dermis. The morphology of LD bodies in histopathological sections were rounded with a nucleus and kinetoplast, in some sections spindle shape form similar to smear morphology were detected^(7, 8).

Serum Anti-Mullerian Hormone Concentration and Function of The Pituitary-Gonadal Axis in Iraqi Patients with Chronic Kidney Disease

Athraa K. Falhi¹, Noori M. Luaibi¹, Ali J. Alsaedi²

¹Biology Department, College of Science, Mustansiriyah University/Iraq,

²Consultant Nephrologist, Medical City, Baghdad-Iraq

Abstract

Infertility among patients with chronic kidney disease (CKD) has been extensively investigated. However, reproductive function in these patients is less well-characterized. The present study was aimed to examine the associations among chronic kidney disease (CKD) and fertility status by evaluation levels of: Luteinizing hormone (LH) and Follicle-stimulating hormone (FSH). Estrogen (E2) and Progesterone (P4) for females and Testosterone for males along with Anti-Mullerian Hormone (AMH) in CKD patients. The study has been registered at Nephrology and Transplant Center in Medical City of Baghdad- Iraq from April 2018 to July 2018. The study included 50 patients who are diagnosed to have CKD stage-5, their ages ranged between 20-50 years (25 males and 25 females) and 20 matched apparently healthy as control, their ages ranged between 20-48 years (10 males and 10 females). This study showed a highly significant ($P<0.01$) increase in LH, FSH levels in CKD patients compared to the control group. Highly significant ($P<0.01$) decrease in E2 level in CKD females patients compared to the control group, while there was non-significant ($P>0.05$) decrease in P4 level in CKD females patients compared to the control group. In parallel, there is significant ($P<0.05$) decrease in Testosterone level in CKD males patients compared to the control group. On the other hand, the study showed non-significant ($p>0.05$) increase in AMH level in CKD patients compared to the control group.

Keywords: CKD, AMH, LH, FSH, E2, P4, Testosterone.

Introduction

The genesis of sexual dysfunction in patients with chronic kidney disease (CKD) is multifactorial [1]. Hormonal dysfunction in CKD is clinically accompanied by sexual dysfunction that influences the life quality of these patients, in advanced stages of CKD, these sexual dysfunctions can be more evident, several changes in hormone levels have been demonstrated, these changes can be because of decreased renal excretion and disturbance of the endocrine system because of uremic effects [2]. Disturbances in the hypothalamic-pituitary-gonadal axis, resulting in alterations in signal-feedback mechanisms and hormone production, are seen already in patients with moderate reduction in the glomerular filtration rate and often become more obvious as kidney failure progresses [2,3]. Earlier studies have shown elevated levels gonadotropins, luteinizing hormone (LH) and

follicle-stimulating hormone (FSH) [4]. Decreased levels of free and total testosterone have also been reported in patients with CKD [5,6]. In those patients, level LH and FSH rise up [7]. In uremic patients, GnRH releasing from the hypothalamus and GnRH- LH signal are impaired. In these patients, bioactivity of LH changes and then a series of function inhibitors of LH are made [8].

Anti-Müllerian hormone (AMH) is a glycoprotein with a fundamental role in male sex differentiation [9]. As such, AMH is now recognized as the best available biomarker of both the functional and true ovarian reserve [10]. In male serum AMH is correlated with spermatogenesis, the Sertoli cells secrete AMH, and it is a specific marker of Sertoli cell function [11]. CKD and its consequences affect the production of AMH, resulting in change in AMH levels, this may indicate impaired function of Sertoli cells [12]. In women with CKD the aforementioned fertility disturbances may be

caused by the damage of the ovaries by uremia, this may reflect an intrinsic dysregulation of the granulosa cells leading to higher AMH production or alternatively AMH accumulation in CKD patients requiring dialysis [13,14].

Material and methods

The study has been registered at Nephrology and Transplant Center in Medical City of Baghdad- Iraq from April 2018 to July 2018. This study included two groups, patients and control group. The study included 50 patients are diagnosed to have CKD stage 5, their ages ranged between 20-50 years (25 males and 25 females) and 20 control their ages ranged between 20-48 years (10 males and 10 females). Blood samples

were collected from all groups for estimation of (LH, FSH, E2, P4, Testosterone), All those biomarkers were estimated in serum of all subjects by using an automated quantitative COBAS e 411 test (from Roche, Germany). Serum AMH was measured by ELISA using a kit supplied by Beckman Coulter- Germany.

Results

In this study the level of LH (7.10 ± 0.57) was highly significant increased ($P < 0.01$) in comparison with control (3.62 ± 0.45). Also, the level of FSH showed high significant increase ($P < 0.01$) in patients group (8.01 ± 0.50) when compared with control group (4.79 ± 0.55), Table (1).

Table 1: Comparison between patients and control in level of LH, and FSH.

Group	Mean \pm SE	
	LH mIU/ml	FSH mIU/ml
Patients	7.10 ± 0.57	8.01 ± 0.50
Control	3.62 ± 0.45	4.79 ± 0.55
T-Test	1.897 **	1.732 **
P-value	0.0005	0.0004
** (P<0.01): Highly Significant		

On the other hand the mean of serum E2 and P4 levels in the females of study groups are summarized in Table (2). E2 level (7.89 ± 1.17) in patients group observed highly significant decrease ($P < 0.01$) in comparison with control group (20.80 ± 5.04), while P4 levels showed non-significant decrease (0.407 ± 0.06) in patients compared to control group (0.408 ± 0.10).

Table 2: Compare between patients and control (Female) in E2 and P4.

Group	Mean \pm SE	
	E2 Pg/ml	P4 ng/ml
Patients	7.89 ± 1.17	0.407 ± 0.06
Control	20.80 ± 5.04	0.408 ± 0.10
T-Test	7.318 **	0.249 NS
P-value	0.0008	0.997
** (P<0.01): Highly Significant ; NS: Non-Significant.		

The present study displayed, significant decrease ($P < 0.05$) in Testosterone level in male patients with CKD (1.57 ± 0.25) in comparison with healthy control group (2.73 ± 0.58).as shown in Table (3).

Table 3: Compare between patients and control (Male) in level of Testosterone.

Group	Mean ± SE of Testosterone ng/ml
Patients	1.57 ± 0.25
Control	2.73 ± 0.58
T-Test	1.097 *
P-value	0.0387
* (P<0.05): Significant	

On the other hand, in this study as shown in Table (4), level of serum AMH found to be slightly elevated but not significant in patients with CKD in comparison to control group. AMH levels in both groups (9.03 ± 1.58), (7.76 ± 1.75) respectively showed non-significant difference ($p > 0.05$).

Table 4: Compare between patients and control in level of AMH.

Group	Mean ± SE of AMH ng/ml
Patients	9.03 ± 1.58
Control	7.76 ± 1.75
T-Test	5.490 NS
P-value	0.645
NS: Non-Significant.	

Statistically, the finding in Table (5) indicate a correlation coefficient between AMH hormone and other parameter in this study. As showed there is a highly significant ($P < 0.01$) positive correlation between AMH with Testosterone, non-significant ($p > 0.05$) positive correlation between AMH and FSH, E2. On the other hands there is non-significant ($p > 0.05$) negative correlation between AMH with LH and P4.

Table 5: Correlation coefficient between AMH and other parameters.

Parameters	Correlation coefficient (r) and Level of significant
	AMH
LH	-0.15 NS
FSH	0.09 NS
E2	0.001 NS
P4	-0.16 NS
Testosterone	0.22**
* (P<0.05), ** (P<0.01), NS: Non-significant.	

Discussion

End stage renal disease (ESRD), has a strong influence on the hypothalamic-pituitary-gonadal axis resulting in hormonal disturbances and deterioration in gonads function. [2,15]. The results of this study on elevated levels of LH and FSH in CKD patients are consistent with previous study reported by Anatharamaa and Schmidt [16], who found that changes in pulsatile release of GnRH and LH reduce feedback inhibition of LH production (because of low levels of testosterone) contribute to high levels of LH, FSH secretion in CKD patients. With CKD there was a significant increase in LH and FSH and development of pattern of hyper gonadotropic hypogonadism, which indicates that uremic metabolite tend to increase CKD effect on testes and ovaries more than hypothalamic or pituitary function [17].

The results of this study agree with those that have been found with previous studies [7,8,15], who showed that low concentration of E2 has been seen in uremic patients, nevertheless it has insufficient concentration in the puberty, while in the second half of menstrual cycle serum P4 concentrations are decreased due to the defective follicle luteinization. In this study P4 levels are slightly decreased with no significance compared to the control group, previous reports go in agreement with the results of this study which reported that mean P4 levels in patients were not significantly different from those of control subjects [18,19].

In this study, the results of testosterone in male patients indicated significant decrease ($P < 0.05$) in CKD patients, and this result was also approved by several previous studies as testosterone which is normally reduced in CKD patients and when LH level is arise in response to low levels of testosterone, so that the hypothalamic pituitary axis in CKD is reset in such a way that it is more sensitive to the negative feedback inhibition of testosterone [16,17,20,21]. Rathi and Ramachandren. [22], showed that low testosterone is due to decreased production, increased metabolic and dialytic clearance, alteration in testosterone binding capacity.

The data of this study suggest that patients with CKD stage-5 have elevated but not significant AMH compared with control and this results go in agreement with those that have been found with Stoumpos *et al.* [14], who showed that CKD patients were found to have non-significant increase in AMH concentrations compared with control. Also, the results of this study was compatible with data reported by Sikora-Grabkaa *et al.* [13], who found that serum AMH concentration was higher in haemodialysed women with CKD and had menstrual cycle abnormalities in comparison to those with regular menstrual cycles, and suggested that serum AMH clearance is reduced in CKD patients and AMH similar to other protein hormones probably accumulates in those patients [14]. On the other hand, AMH is of similar size to other molecules perceived to be uremic 'toxins' [1].

This study disagrees with those that have been found with Eckersten *et al.* [1], who they reported that male patients with CKD have lower serum AMH levels versus controls and this was an unexpected finding, the author explained that this finding of low AMH levels indicate a dysfunction of both Sertoli cells and Leydig cells in men with CKD. The results of this study also in disagreement with Eckersten *et al.* [23], who showed that plasma AMH levels were lower in CKD stages 1–4 by 30% and by 70% in CKD stage 5 compared with controls, the author said that this reduction in AMH is unclear, but can be linked to altered Sertoli cell function. The cause of decreased plasma AMH levels is unknown, but it speculate on effects of inflammation, uremic toxicity, or other causes. The results of this study support that the molecular weight of AMH (140 kDa) indicates that it is not eliminated by glomerular filtration or dialysis, if this is the case, an increase in plasma AMH levels would be expected with advancing CKD stages [1,14,24].

Results of this study showed that LH has negative correlation with serum AMH in men and women with CKD, this finding disagree with another finding [25], who found no relationship between AMH and LH. Another study also showed no significant correlation between AMH and LH [26]. Results of current study showed positive no significant correlation between AMH and FSH and this result was in agreement with other study which reported that AMH positive correlated with FSH [27]. Fiza *et al.* [28], showed a negative relationship between the levels of AMH and FSH and this results disagreement with the results of this study.

Thus, the higher levels of AMH are associated with lower level of the FSH and support this result by another study which reported that the excess of AMH is involved in diminishing FSH induced aromatize activity and this results disagreement with this study [9,29,30]. High AMH levels are probably related to the follicular arrest during the selection process of the dominant follicle, through a negative interaction between AMH and FSH [31].

In this study E2 showed non-significant positive correlation with AMH and this result was in agreement with other study which reported that AMH was negative correlated to LH and positive correlated with FSH and E2 [27].

Conclusions

This study confirms the noxious role of CKD in hormonal disruption and infertility among patients with CKD.

Abstract

Hepatitis an infection in the liver is very contagious and is caused by the hepatitis virus. Objectives: The study aims to evaluate nurses performance concerning infection control practices, and to determine the relationship between nurses performance and their demographic characteristics. As well as, to determine the relationship between nurses performance and patients clinical data. A quantitative descriptive design was conducted in Hilla City Hospital for the period of from September 2018 to March 2019. A checklist was used as a means of data collection from those who works at Hemodialysis unit. Non probability sampling (purposive) has been performed on (30) nurses and (30) patients in dialysis unit. direct observation as mean of data collection. Nurses were observed three times while they are working in the dialysis unit. The data were analyzed through the application of descriptive and inferential data analysis. The study results reveals that (80%) sometime applied hand washing, (76.7%) were sometime apply uniform, and (66.7%) were always apply gloves, (53.3%) never wearing gown, and (86.7%) never wearing mask. A majority of (63.3%) of nurses were partially performed infection control measures. There is insignificant association with nurses demographic characteristics at $p\text{-value} > 0.05$.

Keywords: Infection, Control, Nurses, Hepatitis.

Introduction

One of the most challenges is health care-associated infections, or infections acquired in health-care settings are the most frequent adverse event in health-care delivery worldwide. Hundreds of millions of patients are affected by health care-associated infections worldwide each year, leading to significant mortality and financial losses for health systems¹. The World Health Organization (WHO) estimates an average of 9 million individuals are affected by nosocomial infections and approximately 1million patients die each

year because of these diseases². Patient safety is one of the most important aspects in evaluating the quality of healthcare. However, healthcare associated infection is a major cause of morbidity and mortality in the critical care units. It is imperative for health care administrators to ensure implementation of the infection control program in healthcare facilities³. Control measures is a set of specific practices and procedures performed under carefully controlled conditions with the goal of minimizing contamination by pathogens⁴. It is well known that patients undergoing dialysis treatment, and in particular hemodialysis (HD), are at increased risk for contracting viral infections. This is due to their underlying impaired cellular immunity, which increases their susceptibility to infection. In addition, the process of HD requires blood exposure to infectious materials through the extracorporeal circulation for a prolonged period. Moreover, HD patients may require blood

transfusion, frequent hospitalizations and surgery, which increase opportunities for nosocomial infection exposure⁵. After the identification of HCV in 1989 and HEV in 1990, there were still unexplained cases of post transfusion and “community-acquired” hepatitis, implying that cryptogenic hepatitis and cirrhosis may be related to viruses other than hepatitis A, B, C, D or E. By the mid-1990s, between 3% and 4% of anti-HCV-negative patients on chronic HD had elevated serum aminotransferase levels with no apparent etiology^{6,7}.

Methodology

Study Design:

A quantitative descriptive design was conducted to evaluate nurses performance concerning infection control practices, and to determine the relationship between nurses performance and their demographic characteristics. As well as, to determine the relationship between nurses performance and patients clinical data in has been carried out in Hilla City Hospital.

Instrument Construction:

The checklist (observation tool) include three part. They are: Nurses demographic data, patients clinical data, and observation tool. The last part consists from 55 items divided (8) section; includes: hand washing, uniform, gloves, gown, mask, instruments and equipment, intra venous iv fluids and medication, medical waste management and sharp disposal.

Participants Sample:

Non probability sampling (purposive) has been performed on (30) nurses who work in dialysis unit and (30) patients.

Data Collection:

The researcher has gathered the objective’s responses through an application of direct observation as mean of data collection. Nurses were observed while they are working in the dialysis unit . The researcher observed each nurse three observations and among each observation (10) days’ time period. Three correct practices out of 3 episodes were rated as always , 2-1 correct practice out of 3 episodes were rated as sometimes, and no correct practice out of 3 episodes was rated as never.

Data Analysis: Through the used descriptive

statistical (SPSS) version XX analysis approach that includes, frequencies, percentages, mean of scores, standard divagation and graphical presentation of data; and inferential statistical data analysis approach that include Chi-squared test.

Results and Discussion

In light of frequencies and percent, results depicts that the nurses were female within age groups (19-29) years old and single state residences in urban areas. Concerning education, (53.3%) were bachelor in nursing graduated, works for (1-3) years in nursing field and in Hemodialysis unit without training in-outside of country. This results come because most of them are new appointments at the same time that unity needs effort. These results agree with study deals with case control educational program on nurses knowledge find that the majority of nurses at 20-29 years⁸. Also, study conducted in Baghdad City has been evaluate the nurses’ practice concerning infection control. Finds that the high percent of nurses have 1-5 years of experiences in nursing⁹. Finding reveals that 96.7% of patients with hepatitis C is for duration (1-2) years diagnosed after dialysis for a two dialysis times per week . In light of these results, a study has been assessed the “Hepatitis B and C infection in hemodialysis patients in Libya, the results indicated that the patients on maintenance HD in Libya have a high incidence and prevalence of HCV infection and lower rates of HBV infection¹⁰. Also, in another study (Yousifetal., 2018), the result indicated that the prevalence of HBV, HCV, and coinfection in the studied subjects was 1.8%, 9.2%, and 0.2%, respectively¹¹. The results reveals that the majority of nurses measures regarding hand washing and uniform were sometime apply. In contrast a study conducted in Turkey , they found that the majority of nurses have a partially level of practices concerning quality of hand washing¹². Also in another study in Al-Najaf AL-Ashraff City Hospitals, their findings indicate that 72.5% of study sample are not applying the practices of hand washing¹³. While another study in Palestine, show that the high percentage of nurses are wearing the special uniform¹⁴.

Concerning with personal protective equipment, the results reveals that the majority of nurses were always apply gloves, and never apply gown, and mask. In another study done by (Cason and others, 2007), which reported that 75% of nurses are wearing gloves. The researcher believes that the present result related to not available of sterile gloves, but they can be used clean

gloves during the nursing intervention ¹⁵. These results supported by (Chan et al., 2008), show that the nurses have negative attitudes and practices toward standard precaution. These results may be to not the availability of sterile gown in the hospital ¹⁶. In another study done by (Nichol et al., 2013), their study showed that the 56% nurses reported adherence to recommended use facial mask ¹⁷.

Concerning with nurses measures deals with instruments and equipment the results depicts that the majority of nurses measures regarding instruments and equipment were sometime apply. In another study done by (Kandeel et al., 2012), which revealed that high percent of nurses were used a sterile technique in preparing the instrument in critical care units ¹⁸.

Concerning with nurses measures deals with dialysis Catheters and port catheter systems, intravenous fluids and medication and medical waste management and sharp disposal, the results show that the majority of nurses were always applied. The present results disagree with (Alkubati et al., 2015), they founded that the majority of nurses had poor compliance with the standard strategies for prevention PVC infection ¹⁹. In addition the results agree with (Dolan et al., 2010), they confirmed in their study that an infusion, safe injection, and medication vial practices in health care needed to adhere sterilization technique during the administration of intravenous fluids and medication for the patient ²⁰. The present result also disagrees with (Ferreira et al., 2010), they founded in their study that a healthcare worker was inadequate practice and knowledge related to the correct separation of wastes and sharps disposal ²¹. Findings of present study demonstrated that there demographic characteristics of nurses have been not affected their control measures at *p-value* >0.05. The present finding agree with study done by (Bakey, 2012), which indicated that there was no significant relationship at *p-value* (0.464) level between nurses' practice and their age, level of education, years of experience in

hemodialysis unit ²². Also the present finding disagree with study done in Korea, they found that there were significant relationship between nursing practice concerning infection control and age and significant between the type of units and nurses practices ²³. Results demonstrated that there were non-significant association between nurses control measures and patients their clinical data at *p-value* >0.05. The result disagree with study of (Alashek, 2012), which indicated that their is a significant relationship between duration of hemodialysis and prevalence of HCV, and longer dialysis times increase the probability of hepatitis C in Libya ¹⁰. Also in another study done by (Sarhan et al., 2015), the result show that the prevalence of HCV antibody (HCV Ab) at the start of dialysis was 45.2%, and the prevalence of HCV Ab by the time of data collection was 51%; the incidence rate of seroconversion was 10.7% after a mean duration of dialysis of 3.35±2.048 years ²⁴.

Table (1): Distribution of Patients by their Clinical Data about Hepatitis

Demographic data	Rating	No	Percent
Type of hepatitis disease	C	29	96.7
	B	1	3.3
Duration of disease	<1 years	1	3.3

Gingival and Salivary Changes in Correlation with Multiple Sclerosis

Esra Hassan Abd Ali¹, Suzan M. Abdul Raheem²

¹Assi.Prof.) M.SC, Ph. D College of Dentistry/Al-Mustansiriyah University, ²B.D. S, M.Sc., Lecturer; College of Dentistry, Al-Mustansiriyah University

Abstract

Multiple sclerosis: chronic degenerative autoimmune disease of the central nervous system marked by patchy destruction of the myelin sheath that surrounds the nerve fibers. The gingival or oral changes that associated with multiple sclerosis might be related to disease itself or as sequel of medications that used for treatment. Aims;-to determine the gingival index and assess the SIgA, SFR and PH in MS patients in compare to control group as well as analyses theses parameters according to age group, gender and type of MS. 36 patients with proven diagnosis of MS were selected randomly between 1st Nov.2016-1st nov.2017 from MS center. Medical city .Baghdad. Iraq. Oral examination was done to measure the gingival index as well as saliva was taken to assess the salivary IgA level, salivary flow rate and PH of saliva, in addition 20 subjects who are free of MS or any others autoimmune disease were selected as control group. The GI of patients group was significantly higher than control group(3.4 ,1.4) respectively while the SIgA ,SFR and PH of saliva was significantly lower with patients group in compare to control group(510,0.56,6.6 for patients group) 941.8,1.7,7.1 for control group

Key word: Multiple sclerosis, salivary immunoglobulin A, gingival index, saliva flow rate

Introduction

Multiple sclerosis (MS) is a progressive, neurodegenerative disorder of the myelin sheath, in which plaques created on the central nervous system (CNS) alter nerve function. ⁽¹⁾ Although the exact cause of MS is unknown, a combination of genetic susceptibility, environmental factors, immune system response and systemic inflammation is suspected. Progression of MS and new plaque formations cause CNS changes in motor, sensory and cognitive functions, leading each individual to experience symptoms that vary in degree and severity.⁽²⁾ The prevalence of MS varies considerably, from high levels in North America and Europe (>100/100,000 inhabitants) to low rates in Eastern Asia and sub-Saharan Africa (2/100,000 population). Concerning mortality, in a large French cohort of 27,603 patients, there was no difference between MS patients and controls in the first 20 years of the disease, although life expectancy was reduced by 6–7 years in MS patients. MS starts attacks people from age 20–50 years old and the records investigated that females' attacks double than males' attacks ⁽³⁾ There are 4 types of MS. They're named according to the way the

disease acts on the body over time. Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system (CNS), usually characterized by a relapsing-remitting (RR) course, or by disability accrual over an extreme variability of time. At diagnosis, about 75% of persons with MS suffer from RRMS, while about 25% of such persons will convert to secondary progressive MS (SPMS) within two to three decades from the onset. About 10% of patients with MS manifest primary progressive MS (PPMS) at diagnosis, and they show gradual worsening of neurological disability from symptom onset ⁽⁴⁾. With the term progressive MS (PMS), we usually refer to the combined population of secondary progressive MS (SPMS) and primary progressive MS (PPMS) that still remains a distinct phenotype in the 2013 revision of clinical course in MS ⁽⁵⁾

THE 4 TYPES OF MS

Relapsing-Remitting MS (RRMS). This is the most common form of multiple sclerosis. About 85% of people with MS are initially diagnosed with RRMS. People with RRMS have temporary periods called relapses, flare-ups or exacerbations, when new symptoms appear ⁽⁶⁾

□ Secondary-Progressive MS (SPMS). In SPMS, symptoms worsen more steadily over time, with or without the occurrence of relapses and remissions. Most people who are diagnosed with RRMS will transition to SPMS at some point ⁽⁷⁾

□ Primary-Progressive MS (PPMS). This type of MS is not very common, occurring in about 10% of people with MS. PPMS is characterized by slowly worsening symptoms from the beginning, with no relapses or remissions²

□ Progressive-Relapsing MS (PRMS). A rare form of MS (5%), PRMS is characterized by a steadily worsening disease state from the beginning, with acute relapses but no remissions, with or without recovery^{2 (6)}

The hypothesis states that the pathophysiology of MS is related to myelin antigen-specific CD4+ T cells which become activated. The exact trigger for the activation of the T cells is still unknown. One theory suggests that T cells might become activated by cross-reacting with a particular antigen, such as a microbial agent, known as “molecular mimicry”. This theory explains why some viruses have been studied as a possible trigger for the disease. These cells then cross the blood-brain barrier, recognize myelin basic protein, attack the neuronal myelin sheaths, and trigger the onset of muscular symptoms and can lead to cognitive decline. These areas of axonal damage are known as lesions. The actual mediator of myelin and axonal destruction has not been established, but it may reflect a combination of macrophages, antibodies, cytokines, and reactive oxygen intermediates.⁽⁸⁾ To our knowledge this is the first study in our country studying the changes in salivary IgA, SFR, PH of saliva in MS patients in compare to control health group as well as assessment the changes according to type of MS.

Subjects and methods

Between 1st Nov.2016-1st Nov.2017 and after approval was obtained from concerned authouritis,36 patients with proven diagnosis of MS who are attending the MS center of medical city. Baghdad.Iraq were selected randomly and oral examination was doing to measure the Gingival Index as well as saliva was taken to assess the salivary IgA level, Salivary Flow Rate and PH of saliva, in addition 20 subjects who are free of MS or any others autoimmune disease were selected as control group.

Saliva sample:

Un stimulated whole saliva (2 ml) were collected from patient group and control by expectoration into sterilized vials then saliva sample were centrifuged at 12000 rpm for 10 minutes and the supernatants were stored at -20°C until use .

Estimation of SIgA by ELISA procedure of the test: -

1- Standard was constituted to 1000 pg/ ml with standard dilution buffer. a serial diluents of the standard were prepared from original standard.

2- One hundred ml of standard or sample was added per well, then 100 ml of diluent were added for each well. The plate was incubated for 4 hours.

3- The contents of well were discarded and washed by washing solution.

4- Two hundred ml of conjugate reconstituted was added into each well and incubated at 25 C° and then washed three times.

5- Two hundred ml of substrate was added into each well, followed by incubation for 15 minutes at 25 C° with continuous shaking in the dark.

6- Fifty ml of stopping solution H₂SO₄ was added into each well and mixed gently.

7- Absorbance was measured by spectrophotometer at 450 nm within two hours.

The flow rate of saliva (SFR) ml/min was estimated by dividing the total collected saliva volume (ml) by collecting time (min) that was measured by sample collection:

$$\text{SFR ml/min} = \frac{\text{saliva sample volume (ml)}}{\text{collection time (min)}}$$

Salivary pH was measured with a digital pH-meter (Hanna Instruments, USA) 30 to 60 minutes after saliva samples were collected, and pH was considered as a quantative variable. The BMI for a person is defined as their body mass divided by the square of their height with the value universally being given in units of Kg/m².

Statistical Design

SPSS version 23 was used for data entry and analysis, mean and standard deviation was used to represent the continuous data. ANOVA and student t test were used

to confirm significance. P-value \leq 0.05 was considered significant.

Results and Discussion

The findings indicated that the mean age of patients group was 37.2 \pm 4.3, 47.2% belong to age group of 20-

40 years, 75% was females and 72.2% of RRD type. With regards to control group; the results revealed that the mean age was 38.7 \pm 6.8 years, 45.5% was fall to age group of 20-40 years and 63.6% was females as seen in table.1.

Table.1. descriptive characteristics of studied groups

	Groups				
	Patients(n=36) Mean age=37.2 \pm 4.3years		Control(n=22) Mean age=38.7 \pm 6.8 years		
	No.	%	No.	%	
Age groups	<20	8	22.2%	6	27.3%
	20-40	17	47.2%	10	45.5%
	>40	11	30.6%	6	27.3%
Gender	Female	27	75.0%	14	63.6%
	Male	9	25.0%	8	36.4%
Type	RRD	26	72.2	-	-
	SPD	3	8.3	-	-
	PPD	4	11.1	-	-
	PRD	3	8.3	-	-

The results demonstrated that the mean value of GI, SIgA, SFR and PH of patients group were significantly higher than that of control group (p \leq 0.05 for all) as displaced in table.2.

Table.2. Mean of GI, SIgA, SFR and PH of patients and control group.

	Groups				
	Patients group		Control group		
	Mean	Std. Deviation	Mean	Std. Deviation	p-value
GI	3.4	0.6	1.4	0.5	0.01
SIgA	510.8	59.7	941.8	63.8	0.01
SFR	0.56	0.1	1.7	0.2	0.01
PH	6.6	0.2	7.1	0.1	0.01

Our data showed that the mean value of GI was significantly increased with aging while the mean value of SIgA, SFR and PH were decreased as the patient get elderly but the significant difference was reported with SIgA and SFR only as illustrated in table.3.

Table.3. Mean of GI, SIgA, SFR and PH of patients according to age groups

		N	Mean	Std. Deviation	p-value
GI	<20	8	2.8	0.3	0.01
	20-40	17	3.1	0.2	
	>40	11	3.4	0.12	
SIgA	<20	8	561.0	58.8	0.02
	20-40	17	512.0	62.3	
	>40	11	415.3	66.1	
SFR	<20	8	0.6	0.05	0.03
	20-40	17	0.4	0.1	
	>40	11	0.3	0.08	
PH	<20	8	6.5	0.05	0.09
	20-40	17	6.4	0.23	
	>40	11	6.1	0.18	

The results showed there was no significant difference ($p \geq 0.05$ for all) regarding the mean value of GI, SIgA, SFR and PH when compared according to the type of multiple sclerosis, however the patients who had remission relapsing type showed higher value for all these studied parameters but the difference did not reach the significant level as displaced in table 4.

Table.4. mean of GI, SIgA, SFR and PH of patients according to MS types

		N	Mean	Std. Deviation	p-value
GI	RRD	26	3.6	0.5	0.06
	SPD	3	3.4	0.3	
	PPD	4	3.5	0.7	
	PRD	3	3.4	0.4	
SIgA	RRD	26	517.4	67.3	0.06
	SPD	3	482.0	69.2	
	PPD	4	502.8	66.4	
	PRD	3	506.7	61.8	
SFR	RRD	26	0.6	0.08	0.07
	SPD	3	0.4	0.05	
	PPD	4	0.5	0.08	
	PRD	3	0.5	0.15	
PH	RRD	26	6.7	0.18	0.09
	SPD	3	6.4	0.25	
	PPD	4	6.4	0.08	
	PRD	3	6.6	0.2	

Cont... Table (4): Association between (IgG) and (IgM) anti -*T.gondii* seropositivity and risk factors

The result of current study demonstrated that the mean value of GI, SIgA, SFR and PH of MS patients were higher with females in compare to male patients but the difference not significant statistically ($p \geq 0.05$ for all) as showed in table 5.

Table.5. mean of GI, SIgA, SFR and PH of patients according to their gender.

	gender				p-value
	Female(N=27)		Male(N.=9)		
	Mean	Std. Deviation	Mean	Std. Deviation	
GI	3.6	0.4	3.4	0.3	0.06
SIgA	562.4	78.8	554.3	81.03	0.07
SFR	0.6	0.1	0.5	0.09	0.7
PH	6.5	0.2	6.6	0.15	0.09

The results showed there was significant direct correlation between duration of disease in years and gingival index while negative correlation was reported between each of SIgA, SFR and PH and duration of disease as displaced in table.6.

Table.6. correlation of age,

		GI	SIgA	SFR	PH
Duration	Pearson Correlation	0.8**	-0.9**	-0.9**	-0.3
	p-value	0.001	0.001	0.001	0.1

Multiple sclerosis (MS) is a chronic inflammatory demyelinating disorder of the central nervous system affecting white and possibly grey matter. MS characterized by multiple focal demyelinating lesions affecting the white matter, which is not infrequently associated with cortical demyelination. The finding of this study indicated that the mean age of patient group was 37.4 ± 6.3 SD (ranged from 20-40) year while the control group was 36.3 ± 4.8 SD years old. The studies showed that the age at MS onset follows a similar pattern across different regions, with incidence low in childhood, rapidly increasing after adolescence, reaching a peak between 25 and 35 years, and then slowly declining⁽¹¹⁾; this opinion support our work in the term of spread of the MS in this age group. With regard to gender distribution, our data indicated that female was 75% of patient group and 63.6% of control group,

this result in consistent with finding of other studies that revealed the women are affected more commonly than men, with the female-to-male ratio varying between 1.5:1 and 2.5:1, with a trend toward higher values in the most recent studies^(17,18). Recent research though anyone can be affected, but MS most frequently occurs in white women ages 20 to 45.^(1,2) According to some authors the lifetime risk of developing MS in high-risk populations is approximately 1 in 200 for women which coincide our study, others supposed MS 3 times more common in females than in males. Although controversy surrounding sex factor. several investigators indicated that females had a relatively favorable course⁽¹⁹⁾. For salivary IgA changes that associated with MS, a studies reported that chronic stress mostly reported with MS patients result in an increased levels of salivary cortisol and decreased level of salivary IgA.⁽²⁰⁾ This study revealed effect of

MS on saliva immunoglobulin A comparing with saliva of healthy individuals (control) group which show decreased salivary IgA levels as well as the (SFR) with duration. Increased autoimmunity with age may result from increased numbers of auto aggressive T-cells or reduced immune regulation. Autoimmune diseases with interleukin-17 as an important messenger cytokine may also be relevant in periodontitis⁽²⁷⁾, T cells protect from autoimmune inflammation despite reduced STAT3 activation and decreased constraint of IL-17 producing T cells. This may be an appropriate explanation for this outcome in this study. However, many other studies correspond our result it is observed Individuals with MS are at increased risk for dental caries, gingivitis and periodontitis due to the physical effects of MS, as well as these patients' reduced immune response^(2,10)

Conclusion

The gingival index increased but the S.IgA, SFR, and s.PH in MS patients but we could not prove these changes due to the disease itself where they might be induced by used medications that used for MS treatment

Impact of Caring Child with Diabetes Mellitus Type1 upon Mothers at Specialized Center for Endocrinology and Diabetes in Baghdad City

Khamees Bandar Obaid

College of Nursing /University of Baghdad, Dean .College of Nursing / Warith al-Anbiyaa University, Iraq,

Abstract

The purposes of the study to assess the impact of caring children with Diabetes Mellitus Type 1 upon mothers. A descriptive study was conducted at Specialized Center for Endocrinology and Diabetes in Baghdad City. To achieve the objectives of the study, a (Convenience) samples of (50) mothers who have children with Diabetes Mellitus Type 1. Data were collected by an application of direct interview as a means of data collection. The results indicated that mothers of diabetic children are experiencing a moderate level of burden regarding care of their children (86.5%), in which they are experiencing a moderate psychological and social burden (61.5% and 51.9%), while they show moderate to high financial burden of care for their children (40%). The study concluded that child with Diabetes Mellitus Type I are experiencing a moderate impact on their mothers .

Key Words: *Burden, Caring, Diabetes Mellitus Type1, Mothers*

Introduction

Type 1 diabetes mellitus one of the most common chronic diseases of childhood, can be diagnosed at any age; peaks in onset occur between 5 years and 7 years of age and at or near puberty. T1DM accounts for ~10% of all diabetes cases, and the incidence rate of childhood T1DM has risen worldwide by ~2.8%–4.0% each year in all age groups in the last several decades. T1DM is most common in Europe (129,000) and North America (108,700) and far less common in People's Republic of China, India, and Africa. ^{1,2} Iraq is one of the 19 countries and territories of the IDF MENA region. 415 million people have diabetes in the world and more than 35.4 million people in the MENA Region; by 2040 this will rise to 72.1 million. There were 1.2 million cases of diabetes in Iraq in 2015 ¹ Type 1 diabetes mellitus is a challenge for children, adolescents and their parents as they need special support to keep it under control. After the diagnosis of T1D, the lifestyle of all family members' changes and this interferes in their quality of life ³. Mothers were considers the

primary caregivers in most families, and many had to rearrange work schedules or leave work in order to care for their child full-time. Parenting roles also changed dramatically ^{4,5}. Mothers are ultimately responsible for daily management of T1DM, which has a significant impact on family life. Daily management of T1DM is time-consuming and requires a change to many well-established family routines. Although technological advances have greatly enhanced the ability of parents to monitor and manage T1DM in youth, the responsibility of T1DM management can contribute to parental stress, distress, and diminished quality of life. Understanding the experience of parenting a child with T1DM can provide insight into the challenges and needs of parents ^{6,7}. Type 1 diabetes mellitus is early age of onset, and a major burden of care on to the family members, especially parents. Parents with psychological morbidity had more dysfunction in social, personal and cognitive domains and also had significantly poorer quality of life in the physical health, psychological health and general well being domains ⁸. The diagnosis and treatment of a chronic illness or disability, such as type 1 diabetes, in a child leads to family upheaval and reorganization ⁹. The effects of this stress on parents not only may adversely affect parents' mental health but also could affect the health of the child with diabetes. According to family

systems theory, what happens to a target member of the family affects other family members and their response in turn affects the target family member (10). Moore et al; (2013) and Simsek et al., (2013) reported that 20% to 30% of parents report clinically significant distress, which has been defined as stress (life stress or parenting stress) and symptoms of anxiety, depression, and/or posttraumatic stress.6–8 Parental psychological distress at the time of diagnosis has been found to predict later parental distress(3,11). Parents and particularly mothers of children with T1DM are at increased risk for depression, which was associated with negative effects on parenting, the child's quality of life, and the child's psychosocial adjustment (12).

Methodology

A descriptive study was conducted at Specialized Center for Endocrinology and Diabetes in Baghdad City. To achieve the objectives of the study, a (Convenience) samples of (50) mothers who have children with Diabetes Mellitus Type 1. In order to assess burden of caring children with Diabetes Mellitus Type 1 upon mothers,

a constructed questionnaire was design and means of an interview technique with the mothers was constructed to measure the variables underlying study. Questionnaire based on comprehensive review of relevant literature and previous studies was also used. These instruments consist of two parts Part one concerned with personal information includes, the demographic data of the mothers, child and child's illness. Part two contained of (25) items concerning burden (psychological, social and economical) of caring children with Diabetes Mellitus Type 1 upon mothers. The questionnaire was answered by one of these answers (always, sometime and never). Constant validity determined for questionnaire through the use of panel experts who are faculty members from College of Nursing. The experts were asked to review the questionnaire for content with clarity. Such changes were employed according to their suggestions and valuable comments. The data collected with constructed questionnaire through an application of direct interview as mean of data collection. Appropriate statistical approach was used

Results and Discussion

Table 1: Demographic Characteristics for Mothers

No.	Characteristics		F	%
1	Age Group:	20 – 29 years	13	25
		30 – 39 years	26	50
		40 – 49 years	12	23.1
		50 ≤ years	1	1.9
		Total	52	100
2	Educational Level:	Doesn't read & write	1	1.9
		Read & write	0	0
		Primary school	19	36.5
		Intermediate school	19	36.5
		Secondary school	5	9.6
		Institute/College	8	15.4

Cont.... Table 1: Demographic Characteristics for Mothers

		Total	52	100
3	Marital status:	Married	49	94.2
		Divorced	1	1.9
		Widowed	2	3.8
		Total	52	100
4	family members:	1 – 5	34	65.4
		6 – 10	17	32.7
		11 ≤	1	1.9
		Total	52	100
5	Monthly income:	> 300,000 IqD	19	36.5
		300,000 – 600,000 IqD	21	40.4
		600,000 – 900,000 IqD	9	17.3
		900,000 IqD <	3	5.8
		Total	52	100
6	Occupation:	Housewife	48	92.3
		Governmental employed	3	5.8
		Self-employed	1	1.9
		Total	52	100

The analysis of table (1) shows that half of the mothers are with age group ranged 30 -39 years old (50%), who were graduated from primary and intermediate school (36.5%). The marital status is normal for most of mothers in which 94.2% of them are married. The number of family members reveals that more than half

mothers are living in family composed of 1-5 members (65.4%). Regarding monthly income, 40.4% of mothers are having monthly income of 300,000-600,000 Iraqi dinars per month. The occupational status shows that most of mothers are housewife (92.3%).

Table 2: Demographic Characteristics of Children with Diabetes Mellitus

No.	Characteristics		F	%
1	Age:	> 2 years	1	1.9
		2 – 5 years	14	26.9
		6 – 12 years	26	50
		13 – 18 years	11	21.2
		Total	52	100
2	Gender:	Male	30	57.7
		Female	22	42.3
		Total	52	100

		Total	52	100
4	Age at diagnosis:	> 2 years	5	9.6
		2 – 5 years	22	42.3
		6 – 12 years	24	46.2
		13 – 18 years	1	1.9
		Total	52	100

This table presents the characteristics of children with diabetes mellitus; the table shows that 26.9% of them are male toddler, preschool children with age group 2-5 years old (57.7%). 28.8% of them are fourth born in the family. More than third of children are diagnosed at school age of 6-12 years (46.2%) and 42.3% of them are diagnosed at preschool age.

Table 3: Total impact of Care of Children with Diabetes Mellitus on Mothers (N=52)

Burden	Levels	F	%	M.S	SD
	Low	23	1.9		
Psychological	Moderate	32	61.5	2.35	0.520
	High	19	36.5		
	Low	23	44.2		
Social	Moderate	27	51.9	1.60	0.569
	High	2	3.8		
	Low	10	19.2		
Financial	Moderate	21	40	2.21	0.750
	High	21	40		
	Low	2	3.8		
Total	Moderate	45	86.5	2.06	0.366
	High	5	9.6		

The findings in this table indicate that mothers of diabetic children are experiencing a moderate level of burden regarding care of their children (86.5%), in which they are experiencing a moderate psychological

and social burden (61.5% and 51.9%), while they show moderate to high financial burden of care for their children (40%).

Table 4: The Relationship between Mothers’ Burdens of Care with Their Children’ Characteristics (N= 52)

	Burden	Chi-square	d.f	P-Value	Significance
Characteristics				≤ 0.05	
Age		4.691	6	0.584	N.S
Gender		0.788	2	0.674	N.S

Occupation		0.674	4	0.954	N.S

d.f: degree of freedom, P: Probability, N.S: Not significant, S: Significant

This table indicates that there is no significant relationship between mothers' burden of care with their demographic characteristics, except number of family members that shows significant at $p\text{-value} \leq 0.05$.

The finding of this study found that half of the mothers are with age grouping ranged 30 -39 years old (50%), who were graduated from primary and intermediate school (36.5%). The marital status is normal for most of mothers in which 94.2% of them are married. The number of family members reveals that more than half mothers are living in family composed of 1-5 members (65.4%). Regarding monthly income, 40.4% of mothers are having monthly income of 300,000-600,000 Iraqi dinars per month. The occupational status shows that most of mothers are housewife (92.3%). characteristics of children with diabetes mellitus described in table that 26.9% of them are male toddler, preschool children with age group 2-5 years old (57.7%). 28.8% of them are fourth born in the family. More than third of children are diagnosed at school age of 6-12 years (46.2%) and 42.3% of them are diagnosed at preschool age. The study found that table (2) demonstrates the findings indicate that mothers of diabetic children are experiencing a moderate level of burden regarding care of their children (86.5%), in which they are experiencing a moderate psychological and social burden (61.5% and 51.9%), while they show moderate to high financial burden of care for their children (40%). Helgeson (2012) agree with this study said that found that caring for a child with diabetes had implications for both parent mental health and the health of the child with diabetes, he found that both were associated with increased parent depressive symptoms and decreased parent life satisfaction ⁽¹³⁾. Whittemore (2012) reported that prevalence of parental psychological impact ranged from 10% to 74%, with an average of 33.5% of parents reporting distress at diagnosis and 19% of parents reporting distress 1 to 4 years after diagnosis ⁽⁶⁾. The result of this study contrast with study done by Bhadada (2011) indicates that nearly two-third of parents (64%) had psychological morbidity. Parents with psychological morbidity had more dysfunction in social, personal and cognitive domains and also had significantly poorer quality of life in the physical health ⁽⁸⁾. Another study focused on Economic burden done by (Shorer et al., 2011; Zysberg and Lang ,2015), concluded that families with lowest incomes bear the highest relative financial burden of diabetes ^(14,15). Study done by Abolhassani, (2013) indicated that findings of this study provide an insight about effects

of diabetes on the parents' life. Participants' reactions for their children were denial, shock, presentiment and concern, anger, anxiety, and impatience, and crying ⁽¹⁶⁾. Hanif and Felimban (1998) concluded in their study that Psychological symptoms shown by mothers such as nervousness, irritability, insomnia, fatigue, poor concentration, fear and indecision, were significantly higher in mothers of diabetic children ⁽¹⁷⁾.

Conclusion

Mothers of children with Type 1 Diabetes Mellitus experience considerable many burden related to the caring of diabetes. Although many mothers find ways to effectively manage this burden, such as developing routines and finding sources of support, others experience clinically significant levels of psychological distress, including symptoms of depression, anxiety, and posttraumatic stress. These symptoms have been shown to have negative effects on parenting, child quality of life. A better understanding of the experience of parenting a child with T1DM may help providers to identify parents at highest risk.

Abstract

A large body of research has highlighted self-esteem and self-concept for their importance and relatedness to various aspects of students' academic and personal life. Self-esteem is significantly associated with the positive psychological outcomes of both individual and society, including, but not limited to psychological adjustment, positive emotion, and academic performance. A descriptive-correlational study was done through the period of November 10th, 2017 to February, 11th, 2019. The study also aims to assessing levels of self-esteem in the study sample, and to determine the relationship between self-esteem and the following variables: age, gender, academic year, residency place, father job, mother job, family's monthly income, and interest of attending the nursing college. A non-probability, convenience, sampling of (600) undergraduate nursing students were selected from four nursing colleges located in Middle Ephorates region. A two parts questionnaire was used to fulfil the study objectives. The first part includes student's sociodemographic information. The second part is the Rosenberg self-esteem scale to measure levels of self-esteem. The finding indicates that in majority of nursing students had a self-esteem levels range between average (52.2%) to high level (44.8%).

Keywords: *self-esteem, nursing students*

Introduction

Nursing is a humanitarian profession that cares about caring for people, families and communities, so that they can be fully healthy, preserved or restored to good health in the best possible way ¹. As for nurses, they can be distinguished from each other through their theoretical and scientific training ². Nursing also includes independent care and cooperative care for individuals of all ages, families, groups and communities, whether healthy, sick or ill, and in all circumstances. Nursing includes health promotion, disease prevention, patient and disability care, and pre-death care. Promoting a safe environment, scientific research, participation in shaping health policies, management of disease and patient systems, and health and nursing education are key nursing roles ³. The concept self-esteem is multi-dimensional and is present in varying degrees among

people, and is considered important within the concept of self, which reflects the sense of human value and efficiency. When the attitudes of people are positive towards themselves, they are highly appreciated, and conversely, when people have negative attitudes towards themselves, with a low self-esteem, the contrary happens ⁴. Self-esteem is thus the overall assessment of the value of the individual as seen by himself/herself ⁵. Rosenberg (1965) defined self-esteem as a set of positive or negative attitudes towards the self; self-esteem is a prominent psychological trait that concerns a person's image of self-esteem and self-confidence in the overall aspects of human activity in general. Many studies and research in different countries have linked the level of self-esteem with psychological well-being. This influence can be explained by the extent to which one has control over the management of things, the resources available to him/her and how effectively life's problems are dealt with and solved. Moreover, there seems to be a significant effect of the strength of personality and high self-esteem on the rate of stress and regardless of the conditions experienced by the individual. High self-esteem is an essential aspect of human well-being, happiness and adaptation ⁶. Individuals with low self-esteem perceive

life in a dark and negative way. These negative views felt by a person can lead him/her to believe that life is worthless (Crocker, 2006). This feeling may lead one to despair, inability and lack of motivation to exert more, because one sees one’s experiences as meaningless. Low self-esteem leads to the feeling that others are better than us, which is a feeling of lack of will, firmness and trust that leads us to make room for others to benefit us.

Materials and Method

descriptive-correlational analytic study. This design was carried out in order to attain the purposes of the study by using an assessment technique on undergraduate nursing students. The chosen period for measuring self-esteem among undergraduate nursing students was from 10th June, 2018 to 11th February, 2019. A study was conducted at Middle-Euphrates Region in Iraq, which is a group of four Iraqi provinces Babylon, Al-Kufa, Kerbala, and Al-Qadisiyah Province; each province has one nursing college. The subjects of current study were selected from all the nursing colleges of the Middle-Euphrates Region. Target population: A convenient sample of 600 consenting nursing students was chosen out of a total of (1600) nursing students in the four nursing colleges in the Middle Euphrates Region. The selected study sample was used to reflect the general

characteristics of target population and to improve a generalizability of study results.

Results and Discussion

Table (1) Chi-square analysis was run to determine the association between the nursing collegians self-esteem and their demographic data. The study results indicate that there is a significant association between the nursing collegians self-esteem and their academic year at p-value less than 0.05. While there is a non-significant association with the other demographic data at p-value more than 0.05. Table (2) As it is seen in Table 2, there were the students (44.8% of the sample) with high self-esteem level, while there were students (52.2 % of the sample) with Average self-esteem level, and the students (3.0% of the sample) was with poor self-esteem. T6able (3) The analysis of variance was used to find group mean difference between academic years in response to students’ self-esteem. Previous table shows that there is a significant difference in nursing students’ self-esteem according to their academic year. Based on the statistical mean, the study results indicate that the students in fourth academic year perceive a more self-esteem compared with those in other academic years with a mean score equal to 2.5.

Figure (1) Overall Assessment of the Nursing Students' Self-Esteem

With the aim of assessing the level of self-esteem, the study evaluated the level of self-esteem among the study sample. The findings from the present study indicate that most of the students, amounting to 52.2 percent, had an average score of self-esteem. Also, 44.8 percent of the employees had a high level of self-esteem reflecting that low self-esteem level was not a major issue among the sample population investigated. Several authors have proved that when individuals have portrayed that persons high level of self-esteem are not susceptible to life stressors when compared to persons with low self-esteem. The focus by research in differentiating between participants with varying levels of self-esteem is focused on such aspects as their approaches towards perceiving a wide range of objects, their distinctive self-image, and an understanding of the personal strengths and weaknesses. Through these traits, the persons with high self-esteem levels are more likely to portray high acceptance to the different events they face thus minimizing the likelihood that they will be adversely affected by the nature of these effects. On the other hand, learners with low levels of self-esteem tend to be characterized by the feeling and perceptions of powerlessness, helplessness, and even ineptness. When faced by different tasks and challenges in their personal lives, the group with low self-esteem is highly susceptible to stress where they can perceive a normal challenge to be insuperable. The findings from the present study align from the findings from a study by Fahren & Khan (2015) that identified that individuals with lower levels as compared to the average level of self-esteem portrayed lack of confidence and self-assurance. The study by Fahren & Khan (2015) emphasized that the lack of assertiveness is negative for these individuals, especially if they are nursing students. Such negativity is linked to contributing to the students accepting tasks that are beyond their capabilities. Due to the lack of the necessary skills and competencies required to complete these tasks, the students are more likely to demonstrate increased stress levels. Several aspects can be linked

with the behavior of individuals with lower levels of self-esteem. These factors include challenges with alcohol usage, poor time management, study behavior and even reflecting self-defeating practices. Another research by Georgios et al. (2017) pointed out that self-esteem levels tend to decline when individuals are at the adolescent stage. Such a decline in self-esteem is linked with the growth in the cognitive ability of these individuals which makes them increasingly sensitive to social issues. The lowered self-esteem is also attributed to the widening gap between the real identity and the ideal selves. The gap between the two identities has been identified to be wider among the adolescent girls compared to the boys. These findings have also been contradicted by other studies that identify the female adolescents and having a more positive perception of themselves compared to the male adolescents and also those that identify no difference between the self-esteem levels across different genders.

Conclusion

Conclusions, despite that most of the students have good levels of self-esteem is still critical issue that needs close attention to minimize the expected impact on student's academic performance, because of the fact that self-esteem significantly in this study. There are gender differences in respect to self-esteem. In which that male had higher level of self-esteem than female students. Recommendations, it is important to raise awareness of faculty members about the alarming level of stress among students to help them find new ways of supporting their students. Teach and encourage students to use more effective stress management strategies to minimize the risk of academic stress. Maintain student's self-esteem to improve their academic wellness. Further, research is needed to target academic-related aspects (learning environments, teaching style, course workload, and tests) and their effect on the students' academic stress.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Kerbala, Kerbala City, Iraq and all experiments were carried out in accordance with approved guidelines.

Patterns of Haemoglobinopathies Diagnosed by High Performance Liquid Chromatography in Karbala Population and Correlations between Different Hematological Parameters

Enass Abdul Kareem Al-Saadi,¹ Duha Maithem Hassan,² Wafaa Redha Al-Sabbagh³

¹FIBMS, Lecturer of Hematopathology, Department of Pathology, College of Medicine, University of Karbala, Karbala, Iraq, ²Hematopathologist, working in Teaching Laboratories, Al-Husseini Teaching Hospital, Karbala, Iraq, ³FIBMS, Lecturer of Histopathology, Department of Pathology, College of Medicine, University of Karbala, Karbala, Iraq

Abstract

Aim: To know the patterns of hemoglobinopathies and their prevalence in Kerbala society by using high performance liquid chromatography and to conclude if there is any correlations between different hematological parameters in Hemoglobinopathic patients. A total of 70 cases studied from 16th of February 2018 to 20th of June 2018 for hemoglobin variant analysis at the teaching laboratories of Al- Husseini Teaching hospital which were studied for patterns of hemoglobinopathies. When the samples were received, Complete Blood Counts including: Hemoglobin concentration, Total White blood cells count (WBC), Mean Cell Volume (MCV), Mean Cell Haemoglobin (MCH), Mean Cell Hemoglobin Concentration (MCHC), Serum ferritin, Total Iron Binding Capacity (TIBC), Hemoglobin H (HbH) preparation were done. Out of total 70 patients screened for patterns of hemoglobinopathies the result of the study revealed that 48 Patients which represent (68.57 %) of total patients had B-thalassemia trait which form the predominant percentage of patients with haemoglobinopathy, 11.85% of patients had sickle cell trait, 5.71% of them had B-Thalassemia Major, 4.29% had Hb S/B+Thalassemia Trait, 2.86% had HbS/Alpha thalassemia trait, 1.43% of them had Hb S homozygosity, 1.43% Alpha thalassemia trait, 1.43% had D-Los Anglos, 1.43% had HbS/B+ Thalassemia trait and 1.43% had HbC/B-Thalassemia trait.

Key Words: Hemoglobinopathies, Hb electrophoresis, Hemoglobin Variants, retention time, hemoglobin A2.

Introduction

Haemoglobinopathies are groups of inherited disorders which result either by an abnormal structure of hemoglobin as in sickle cell anemia or by decreased formation of one or more globin chains as in thalassemia¹ There is worldwide increment of the prevalence of inherited hemoglobinopathies such as thalassemia and sickle-cell disorders due to people's migration^{2,3}. Hemoglobin abnormalities are present as carrier states in About 5% of the world's population.⁴ The normal

structure of hemoglobin in healthy individual consisted of tetramers of 4 globin chains of polypeptide, every one of them connected to haem protein. The predominant hemoglobin in normal adults is HbA (forming about 97%) and it has 2 α and 2 β chains. A remaining part of hemoglobin consists of approximately 2-3% HbA₂ which has two α and two δ chains, and a few portion of hemoglobin of fewer than 1% represents HbF, which has two α and two γ chains. In the neonatal period, the major haemoglobin is HbF (approximately 80-90%), with a variable amount of HbA (approximately 10-20%). The switch from γ chain synthesis (which is the predominant form of hemoglobin in the fetus and neonate) to β chain synthesis (which predominates in children and adults), together with the production of δ chains, is usually finished by about one year from time of baby delivery. So, at that period of life, the infant

get full maturation of HbA₂ and Hb F levels.⁵ HPLC is used for identification, and estimation of both normal and many abnormal Hb categories.⁶ HPLC provides the clear benefits and priorities in comparison to traditional Hb electrophoresis because of its ability to detect and estimate the quantities of different types of disrupted Hbs in very accurate and perfect manner.⁷ It has been proved that HPLC is very rapid, sensitive, specific, and reproducible replacing technique to conventional Hb electrophoresis.⁽⁸⁾ It's important to mention that every disordered haemoglobin (variant of hemoglobin) can be represented in HPLC in specific area and had specific imprecision of retention time that can differentiate it from other types of hemoglobin's. Retention time is the time that extended from the moment of the person's sample injection to the appearance of the summit (apex) of a haemoglobin high point (peak). The established values at which the well-known disrupted hemoglobin's (variants) were noticed to be eluted and separated by applying the "Variant Beta-thalassemia's short scheme or program are termed as "Windows". During printing the chromatogram's paragraph, there is existence of the following components: all portions of the separated disordered haemoglobin (variants), retention times, the reasons of hemoglobin's peaks and the levels (%) of various haemoglobin elements. If hemoglobin peaked area was separated at an imprecision of retention time that is not pre-identified, it will be named as an "unknown" area.⁽⁹⁾ Several structural Hemoglobin disorders and the rarest hemoglobinopathies that can't be identified and diagnosed by Hb electrophoresis, they were detected by HPLC which is preferred in such cases and gave very accurate results as it's the ideal, sensitive and gold standard technique.⁽¹⁰⁾ Beside HPLC, there are numerous hematological tests and tools could be used in the assessment and diagnosis of many hemoglobin abnormalities, as example for these tests: sickling test, alkaline and acid electrophoresis, isoelectric focusing (IEF), capillary electrophoresis and DNA testing /protein testing and analysis. On the other hand, it is mandatory to correlate the results of all above mentioned tests when applied with the peripheral blood smears findings of the patients as there is pathognomonic picture of blood film for many hemoglobin abnormalities and disorders.⁽¹¹⁾

Methodology

This Descriptive Cross Sectional study analyzed 70 blood samples received from February 2018 to June 2018 in Teaching Laboratories In Al-Hussaini teaching hospital in Kerbala governorate / Iraq. Patients with

the following eligibility criteria included in the current study: anemia with Hb level extending from 9 to 11.2 g/dl, generalized weakness, patients from both genders with age limits from 17 to 30 years old with suspected haemoglobinopathy depending on the bases of clinical and family history and the results of blood film for those patients which show accordingly: hypochromic microcytic red cells, anisopoikilocytosis, target cells, sickle cells in sickle cell disease confirmed by sickling test were included for study on High Performance Liquid Chromatography (HPLC). Beside above mentioned Criteria, Patients with a recent blood transfusion and inadequate sample did not included in the current study. About Five milliliters of patient's blood was collected in dipotassium ethylenediaminetetraacetic acid vacutainers and was run in Sysmex autoanalyzer for hemogram and red cell indices; The initial laboratory tests done for the patients were: Complete Blood Picture CBP (RBC count, Hb level, Packed Cells Volume (PCV), Mean Cells Volume (MCV), Mean Cells Hematocrit (MCH), Mean Cells Hematocrit Concentration (MCHC), Total and differential white blood cells counts and Platelets Count in which the normal RBC count is $4.06-5.30 \times 10^6/\mu\text{l}$ and normal Hb level is $12.0-16.0 \text{ g/dl}$. The manual blood film was performed using the method of Leishman stain⁽¹²⁾. The samples were run on High Performance Liquid Chromatography instrument HPLC manufactured by Bio-Rad Laboratories. Based on retention time and proportion of Hb variants, different hemoglobinopathies were diagnosed and their prevalence was analyzed. The assigned windows of Manufacturer for Bio-Rad variant HPLC system was shown in Table 1. The presence of Hb H was proved by the usage of brilliant crystal blue staining for the visualization of Hb H inclusions by the light microscope. Another parameters tested in present study are: Serum Iron, Serum ferritin, Total Iron Binding Capacity (TIBC) which were evaluated for all patients in this study.

Results and Discussion

This descriptive cross sectional study was attempted to see the difference in the prevalence of various hemoglobinopathies in Kerbala Governorate in Iraq Country and to conclude if there is any significant correlations between different hematological parameters. Different types of Hemoglobinopathies including thalassemia's and other groups of hemoglobin disorders are distributed worldwide and are known to be autosomal recessive in inheritance with defects in Hemoglobin synthesis.⁽¹⁴⁾ Thalassemia is a haemoglobinopathy

that result from defect in the quantity and amount of hemoglobin formed in which there is reduction in the level of hemoglobin synthesized resulting in a form of anemia .with RBCs have reduction in their size and their hemoglobinization (hypochromic microcytic) RBCs. There are many forms of thalassemia which are classified according to which type of globin chain are mutated and depleted for example there is α and β thalassemia due to depletion of α and β chains synthesis. Also there is further clinical sub classifications of thalassemia's in to thalassemia major and minor(homozygous and heterozygous) respectively which is based on number of genes affected , either one gene mutated or two genes affected in respective manner. Thus the patients presented in different clinical manifestation. The patients who are of homozygous in type are so ill in which only very limited number of them can still alive to the adulthood period of life and this fatality is due to the severity of anemia and due to cardiopulmonary deteriorations. Regarding thalassemia of heterozygous gene defect, also categorized as thalassemia trait and the clinical finding in such type is solely very mild anemia with hemoglobin concentration not getting below 9g/dL.⁽¹⁵⁾ The current research conclude that the predominant number of Hemoglobinopathic cases were of Beta thalassemia trait (68.57%) and were common in the age limit of 20-30 years and this is in consistent with Buch et al study . The high incidence of thalassemia trait require antenatal screening tests and screening of marriageable age groups. This will help in the limitation and prevention of thalassemia major in the offspring's. This may be the cause for detecting less number of cases of thalassemia major in our study group. We think that antenatal screening or screening of higher secondary school children to detect hemoglobinopathies, counseling of the individuals with hemoglobinopathies will definitely help in drastically reducing the incidence of the thalassemia major and sickle cell disease. This study found that the incidence of B-Thalassemia

Major was (5.71%), Similar research done by Patel et al in Gujarat had reported the incidence of thalassemia major (5.63%).⁽¹⁶⁾ The Current study concludes that the incidence of remaining Hemoglobinopathies was as Follows: Sickle/B+-Thalassemia trait(2.86%), sickle cell trait (10%), Hemoglobin S homozygosity (1.43%), Hemoglobin S/alpha thalassemia trait(2.86%), Hemoglobin C/B-Thalassemia(1.43%), Hemoglobin D-Los Anglos (1.43%). There was no gender difference in the different hematological parameters in the sample and this agreed with *Bhokare SB et al*⁽¹⁶⁾ The present study shows that there were significant differences regarding some hematological parameters between the patients of different hemoglobinopathies including: Hemoglobin A, Hemoglobin F and White Blood Cell Count and this agreed with Patel et al. ⁽⁸⁾ Also there were significant differences between Thalassemia trait patients and Those with Thalassemia Major regarding HbA, HbA2, HbF, Hemoglobin Level, Mean Cell Hemoglobin Concentration (MCHC), Hb H preparation and Serum Iron and this is in consistent with Colah et al.⁽¹⁷⁾ And Patel et al⁽⁸⁾ HPLC also helped us in detecting various heterozygous states. Though these abnormal variants have less clinical significance but they can produce severe disease when coexisted with other variants. This once again highlights the significance of mass screening of the population. Although these states can be detected by both HPLC and gel electrophoresis, while there is further advantage of using HPLC further sub-classifying these syndromes based on detection and estimation the amount of various Hemoglobin's depending on their retention time. Regarding Hb D Los Anglos it had identical electrophoretic finding and existence at alkaline pH, on the other hand the average of its retention time in chromatography is creative and had variable results in predictable manner. This differentiation is in fact quite significant especially in a double heterozygous state with Hb S, as Hb SD ^{18, 19}

Conclusion

The current study conclude that B-Thalassemia Trait represent the higher frequency or incidence of hemoglobinopathies among Al-Hussaini teaching Hospital Patients followed by Sickle cell/B+Thalassemia trait disease. There is no gender difference in relation to different hematological parameters among Hemoglobinopathic patients. There in significant differences regarding some hematological parameters among Hemoglobinopathic patients including: HbA, HbF, MCV, MCH, MCHC. There is significant differences between some hematological parameters between Patients of Thalassemia Major and those of Thalassemia Trait including: HbA, HbA₂, HbF, HbH preparation, MCV, Hb Level, MCHC and Serum Iron. We conclude, HPLC is an ideal method for routine diagnosis of hemoglobinopathies.

Risk Factors of Acute Otitis Media among Infants Children in Kerbala Pediatric Teaching Hospital: A Case-Control Study

Hassan Abdullah Athbi ¹, Haider Nawaf Abed-Ali ²

¹Instructor/Adult Nursing Department/College of Nursing/Kerbala University,

²Registered Nurse/ Karbala health directorate/ Imam Hussein medical city.

Abstract

Objective of the study: To explore the most prevalent risk factors those are associated with AOM among infant children. A case-control study design was carried out in the outpatient clinic at Kerbala pediatric teaching hospital, from the period from January 2017 to February 2019. A purposive sampling method of 100 infants was included in this study, 50 of them were infected with AOM and the others are not. A data were collected directly from infant's parent by the researchers through the interviewing technique, then the collected data were analyzed by using the program of IBM Statistical Package of Social Sciences (SPSS) Version 24. The results of this study revealed that about 40%, 64% and 40% of infected infants were 7-9 months of age, females and urban residency respectively. The study showed a significant association between AOM and nasal obstruction at p-value 0.02, child's position during feeding at p-value 0.00, mother's position in case of bottle feeding at p-value 0.00, and using bottle feeding at night (for breast feeding infants) at p-value 0.002. Infants exposed to cigarette smoking, and that's were using pacifiers when sleeping also identified a significant risk factors for AOM at p-value 0.00, and 0.00 respectively.

Key Words: Risk Factors, Acute Otitis Media, Infants.

Introduction

Otitis media are well identifying as an infection and/or inflammation of the middle ear ¹, it is the second most common childhood disease after upper respiratory tract infection ² AOM is the most frequently recognized ear infection ³, and it is one of the most widespread communicable diseases of childhood that is most frequently occurs between 3 months to 3 years of age. In the United States of America (USA), 80-90% of AOM occur in children less than six years, the main incidence is between 6 months to 24 months of age ⁴. Newborns and infants are more likely to infect with AOM because of the immature immune system ⁶ reported that the AOM is a disease of infancy; it can affect more than 33% of children less than one year of age. Ginkel et al., (2017) mentioned that about 25-36% of children less than one year have experienced at least one event of AOM and approximately 20% of the infants developed more than one event of AOM. It is an estimated that about 709 million new AOM cases annually worldwide, with greater than half in children less than five years of age ⁸. A recurrent and prolonged episode of AOM may lead

to many health problems such as hearing impairment, delayed speaking development, and delayed language and educational development ⁹. In the United States of America, the annual cost of AOM is approximately 5 billion dollars ¹⁰. Several influences have been identified to be accompanied with the development of AOM, some of these influences are unanimously recognized such as environmental tobacco smoke exposure and adenoids hypertrophy; other influences are more controversial such as gender or poor economic status ¹¹ stated that's the possible risk factors that are associated with otitis media are family history of otitis media, recurrent upper respiratory infections, younger age, and second hand smoking. ¹² reported other risk factors for ear infections involve low birth weight, younger motherly age, inadequate housing conditions, lack of access to health care, and mothers who smoke during pregnancy. Numerous studies have been documented that the pacifier use for some babies was determined as an additional risk factor for developing otitis media. Other risk factors that are associated with recurrent otitis media among infants are includes orofacial anomalies such as cleft palate, overcrowding, lack of breast feeding or shorter duration

of breastfeeding, and prolonged bottle-feeding while lying. Supine-feeding positions, immune deficiencies, and gastro-esophageal reflux are also identified as a risk factors of AOM. Identifying of otitis media risk factors can contribute to improving management and effective prevention plan. Pawathil, and Rajamma (2016) mentioned that are by recognizing the risk factors if AOM, the clinician can notify parents about preventive measures to avoid these factors. Ginkel et al., (2017) reported that the documented of preventable risk factors is a significant effort in the prevention of AOM. In this study, we aim to determine the impact of several risk factors that are associated with AOM among children less than 12 months of age in order to improve preventive methods of this disease.

Methodology

A case-control study design was carried out in the outpatient clinic at Kerbala pediatric teaching hospital, in the period from January 5th 2017 to February 1st 2019, in order to investigate the most prevalent risk factors that are associated with AOM among children less than one year of age. A purposive sampling method of 100 infants was included in this study, 50 of them were infected with AOM and the others are not. A verbal informed consent was obtained from the infant's parent to be enrolled in this study. A questionnaire form was prepared by the researchers in order to collect all the relevant data associated with the study sample. The questionnaire form contains of (11) items that are (Age, gender, residency, type of feeding, nasal obstruction condition, child position during feeding, mother's position during feeding, upper respiratory tract infection, using bottle feeding at night, exposed to second hand smoke, and using the pacifiers when sleeping). Data were collected directly from infant's parents by the researchers through the interviewing technique. Finally the collected data were analyzed by using the program of IBM Statistical Package of Social Sciences (SPSS) Version 24, both descriptive statistical analysis procedures (frequency, percentage) and inferential statistical analysis were used in order to analyze and assess the results of the study, a p value <0.05 was considered statistically significant.

Results and Discussion

As shown in table (1), there are a statistically significant association between female gender with AOM, and no significant association with the other listed factors. Analysis of the risk factors associated with

AOM among infants as shown in table (3), indicates that the nasal obstruction, infant's position during feeding, mother's position in case of bottle-feeding, using bottle-feeding at night, second hand smoke, and using of pacifiers when sleeping were found to be a significant risk factor associated with AOM among infants. A total of (50) infants who are infected with AOM, and (50) non-infected infant were involved in this study to investigate the most prevalent risk factors that are associated with AOM. Data that listed in table (1 and 2) show that are many risk factors are contributing to the occurring of AOM in the examined group of infants. The results in table (1) revealed a significant association between female gender and AOM (at P value 0.005), this result was disagreement to the findings of the study which was done by Abed Alsalama, et al, (2018) revealed that the male gender were determined a significant risk factor for the occurrence of AOM. Another study, which was done by Sangeetha, et al., (2014) revealed that the boys infant were found to have a higher incidence of AOM than girls. Concerning to the association between nasal obstruction and AOM among the study subjects, the results in table (2) exposed a significant association between AOM and nasal obstruction (at p value of 0.02), this result was corresponding with the findings of a meta-analysis study which was done by Ilechukwu, et al., (2017) that identified the upper respiratory tract infection as an important risk factor for the occurrence of AOM. Regina, et al, (2017) reported that the AOM is mostly occurring secondary to viral upper respiratory tract infection and subsequent microbial colonization of the nasopharynx and the middle ear. Supine position of infants during feeding as shown in figure (2) also determined as a main factor contributing to AOM because this position lead to leakage of milk into the ear canal and therefore increase the chance for developing AOM, the result in table (2) show that are about 66% of infant infected with AOM were putting in supine position by their mothers during feeding, this finding was corresponding with the study of Regina, et al, (2017) emphasized that the use of supine position during feeding was significantly increases the risk of AOM in infant. Another studies that were done by Sangeetha, et al., (2014), Swamy, et al, (2017), and Abed Alsalama, et al, (2018) revealed that there is a significant association existed between supine feeding position and AOM in infants. Furthermore, the findings of the study of Regina, et al, (2017) illustrated that the using of supine or near so position by mothers for feeding their babies facilitates the reflux of milk into middle ear, with carriage of respiratory flora into

the middle ear space, thereby leading to otitis media. Pawathil, and Rajamma (2016) indicate that the supine feeding position was identified to be highly significant risk factor for otitis media in infancy. Bottle feeding as shown in figure (1) and the mother’s position in case of bottle-feeding are considered as an important factor that are associated with AOM, the findings in table (2) show that about 68.5% of mothers are always away from their infants when using bottle-feeding. Many studies have been evaluated breast-feeding role in the prevention of AOM and showed that the breast milk protects against AOM. Some studies also have been exposed that the wrong position of feeding can increased AOM among children (Regina, et al, 2017). Abrahams and Labbok (2011) highlight that the breast milk feeding, unlike bottle feeding formula, because human milk is a containing antimicrobial, and anti-inflammatory substances, therefore infants with bottle feeding show a relative immunodeficiency compared with those receiving breast feeding, placing them at significantly greater risk of infections. In a case-control study that was done by Pawathil, and Rajamma (2016), confirmed that are a significant association between bottle-feeding and the occurrence of AOM.

Figure1: Association of AOM with type of feeding

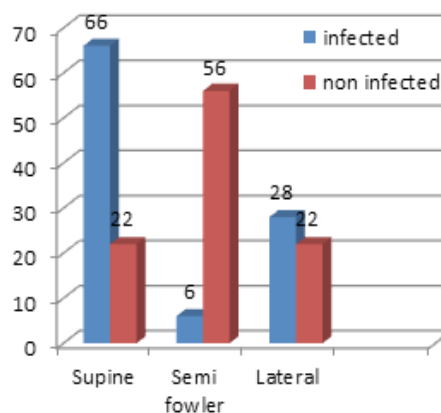

Figure 2: Association AOM with infant's position during feeding

Table (1): Demographic characteristics for infant infected and non-infected with AOM.

No.	Demographic characteristics	Frequency (F) Categories	Case N=50		Control N=50		p. value	Significant level

		Semi fowler's	3	6	28	56		
		Lateral	14	28	11	22		
		Total	50	100	50	100		
4.	Mother's position in case of bottle feeding	Away from infant	24	68.5	8	23	0.00	S
		Near of infant	11	31.5	27	77		
		Total	35	100	35	100		
5.	Upper respiratory infection	Yes	22	44	29	58	0.1	N.S
		No	28	56	21	42		
		Total	50	100	50	100		
6.	Using bottle feeding at night (for breast feeding infants)	Yes	12	80	4	26.7	0.002	S
		No	3	20	11	73.3		
		Total	15	100	15	100		
7.	Children exposed to passive smoking	Yes	42	84	22	44	0.00	S
		No	8	16	28	56		
		Total	50	100	50	100		

Furthermore, data in table (2) have been recognized that the using of bottle-feeding at night for breast feeding infants are also contributing to development of AOM in 80 % of infant, and determine statistically significant (at P value 0.002), this finding was corresponding with the results of the study of Sangeetha, et al., (2014) who stated a higher prevalence of otitis media were associated with bottle-feeding than with breast feeding. A study of Abrahams and Labbok (2011) emphasized that the

introduction of infant bottle-feeding formula in the first 6 months of life is associated with increased risk of otitis media when compared with 6 months of exclusive breast-feeding. In a meta-analysis study which was done by Bowatte, et al., (2015) provided an evidence that the breast-feeding protects against AOM until two years of age.

Concerning the children exposed to passive smoking, the finding of the study indicates a statistically significant association (at P Value 0.00) for the development of AOM in 84% of infants who have exposed to second hand smoke, this was consistent with the findings of a meta-analysis study that identified reliable passive smoke are important risk factor for the occurrence of otitis media. The results in table (2) also demonstrate that are the using of pacifiers for infants was determine a significant risk factor for 82% of infants (at P value 0.00), its believes that the saliva may be leakage into the ear canal of infants due to the pacifiers use, that's leads to increase the chances for developing AOM. The results of the present study confirms the findings of previous studies regarding the association between pacifier use and otitis media, and largely agrees with other findings of the previous studies regarding otitis media occurrence and its risk factors.

Conclusion

Many risk factors that are associated with AOM, these include nasal obstruction, infant's and mother's position, using bottle-feeding formula, exposure to cigarette smoking, and using pacifiers when sleeping.

The impact of L-carnitine Supplement on Semen Variables and the Levels of Sexual Hormones (Serum LH, FSH, Testosterone, and Inhibin) in Males with Infertility

Azzawi M.Hadi¹, Yassir Ismael Abbass¹, Mazin Anwar Yadgar¹

¹M.B.Ch.B. FIBMS. Urology. Department of surgery, Tikrit Medical College, Tikrit, Iraqs

Abstract

Background: It had been estimated that tenth of partners had infertility, and in approximately half of these cases, the imperfection can be ascribed to male related causes. Fecundity in men necessitate regular functioning hypothalamus, pituitary gland, and testes axis. aberrant spermatogenesis is habitually incorporated to permuted serum gonadotropins and testosterone. L-carnitine is an supreme antioxidant existing in a lofty concentration in epididymal excretions. It affords liveliness for sperms to earn their dynamism in the epididymis.

Aim: The study proposed to explore the effect of L-carnitine supplement on semen parameters, and sex hormones milieu in patients with primary or secondary infertility.

Patients and Methods: A clinical trial conducted on a 58 patients (mean age \pm SD: 30.6 ± 6.07) treated with 2gm of L carnitine, which prescribed orally at a daily dose of 2gm a day in divided doses for 3 months. Before, and after the end of the L-carnitine treatment, semen analysis and serum levels of LH, FSH, Testosterone, and inhibin were performed.

Results: The mean values of sperm count, total motility and normal morphology of and oligo-asthenoteratospermic were found notably changed ($p < 0.05$) with 3 months carnitine supplement. The outcome of this trial exhibited that L-carnitine supplement can improve sperm concentration, and count, as well active motility. Additionally it has been noticed that the serum gonadotropin (FSH and LH) levels were noteworthy declined, while serum testosterone and inhibin levels were upraised in infertile males when compared with the levels before, the 3 months course of L-carnitine treatment.

Keywords: L.Carnitine, semen variables, sex hormones, OAT.

Introduction

Infertility is a failure to procure conceiving over a year of orderly unguarded coitus. It affects nearly 15% of sexually active partners; however, male factor accords to up to 40% of instances⁽¹⁾. The male aspects of aberration marked by decrease sperm tally and/

or sperm motility and/or raised anomalous sperm morphology. These changes are altogether named oligo-asthenoteratozoospermia (OAT) and they are regarded noteworthy only if discovered in 2 sequential perusals of semen samples collected apart within one to four weeks. This accordant with the WHO guidelines (2010)⁽²⁾. Around 30% of sufferer have idiopathic (iOAT), which may be linked to aging or to non-inflammatory, or functional changes in epididymis or due to some viral or chlamydial infections⁽³⁻⁴⁾.

Semen analysis prevails the most trustworthy laboratory workup for the assessment of non-fertile male.⁵ The remarkable elements that takes primacy in in-vivo and in-vitro fertilization are sperm total number

and the percent of motile and morphologically normal sperms.⁶⁻⁷ furthermore, experiences suggested that computer-assisted semen analysis (CASA) exactly and trustably evaluate kinematics of the sperms, which sequentially, highly related to the fertility rate in-vitro and in-vivo time to conceive.⁸⁻⁹

The therapy of male infertility particularly iOAT can be burdensome. Many medicines, dietary supplementations and antioxidants are tried but a verifying evidence reinforcing their efficacy is not yet proved⁽¹⁰⁾.

L. carnitine (LC) is a water-soluble, and a vitamin-like structured molecule. Three quarters of the body requirements of LC is of dietary source and only 25% is endogenously synthesized from lysine and methionine the two essential amino acids, and they are hoarded in striated muscles, cardiac muscles, brain tissues, and testicles.⁽¹¹⁾ The lofty level of LC is detected in epididymal excretions and sperm, with a level of about 2000 folds higher than that of the plasma giving a clue about its pivotal task in energy metabolism and sperm maturation.¹² Furthermore, LC convey the long-chain fatty acids from the cytosol into mitochondria and promote β -oxidation of long-chain fatty acids so it plays vital role in energy production.^{13,14} LC have an essential duty as it act as an outsized non-enzymatic antioxidant and helps in cell, mitochondrial membrane, and DNA protection against structural disfigurement induced by oxygen free radicals. Many experiments have been conducted to assess the antioxidant role of carnitine, their results demonstrate upswing of antioxidant enzyme activities, and the curtailment of oxidative stress in diverse cells.¹⁵

The balanced endocrine interplay of hypothalamus, pituitary and the testis, determine the flourishing and utter development of male gametes. Hypothalamus excreted gonadotropin releasing hormone (Gnrh) evoke the libration of gonadotrophins i.e follicle stimulating hormone(FSH) and lutenizing hormone(LH) from the pituitary gland⁽¹⁶⁾. FSH ties up with the sertoli cells receptors, and triggers spermatozoa production. LH triggers the excretion of testosterone in Lydgc cells, which seriatimly exploit on the Sertoli and peritubular cells of the seminiferous tubules and trigger spermatozoa production⁽¹⁷⁾. The failed secretion of FSH and LH by the hypophyseal stalk will result in turmoil of testicular function causing infertility. Testosterone, estradiol as well as inhibin orchestrate the excretion of

gonadotropins⁽¹⁸⁾. The upraised FSH level in men with azoospermia or severe oligospermia (less than 5million sperm/ml) stipulate seminiferous tubules damage⁽¹⁹⁾. Moreover if inhibin, testosterone, dihydrotestosterone and estradiol secretion is changed, this will disorganize the negative feedback mechanism which lead to disturbance of the levels of FSH⁽²⁰⁾. Customarily, the amount of FSH correspond to the production of sperms, when spermatogonia are non-existent or strikingly reduced, FSH level will be skywarded ; when the quantity of spermatogonia within normal limits, but their maturation is arrested at a specific stage (spermatocyte or spermatid), FSH values are in the ordinary range.⁽²¹⁾

The study proposed to explore the effect of L-carnitine supplement on semen parameters, and sex hormones milieu (serum LH, FSH, Testosterone, and Inhibin levels) in patients with primary or secondary infertility.

Patients and Method

A clinical trial conducted between November 2016 to the end of December 2018, a total number of 82 infertile male patients (aged 18-47 years) referred to the infertility clinic in Salahaldeen General Hospital, after the exclusion of 15 patients with varicocele, orchitis, cryptorchidism, and those males who taking herbals or medications that might affect seminal parameters in the last 3 months prior to the study, and 9 patient dropped out because of incompliance of treatment; 58 treated with L-carnitine 2 mg given orally in 2 divided doses a day. The treatment period was 3 months. Seminal fluid analysis and serum levels of LH, FSH, testosterone, and inhibin, was done prior to the onset of the study and after the end of the treatment course. Semen samples were collected after 3-5 days of sexual abstinence and the standard manual semen analysis was performed according to the WHO guidelines⁽²⁾. During the study period, the patients were interviewed monthly to assess their compliance with treatment.

Infertility assigned depending upon (WHO) guidelines. Infertile males, with more than 1year infertility, in spite of regular coitus with a normal female partner were chosen. The diagnosis was made after clinical assessment that includes: history; clinical examination especially for varicocelle and testicular volume which further evaluated by sonography of genitalia. Semen analysis; Follicular stimulating Hormones (FSH), Leutinizing Hormone(LH), testosterone, and inhibin

levels were done for each patient before and after treatment course. The semen parameters, including sperm concentration, total and forward sperm motility (percentage at one hour after ejaculation) and sperm morphology (percentage of atypical forms), according to WHO standard procedures. Data presented with simple tables and analyzed statistically to test significance at p value < 0.05

Result

In this prospective study we considered a total of 58 patients with infertility due to unexplained astheno, oligo, and/or teratospermia before and after treatment with L. carnitine for 3 months. The mean age was 29.7 ± 5.07 years. The mean duration of infertility was 3.9 ± 4.65 (1.5 to 11 years). 58 patients given L carnitine for three months. The median seminal fluid volume, total sperm count, normal appearance, the actively motile and Viabile sperm percentage of the treatment group before treatment were 2.1 vs. 3.1ml, 21 vs. 41million, 21% vs. 51%, 28% vs. 47% and 36% vs. 72% respectively, which a noteworthy increment ($P < 0.05$).

Additionally a significant drop in sluggish and non-motile sperm percentage, as well the teratospermia percentage (47% vs. 23%, 43% vs. 26% and 58% vs. 29% respectively) was beheld. ($P < 0.05$).

Table (1): Semen parameters before and after 3months treatment with L. carnitine

Parameters	Mean \pm S.D. before	Mean \pm S.D. after
Volume (ml)	2.10 \pm 0.39	3.12 \pm 0.74*
Count	21 \pm 2.3546	41 \pm 3.7651*
Active	28 \pm 5.887	47 \pm 6.416*
Sluggish	47 \pm 5.226	23 \pm 3.709*
Non Motile	43 \pm 5.472	26 \pm 3.756*
Normal	21 \pm 4.561	51 \pm 5.103*
Abnormal	58 \pm 5.082	29 \pm 4.110*
Viability	36.88 \pm 12.31	72.7 \pm 5.2*

* P value < 0.05

As it is clear in table 2, after 3 months of 2gm of L-carnitine for the selected infertile patient with hypofertility, a significant decline in the serum levels of gonadotropins (FSH, LH) 9 vs. 5 IU/L, and 6 vs. 4 IU/L respectively. On the other hand, a notable elevation in serum testosterone and inhibin B levels (4 vs. 7 ng/ml and 99 vs. 232 pg/ml respectively) have been recorded.

Table (2): Hormonal assay before and after 3months treatment with L. carnitine

	Before L-carnitine	After L. carnitine
FSH (IU/L)	9.534(\pm 1.418)	5.650(\pm 0.721)*
LH (IU/L)	6.346(\pm 9.112)	4.234(\pm 1.109)*
Testosterone ng/ml	4.556(\pm 1.167)	7.122(\pm 0.571)*
Inhibin B pg/ml	99.436(\pm 6.472)	232.756(\pm 5.945)*

* P value < 0.05

Discussion

In the near past time, male has not been accused as a cause of infertility. Male hypo-fertility has no distinct existence but it displays a diversity of pathophysiologic mechanisms. Sperms in the environment of Epididymis use a various substrates as sources of energy, but oxidation of fatty-acid which involves carnitine dependent system appears to be the crucial energy vouchsafing operation⁽²²⁾.

Mazzilli et al divulged a solid relation between spermatocytic cytoplasmic L-carnitine reserve with spermatocytic activity and viability in the mucus of uterine cervix of bovine. This correlation could be described by the fact that fats are prime energy resource for sperms in cervical mucus plug and to utilize these fats, it is important to have adequate cytoplasmic spermatocytic L-carnitine. L-carnitine not only aids in metabolism of lipids, but it adjusts the hoards of the free CoA as well, which is vital for tri-carboxylic acid cycle adjustment. That's why, L-carnitine reserves can be regarded as an index of spermatocytic activity extent in cervical mucus.²³

The refinement in the fertility tally achieved by L-carnitine supplement allocated by the noteworthy upgrading in sperm concentration and total counting, volume of ejaculate and proportion of highly motile spermatozoa in our trial could be explained by the inkling

that L-carnitine is a vital cofactor that may enhance lipid metabolism and play a crucial role in mitochondrial beta-oxidation of long-chain fatty acids for cell life maintenance and energy production.^(24,25)

A controlled trial conducted in (2004) by Lenzi et al. written account of a noteworthy relations between LC/LAC and ameliorations in all seminal indices in 56 infertile males with unexplained Oligo-Asthenospermia who treated by 2 g/day of LC and 1 g/day of L-acetyl carnitine (LAC) for a 180 days duration.⁽²⁶⁾ An observational study of infertile men conducted by Haseen and his team research in (2017) approved that free LC seminal proportions were further down in hypo-fertile male than in control group, and a sturdy positive relations were noticed between semen plasma LC proportions and sperm number, activity, and normal morphology.⁽⁴¹⁾

A randomized trial conducted by Ramesh Babu and his team in (2004), described an increment with significant differences ($p < 0.05$) in the mean FSH and LH levels in all of non-fertile males studied when compared with the control arm of the study. Though, difference in the mean levels of testosterone in both arms was insignificant.⁽²⁸⁾ Reports as early as (1994) demonstrated by Zabul and followers when they established that gonadotropin (FSH and LH) levels were significantly higher in non-fertile men in comparison to the levels in controls with proved fertility.⁽²⁹⁾

FSH is mandatory for initiation of production and evolution of spermatozoa. FSH is regarded as a reliable marker of damage of germinal epithelium, so it's found in higher concentration, in the sera of hypo-fertile men, and it was shown that this elevation is associated with azoospermia and severe oligozoospermia.⁽¹⁹⁾

Upswing of seminal fluid indices, after 3 months of 2gm daily dose of L-carnitine that has been noticed in our trial suggesting the boosted spermatogenesis and maturation of spermatozoa that seemed to be governed by the antioxidant power of L-carnitine, and by enhanced level of serum testosterone. While the induced spermatogenesis, and increased levels of serum testosterone and inhibin hormones may be the stand behind factors that resulted in reduction of LH and FSH hormones levels by its negative feedback effects.

Conflict of Interest - (nil – There are “No Conflict of Interest”).

Source of Funding - By both researchers (**self**).

Ethical Clearance: Committee members are approved to perform a study about “The impact of L-carnitine supplement on semen variables and the levels of sexual hormones (Serum LH, FSH, Testosterone, and Inhibin) in males with infertility” after discussion of study plan with researchers.

Assessment of the Understanding of Medical Ethics Subject among Anbar Medical Group Students

Waleed AT Al-Ani¹, Ahmed K. Al-Delaimy²

¹Assistant Professor: Family & Community Medicine Department/ Al-Mustansiriyah Medical College, Baghdad, Iraq, ²Lecturer: Family & Community Medicine Department / Al-Anbar Medical College, Ramadi, Iraq

Abstract

Background: Future doctors and medical students are expected to learn about the important moral ethical communication with their patients and health care personnel.

Objectives: The study aimed to have opinion of medical students on medical ethics education.

Methodology: Cross sectional study carried out in both medicine and pharmacy colleges of at Anbar University for a period extended from 4th of November 2018 till the 28th of May 2019. The study was conducted on total sample size of 211 both males and females in medical and pharmacist students at Anbar University who age group ranging from 20-24 years old.

Results: About 86.3% of students under study believe that medical ethics subject is important in the curriculum of medical group colleges so as to learn basic knowledge of attitude (47.8%), and about 48% have the opinion of taking such subject in the first/second year of college. At the same time, 45.6% of students believe that the subject is boring and patient communication lecture was the highest percentage (47.9%) chosen by students as the most important item among the medical ethics subject.

Conclusion: Low perception and knowledge about the importance of medical ethics subject among medical group students in their near future career.

Keywords: *Understanding, Medical Ethics, Medical students*

Introduction

Huge social change is undergoing and people is aware of social determinants of health, so nowadays, the public has a negative view and low trust towards medical doctors because they believe that doctors are putting their own interests before those of their patients. These believe has resulted in reducing the compliance of the patient and increasing the communication conflict between doctor and his patient⁽¹⁾. For these reasons, doctors should be aware of these determinants that influence patients'; and a process of effective and good doctor-patient communication should be established to improve patient compliance and recall, adherent to treatment and even symptom reduction. In addition community participation, health services and social groups can share and built right communication between the two sides^(2,3).

Healthcare professionals should understand ethical communication with their patient and begin to practice it in their career which includes, autonomy, justice, beneficence and non-maleficence⁽⁴⁾. Hippocratic Oath and Helsinki declaration put these ethical philosophies to be practice in real medical life⁽⁵⁾. Although in developing countries this item and matter it is still challenging, but future doctors should learn these moral ethical principles and such programme for medical professional ethics shouldn't be weak in such countries⁽⁶⁾.

Incorporating ethical elements into the medical group education curriculums is an ongoing process in medical institutions and it gives an accreditation of medical schools⁽⁷⁻⁹⁾.

Medical students as future healthcare professionals better to enhance their knowledge on professional practice and safeguarding ethics and their rights as well

as their patient's rights⁽¹⁰⁾.

Assessment of the students is also required in medical ethics education, just like in other fields of medicine^(10, 11). Proper assessment of students should be performed in a way to ensure efficiency of ethics education and to help students recognize the humanitarian aspect of medicine and gain necessary skills to analyze ethical dilemmas in clinical practice⁽¹²⁾.

Medical students in Iraq in the last three academic years in the college are in direct clinical practice experience with health care personal and with patients in both hospitals and primary health care centers, while in the last academic year, pharmacy students are in orientation and clinical practice with health care services and patients. The current study aims to assess the knowledge of medical and pharmacy students in Anbar University for medical ethics subject and practice.

Methodology

After taking the ethical approval from both medical and pharmacy colleges, informed consent and permission from students, this cross sectional study carried out in both college of medicine and pharmacy in Anbar University for a period extended from 4th of November 2018 till the 28th of May 2019. The study was conducted on total sample size of 211 both males and females in medical (4th, 5th and 6th grades) and pharmacist (3rd, 4th, 5th grades) students at Anbar University who age group ranging from 20-24 years old. A non-response rate or incomplete information of 6% only.

All students in all grades included in the study have taken medical ethics subject in their curriculum "medical students at fourth, fifth, & sixth grade, while pharmacy students at third, fourth, & fifth grade".

The questionnaire include demographic characteristics of students (age, grade, type of study, and gender) in addition to questions related to the importance of medical ethics, about the year they prefer to take the subject, ethical attitude towards different aspects of the subject in college and hospital. Their relationship with medical staff in their future career. Questions about the intension to apply what they have learned in their career and the fields covered by the curriculum lectures in medical ethics were also included.

The questionnaire form has been distributed to students and was collected at the end of the day, some

students have the time and opportunity to answer the questions immediately through closed and opened ended questions.

Data and variables were coded and entered in IBM SPSS Statistical Packages for Social Sciences version 25. Data were presented as frequency and percentages and descriptive results were done for each questionnaire in form of tables and charts.

Results

Table 1 describes the basic characteristic of study population of students. Male represent 43.6% in the study while female were 56.4% of the total sample size. 54.4% were medical students (fourth, fifth, & sixth grade) and 45.5% were pharmacy students (third, fourth, & fifth grade).

Table 1: The basic characteristic of study population (n=211)

		No	%
Gender	Male	92	43.6
	Female	119	56.4
College	Medicine	115	54.5
	Pharmacy	96	45.5
Grade	Third pharmacy	34	16.1
	Fourth pharmacy	38	18.0
	Fifth pharmacy	24	11.4
	Fourth medicine	46	21.8
	Fifth medicine	27	12.8
	Sixth medicine	42	19.9

Regarding medical ethics subject, table 2 shows that 86.3% of students agreed that medical ethics is important subject in medical and pharmacy colleges curriculum "and better to be taken at first/second years of study (47.9%)". 47.8% of students think that it is important as it provides basic knowledge to student's attitude while only 7.7% relates its importance as it is studied in all other universities and it provides students with guidelines (44.5%).

Table 2: The importance of medical ethics subject

		No	%
Think the subject is important	Yes	182	86.3
	No	29	13.7
Why it is important	Basic knowledge to attitude	87	47.8
	Important & studied by other universities	14	7.7
	Provide students with guidelines	81	44.5
At which year students prefer to take the subject	First/Second year	101	47.9
	Third year	64	30.3
	Fourth year/Higher	46	21.8

Results of the study revealed that 73.0% of the students like the subjects and finding it interesting (46.8%), easy (34.4%), good marks can be get in it (11.7%), taught in good aspect by teachers (2.6%), the subject focused on important ethical issues (1.3%), and finally help them to learn how deal with patients in good manner (3.2%). The rest (27.0%) who did not like the subject, they believe that the subject is boring (45.6%), has no clinical knowledge (35.1%), difficult to be understood (3.5%), and teacher couldn't deliver the subject properly (15.8%) (Table 3).

Table 3: Students like the subject or not and why.

		No	%
Do you like the subject	Yes	154	73.0
	No	57	27.0
Why do you like the subject	Interesting	72	46.8
	Easy	53	34.4
	Good marks can be get in it	18	11.7
	Taught in good aspect by teachers	4	2.6
	Focusing on important ethical issues	2	1.3
	Learn how to deal with patients in good manner	5	3.2
Why you did not like it	Boring	26	45.6
	No clinical knowledge	20	35.1
	Difficult to be understood	2	3.5
	Teachers could not deliver the subject properly	9	15.8

The intension of students was explored and showed that 38.9% would always apply what they have learned in their future career while only 8.5% reported that they rarely or never use it later on in practice life (Table 4).

Table 4: The intension of students to apply what they learned.

		No	%
Do you have the intension to apply what you have learned in your career	Always	82	38.9
	Not always	50	23.7
	May be	61	28.9
	Rarely	10	4.7
	Never	8	3.8

Regarding items provided by lectures, table 5 shows that patient communication item was among the highest percentage (47.9%) chosen by students, then confidentiality, respect patient, and relationship with other colleagues (27.0, 26.5 & 24.6% respectively) followed by euthanasia (16.1%).

Table 5: The opinion about the most important lecture in the subject.

		No	%
In students opinion, the most important lecture they took that will be of concern about in their career	Patient communication	101	47.9
	Confidentiality	57	27.0
	Respect patient	56	26.5
	Relationship with colleagues	52	24.6
	Euthanasia	34	16.1
	Medical report	16	7.6
	Anonymous	8	3.8
	Breaking Bad News	2	0.9

Table 6 describes how to deal with colleagues mistakes, 34.6% believed they should give him an advice after his mistake while 22.7% believe one should correct his mistake, tell other colleagues (14.2%), warn hospital management (11.4%) and even tell his patients about the mistake (10.9%).

Table 6: Dealing with colleagues' mistakes and deal with other health staff.

		No	%
How would you deal with your colleagues mistakes	Give him advice	73	34.6
	Try to correct the mistake	48	22.7
	Tell other colleagues about him	30	14.2
	Warn hospital management	24	11.4
	Tell his patient	23	10.9
	Do nothing	6	2.8
	Don't know	7	3.3

Discussion

In the recent years ministry of higher education in Iraq has been focusing on such subject to be enrolled in the curriculum of medical group colleges including medical, dentistry and pharmacy colleges because of its important for future doctors and pharmacist. In our study, although about (86.3%) of students agreed that the medical ethics is important subject in their curriculum and only (13.7%) of them consider it not that important. Also in our study (44.5%) of students think it gives students and future doctors guidelines for their career in medical practice while (45.6%) and (35.1%) they think medical ethics subject and practice are boring and lack of clinical knowledge respectively. These findings in our study are in agreement with the results reported by other studies that highlighted the presence of major important gaps in knowledge and attitude of doctors in recognizing autonomy, patients' right and ethical principles importance their profession⁽¹³⁻¹⁶⁾. Cruess *et al.* alerts the fact of medicine has lost the autonomy in addition to the influence throughout the world⁽¹⁷⁾. Although our study was mainly on students but it reflects their thinking and attitude towards medical ethics in the near future, as we found in the current study that only 38.9% of students will "always" apply what they have learned in medical college about medical ethics and commitments.

Saeed & Al-Jawadi (2017) in their article identify that 50% of participant in study was not sure about physician's commitment towards their patients and that there physicians are focusing mainly on clinical practice more than ethical practice⁽¹⁸⁾. In our study, about (48%) chose first/second grade in medical group colleges to give medical ethics subject and (30.3%) chose third year medical group colleges to give such subject. In a study done by Sadaf *et al.* suggested that it is important to give these components of medical ethics to third year medical students so as to build trust and respect relationships with patients⁽¹⁹⁾. In this study, (4.1%) of students claim that the teacher couldn't deliver medical ethics subject to students, this make us to think to change learning activities approach or tools such as role play exercises, programmers and interactive seminars⁽²⁰⁾.

In conclusion, low perception and knowledge about the importance of medical ethics subject among medical group students to their near future career. Still medical students thinking towards clinical practice side and view more than ethical side and this give us alarming sign to change learning tools used in teaching such

essential subject in their medical curriculum. Patient communication was among the highest percentage chosen by students concern among other different lecture items. More efforts should be done by the college, department and lecturers to give rise to new teaching approach to this subject and to decide on which grade it should be given to medical group students.

Isolation and Identification of Facultative Anaerobic Bacteria from Feces of Pet Dogs

SMA AL-Kubaisi¹, Omar-Althani Shareef Saed², Jassim Mohamed Suleiman², Mustafa Salah Hasan¹,
Maher Saber Owain², Ahmed Sami Jarad¹

¹Department of Internal and Preventive Medicine, College of Vet. Med., University of Fallujah, Iraq,

²Department of Internal and Preventive Medicine, College of Vet. Med., University of Tikrit, Iraq

Abstract

A fifty fecal swabs (25 from Anbar province and 25 from Salahuddin province) were collected from both sexes dogs with different global breeds, different ages. These swabs were cultured onto blood, nutrient and MacConkey agars, then the colonies were purified on nutrient and MacConkey agars. A gram stain and biochemical tests were done including catalase, oxidase and TSI. The results of isolation and identification showed that *Salmonella* spp. were isolated from 5 out of 14 puppies (35.7%), while *E. coli* from 9 (64.3%) and *Serratia* spp. from 1 (7.1%), whereas, from adults, *salmonella* spp. isolated from 9 (25%) dogs and *E. coli* from 24 (66.7%) out of 36 adult dogs.

It is concluded that *Salmonella* spp. and *E. coli* are the most prevalent in asymptomatic dogs and puppies in Anbar province and Salahuddin which means that the dogs are a reservoir for these bacteria and it is considered as a bad indication for transmission of this pathogen to human being and other animals.

Key words: Facultative anaerobic, dog, *E. coli*, *Salmonella*, puppies.

Introduction

Dogs are the pet animals that have been kept from 14 centuries, numerous studies have shown that pets play an important role in human life, and the infected pets threaten the lives of individuals, especially those immunocompromised, it has been found that pet dogs that live in contact with human have a significant role in transmitting diseases to their own^(1; 2).

Dogs transmit viral and bacterial diseases to humans being through saliva, contaminated feces and urine or via direct contact, and the most important bacteria that transmitted by dogs are *Salmonella* spp., *Yersinia* spp., *Capnocytophaga* spp., *Coxiella burnetii*, *Staphylococcus intermedius* and *Leptospira* spp., in addition to MRSA⁽³⁾. It has been documented that dogs are potential reservoirs of pathogenic *Salmonella* spp. and *E. coli*⁽⁴⁾. The most common sources of *Salmonella* spp. and *E. coli* in dogs are from chicken and meat that undercooked⁽⁵⁾.

The subclinical carrier cases in dogs are regarded as the common form of salmonellosis seen in dogs which shed these organisms in feces without showing clinical

signs and contaminate the surrounded environments⁽⁶⁾.

It has been reported that the prevalence of dogs which carry *E. coli* is 26.9%⁽⁷⁾, whereas⁽⁸⁾ reported that the *Salmonella* prevalence in dogs varies greatly between 5% to 70%.

The most prevalent bacteria isolated from dogs were *Salmonella*^(9; 10, 11, 12), *E. coli*^(13, 14, 15; 16).

This study was aimed to isolate the facultative anaerobic bacteria from canine feces.

Materials and method

Animals

From March 2019 to the end of April 2019, A fifty dogs (25 dogs from Anbar province and 25 from Salahuddin province) from different global breed and both sexes at 2 months-6 years of age were used in this study.

Examination of animals

All animals were examined clinically for

temperature, pulse and respiratory rates and for presence of any abnormal clinical signs.

Collection of the Samples:

A fifty fecal swabs with transport media were collected and transported anaerobically by special containers to the college of veterinary medicine, universities of Fallujah and Tikrit lab's for bacterial isolation and identification.

Bacteriological examination:

The isolation and identification of bacteria from samples were done according to (17), all swabs were cultured on nutrient, blood and MacConkey agars and incubated for 24-48 hours. at 37°C. in anaerobic jar with 10% CO₂. The colonies were subjected to Gram stain, then suspected isolates subcultured on MacConkey, EMB

and nutrient agars for purification and characterization of the colonies. Catalase, oxidase and other biochemical tests includes TSI, Indole and citrate were done for identification of the isolated bacteria.

Results

All animals that were clinically examined showed normal signs and parameters and appeared to be healthy.

1. Bacteriological isolation:

In the present study, culturing of faecal samples from 50 dogs and puppies revealed a presence of some gram negative bacteria including *E. coli*, *Salmonella* spp. and *Serratia* spp.

Cultural and biochemical characteristics of different species of bacteria isolated from faecal samples of affected dogs are depicted in figure 1.

a) *Salmonella* spp. on SS agar

b) *E. coli* on EMB agar

c) Indole for *E. coli*

d) TSI, *Salmonella* spp. on right and *E. coli* on left

Figure 1. Different cultural appearance and biochemical tests

2. Rate of infection

Out of 14 puppies, only 5 (35.7%) had a subclinical infection with *salmonella* , 9 (64.3%) with *E. coli* and 1(7.1%) with *Serratia* spp., while the adults revealed 9(25%) dogs with *salmonella* spp. and 24 (66.7%) with *E. coli*, while there was not infection with *Serratia* spp. (Table 1).

Table (1) Rates of subclinical infection with *Salmonella* spp., *E. coli* and *Serratia* spp. of puppies and adults.

Animals	No. of animals	Animals positive For <i>Salmonella</i> spp.	%	Animals positive For <i>E. coli</i>	%	Animals positive For <i>Serratia</i> spp.	%	Animals negative for culturing	%
Puppies	14	5	35.7	9	64.3	1	7.1	0	0
Adults	36	9	25	24	66.7	0	0	2	5.6
Total	50	14	28	33	66	1	2	2	4

Discussion

Many studies were done to estimate the incidence of *Salmonella* spp. in puppies and dogs, Carter and Quinn⁽¹⁸⁾ and Sanchez *et al.*⁽⁶⁾ found that the percentages of *Salmonella* in clinically appeared healthy dogs was ranged between 0- 44 % , this results were in agreement with our results.

At the opposite side, the current results were disagree with many researches, the study of Shimi *et al.*⁽¹⁹⁾ in Iran was performed to detect *Salmonella* in feces of 181 dogs, they found that 28 (15.5 %) were carry the *Salmonella*. Also, Kocabiyik *et al.*⁽²⁰⁾ found that dogs positive for *Salmonella* were 11 % in Turkey, also , Fukushima *et al.*⁽²¹⁾ examined stray dogs that appeared healthy and found that the percentages of carrying *Salmonella* was 5.9 % in Japan. While the percentages of *Salmonella* in feces of stray dogs found in Taiwan were 6.3 %⁽²²⁾.

The reason for presence a higher percentages of *Salmonella* as observed in our study may be due to the potentially higher exposure of dogs to this genus of bacteria.

The results of the current study are compatible with the results of Ojo *et al.*⁽⁷⁾ who showed that the percentage of *E. coli* in apparently healthy dogs was 26.9% , while the presented results were disagree with Beutin⁽²³⁾ who examined the healthy dogs for presence of *E. coli* and they found that the percentages of this bacteria ranged

from 3.2 to 12.3%. Also, it has been reported that the percentages of *E. coli* was 1.1% in healthy dogs⁽²⁴⁾, while in Japan was 0.16%⁽²⁵⁾.

Serratia spp. and *Escherichia coli* were also isolated from bacteriological culture of fecal swabs obtained from dogs^(26;27).

Hancock *et al.*⁽²⁸⁾ reported that the higher percentages of *E. coli* and other bacteria is due to younger age susceptibility, transport, sudden alteration in feed and using of antimicrobial therapy which may lead to disorder in microflora of intestine.

Conclusion

These results refer to that large percent of dogs that appear clinically healthy may carry *E. coli*, *Salmonella* spp. or other bacteria and may be act as a source for infection to human being and other animals , and this is considered as a bad indication for transmission of these pathogens to human , and the dogs act as a good reservoir.

Molecular characterization of *Eae* and *Stx_s* genes for *E. coli* O157:H7 isolates from Calves

Jassim Mohamed Suleiman¹, Omar-Althani Shareef Saed¹, SMA AL-Kubaisi², Mustafa Salah Hasan²,
Maher Saber Owain¹, Mohammed Ali Hussein², Ahmed Sami Jarad²

¹ Department of Internal and Preventive Medicine, College of Vet. Med., University of Tikrit, Iraq,

² Department of Internal and Preventive Medicine, College of Vet. Med., University of Fallujah, Iraq

Abstract

This study aimed to detect *eae* and *Stx* genes of thirty two *E. coli* O157:H7 isolates recovered from calves. These isolates were isolated and identify by traditional methods of culturing and latex agglutination test from fecal swabs of four diarrheic calves and twenty eight apparently healthy calves. The *eae* and *Stx* genes were detected by a realtime PCR applied on the extracted bacterial DNA. The results showed that 19 isolates had *stx1* gene, 10 isolates had *stx2* gene and 17 isolates had *eae* gene. It is concluded that molecular characterization by using real time PCR is a good test for confirming infection with *E. coli* O157:H7 and detection of their *eae* and *Stx* genes .

Keywords: Real time, PCR, *stx*, *eae*, Calves, *E. coli* O157:H7.

Introduction

Escherichia coli regarded as one of the main cause of calf diarrhea in newborn livestock, by causing high economic losses, the prevalence of enterohemorrhagic *E. coli* (EHEC) in calves with diarrhea ranged between 70 – 75.6 %⁽¹⁾. It has been stated that cattle may act as reservoir for EHEC⁽²⁾. Also, Osman *et al.*⁽³⁾ reported a prevalence of O157 serotype in 63.6% of their studied calves.

Escherichia coli strain O157:H7 is one of the most significant bacteria that convey by the food, it mostly cause a series of clinical signs , such as diarrhea, haemorrhagic colitis and hazardous problematics in other body organs or systems. It have many virulence factors, most significant one was *Stxs*⁽⁴⁾, therefore, the strain nomenclatured as shiga-toxic *E. coli* (STEC)⁽⁵⁾.

It infects adult cattle even the calves⁽⁶⁾; human being⁽⁷⁾; ovine⁽⁸⁾; canine⁽⁹⁻¹¹⁾ and other animals , and may cause fatal disease in human being and other animals,

The most significant confirmatory tests used for detection of ETEC and STEC are PCR⁽¹²⁾ or realtime PCR (RT- PCR)⁽¹³⁾ which is considered as an appropriate, dependable way for confirmatory diagnosis of *E. coli* O157:H7⁽⁹⁾.

The aim of the presented study was to corroborate the *eae* and *stx* genes of virulent *E. coli* O157:H7 isolated from calves by using realtime PCR.

Material and Method

Source of bacteria : A number of 32 isolates of virulent *E. coli* O157:H7 were used in this study and obtained from college of veterinary medicine / University of Fallujah and were confirmed previously by⁽³⁾.

Bacteriological Method: All 32 isolates were identified as shown in a previous study⁽¹⁴⁾ prior to the PCR test to confirm the presence of *Eae*, *Stx1* and *Stx2* genes.

Serotyping was made as mentioned in⁽¹⁴⁾ and⁽¹⁵⁾.

PCR assay:

This test was performed on the thirty two virulent *E. coli* O157:H7 strains, a bacterial DNA extraction was done by using Geneaid kit, USA. The assay of RT- PCR was done via using Applied Biosystems™ RapidFinder™ STEC Screening Assay in Sacace Real-Time PCR System. A twenty eight micron of water free nuclease was added to two micron of DNA. The conditions of RT- PCR were adjusted as follows: hold at

95 °C for 2 min., then denature at 95°C for 1 second and lastly, anneal/ extend at 60 °C for 20 seconds, for 40 cycles.

Results and Discussion

The RT- PCR assay of the examined virulent isolates exposed that nineteen isolates had *stx1* gene and 10 isolates had *stx2* gene , while 17 isolates had *eae* gene and this is compatible with previous results of Yousif and Hussein, 2015 who found the same results by using conventional PCR on the same isolates (Fig. 1).

Figure (1) Results of RT-PCR, positive samples were Cycle Threshold (CT) less than 35

It has been reported that RT-PCR is a screening and effective method for detecting shigatoxigenic *E. coli* from fecal samples ⁽¹⁶⁾.

The current results were in compatible with results of Rebekka *et al.* ⁽¹⁷⁾ who reported that real-time PCR has a high sensitivity and accuracy for recognition of EHEC and they mentioned that RT- PCR is a quick method for detection presence or absence of EHEC.

RT- PCR method described as a “golden test” for identification of EHEC ⁽¹⁸⁾. Other studies reported similar results, where Abbasi *et al.* ⁽¹⁹⁾ reported that the RT- PCR conventional form is the quicker and more accurate assay and it doesn’t need any other ways for confirming the diagnosis when it used to detect the incidence of virulence factors of *E. coli* isolated from diarrheic children, as well as , Mondani *et al.* ⁽²⁰⁾ used RT-PCR for detect STEC, they found that this test have many advantages from these: reduction the time and reducing the limitations which found in alternative traditional tests.

Also , a study done to estimate the efficacy of RT-PCR test in testing the presence or absence the virulence

genes *rfbO157*, *Stx1*,*Stx2* from pediatric stool samples, out of fifty nine samples that positive for PCR, a twenty nine samples were +ve for *Stx* and they concluded that this test is quick way for diagnosis STEC in pediatric ⁽²¹⁾.

Conclusions

The Real time PCR test is an exact method for specific recognition of EHEC O157:H7 and their *eae* and *Stxs* genes.

Estimation of Serum Cystatin-C as early marker of Kidney Dysfunction in correlation with Serum Ferritin among β -Thalassemia Major Patients

Mohammed Abdulrazzaq Assi

¹Department of Community Health, College of Health and Medical Techniques, Al-Furat Al-Awsat Technical University, Iraq

Abstract

The Cystatin C is early predictor for evaluation the kidney functions. The Serum Cystatin C is a cysteine proteinase inhibitor, that the nucleated cells produce it at stable rate. It is filtered through the glomerular filtration membranes of kidneys, and the filtration rate will be unaffected by external factors. A group of recessively inherited hemoglobin disorders called Major Beta-thalassemia and considered the most common genetic disorder all over the world, which could be noticed by the reduction in of β -globin chain synthesis.

Objective: To study Serum Cystatin-C estimation as early marker of renal function in relation with other parameters in beta thalassemia patients.

Materials and Method: A case-control study was executed on thalassemia patients between February and April 2019 at Al-Zahra'a Teaching Hospital in Najaf/Iraq.

Results: the results in this study showed there are significant differences ($p \leq 0.05$) between major beta thalassemia patients and control group in regarding to hematological parameters. The result of biochemical parameters showed there are variations between patients and control where there were significant statistical increases in our thalassemic patients comparing to the control about Cystatin-C (1.27 ± 0.33 and 0.7 ± 0.24 ng/ml respectively).

Conclusion: the cystatin -C is useful marker at major beta thalassemia patients that suffering from renal dysfunction.

Keyword: cystatin -C, Ferritin, liver enzymes.

Introduction

A group of recessively inherited hemoglobin disorders called Major Beta-thalassemia and considered the most common genetic disorder all over the world, which could be noticed by the reduction in of β -globin chain synthesis⁽¹⁾. Most of the types come from severe anemia that requires even transfusion of the blood. For fifth decades of life, the grouping of chelation treatment and transfusion has lengthened the

life of thalassemia cases^(2,3). The totally insufficient production of hemoglobin Hb A ($\alpha_2\beta_2$) in human adult is the Thalassemia disease, which is produced from the absence or decrease in the synthesis of alpha α - or beta β - globin chain and thalassemia is categorized into α and β thalassemia based on those chain disorders. Important medical indications of these patients are severe anemia, hemolysis, and ineffective erythropoiesis^(4,5). The autosomal receding genetic anemia is Beta-thalassemia major (β -TM) in which there is a lack in creating of 1 globulin chain resulting hemoglobin (Hb) molecule. Generally, in the first year of life, blood transfusion is needed for patients of beta thalassemia⁽⁶⁾. For instance, renal difficulties are one of the new unrecognized difficulties appeared with the progresses in chelating

Corresponding author:

Mohammed Abdulrazzaq Assi,

E-mail: razaq_assi@yahoo.com

and treatment agents of β -TM patients (7). Numerous researches proved that common difficulties among β -TM patients are low urine osmolarity, aminoaciduria, proteinuria, dysfunction, and proximal tubular (8,9). All human nucleated cells can secrete and synthesize the Cystatin-C, which is a low-molecular-weight non-glycosylated protein, and has the ability to inhibit cysteine protease (10). Cystatin-C is not reabsorbed back into the serum or secreted by the renal tubules due to its sensitivity as a biomarker for glomerular filtration rate (GFR). It is better than creatinine clearance in the renal function impairment diagnosis, because muscle mass, diet, sex, and height could not affect it (11). Cystatin-C is a cysteine protease inhibitor that is secreted into the blood after it is synthesized from all human cells. In comparing to the creatinine clearance, the benefit of measuring Cystatin-C is that height, sex, diet, and muscle mass could not affect it (12).

Materials and Method

A case-control study conducted between February to April 2019 in the Thalassemia Center at the Teaching Hospital of Al-Zahra'a in Najaf/Iraq. A group of 40 β -thalassemia major intermedia patients (10 females and 30 males) have been enrolled in this research, as well as 40 healthy control, ranged between 4 and 20 years old. Both control and patients were matched in gender and age. 5ml of blood was taken from beta-thalassemia patients as well as from healthy control for *biochemical tests*.

The patients are employed for measuring of the following parameters:

1. *Determination of Human CST3 (Cystatin C) concentration in serum by using ELISA kit performed by (Abcam, USA).*
2. *Determination of Creatinine concentration in serum using automated chemistry instrument from LANDWIND Company.*
3. *Determination of urea concentration in serum using automated chemistry instrument from LANDWIND Company.*
4. *Determination of ALP concentration in serum using automated chemistry instrument from LANDWIND Company.*

5. *Determination of AST concentration in serum using automated chemistry instrument from LANDWIND Company.*

6. *Determination of ALT concentration in serum using automated chemistry instrument from LANDWIND Company.*

7. *Determination of hematological parameters (complete blood count) by using automated hematological analyzer instrument from MINDRY Company.*

Statistical Analysis

Statistical Package for Social Sciences (SPSS) program version 24 has been used for data analysis. T-independent test was used to find the variances between patients and control, the results were expressed as (Mean \pm SD). Pearson correlation coefficient (r) were calculated to evaluate the correlation between parameters. A p-value of (<0.05) has been considered significant and (<0.001) has been considered highly significant.

Results and Discussion

Hematological Parameters of Study Groups

Our study included 40 beta thalassemia major patients their age ranging between 4-20 years (30 males and 10 females), and the control group included 40 healthy participants their ages and sex mated with patients group. There were statistically highly significant differences between beta thalassemia major patients and control as regarded with hematological parameters (CBC) included in this study, sever anemic presentation were seen in patients indicated by the levels of hemoglobin (7.7 ± 1.2) (13.8 ± 1.1) and RBCs count (3.83 ± 1.01) (5.22 ± 1.4) in comparison with the control. The hypochromic microcytosis observable in patients than control with MCH and MCV values (17.2 ± 2 fl) and (62.3 ± 6 pg) in patients compared to (30.7 ± 2.6 fl) and (84.7 ± 5.4 pg) in controls, with p-value 0.001 for both. In addition, a remarkable significantly increases in platelets count reported in patients (378 ± 80.3) as compared with control (246 ± 82.7) with p-value 0.001. Furthermore, a highly important leukocytosis also realized in patients than control (11.12 ± 1.18) and (7.04 ± 1.8) respectively (table 1).

Table 1. Hematological parameters of study groups

Parameters	Patients (n=40)	Control (n=40)	P-value
	Means ± SD	Means ± SD	
Hb g\dl	7.7± 1.2	13.8±1.1	<0.001**
MCV(fl)	17.2±2	30.7±2.6	<0.001**
MCH (pg)	62.3± 6	84.7±5.4	<0.001**
RBCX 1012/L	3.83±1.01	5.22±1.4	<0.001**
WBCX 109/L	11.12±1.18	7.04±1.8	<0.001**
PLT 109\ L	378±80.3	246±82.7	<0.001**

** : highly significant

The beta-thalassemic patients enrolled in the present study showed a significantly changed specially with red blood cell mass (RBC count and Hb) in association with RBCs indices (MCV and MCH) attendant to a significantly observable microcytosis, the plain anemic appearances have been seen in the patients where hemoglobin levels as comparing with the controls. The RBC related differences are also related to an important secondary leukocytosis and thrombocytosis, these results agrees with Hagag et al. ⁽¹³⁾, and Ayyash & Sirdah ⁽¹⁴⁾. Arshad et al. ⁽¹⁵⁾, described that thalassemic patients have different problems related with less Hb level, because of the reduction of erythrocyte numbers and lessened values of RBC indices (MCV, MCH, MCHC, HCT). So, those patients undergo anemia resultant in less oxygen content in blood. The study carried out by Shanthi et al. ⁽¹⁶⁾, concluded that the decreasing in the RBCs count, PCV and levels of Hb, that detected in beta thalassemia patients are because of continuous breakdown of erythrocyte and increased early degradation, as the presence of abnormal globin molecule leads to erythrocytes ruptured before maturation. Regarding to leukocytosis and thrombocytosis in our thalassemia patients due to the severe anemia that complemented by hyper cellular (thrombocytosis and leukocytosis) that causing encouragement of erythropoietin hormone which acts on bone marrow to increase proliferation of

blood cells, or resulting from the activation of immune system by receiving blood from various donors ⁽¹⁷⁾.

Biochemical Parameters of Study Groups

The result of biochemical parameters showed a variation in the serum level (Cystatin-C, ferritin, creatinine, urea and liver enzymes includes AST, ALT and ALP) in beta thalassemia major patients as compare with control. When compared to control, there were statistically significantly increase in the our thalassemic patients regarding Cystatin-C (mean=1.27±0.33 and 0.7±0.24 ng\ml respectively), Ferritin (mean=3480±232 and 90.6± 43.5ng/ml respectively), Creatinin (mean=1.02±0.4 and 0.5±0.16 mg\dl respectively), Urea (mean=25.9±4.8 and 17.4±3.9mg\dl respectively),AST (mean=67.47±26.3 and 23.14±8.1U\l respectively), ALT (mean= 75.79± 28.6 and 21.49±8.81 U\l respectively), and ALP (mean=289.78±113.43 and 97±52.12 U\l respectively) table (2). There was statistically positive correlation between creatinine and cystatin (fig.1) (r=0.569) and urea (fig.2) (r=0.137), the result agrees with Behairy et al. ⁽⁶⁾. In accordance with our results, Elbedewy et al., concluded that beta thalassemia major patients suffer from glomerular and tubular dysfunction due to poor chelation therapy and inadequate transfusion ⁽¹²⁾.

Table 2: Biochemical parameters of study groups.

Parameters	Patients (n=40)	Control (n=40)	P-value
	Means ± SD	Means ± SD	
Cystatin C (ng/mL)	1.27±0.33	0.7±0.24	<0.001**
Ferritin ng/ml	3480± 232	90.6± 43.5	<0.001**
Creatinine (mg/dl)	1.02±0.4	0.5±0.16	<0.001**
Urea (mg/dl)	25.9±4.8	17.4±3.9	<0.001**
AST U/L	67.47±26.3	23.14±8.1	<0.001**
ALT U/L	75.79±28.6	21.49±8.81	<0.001**
ALP U/L	289.78±113.43	97±52.12	<0.001**

** : highly significant

The DFO, iron overload, chronic hypoxia, and long-standing anemia implicated in the mechanisms of tubulopathy in patients with β-thalassemia major (6). In the current study, there were highly significance increases in the levels of urea, creatinine, ferritin, cystatin shown by thalassemic patients. These results were in agreement with Ali and Mohmoud, as they reported considerably higher levels of serum ferritin and serum creatinine in thalassemic group than controls (18). Serum Cystatin-C is supposed to be a more potent endogenous marker of GFR than creatinine as it is believed to be produced at a constant level by all nucleated cells, generously

filtered by the glomeruli, minimally bound to proteins, and completely reabsorbed and metabolized in the proximal tubule (12). Our result show increase in serum level cystatin when compared with control. Some study found a positive association between serum ferritin and serum cystatin Papassotiriou et al. (19). Serum ferritin in our result at high levels this indicate to iron overload and many studies concluded that cirrhosis of liver is associated with increase in serum ferritin levels (20), this accordance with the result of our study that show highly significant increases in the liver enzymes (AST, ALT and ALP) when compared with control group.

Figure 1: Correlation between Cystatin-C and creatinine in beta thalassemia patients.

Figure 2: Correlation between Cystatin-C and Urea in beta thalassemia patients

Figure 3: The Cystatin –C concentration distribution at age groups.

Conclusion

In this paper, we concluded that Cystatin C could be used as early predictor for major beta-thalassemia patients, which can be developed for renal dysfunction in the future.

Comparative Assessment of Patients' Satisfaction in Secondary and Tertiary Outpatients of Marjan Medical City in Babil Across Sectional Study

Qais Ismaeel Kadhem¹, Ameer Kadhim Al-Humairi¹, Ashraf MA Hussain¹,

¹Family and community department, College of medicine/ university of Babylon / babil / Iraq

Abstract

Introduction: Patient satisfaction is a basic measure by which the value of health care facilities is assessed. It is a personal assessment of the service received and the person's prospects. This study would have significant input in assessing the level of patients' satisfaction in secondary and tertiary outpatient health care services. **Methods:** Across-sectional study of 300 patients random sample visit outpatients of Marjan medical city the interview was conducted at general and specialist outpatient only. The specialist outpatients include cardiac, gastrology, nephrology and diabetology outpatient. 150 patients from secondary outpatient & 150 patients from tertiary outpatient. The purpose of study was to assess the level of patients' satisfaction in secondary and tertiary outpatient health care services. **Results:** Majority of patients visit general and specialist outpatients with age 31-50 (45.5%, 46%), female (57.3%, 62.75%), low income patients <500000ID (61%, 53%), majority of patients visit general outpatients are rural and primary education (50.7%, 49.3%) and visit specialist outpatients (54%, 42%), most patients came for follow-up for both types of outpatient (56%, 62%), and seen by consultants themselves for both types of outpatients (78.7%, 88%), majority referred by their family medicine (62%, 48%), and came from far distance > 5 km (77%, 79%), the majority of patients were not satisfied with health services produced to them (53%, 63%) **Discussion:** showed no. of patients not satisfied health services more than patients satisfied, majority of patients with low income and just primary level of education, the majority of patients came to outpatients from rural area these data for both secondary and tertiary outpatient. Patients with bad satisfaction are 18-50 years, self-referral to tertiary outpatient, not satisfaction also in urban patients.

Keywords: patient's satisfaction. Outpatients. health services. Marjan medical city

Introduction

Patient satisfaction is a basic measure by which the rate of health maintenance facilities is assessed^{1,2}. It is well-defined as a personal assessment of the facility received contrary to the person's prospects³. Patients' decision of hospital facility class and their opinion are important in class of care checking and development^{4,5}. Patient satisfaction information are usually saved and recycled for incessant quality development by health-care organizations and hospitals in developing states^{6,7}. Patient satisfaction is dignified over a widespread of health facility scopes, including obtainability, accessibility and suitability of facilities, interpersonal skills, procedural ability of the workers, and the physical background where services are provided^{3,8,9}. Patient opinions of quality are a lot subjective by their

communication with the health worker; the care with which the suppliers observe and connect with them¹⁰. It has been presented that when patients are glad with the quality of facilities gotten from a hospital they agree medical recommending by taking their medications suitably and continue friendly relationship with the hospital workers¹¹. Patient satisfaction studies in developing republics are progressively, being stimulated as a means of accepting wellbeing care quality. Asking patients what they reflect about the care and management they have expected is a vital step towards progressing the class of care, and confirm the health facilities are gathering patients' requirements¹². Assessing patient satisfaction has become an essential part of hospital/ clinic management approaches crossways the world. Also, the quality guarantee and certification progression in most countries need that the satisfaction of patients

is measured on a systematic root13. The knowledge of satisfaction may also be related to pleasure, prosperity and class of a lifetime. Henceforth, satisfaction tends to reflect the quality of health facilities transported14. This study would assess the level of patients' satisfaction in secondary and tertiary outpatient health care services, classify the elements affecting the patients' satisfaction, and afford a recommendation on an enhanced health service supply that will be helpful to fill research awareness holes which eventually contribute to improve quality of patient services in the hospital and develop the level of patients' satisfaction.

Method

Study participants:

Across-sectional study of 300 patients random sample visit outpatients of Marjan medical city from January 2019 to March 2019, the interview was conducted at general and specialist outpatient only (for adult 18 years and above). The specialist outpatients include cardiac, gastrology, nephrology and diabetology outpatient. We take 150 patients from general outpatient and 150 patients from a specialist, comparison assessment about the satisfaction of patients for health services. The sociodemographic data include gender, the age of patients, income, place of living, education level if it is first to visit or follow up, see by a consultant or not, referral system and finally distance of the hospital. Satisfaction assessing by modify questionnaire (patients satisfaction questionnaire PQ1815,16 consist of 3 points Likert scale give agree=2, I don't know=1 and disagree=0. 27 and

above mean patient satisfied on health services, the time of interview after taking permission from the patient was 15 minutes, The team managing the questionnaire contained an MBBS student posted in the Department of family and community medicine, was educated for the determination. Sample size thus produced was of nearly 300 patients. Statistical analysis done by SPSS 23 use chi-square and Fischer test for categorical variable and put p value < 0.05 mean significant.

Results

Among the 300 patients questioned during the data gathering, all patients included in the statistical and no missing data. Majority of patients visit general and specialist outpatients with age 31-50(45.5%,46%), females visit generally and specialist outpatients more than male(57.3%,62.75), low income patients <500000ID more than other patients visiting general and specialist outpatient(61%,53%), majority of patients visit general outpatients are rural and primary education (50.7%,49.3%)and visitspecialistoutpatients(54%,42%), most patients came for follow-up for both types of outpatient(56%,62%), most patients see by consultants itself for both types of outpatients(78.7%,88%), majority of patients visit general and specialist outpatients refer by his family medicine(62%,48%), most of the patient came to general and specialist outpatients from far distance > 5 km(77%,79%), the majority of patients visit generally and specialist outpatients are not satisfied with health services produced to them (53%,63%), All showed in table 1, fig 1 and 2.

Table 1: frequency and percentage of study variable.

variable	General outpatient	%	Specialist outpatient	%
Age 18-30	33	22.0	28	18.7
31-50	68	45.3	69	46.0
above 50	49	32.7	53	35.3
Gender male	64	42.7	56	37.3

Comparison between satisfaction of patients according to studied variable in general and specialist outpatient show in table 2, according to the age there is positive correlation and significant association with age group 31-50y who are not satisfied, while in general outpatient age undependable, in place of living there is significant association between place and nonsatisfaction in general outpatient with negative correlation, also the level of education significant associated with

nonsatisfaction in both types of outpatients with negative correlation, significant depending between nonsatisfaction and patients visit for follow up in specialist outpatient with positive correlation, and finally there is a significant association between referral variable and patients satisfaction with positive correlation. All other variables have not significant (undependable) association with patients satisfaction.

Discussion

Patient satisfaction organizes an important element of the feature of health care facilities. . Since health care facilities cannot be ‘kept for upcoming use’ and they are predisposed by many issues, it is solid to quantify the class of service. The attendance of many powerful factors such as situations related to patients, medical staff, and organization complicate measurement of the class of the facility. This study was done to measure the satisfaction of patients with the health services produced in the secondary and tertiary outpatients in Marjan medical city, so in study showed that most patients not satisfied to the health services produced in secondary and tertiary outpatients but more no satisfied patients are in tertiary outpatient 95%it may be similar to study in Uganda “The mean patient satisfaction score was fairly little”¹⁷ but another study in Delhi showed high satisfaction¹⁸. In our study there was significant association and positive correlation between age and satisfaction of patients towards health services in tertiary outpatient in age group 31-50 years majority not satisfied may be health services not suitable to them, the above than 50 years had most satisfaction it may be due to availability of health services more toward them similar to study done in Riyadh, and USA^{1,19} while in secondary outpatient the age not significant association with satisfaction similar to study done in Nepal²⁰. According to gender there was no significant association with satisfaction although there were no significant differences between men and women, we should not completely simplify the findings to all outpatients similar to paper in Uganda¹⁷, the income of patients not significant association with satisfaction for both group of outpatients in compare to study do in Uganda and China the income and satisfaction is strongly association may be due to the health services in Iraq are semi-free^{17,21}. According to place of living there was significant association between satisfaction and place of living in secondary outpatient with negative correlation mean more patients from urban area lead to decrease satisfaction may be due to decrease health literacy and lower socioeconomic are more in patients live in rural area compared to urban colleagues similar to study done in Nepal²⁰, while in tertiary outpatient there was no significant association between and living place it may be due to all cases referral from primary and secondary outpatient to tertiary so all patients well preoccupied about health services. In our study the education level had significant and important association with patients satisfaction in both types of outpatient with negative correlation mean when increase the level of

education may lead to decrease in satisfaction so we see the primary education level more satisfy may be due to able to follow instructions compared with those with secondary and graduate education level those had more information about health services and not satisfy by little quality of services similar to study done in Uganda Malaysia and Riyadh^{17,19,22}.

In our study the association between satisfaction and types of visit was significant with positive correlation in tertiary outpatient mean patients with came for follow-up more satisfy than patients came for first visit possible description for improved satisfaction could be that chronic patients are self-selected for large observed satisfaction at this hospital but the insights of those who first visit maybe because of reduced satisfaction are not taken similar to study do in Uganda and South Africa¹⁷, while in secondary outpatient the types of visit not associated with satisfaction.

Our study appeared the significant relation between referral system and satisfaction especially in tertiary outpatient with positive correlation mean patient referral by his family doctors more satisfied than patients came by itself or other way of referral may be due to family physician more orient to disease of all family members and health services and referral system and how to deal with health problem, similar to study do in Delhi, Poland¹⁸ but referral system in secondary outpatient not association with satisfaction but still patients more satisfied when refer from family physician.

Conclusion

Our study showed no. of patients not satisfied health services more than patients satisfied, the majority of patients with low income and just primary level of education, the majority of patients came to outpatients from rural area these data for both secondary and tertiary outpatient.

Patients with bad satisfaction are 18-50 years old and self-referral system in only tertiary outpatient, not satisfaction also in urban patients visit the medical city.

Secondary and tertiary level of education had bad satisfaction in both secondary and tertiary outpatient. Further study is recommended to know the causes of all this bad satisfaction.

Good satisfaction appears in patients referred from his family physician also this may need farther study to

improve the health system in Iraq.

High Levels of Tumor Necrosis Factor-Alpha and Interferon-Gamma in Patients with Gingival Recession

Sura Dakhil Jassim¹, Luma Jassim Witwit², Fatima Malik Abood³

¹MSc in Periodontology, College of Dentistry, Babylon University; ²MSc in Microbiology, College of Dentistry, Babylon University; ³PHD in Microbiology, College of Dentistry, Babylon University.

Abstract

Background: Gingival recession considers as a common condition that associated with transposition of the margin of the gingiva in to the position apical to the cemento-enamel junction which consequently result in an exposure of the root . Inflammatory biomarker including interferon-gamma and tumor necrosis factor-alpha associated with a significant role in periodontal tissue destruction . The main goals of current study were to compare the levels of interferon-gamma and tumor necrosis factor-alpha in patients with different degree of gingival recession and control participants.

Material and method: Blood samples taken from twenty four male participants and they grouped in to three groups as: group 1(8 control subjects) , group 2 (8 patients with class 1 and 2 gingival recession)and group 3 (8 patients with class 3 and 4 gingival recession). Enzyme-linked Immunosorbent Assay was utilized to evaluate tumor necrosis factor-alpha and interferon-gamma levels.

Results : The levels of both biomarkers were greater in group 3 than group 1 and group 2 as well as group 2 had higher levels of these biomarkers than group 1.

Conclusion: Interferon-gamma and tumor necrosis factor-alpha could reflect periodontal destruction in patients with gingival recession.

Keywords: *gingival recession, interferon-gamma, tumor necrosis factor-alpha and Enzyme-linked Immunosorbent Assays.*

Introduction

The deposition of the gingival margin in an apical direction which consequently leads to revealing of the root surface to oral environment is called gingival recession ⁽¹⁾. Periodontal disease, tooth malposition, trauma, aberrant frenal attachment strongly considered as etiological factors of gingival recession ⁽²⁾.

It is a very common condition , about 50% of persons in the populations have at least one or more sites of 1 mm of root exposure or more ⁽³⁻⁵⁾ . Besides aesthetic shortcomings ^(6,7) , gingival recessions have a high

predisposition to be associated with functional problems related to root exposure, such as dentinal hypersensitivity ⁽⁸⁻¹⁰⁾, plaque retention, gingival inflammation, root caries ⁽¹¹⁻¹⁵⁾ , alveolar bone loss and eventually tooth loss ^(15, 16).

According to Miller (1985) , 4 classes of gingival recessions were proposed. In class I the recession not includes mucogingival junction (MGJ) , if the recession includes the MGJ the case considered as class II, both classes presenting no interproximal bone loss. In class III the recession extend to or include the MGJ with destruction of the interproximal bone and/or malpositioning of the tooth. Lastly, class IV presented with a severe destruction in the interdental bone and/or serious malpositioning of the tooth ⁽¹⁷⁾.

Proteins that are formed by different types of cells and represent a messenger to another cells are called

Babylon University, Babylon, Iraq,
Suradak85@yahoo.com.

cytokines. They start , control and mediate inflammatory and immune reactions; as well they control differentiation and growth of cells⁽¹⁸⁾. Cells of gingival epithelium secrete a wide variety of cytokines, like , tumor necrosis factor-alpha (TNF- α), interleukin- 1a (IL-1a), interleukin-1b (IL-1b), interleukin-6 (IL-6) and interferon-gamma (IFN- γ) these are the pro-inflammatory cytokines while the anti-inflammatory cytokines include interleukin-10 (IL-10) and interleukin-4 (IL-4)⁽¹⁹⁻²¹⁾.

In chronic inflammation, cytokines like TNF, IFN, IL-1, and IL-6 perform a significant role in bone destruction by activating osteoclasts⁽²²⁻²⁴⁾.

Material and Method

A total twenty four male subjects with age range (30-40) were included in present study. Patients presenting at least two buccal gingival recession were enrolled while control showing no gingival recession . The participant were categorized as control (group 1) and patient groups furthermore patients divided in to two groups according to Miller gingival recession classification⁽¹⁷⁾ . The first group include class 1 and 2 gingival recession (group 2) while the second group include class 3 and 4 gingival recession (group 3).

All patients were signed a written informed consent to participate in present study . Periodontal measurements involving plaque (PI) and gingival (GI) indices were recorded for each patients^(25, 26).

Exclusion criteria include:

Patients with systemic diseases.

Patients with previous periodontal treatments or who take medication.

Tooth with restoration or crown involving cemento-enamel junction (CEJ).

Tooth with root abrasion at the CEJ.

Presence of periodontal pocket.

Blood collection and storage:

Blood were collected using sterile disposable syringes from each group. Clotting of the blood samples were gained by leaving the blood samples overnight at 4°C or for 2 hours at room temperature then centrifuge for 15 minutes at 1000×g. Supernatant were collected and stored at -20. °C, the assay was carried out during

the first month after storage.

Quantitative determination of cytokines:

Quantitative determination of both biomarkers in serum of patients groups and control group using Sandwich- Enzyme-linked Immunosorbent Assays (ELISA) as in manufacture instructions (Elabscience Biotechnology Co., Ltd).

Statistical analysis .

Statistical analysis include mean and standard deviation (SD) also analysis of variance (ANOVA) test was utilized to estimate the differences among groups . *P* value less than 0.05 regarded as significant.

Results

Means of TNF were (17.48± 11.93) ,(52.76 ± 18.81) ,(72.27 ± 42.54) in control group ,group 2 and 3 respectively with significant difference between groups (P=0.003) as shown in table 1 and figure 1. Regarding IFN- γ control group had the lowest mean (47.59 ± 29.33) while group 3 had the highest mean (280.08 ± 121.35) also there was a high significant difference among groups as shown in table 1 and figure 2.

The results of present study revealed that there were highly significant differences in plaque and gingival indices among groups (P<0.001) as shown in table 1.

Table 1: Mean and standard deviation of plaque index, gingival index, TNF- α and IFN- γ of all groups.

	Group 1 Mean ± SD	Group 2 Mean ± SD	Group 3 Mean ± SD	p- value
PI	0.34±0.10	1.56 ±0.26	1.75 ± 0.24	0.000
GI	0.35±0.09	1.80 ±0.24	1.87± 0.24	0.000
TNF- α	17.48 ±11.93	52.76 ±18.81	72.27± 42.54	0.003

Figure 2- The mean of IFN- γ in group 1, 2, 3.

Discussion

Gingival recession may occur in dentitions with otherwise healthy periodontium. About the significance of gingival inflammation and dental plaque in progression of gingival recession, other researches have revealed that the most common cause of gingival recession was gingival inflammation. They proposed that the breakdown of connective tissue caused by a localized inflammatory process. Gingival recession results from epithelial cells reproduction into the connective tissue which cause a collapsing of the epithelial surface (27,28). Current study showed that the patients with gingival recession in both groups had higher gingival and plaque indices than control group and these results were in concurrence with other studies who revealed that the gingival recession was related to the high levels of both dental plaque and calculus as well as it related to the gingival bleeding on probing (27,29-33). Also, a study conducted by Goutoudi et al. (34) shown that the gingival recession was concomitant with both high plaque scores and inflammation. One study (35) revealed a negative association between gingival recession and dental plaque.

The proinflammatory cytokine, TNF- α , induces the secretion of collagenase by the fibroblasts, bone and cartilage destruction. Tumor necrosis factor - α is part of

the main proinflammatory cytokines which are usually produced on inflammatory sites by the mononuclear cells infiltration (36,37). In consequence, this cytokine is part of the periodontal tissue destruction. Previous studies reported an elevated levels of TNF- α in serum of periodontitis patients (38,39). Our results are corroborating with the previous data as we found great levels of TNF- α in serum of subjects with gingival recession (40).

Raised levels of numerous inflammatory mediators, like TNF- α , IFN- γ , IL-1, IL-6, and prostaglandinE2 (PGE2) have been identified in gingival crevicular fluid (GCF) and in gingival tissues of subjects presented with periodontal diseases (41,42).

The structure of bone tissue relies on the equilibrium between bone destruction and bone formation (43, 44). As key factors that contribute to the breakdown of periodontal tissue, several proinflammatory cytokines were identified, involving IL-1, TNF- α , IFN- γ , and IL-6 (45,46). It is possible that the higher levels TNF- α and IFN- γ found in our patients may have acted as an important osteoclastogenic factor by inducing the local osteoclast differentiation that could culminate in bone destruction.

Conclusion

Gingival recession presents an increase in inflammatory markers such as TNF- α and IFN- γ , which could be predictors of local bone destruction and disease spreading.

Ethical clearance : All participants received learned consent to join in current study, the study was accepted by Ethics team of Collage of Dentistry / Babylon University.

Efficiency of *Aspergillus* Species to Produce the Lipase Enzyme from Various Types of Oil Seeds

Thakra Ahmed Hamada⁽¹⁾, Raghad Saad Abdulkreem⁽¹⁾, Hadeel Mizher Younus⁽²⁾

¹Iraq/College of Medicine , Tikrit University, ²Iraq/College of Dentistry Tikrit University

Abstract

Filamentous fungi can easily degrade agroindustrial wastes in solid- state fermentation processes synthesizing many important commercial biocompounds such as lipolytic enzymes. Lipases have various applications in industry so the aim of this study to evaluate the effect of the composition of the solid culture medium on the production of lipolytic enzymes by various species of *Aspergillus*, so in this study we use different types of oil seeds to isolate different species of *Aspergillus* and study their effect on production of lipase enzyme by using of this different seeds as a substrate for culturing of this fungi and in this study *Aspergillus niger* that are isolated from *pistacia vera* seeds is more efficient for production of the lipase enzyme.

Keys word: *Pistacia vera* (pistachio), *Anacardium accidentae* (kazoo) ,*Prunus delicis*(almonds) ,*Arachis hypogavae*(pistachio slaves), *Juglanis regis*(walnut)

Introduction

The demand for microbial lipases is on the increase owing to their application in a wide variety of industrial process and it is used in food, dairy, cosmetic and pharmaceutical industries due to their hydrolytic reaction⁽⁷⁾.

Various types of microorganism, such as fungi are widely recognized as a good source of extracellular lipase⁽²⁾*Aspergillus* is the best candidate because it can produce more enzymes than other microbes in microbial engineering research development related to very high lipase⁽³⁾. The best species of fungi to produce the lipase enzyme is *Aspergillus niger* because it is classified as GRAS (Generally Regarded A Safe) by the FDA (Food and Drug Administration of the United States of America)⁽⁴⁾. So that the lipase from this fungi can be used in various fields including food and pharmaceutical industry⁽⁵⁾. Solid state fermentation is a fermentation technique that allows the use of simple substrates such as oil seeds, marine water, solid waste of agroindustrial products that are induced by using oil such as olive oil⁽⁶⁾.

Lipase (triacylglycerol acyl-hydrolases EC 3.1.1.3) are enzymes capable of hydrolyzing the ester bands of insoluble substrates in water at the substrate – interface⁽⁷⁾.

Many researcher worldwide direct their activities to the screening of new lipase producing microorganism, and subsequently to the optimization of the medium composition to increase the efficiency of the microorganism to produce the lipase enzyme because the composition of the medium can effect on the characteristic and efficiency of the lipase enzyme and change its properties⁽⁸⁾.

Material and Method

I-Isolation and diagnosis of the *Aspergillus* from oil seeds

The fungi used in this study was isolated from oil seeds of (*pistacia vera*(pistachio), *Anacardium accidentae*(kazo), *Prunus delicis*(almond),*Arachis hypogavae*(pistachio slaves),*Juglanis regis*(walnut)),various *Aspergillus* species was isolated from there various oil seeds by washing these seeds well by distilled water and sterilized by adding of 1% sodium hydrochloride solution (Naocl) for one minutes and then this seeds cultured on potato dextrose agar (PDA) that sterilized by adding of streptomycin, and this plates was incubated at (28°C ± 1) for 7 days. The species of *Aspergillus* was identified by macro and micro-morphological analysis⁽⁹⁾. The macro morphological characteristics observed were color, relief and edges of the colonies.

II-Isolation of the *Aspergillus* spp. from the soil

The samples that are used for isolation *Aspergillus* spp. from the soil that taken from 2-5 cm deep and cultured on (PDA) agar with added chloramphenicol in 10µg/ml with 3 dilution for each sample and incubated at 28°C for (2-8 days), then *Aspergillus* spp. colonies was isolated depending on macro- morphological characteristics.

III-Screening for extracellular lipase production

Modified basal salt medium (BSM) containing (g/L): NH_4NO_3 , (1) K_2HPO_4 (1.5) $\text{MgSO}_4 \cdot 7 \text{H}_2\text{O}$ (0.025) CaCl_2 (0.025) $\text{FSSO}_4 \cdot 7 \text{H}_2\text{O}$ (0.015) $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ (0.005), plus distilled water 1000ml and PH must be adjusted to 7. Sterilization of the medium is done and then adding of 250 mg of streptomycin and 1% (VIV) sterilized tween 80 were added.

Then 1 ml of the *Aspergillus* colonies suspension was transferred to 30 ml of the previously prepared medium. The flask that contain the fungi cultures were incubated at 28°C for 5 days, under shaking (150 rpm) and then filtrate was centrifuged under cooling at 1000 xg for 30 min at 4°C, and the supernatants was subsequently collected for lipase activity determination. Lipase activity was determined by using ⁽¹⁰⁾.

IV-Screening of *Aspergillus* spp. for lipase production

Screening was carried out using mineral medium described by ⁽⁷⁾ with olive oil emulsion as the carbon source. Strains that showed by hydrolytic halos on this medium were selected for further lipase determination.

V- Extraction of pure lipase.

The production of lipase was studied in 250 ml flask containing 50 ml of mineral medium with olive oil as a carbon source, it also contain 3 gm of KNO_3 , 1 gm of KH_2PHO_4 , 1 gm of $\text{Mg So}_4 \cdot 7 \text{H}_2\text{o}$ and 2% of sterile olive oil, then the strain of isolated *Aspergillus* was inoculated and incubated at 28°C on a rotatory shaker at 120 rpm up to 7 days, and then the growth was filtered through Whitman No.1 filter paper. The clear culture filtrate then was assayed for lipase activity.

VI- Effect of initial PH.

The fungi can grow on culturing medium at different initial PH ranging from 2 – 12. The initial PH

was adjusted by 0.1 m HCL OR 0.1 M Na oH. After 6 days the fungi mass was grown and yield of lipase produced was determined.

VII- Effect of temperature on lipase activity and stability.

The effect of reaction temperature on the activity and stability of lipase was determined by incubation the enzyme at different range of temperature ranging from 30-70 °c. Immediately after incubation at each temperature, the enzyme activity was then determined at 30°C.

IX- Measuring of enzymes activity.

The enzymes activity was determined using the method standardized by ⁽¹¹⁾ which is based on titration with NaoH of fatty acids released by the action of lipase on the extract on the triacylglycerol of olive oil was added to 250 ml flasks, 2 ml buffer prepared, 5 ml of olive oil and then 1 ml of enzyme extract was added to this system and it was incubated for 30 min. at 30°C. After incubation the reaction was stopped by adding 15 ml of acetone: ethanol: water (1:1:1) and released fatty acids were titrated with a solution of 0.01 mol/2 NaoH using phenolphthalein as indicator.

One unit of activity was defined as the amount of enzyme that releases 1 mol of fatty and per minute per ml of enzyme extract of the submerged fermentation under the test condition.

Results:

In this study 3 species of *Aspergillus* was isolated from soil and different oil seeds included *Aspergillus niger*, *Aspergillus flavus* and *Aspergillus fumigatus* and each one of these species was tested for its ability for production of lipase enzyme, and activity of this enzymes also was studied. The frequency of isolation of *Aspergillus* spp. from different types of substrate. We found that the most common isolate was the *Aspergillus niger* that was isolated from all types of oil seeds that are used in this experience in addition to soil.

As was showed in the table (1) the most active species for secretion of active lipase was *Aspergillus niger* isolated from (*Pistacia vera*) pistachio while (*Pistacia vera*) *Aspergillus fumigates* that are isolated from pistachios show no lipase activity, while *Aspergillus flavus* isolated from pistachios (*Pistacia vera*) showed

moderate lipase activity. *Aspergillus flavus* that were isolated from walnut (*Jugans regis*) also showed – ve activity for lipase production. While all species isolated from soil and pistachios slaves showed activity of lipase enzymes in various values. from this study we noticed

that lipase enzymes can be produced by different species of *Aspergillus* and activity of these enzymes are depended on the substrate that are used for isolation of these enzymes, but the best one is *Aspergillus Niger* and the best substrate was the pistachios (*Pistacia vera*).

Table (1) Efficiency of enzyme lipases that are isolated from *Aspergillus* spp. according to types and substrates:

Types of <i>Aspergillus</i> spp	types of substrate	Efficiency of lipase
- <i>Aspergillus niger</i>	Soil	+++
- <i>Aspergillus flavus</i>	Soil	++
- <i>Aspergillus niger</i>	<i>Pistacia vera</i>	++++
- <i>Aspergillus flavus</i>	<i>Pistacia vera</i>	++
- <i>Aspergillus niger</i>	<i>Arachis hypogavae</i>	++
- <i>Aspergillusfumigatus</i>	<i>Seasum indicum</i>	++
- <i>Aspergillus niger</i>	<i>Seasum indicum</i>	++
- <i>Aspergillus niger</i>	<i>Anacardium accidentae</i>	+++
- <i>Aspergillus flavus</i>	<i>Anacardium accidentae</i>	+
- <i>Aspergillus niger</i>	<i>Prunus delcis</i>	+++
- <i>Aspergillus flavus</i>	<i>Juglans regis</i>	++
- <i>Aspergillus niger</i>	<i>Juglans regis</i>	-
- <i>Aspergillusfumigatus</i>	<i>Juglans regis</i>	+

Discussion

This study appears that the most common species that are isolated from soil and oil seeds were the *Aspergillus niger* and it was the most efficient producer of lipase enzyme by using of pistichios (*Pistacia vera*) as a substrate and this was gone with the study of Tim. ⁽¹⁾. The suitability of pistichios for lipase production may be attributed to the oil present in it. This oil may have induced the production of this enzyme without an additional of carbon source while supplementation of glycerol favored enzyme production ⁽¹²⁾.

Also there are many studies appear that the enzymatic activity of *Aspergillus niger* that are cultured

on solid state fermentation were higher than using other methods. As approved by studies done by ⁽¹³⁾.

This study approves that substrate type can effect efficiently on the types of *Aspergillus* species and their efficiency for production of lipase enzymes and also the activity of these enzymes, that are based on the analysis conducted on the unite of lipase and approved also by study ⁽⁶⁾.

Although the primary function of the substrate was to support the growth of *Aspergillus* but the lipid content in the substrate medium could increase level of lipase activity generated.

Study done by ⁽¹⁴⁾ agree with our study that using of solid lipid substrate that are served as the sole source of nutrient for lipase production may have a combined benefit of utilizing a low-value waste material while producing a commercially valuable product due to using the inexpensive culture media comparison and stability of the enzymes over longer period.

Study of ⁽⁷⁾ approved that the best species of *Aspergillus* to produce lipase enzyme was *Aspergillus*

niger, next to it was *Aspergillus fumigatus*, while *Aspergillus flavus* showed the least potential for lipase production.

We conclude from this study that oil seeds considered as a good substrate for lipase production because beside being a source of carbon and supporting the fungus has lipids that assist in the production of this enzyme. The addition of lipid substrate as oil is essential to obtain highest lipase production.

Figure (1) show frequency of isolation of *Aspergillus* from different source of substrate

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Seroepidemiology of *Toxoplasma gondii* Infection in Drivers Involved in Road Traffic Accidents in Baghdad City

Dunya N. Ahmed¹, Salwa. S. Mushin², Mamdooh AR.Mohsin³

¹Department of Nursing, Iraq, ²Department of Community Health, Iraq, ³Institute of Technical Medicine/ Middle Technical University/ Baghdad – Iraq

Abstract

In this study, a total of (200) people (170 men and 30 women), aged (20-60) years were enrolled during a period of 10 months in Baghdad city. The informed consent of the studied groups was first taken and the blood alcohol levels after accidents showed negative results. The control group consisted of 100 individuals (60 men and 40 women), residents of the same region and in the same age group with no clinical signs and symptoms of toxoplasmosis. The commercial IgG and IgM ELISA kits were used to examine the collected serum samples. The serological test results of the studied group (SG) showed that 92(21.90%) were IgG positive, 75(17.85%) were IgM positive when compared with the control group (CG) who showed 11(2.61%) IgG positive and 33(7.857%) IgM positive. We can conclude that there is a high traffic accident risk to the drivers because of the high seroprevalence of latent toxoplasmosis. Prospective studies are still recommended and latent toxoplasmosis of the car drivers should be considered while strategies are being designed to prevent traffic road accidents in Baghdad.

Key words: *Toxoplasma gondii*, drivers, road traffic accidents.

Introduction

Toxoplasmosis is a global disease caused by an obligate intracellular protozoan known as *Toxoplasma gondii*. The infection is usually caused by consumption of undercooked or raw pork or lamb meat that contains bradyzoites in addition to vegetables and fruits which contain the oocysts. The pregnant women can also transmit the infection to their newborn congenitally, and people can acquire the infection via blood transfusion or organ transplantation and it can also be transmitted to the butchers or people who handle infected tools or accidentally through their exposure to contaminated blood ¹. In about (80%) of the human population, toxoplasmosis develops with no symptoms since tissue cysts have the ability to persist for ever during the life of the host. In immunocompromised people, the tissue cysts act as reservoirs where local or disseminated infections may emerge ³, especially in patients with (HIV/AIDS) ⁴. Many serious diseases can be caused by

T. gondii such as the fatal encephalitis, pneumonitis, myocarditis and choreoretinitis. In Czech people infected with *Toxoplasma gondii*, personality changes were also detected ^{5,6}. Moreover, impaired motor performance and slow reaction times were shown in persons with latent infections ^{7,8}. The behavioral changes can be explained by the high levels of dopamine, because the genes of *T. gondii* encode for the aromatic amino acid hydroxylase enzymes, that result in metabolism of phenylalanine to tyrosine and tyrosine to L-DOPA, which is the dopamine precursor. It is suggested that the higher dopamine levels can lead to changes of neurotransmitters and as a result, to a change in the behavior ^{9,10}. Schizophrenia has been found to be correlated with latent toxoplasmosis ³. The mental disease patients in Mexico showed (37.24%) anti-toxoplasma antibodies, which is (18.26%) higher than those in the whole population ⁴.

Motor cycle accidents were recorded as the leading cause of death by the Ministry of health within the (15-19) years age group, and as the second leading cause in the (20-50) years age group. *T.gondii* was found to cause choreoretinitis, due to their prolonged reaction times and the impaired motor performance. This study

Corresponding author:

Dunya N. Ahmed.

Department of Nursing, Iraq.

aimed to identify the IgM and IgG Anti-*Toxoplasma gondii* antibodies prevalence in drivers who had traffic accidents in Bab-Al-Muadham and Al-Nahdha public transport garages in Baghdad governorate. The study also aimed to determine ocular impairments and risk factors related to *T.gondii* seropositivity in such individuals in comparison with the control group.

Materials and Method

Study population

This group involved (170) men and (90) women drivers presented with injuries, and a positive alcoholmeter test was used as an exclusion criterion.

Study of the population who were not involved in traffic road accidents

This group was composed of (160) drivers, (100) of them were men and (60) were women. All of this study group resided in Baghdad city. They have never been previously involved in traffic road accidents, and were selected randomly from Bab-Al-Muadham and Al-Nahdha public transport garages in Baghdad governorate. These drivers were considered as a control group for comparison of results.

Sample and data collection

From all drivers, blood samples have been obtained during the period from October 2015 to March 2016. For all studied groups, data on sociodemographic, clinical and risk factors associated with *T.gondii* infection were collected through a structured questionnaire form. Information regarding consumption of raw vegetables and fruits, consumption of raw or undercooked meat, cats at home, organ transplantation and blood transfusion have been also taken, while clinical information involved presence of an underlying ocular impairment such as (Astigmatism, hypermetropia, presbyopia or myopia).

Serological test for *T.gondii* antibodies

Blood samples were sent to Biochemistry laboratory / Institute of medical technology / Baghdad – Bab Al-Muadham. Centrifugation of clotted blood has been used to obtain serum sample, which have been kept frozen at (-20C) until use. The commercially available enzyme linked immune sorbent assay (ELISA) kit (Platelia TM Toxo , BioRad, Marnes_la_Coquette_ from France) was used to detect IgG and IgM antibodies to *T.gondii* in the sera of all the studied groups. The wave lengths

(450/620 nm) were applied for reading the results of the plates and the standard curve in (IU/ml) was used for plotting the optical density. For latent infections, a titer less than (6 IU/ml) was considered as negative, (6-9) as intermediate and more than (9-200) as a positive titer. A duplicate testing was done to samples with values more than 200 IU/ml. The manufacturer's guidelines were used to perform all investigations.

Results and Discussion

The results of our study revealed that 211(50.23%) out of 420 traffic accident participants and 33(20.62%) out of 160 controls had positive anti-*T.gondii* IgG antibody results. This finding in part explained the negative relationship between the presence of anti-*T.gondii* IgG antibody titers and the ages of the traffic road accident groups, a result that has not been observed in the control group. As a result, univariate ORs for the relationship between many categorical variables and the traffic road accidents showed a deviant protecting effects on the age group (40-49) years. Tables (1) and (2) show serum testing results in both the experimental and the control groups. As seen in table (2), IgM and IgG antibodies were found in both groups. It has been demonstrated that the number of IgG seropositive results was significantly higher in comparison with the control group. Therefore, it can be concluded that the incidence of chronic toxoplasmosis was three times higher than the control group among people involved in the traffic road injury accidents, and this finding indicates that there is a relation between the road accidents and acute and chronic toxoplasmosis. The anti-*T.gondii* IgG antibody titers were found to be correlated with the occurrence of traffic accident risks. The fact that seropositive status as a categorical variable is not associated with the traffic accident risk is proven when IgG antibodies are considered as continuous variables suggesting that the high antibody titers could be marker of an acute infection or a subclinical reactivation. However, this hypothesis is supported by the finding which revealed that increased IgG levels took place in people who showed seropositivity to anti-*T.gondii* (IgM) antibodies. In general. It is thought that the mechanism in such conditions is correlated with dopamine level modulations (decreased or increased) because of the existence of toxoplasma parasite in the brain tissues [11,12]. The prevalence of IgG anti-*T.gondii* antibodies was shown to be increased with the age of both groups. Similar results were demonstrated in the blood donor individuals where the prevalence of anti-*T.gondii* elevated after (20) years of age [4]. Regarding

the relationship between gender and anti-*T. gondii* antibodies, it was demonstrated that the percentage of positive males to those antibodies was more than those of females despite the statistical variation. These results were consistent with a previous study conducted by Hye Jin Ahn (2012) who indicated that there was a significant difference in the antibody concentration between males (20.6%) and females (13.1%) ($P < 0.05$)¹³. There was a statistical significant difference in the frequency of recent toxoplasmosis determined by IgM anti-*T.gondii* antibodies between traffic accident drivers (75(35.54%) and the control group 11(6.87%)¹⁴.

There is an interrelation between socioeconomic strata variables and the educational levels. No significant statistical variation was found in our study between the demographic data and existence of anti-*T.gondii* antibodies. Similar results have been revealed within the same geographic region⁴, as well as in the study conducted in Durango state, Mexico¹⁵. However, anti-*T. gondii* positive drivers with low and medium socioeconomic levels showed a trend for a risk in traffic road accidents in comparison with the high socioeconomic level drivers. The same results have been detected in Mexican population in Durango state when significant statistical difference was revealed in anti-Toxo antibody titers between low socioeconomic levels and workplace accident individuals¹⁴.

In our study, it was shown that some toxoplasmosis risk factors like consumption of raw vegetables and fruits, consumption of raw or undercooked meat and cats at home are not correlated with anti-*T.gondii* antibody existence, and other risk factors like drinking of contaminated water may clarify the highly prevalence of anti-*T.gondii* antibodies. However, in our study, contaminated water was not included¹⁶.

In regard to visual and ocular results determined by the questionnaire form designed in our study, both the involved groups showed the presence of ocular abnormalities. The control group revealed more frequency of astigmatism, presbyopia, myopia and glaucoma than the experimental group. No ocular injury due to toxoplasma infection in drivers with positive serum anti-toxoplasma has been shown in studying the ocular fundus. In immunocompetent persons, the toxoplasmosis ocular signs and symptoms did not result from the toxoplasma parasite itself but from the inflammatory immune responses. In the current study, all individuals positive to IgG anti-*T.gondii* antibodies had no signs and symptoms related to visual toxoplasmosis. Probably, the strains of Toxo which infect our study population differ from the type-1 virulent toxoplasma, and this strain was found to be related to visual toxoplasmosis among healthy Brazilian populations^{17,18}.

Table (1): Prevalence of toxoplasmosis in the experimental and control groups by ELISA test according to gender

Group	Examined samples	Elisa test	
		Positive %	Negative %
Men	270	148 (54.81%)	122 (45.18%)
Women	150	63 (42%)	87 (58%)
Total	420	211 (50.23%)	209 (49.76%)

Table (2): Prevalence of IgG and IgM anti-Toxoplasma gondii antibodies in the experimental and the control groups

Group	Anti - <i>T. gondii</i> +ve				Anti – <i>T.gondii</i> -ve		Odd ratio (1.95)	p-value
	IgM		IgG		Men	Women		
	Men	Women	Men	Women

Conclusion

Toxoplasmosis may show no symptoms in approximately (80%) of immunocompetent host in the latent stage. Cysts may persist in the host's muscles and brain for a life span. However, the motor function may be diminished to represent a major factor of traffic road accident of toxoplasmosis among humans. In our study, we could not explain the relationship between traffic road accidents or toxoplasma infection and parameters like longer reaction times and impaired motor performance, because we did not evaluate these parameters. Further studies should be done in the future to detect the effect of neurological damage caused by toxoplasmosis on the driver's motor reflexes.

Therapeutic Evaluation of the Partial Movement of the Center of the Nerve Bundle

Imad Kadem Yasser¹, Ahmed Atshan abdalreda¹, Abbas mohsin Oleiwi¹

¹Physical Education and Sports Sciences / Dhi Qar University, Iraq; drsportam@gmail.com

Abstract

Neuroscience in the human body is one of the basic components and any defect in it, although it has a simple effect in many aspects of organic or inorganic because it is the precise organizer of most movements and instructions and others, and the problem is based on the most important reasons that it was observed that most of the activities and activities carried out by An individual in his daily life must be in accordance with mechanical foundations such as load weights, sudden movements, sitting, abnormal sleep and other things that have a direct impact on the movement of the nerve beam from its exact position may be up or down, making the body in an abnormal state, And move them out of place as a result of these factors that we mentioned are natural factors and not satisfactory and also cause some of the problems of organic diseases, such as diarrhea, vomiting and inability to eat in addition to pain in the lower abdomen and the symptoms of inorganic.

Keywords: *Nerve bundle, Therapeutic evaluation*

Introduction

The combination of science between them in order to find appropriate solutions to the problems that hinder work wherever they are and topical treatments is one of the important procedures in this aspect, and the process ¹ of appropriate diagnosis of the movement of the nerve bundle due to exposure to movement from its natural position in response to sudden movements or carrying some weights and other things Is important in the treatment methods, including topical treatment ² of the follow-up procedures of one of the nerve endings associated with the nerve bundle, and this type is special to return this package to its natural position without medical interference, through the simple procedure ³ that does not have any side effect on the body . As a result of the therapeutic application of the partial motion of this package we obtained a clear amount of improvement of most of the injured by a very high rate ⁴. The degree of scientific progress in obtaining better results and greater development in the process of acquiring information for development, which helps in the acquisition of information and development in which we achieve the requirements of success at the required level, and the concept of comprehensive measurement means the accuracy of accurate decision-making,

measurements of tools Which can be identified on many indicators through the analysis or quantification of the components that indicate the knowledge of scientific ⁵ facts and the amount of prediction between them during what is required of the performance of the athlete, which achieves development rates in the side that works by this contribution to the formation of a scientific experience for coaches Or workers within their specialties and thus we may get to the desired optimum performance in the sports movement according to a scientific measure, which is a direct goal in this aspect ⁶. The research in the field of tests and measurement in the field of sports has proven qualitative changes in order to secure the requirements of athletic achievement and raise the level from the health aspect, by giving us a precise description and analysis of this variable which has a simultaneous or cumulative health effect occurring to different body cells when practicing sports activity ⁷ The calendar is the program or measurements to determine the correct starting point, which determines the available characteristics or the objective treatment that is related to the subject of the reform, that this type of role after the diagnosis for the scientific interaction of microprocessors ⁸. The importance of the research to some non-chemical procedures to treat the sudden movement of the movement of the nerve bundle, which

has no side effect or other complications. The researcher noted the lack of scientific research on the movement of the motor neuron, as well as the lack of interest by athletes or workers in this field to this type of injury, which may be an obstacle in sports performance, which result from the misuse of the optimal mechanical aspects of pregnancy Balances and sudden movements such as jumps or rapid fall from different places and other natural factors that help move the abdominal nerve bundle from its natural place⁹, which has an effect in some aspects of organic nausea and diarrhea and lack of desire to eat and inorganic ones idle and lack of movement promise M sense of activity and other related things, hence we want to highlight the treatment of this injury without chemical interference¹⁰.

Research Objectives:

1 - Application of scientific methods to address the movement of the nerve bundle in the members of the research sample.

2- To know the effect of the scientific methods in the treatment of this type of origin.

Research hypotheses:

1 - the presence of different rates of movement of the nerve bundle in the members of the research sample.

2 - the effect of the treatment methods used for this type of injury in the members of the research sample.

Research Areas:

a - The human field: - The players of the individual and the individual games in the province of Thi - Qar.

b. Time domain: 1/1/2015 to 23/6/2015.

c - Spatial field: - Laboratory physiology in the Faculty of Physical Education and Sports Sciences at the University of Thi - Qar.

Methodology

The choice of the curriculum usually depends on the exact solutions and objectivity through which to find a solution to the problem, so the researcher adopted the descriptive method in the survey method to suit the nature of the research.

Community and Research Sample:

The methods and methods of selection of the

research sample are numerous and multiple, but there are things to consider when selecting the sample of the research. "The selected sample should represent the community of origin in a real and real representation so that the researcher can later circulate the results of his research to the community" Athletes with this type of injury were selected after their diagnosis by scientific methods and according to the precise measurements of the (20) players from various individual and individual events in the province of Dhi Qar.

Tools used: Stopwatch to calculate the pulse period, cotton, pot, water.

Exploration Experience:

The researcher conducted a survey of 2 members of the research community. The experiment was conducted within one day during which the measurements were conducted. The purpose of the experiment is as follows:

- Ensuring the total time to carry out the experiment.
- Ensure the work and field and the extent to which the implementation of measurements.
- Know the obstacles that appear and avoid the occurrence of errors and overlap in the work.
- Know the time needed to make measurements for each individual.
- Know the errors that occur in this experiment to avoid in the final experiment.

Procedural Methods:

The process of scientific evaluation should be objective so that we can accurately evaluate and the treatment method is appropriate. There are many ways and many, we do not take the scientific direction in this research has resorted to the researcher to choose the appropriate measurement method leads us to the diagnosis of appropriate and simple according to common symptoms such as nausea and loss Anorexia nervosa in the ventral nerve bundle area is close to the nerve center with a clear pulse appearance in the center. The measurements that have been adopted are:

A - Pulse Sensitivity Test¹:

If the pulse is directly under the finger, such as the heartbeat, this indicates that the system is compatible and that the packet is controlled, or vice versa, you will

notice the movement of the pulse from the center of the region either up or Down or you may not find the throbbing at all and you may find a weak pulse, we show that the beam moving from its place and the period is calculated to feel the pulse of a steady non-oscillating within ten seconds.

B- Direct pressure measurement ² :

The large finger is pressed at the center point of the leg joint from the back after lying on the abdomen. Both legs, which have a very strong pain in this area, indicate that the abdominal nerve bundle is moving from its normal position and can be treated from the leg which is

Where the source of the mother was calculated and the emergence of pain when the pressure on the region within a period of ten seconds.

Calendar: After confirming the scientific presence of a partial movement of the center of the nerve bundle according to the measurements that have been conducted, we do some of the following:

a - lying injured upright on the ground and the back facing the top and the arms stretched back.

b. The body is completely relaxed.

c. We take a piece of cotton with the size of the palm and put a quantity of water, we scan the leg from the middle of the knee to the end of the leg from the back, to facilitate the withdrawal of the nerve.

d - We press both thumbs on the center of the knee from the back and then drag down to the end of the leg.

e - Push the entire body through the feet forward in order to adjust the procedure for the withdrawal and return of the package.

Main experiment:

The main experiment was conducted on 23/6/2015 after completion of the exploratory experiments and the validity of the application and the time of the diagnosis, after which the researcher emptied the data with special forms for the purpose of conducting statistical treatments on them.

Statistical Methods

The researcher used the statistical bag (spss) in the extraction of the search results.

1. The arithmetic mean 2. The standard error, 3. The link box difference,

4. The simple correlation, 5. The degree (t) of the sample, 6. The contribution ratio.

Some statistical means of the sample of the research, which indicate the extent of achieving the objectives desired by the researcher according to the contribution rates and the amount of measurements that have been applied and the field of achieving its impact in the sample of the research chosen by the researcher, the researcher finds through these results there are a set of reasons that Led to this change in the level of therapeutic evaluation of individuals in this research, including us that the movement of any part of the nerve package from the original basis shows a defect in the functional aspects in addition to a defect in the physical aspects, and that the movement of the result of multiple causes, but weightlifting inappropriate and jump The sudden Or abnormal movement is one of the most important reasons for this move, and as a result of the diagnosis process, which most of the cases are dysfunction in the functional side as well as the motor side, the movement, although partially causing imbalance in the overall balance of the body because of its direct association with members of the body, The abdominal nerve bundle from its center has a clear effect on the various organs of the body and it is considered one of the important signs of moving this package from its place, because it is a center for mechanical distribution, but the main regulator of the process of balance in the body. The movement of the abdominal nervous system, although a simple movement has a significant impact in the spasms of the muscles of the diaphragm, which cause respiratory imbalance, where the diaphragm is one of the most important organs responsible for natural breathing, and believes “movement of the abdominal nerve plexus is a factor in the spasm of the surrounding muscles Diaphragm, which helps him in all his movements in order to complete breathing operations, and the connection of the nerve bundle abdominal through the abdominal artery near the stomach “³ The nerves are one of the main receptors of the instructions and that the occurrence of free, but simple, it prevents the arrival of the orders required for the performance of the motor and where it emphasizes that “the nerves of multiple benefits directly and the other directly and that any disorder in the organization leads to the lack of access to the natural doubt Affects the desired movement performance. On the sporting side, the integration of performance requires

safety in all machines function fully, as the presence of symptoms of organic and inorganic affect directly on the progress of performance and the athlete cannot give any amount of normal to the real level, but it could lose several properties and potential due to the existence of such These obstacles, which confirms that “the injury, although minor, has to have a direct impact on the performance of the sport and have additional aspects, whether they are accumulated or accumulated”^(4,6). These are the injuries that have an effect on the level of sport through the loss of motor balance due to the movement of the nerve beam that causes the presence of abdominal pain continuously, and have no chemical treatments for pain relief because it is caused by the simple movement of this package and is considered inorganic pain to be Treatment of the chemical side, where he points out that “the movement of the nerve bundle, although partially by its natural position, is working on the imbalance so that this imbalance is evident, especially in sports performance.”⁵.

Conclusions

The level of the two measures measured for diagnostic processes varied. There is a high correlation between the two methods of measurement that have been diagnosed. The presence of high contribution rates in achieving the level of the evaluation process on the members of the research sample. The presence of direct impact through the amount of differences obtained statistically.

Investigating the Level of Vitamin E, C and Superoxide Dismutase in Patients with Allergic Asthma and Allergic Asthma with Helminths Infection

Narjis Abdul Rahman Oudah¹, Ahmed A. Mohammed², Kareem S. Chead Al-Teea³

¹Dept. of Biology, College of Science, Mustansiriyah University, Baghdad-Iraq, ²Branch of Clinical Laboratory Sciences, College of Pharmacy, Mustansiriyah University, Baghdad-Iraq. <https://orcid.org/0000-0001-5147-4861>,

³Ministry of Health, Baghdad-Iraq.

Abstract

The aim of this study was to investigate the relationship of antioxidant activity, vitamin E, vitamin C and superoxide dismutase with the severity of allergic asthma by estimating their level in the patients' sera, as well as evaluating their association with the level of total and specific serum IgE in allergic asthmatics and allergic asthmatics with helminths infection. The study applied on 180 subjects divided into three groups, 100 patients with allergic asthma and 50 patients having allergic asthma with helminths infection. The group of patients included 50 males and 100 females age 15-60 years. The control group comprised of 30 healthy individuals, included 14 males and 16 females age range 16-60 years. For each participant, the medical history was considered; the total and specific IgE levels, vitamin E, vitamin C and superoxide dismutase levels were determined in the patient's sera using ELISA technique. The present study has demonstrated an increased level in serum total IgE in the patients' groups (allergic asthma group and allergic asthma with helminths) compare to the control group, mean 374.54 IU/mL; 472.24 IU/mL; 29.21 IU/mL respectively. The level differences among the three groups are highly significant when compared statistically.

Keywords: Allergic asthma, vitamin E, vitamin C, superoxide dismutase, antioxidant, asthma with helminths infection, total IgE, specific IgE.

Introduction

Asthma is a major public health problem affecting many people around the world; men and women, young and old all over the world ¹. Asthma is a chronic disease of airways with acute lung inflammation and bronchial hyperresponsiveness that characterized by different respiratory symptoms including wheezing, dyspnea, chest discomfort, cough and variable airflow limitation (2,3). These symptoms are often caused by several factors such as allergen exposure, exercise, irritant exposure, viral respiratory infections or change in the weather ⁴. Asthma is believed to be trigger by a combination

of complex genetic and environmental interactions. It is divided into two types, both of them have the same signs. These types are allergic (or extrinsic) asthma and non-allergic (or intrinsic) asthma ⁵. Allergens can activate the inflammatory cells in the airways and lungs. This activation leads to generate oxidants (free radicals) (6,7). The antioxidant such as vitamin E, vitamin C and superoxide dismutase (SOD) terminate and inhibits oxidant reaction. As a result of this reaction, antioxidant reducing external attacks in the lung ⁸. However, asthma's patients have been reported to have reduced antioxidant defences in their peripheral blood ⁹. Vitamin E is an important antioxidant vitamin in the body, playing a protective role by which damage free radical and scavenge reactive oxygen species (ROS) ¹⁰. Vitamin E becomes oxidized itself while preventing the oxidation of other factors more important metabolically ¹¹. In allergic asthma and allergic lung inflammation, vitamin E acts as an anti-inflammatory factor and blocks the airway hyperreactivity by regulating leukocytes'

Corresponding author:

E-mail: springlife.na@gmail.com

signals of trans-endothelial migration from the blood to the lung¹². Vitamin E intake is associated with low serum IgE concentrations and low frequency of allergen sensitization¹³. Vitamin C is a critical water soluble vitamin that presents into two active forms, ascorbic acid which is oxidized derivative and dehydroascorbic acid. Vitamin C can act as a hydrogen donor to converse oxidation; therefore, it functions as a non-enzymatic antioxidant which deactivates and reacts with the free radicals^(14, 15).

Materials and Method

Subjects

The current study included 150 allergic asthmatic patients, 100 with allergic asthma and 50 having allergic asthma with helminths infection confirmed by general stool examination (GSE). The group of patients comprised of 50 males and 100 females age 15-60 years. These cases were followed up in the Specialized Center of Allergy in Baghdad/ Al-Rusafah and Al-Zahraa Center of Allergy in Baghdad/ Al- Karkh for the period from July 2018 to January 2019.

Exclusion criteria were included: smoker, oral corticosteroids, respiratory tract infection, cancer, any chronic disease other than asthma, parasitic infections other than helminths and pregnant females.

The control group involved 30 healthy individuals 14 males and 16 females with age ranged between 16-60 years. Exclusion criteria were chronic respiratory disorders, current or past history of allergy, helminths infection and all chronic diseases mentioned in reference to the study group above.

Study design

All patients underwent a detailed clinical examination included total immunoglobulin E test (T.IgE), specific immunoglobulin E test (S.IgE), general stool examination (GSE) and serum level of vitamin E, vitamin C and superoxide dismutase (SOD).

Five milliliters of peripheral blood sample were taken from each subject using disposal 10ml syringes under sterile conditions. The blood collected in a gel tube to get the required serum for serological tests (T.IgE and S.IgE). Samples were centrifuged for 10 minutes at 2500 rpm, then serum divided onto five Eppendorf tubes, one for each test. All serum samples kept frozen at -20°C until they used.

Determination of T-IgE, vit. E, vit. C and SOD

The level of serum T.IgE, vit. E, vit. C and SOD were determined using enzyme linked immunosorbent assay (ELISA) based on the manufacturer's instructions, where microtiter plates have pre-coated with antibodies. The standard and samples were applied on the wells, followed by adding the conjugate, then the TMB substrate to produce a blue color which will be changed to yellow when adding the stop solution. The concentration is proportional to the density of the produced yellow color, which is read using the microplate reader at 450nm to find the concentration of T.IgE, vit. E, vit. C and SOD.

Determination of S-IgE

The determination of S-IgE was performed using ELISA (polycheck kit, Germany). The polycheck strips were firstly coated with the allergens and calibrators, followed by adding the patients' and control sera which incubated on the rocker shaker. In the next step, the conjugate was applied followed by the substrate to quantify the IgE by the scanner and the computer. The inhalation profile kit that used to diagnose the types of allergens contains 20 parameters from the common allergens including: *Dermatophagoides pteronyssinus* (D1), *Dermatophagoides farina* (D2), Timothy Grass pollen (G6), Rye pollen (G12), Plantain pollen,(W9), Mugwort pollen (W6), *Cladosporium herbarum* (M2), *Aspergillus fumigatus* (M3), *Penicillium notatum* (M1), *Alternaria alternata* (M6), Dog epithelia (E2 / E5), Cats epithelia (E1), Horse epithelia (E3), Guinea epithelia (E6), Hamster epithelia (E84), Rabbit epithelia (E82), White Oak pollen (T7), Birch pollen (T3), Hazel pollen (T4) and Alder pollen (T2).

Investigation of helminth infections

The association of helminths infection in the group of allergic asthmatic patients were investigated using the GSE. Fecal samples were collected from the patients and control groups. The specimens were directly examined under 10X and 40X objectives.

Statistical Analysis

Statistical analysis was conducted with Statistical Program for Social Science software (IBM SPSS 23.0). Parametric quantitative data was presented as the mean ± standard error. Least significant difference test (L.S.D) was used to compare among the means of over than three (compare the concentration of T.IgE and vitamin

E, vitamin C and SOD in asthmatics, asthmatic with helminths infection and control groups). Correlation analyses between data were performed using Spearman’s tests, with the correlation coefficients presented as “R”. Level of significance was defined by using ANOVA test with probability $P \leq 0.05$ (significant), $P > 0.05$ (none significant) or $P < 0.01$ (highly significant).

Results and Discussion

Studying the relationship between the infection with allergic asthma and serum level of antioxidants vit. E, vit. C, SOD as well as its relationship with the level of total and specific serum IgE has been addressed in this study. In addition, the effect of the association of helminths infection with allergic asthma and the effect of this association on the immune response of allergic asthmatic patients was investigated for the first time in

this study, particularly in regard with the biomarkers mentioned above.

The current study has observed a significant elevation in the levels of the total serum IgE parallel with declined serum level of antioxidants in allergic asthmatic subjects and allergic asthmatics with helminth infection compared with healthy individuals. The mean serum level of total IgE of asthmatics was 374.540 ± 10.394 IU/mL, which is highly significant than its level in healthy control, mean value 29.216 ± 1.786 IU/mL, $p < 0.01$. In addition, the mean T.IgE level in allergic asthmatic subjects with helminth infection is 472.242 ± 6.273 IU/mL which is highly significant than that of the control. However, the T-IgE level in the patients with allergic asthma and helminth infection was higher than its level in the patients having only allergic asthma, the full comparison is presented in Figure 1.

Figure 1: Serum levels of total IgE in the groups of allergic asthma, allergic asthma with helminths and control.

Allergens sensitization test was also performed in the current study by evaluating the level of serum S.IgE. The results have disclosed that the frequency of the most common allergens in 113 allergic asthmatic patients with positive specific IgE was as in the following: D1

(27%), D2 (26%), G12 (25%), T7 (23%), T2 (22%), W9 (21%), G6 (17%), E1 (17%), T3 (14%), E2 / E5 (14%), W6 (14%), E3 (12%), T4 (11%), M3 (7%), M2 (4%), E82 (3%), M1 (2%), M6 (2%), E6 (1%), E84 (1%), as shown in Figure 2.

Figure 2: The percentage of aeroallergens that sensitize asthmatic patients’ groups.

As shown in Table 1, the mean level of vitamin E in allergic asthma patients was 11.545 ± 0.320 IU/ml and it was 9.413 ± 0.180 IU/ml in allergic asthma with helminths as compared to its mean level in healthy control group that was 23.253 ± 0.726 IU/ml. Statistical analysis shown that there are a highly significant differences when compared between patients’ groups and control group and also between allergic asthma and allergic asthma with helminths.

Table 1: Show the variation in vitamin E concentration among patients’ groups and control.

Groups	Vitamin E ($\mu\text{g/mL}$) Mean \pm S.E.	L.S.D. P-value
Allergic asthma	11.545 ± 0.320	$P1= 0.00^{**}$
Allergic asthma with helminths	9.413 ± 0.180	$P2= 0.00^{**}$
control	23.253 ± 0.726	$P3= 0.00^{**}$

****Highly significant ($p < 0.01$)**

P: probability, $P1$ =Allergic asthma Vs Allergic asthma with helminths, $P2$ =Allergic asthma Vs control, $P3$ = Allergic asthma with helminths Vs control.

The serum level of vitamin C in allergic asthmatics was 36.040 ± 1.367 $\mu\text{g/ml}$, while the recorded mean level in allergic asthmatics with helminths infections was 21.163 ± 0.793 $\mu\text{g/ml}$. The statistical analysis reached that vit. C level in both patients’ groups are significantly different from the level of vit. C in the sera of the control group which was 76.288 ± 2.708 $\mu\text{g/ml}$. On the other hand, there was a highly significant difference in the level of vitamin C between the two patients’ groups as shown in Table 2.

Table 2: Show the difference in the level of serum vitamin C in the groups of allergic asthma, allergic asthma with helminths and control.

Groups	Vitamin C ($\mu\text{g/mL}$) Mean \pm S.E.	L.S.D. P-value
Allergic asthma	36.040 \pm 1.367	P1= 0.00**
Allergic asthma with helminths	21.163 \pm 0.793	P2= 0.00**
control	76.288 \pm 2.708	P3= 0.00**

**Highly significant ($p < 0.01$)

P: probability, P1=Allergic asthma Vs Allergic asthma with helminths, P2=Allergic asthma Vs control, P3=Allergic asthma with helminths Vs control.

Moreover, it has been found that superoxide dismutase is also decreased in both patients' groups. Statistically, there were highly significant differences between the both patients' groups (Table 3) and between the patients in the two groups and the control too. The level of SOD in allergic asthmatic group was 149.048 \pm 6.447pg/mL, whereas, it was 78.271 \pm 3.635 pg/mL in the group of allergic asthma with helminths. Nevertheless, the SOD level in the serum of the control group was 1034.157 \pm 32.659.

Table 3: Demonstrate the difference in the level of superoxide dismutase (SOD) in the groups of allergic asthma, allergic asthma with helminths and control.

Groups	SOD (pg/mL) Mean \pm S.E.	L.S.D P-value
Allergic asthma	149.048 \pm 6.447	P1= 0.00**
Allergic asthma with helminths	78.271 \pm 3.635	P2= 0.00**
control	1034.157 \pm 32.659	P3= 0.00**

** Highly significant ($p < 0.01$)

P: probability, P1=Allergic asthma Vs Allergic asthma with helminths, P2=Allergic asthma Vs control, P3=Allergic asthma with helminths Vs control.

Table 4: Show the variations in the level of antioxidant according to different groups of T.IgE level.

Antioxidants		T.IgE lower than (300) group	T.IgE between (300-500) group	T.IgE upper than (500) group	L.S.D. ANOVA (p-value)
Vitamin C ($\mu\text{g}/\text{mL}$)	Mean \pm S.E.	37.162 \pm 2.110	27.380 \pm 2.021	25.257 \pm 1.632	P=0.00**
Vitamin E ($\mu\text{g}/\text{mL}$)		11.179 \pm 0.348	11.101 \pm 0.602	9.821 \pm 0.240	P=0.01**
Superoxide dismutase (pg/mL)		138.149 \pm 8.281	116.647 \pm 12.328	100.637 \pm 8.320	P=0.03*

*Significant ($p < 0.05$) **Highly significant ($p < 0.01$)

S.E.= standard error

Allergic asthma is the most common phenotype of asthma among patients. The IgE is a well-known component of allergic reactions where it is produced during the process of sensitization which is triggered on the first exposure to the allergen. However, the level of T.IgE is increased with helminths infections too²². The results observed in current study indicating that the T.IgE playing a central role in the initiation and propagation of the inflammatory cascade of the allergic response and also in the immune response to the helminths infection, as shown in Figure 1.

Conclusion

The level of antioxidants, vit. E, vit. C and SOD are correlated with the severity of allergic asthma, where asthmatic patients having antioxidant insufficiency due to the increased oxidative stress. In addition, antioxidant activity has a negative correlation with pathogenesis parameters of allergic asthma such as total and specific IgE as well as with helminth infections.

The Role of Cytomegalovirus (CMV) and Vitamin D in Multiple Sclerosis (MS)

Juman Khaleel Al-Sabbagh

University of Kerbala – Veterinary college / Microbiology Dept. /Iraq

Abstract

Multiple sclerosis (MS) is one of the autoimmune demyelinating diseases involved in the central nervous system (CNS) and its etiological factors believed to be both environmental and genetic factors . The disease affected brain and spinal cord with various characteristic involved defect of myelination , chronic inflammation , pathological effect on axon and oligodendrocyte . The herpesvirus family is play a vital role in pathogenicity of disease . Cytomegalovirus (CMV) from these family members which detected to have a role in MS and our results investigated a significant relation of CMV with MS between patients and controls . Besides a previous data which approved the effect of the level of vitamin D on MS development and modifications in patients . In this study the results achieve significant differences in the levels of vitamin D between the two groups under study .

Key words: *multiple sclerosis (MS), Cytomegalovirus (CMV), (25- hydroxyvitamin D), Vitamin D.*

Introduction

One of the diseases involved in the central nervous system (CNS) is multiple sclerosis (MS) ¹ . The disease affected brain and spinal cord with different clinical features such as blemish of myelination , chronic inflammation , pathological effect on axon and oligodendrocyte ² . Generally , the disease pathogenesis may related to genetic factors of an individual or due to environmental conditions surrounding the patients ³ . The environmental factors can be suggested to related to distribution of the disease , in some population like Jordanians the disease incidence , is ranged from 20-60 cases per 100,000 persons ⁴ . In spite of World Health Organization , showed the incidence of MS reported to be 4 in 100,000 ; in South Asia reported to be region with a medium to high risk for MS ⁵ . While the prevalence in northern Europe or Canada is about 0.1 - 0.2% in population ³ . Multiple sclerosis is considered as idiopathic disease, and many factors can be associated with its progression ; from these are the genetic factors such as the role of the genes responsible of DNA repair in activation of MS and lesions formation ⁶ . As well as the role of polymorphisms in human leukocyte antigen (HLA) genes class II ⁷ . Numerous of genes associated with the disease are the regulatory genes affected the immune cells and their function which lead to

dysregulation of the immune system ⁸ . Auto-reactivation of T cells against myelin may contribute to pathogenesis, and there is increasing attention of the role of human viruses in autoimmune diseases and its progression ⁹ . There is a significant increasing damage in nuclear and mitochondrial DNA in lesions of MS comparing with normal brain white matter and this highlights on the role of repair genes in DNA ⁶ .

Studies shown that multiple genes such as base excision repair genes involved in DNA repair may expressed in lymphocytes and lesions of MS when compared with tissues of control ¹⁰ . The environmental factors are strongly approved to be associated with the triggering of MS , like viral infection , high radiation of UV , climate and temperature , fat intake from animal sources , consumption of dairy products and levels of vitamin D ¹¹ . genotoxic agents ,like cigarettes and nitric oxide may support and involve in MS induction ¹² .

The Role of Vitamin D :

Vitamin D concedes as essential nutrient for the bone homeostasis and plays a role in many disorders like cardiovascular and autoimmune diseases ¹³ . Although the deficiency of vitamin D is common in all ages but it hard to occur in the young and elderly ; and not only bone disorders , but many disorders can be related to

it , such as cardiovascular , autoimmune and neuro-related diseases such as schizophrenia ¹⁴ . In the immune system it is proposed to play a vital and supportive role in controlling of several diseases, as a cancer and neurodegenerative disease and possible relation with MS ¹⁵ .

Enhancement the function of vitamin D is by binding to the vitamin D receptor (VDR) on the cells ; by the ability to converting 25(OH)D to the active form 1,25(OH)2D. The VDR concedes as a mediator for the signaling, and its regulation is unclear until now ¹⁶ More than 2,000 genes can be regulated directly or indirectly by 1,25(OH)2D ; as well as there are at least eighty various metabolic processes regulated by these genes such as repair of DNA , apoptosis , alteration of function of the immune system , oxidative stress ¹⁷ .

Many factors and there accurate roles must be examined because they preventing and treating many disorders related to with VDR and its function by facilitating and improving strategies ¹⁸ . Many studies indicate the protective role of vitamin D on MS patients, and the risk of disease is reduced by Vitamin D supplements and exposure to sunlight ¹⁹ . Moreover, expression of VDR induced by 1,25(OH)2D in both resting and activated cells ; and for homeostasis of T cell during MS , vitamin D plays crucial role , and supplementation of it should be appropriate to treat the disease severity ²⁰ .

Multiple Sclerosis and Viral Association :

Studies connect between viral etiology and MS; that due to the association of viral infection and encephalomyelitis , demyelinating processes in the nerves and axonal damage ; all that may precede the lesions of MS; as well as plaques of active demyelinating caused by T CD8 lymphocytes which involved in viral immunity ²¹ . Processes of cortical and axonal damage with lesions absence are detected in viral demyelinating , are seen generally in MS , and there is a resemblance of relapsing remitting MS form and periods of reactivation and latency of many viruses, such as the herpes virus ²² .

Cytomegalovirus (CMV) , Epstein- Barr Virus (EBV) , Human Herpes Virus 6 and 7 (HHV-6 and HHV-7) are members of the family *Herpesviridae*, and are from plausible viral agents associated with triggering of MS, as well as endogenous retroviruses also considered to be significant agents in MS ²¹ . The infection by CMV may activate the reaction of the immune system

against the constituents of myelin of peripheral nerve ²³ . A wide of inflammatory diseases and brain cancer , CMV was concerned to be as a co-etiological agent ²⁴ . Furthermore a wide range strategies can be caused by CMV can be targeting the host defenses, from disturbing the pathways processing of antigen to modulating of cytokines ; and this establishing success coexistence of CMV during active infection , and in many tissues and organs this virus can be found , as well as in fluids of body ²⁵ .

Types of MS :

There are 4 clinical types according to the course of disease; relapsing-remitting MS (RR-MS), secondary-progressive MS (SP-MS), primary progressive MS (PP-MS), and progressive-relapsing MS (PRMS) ; the first type is the major one and approximately 85% of patients are identified with it , in which exacerbations symptoms is noticeable and remission period is followed by , and the symptoms either progress or withdraw ; in a number of patients RR-MS types of disease may developed into the second type (SP-MS) in which the disease continues to be deteriorate with remission period or without ⁴ . The third types of disease (PP-MS) about 10 percent of total patients be affected ; and the symptoms gradually worsening without remissions or relapses, the rare types of MS is the last one (PR-MS) which affecting less than 5 percent of total patients and from the onset of disease it is progressive intermittent flareups with no remission periods and the symptoms are worsening the way ²⁶ . In the adolescence the disease onset initiates and the peak reaches among the persons in late 20s and the beginning of early 30s , and the females developed the disease in doubling than males ²⁷ . In Arabic populations , all ratio of gender designate that the females affected more over than males ²⁸ .

Materials and Method

In this case control study sixty patients participating . They had MS from all types ,who attendance the MS center in medical city, their ages range between (19-53) years . And the confident diagnosis was confirmed according to examination clinically and neurologically by neurologists . Sixty persons ; females and males included in this study as a control with normal clinical and neurological status and with no history of MS , and their ages approximately matched to that of patients .venous blood samples were collected and the serum separated from patients and control . Vitamin D immediately

examined while the rest of serum stored in -4°C until Anti-CMV antibodies examined . CMV IgM ELISA kit provided by (CALBIOTECH / USA company) .

used to compare means of (Vitamin D and Anti-CMV antibodies) serum level between two groups (patients and controls) . A p-value ≤ 0.05 was considered as significant ²⁹ .

Statistical Analysis

The statistical analysis of this study included the calculation of mean values and percentage. The association between Vitamin D and Anti-CMV antibodies was done by calculated of Chi square and P value with 95% confidence interval (95%CI). T-test was

Results and Discussion

In present study 60 for each of patients and control group taken . All the types of MS included in this study and 38 (63%) were detected with the first type (RR-MS) . The results obtained is illustrated in the Table (1) .

Table (1) : The ages , mean of ages and gender of patients and control groups .

Groups	Ages	Mean of ages	P value	Females	Males
Patients (n=60)	(19-53) years	34.73±8.9	0.9	43(72%)	39(65%)
Control (n=60)	(17-56) years	34.93±10.4		17(28%)	21(35%)

P-value ≤ 0.05 is significant

In this study we found that there is no significant differences of ages between two groups and , the prevalence of females is more than males , our results matched with previous studies who told that , generally MS presents in women higher than in men ; and this may be due to variations in the nervous or the immune system , differences in hormones , variations in the genetic , differences in the environment and modern lifestyle between men and women ³⁰ . And there are markedly increasing of this disease in women than men in last years ³¹ .

This increasing possibly pointed to unclear changes in nutrition or environmental conditions which lead to predominance of this disease in women ³² . Also there is a different response of females and males against factors in the environment ; such as the sun light and supply of Vitamin D ³³ . Moreover , increasing intake of dietary salt may be suggested to develop autoimmune diseases by activation of T-helper 17 cells ³⁴ .

The role of CMV in MS patients :

The level of anti-CMV antibodies of patients and control groups were detected by ELISA kit and our results represented that , there is a significant differences of anti-CMV antibodies between two groups . And CMV showed to have a positive role in MS disease ; table (2) .

Table (2) : Anti-CMV antibodies of patients and control group .

Groups	Anti-CMV antibodies positive (number and %)	Anti-CMV antibodies negative (number and %)	Mean of Anti-CMV antibodies positive (IU/mL)	Border line (number and %)	P value
Patients (n=60)	40(66.66%)	16(26.66%)	2.21±1.5	4(6.66%)	0.005
Control (n=60)	26(43.33%)	29(48.33%)	1.46±1.2	5(8.33%)	

P-value ≤ 0.05 is significant

Many studies about *Herpesviridae* family, talk about the role of these family members in triggering and pathogenesis of MS; and most of these studies recorded the significant role in induction of MS; these viruses have periods of latency and exacerbations within CNS; Epstein-Barr, cytomegalovirus, human herpesvirus 6 and human herpesvirus 7 viruses from these viruses which are possibly triggering MS²¹. Several studies proved a high rates of infection with CMV in MS patients; but with more benign characteristic of this disease²³. In comparison, the high titers of antibodies against CMV, the patients have disease reactivation in lower rates and cerebral atrophy in fewer signs with those patients who had lower antibodies titers³⁵.

Sanadgol *et al.*, support the hypothesis of contribution of CMV with MS and establishment of systemic infection by CMV in induction of immune response²³. As well as induction of demyelinating lesions may be caused by myelin-specific lymphocytes which triggering by CMV³⁶. In contrast of that Najafi *et al.*, revealed, there is no significant differences between the anti-CMV antibodies and MS based on statistical analysis³⁷.

Many surveys correlate between the role of infection by CMV and some types of autoimmune disease; and these studies demonstrated the role of CMV infection in attacking of the immune system to own cells of patient's by antigenic mimicry, and a high titers of IgG antibodies against CMV found in certain autoimmune disease³⁸. In other hand probably CMV is capable to evade the immune system and induce the mechanisms of immune regulation, which may decrease the reactivity of MS disease in patients with MS³⁹.

In general There is controversy about the role of pathogenesis of CMV in MS patients; some studies suggested a positive relationship between MS activity disease and infection with CMV; while others investigated negative role between MS and CMV infections⁴⁰. Many studies needed to improve the role of CMV in MS induction by taking larger samples of patients of MS and healthy control.

The role of vitamin D in MS :

In this study the level of Vit. D is measured and the results of two groups shown in the following table.

Table (3) : the level of vitamin D of patients and control group .

Groups	Deficiency (number and %) of Vit.D level	Sufficiency (number and %) of Vit.D level	Mean of Vit.D deficiency (ng/ml)	P value
Patients (n=60)	47(78.33)	13(21.66)	21.78±13.1	0.000
Control (n=60)	19(26.66)	41(68.33)	36.43±14.1	

P-value ≤ 0.05 is significant

The result revealed that, there is a significant differences between two groups in levels of vitamin D. The patients with MS suffering from deficiency in vitamin D level and Sintzel *et al.* pointed to relationship between vitamin D levels in serum and development and activity modifications of MS in patients; besides the lower level of vitamin D, the higher risk of MS development⁴¹.

Besides the levels of (25- hydroxyvitamin D) in many cases of MS are much lower when compared with healthy peoples, as well as the patients with active form

of disease have lower levels of vitamin D than those with the disease with less active state, and this indicated a significant inverse relationship between serum 25(OH) D and the activity of clinical state of MS⁴².

Evaluation the relationship between the intake of vitamin D from diet or supplements and the risk of development of MS showed that, the women with highly intake of vitamin D supplement had a lower incidence with 33% less of MS development in comparison with women who taking low or no supplements of vitamin D; moreover, the women that used supplements of vitamin D had a 41% reduction in development of MS disease in comparison with non-user women; and that predict to

reducing the onset of MS risk ⁴³ .

Furthermore , an individual etiological factor for MS , vitamin D reported to interact with other causes of MS like , genetic factor as HLA-DR1 to environmental factor as a smoking ⁴² . Decrease in serum level of vitamin D due to genetic causes supposed to increase the susceptibility to MS by fifty percent ; while increasing the level of 25(OH)D by 50% may decrease getting MS at about 50% ⁴⁴ . On the other hand a vitamin D daily dose or a gestational dose per day ; may “*keeps the MS doctor away*” is not proven until now ; in addition in a large majority , the level of serum 25(OH)D may not prevent MS of many peoples ⁴⁵ .

Runia *et. al.* told that risk of relapse may reduce significantly in individuals with medium (20-40 ng/mL) or high as (> 40 ng/mL) levels of vitamin D in comparison to those individuals with levels lower than ⁴⁶ . The association between MS lesions development and the levels of vitamin D showed that individuals with high levels of vitamin D are developing much lower newly lesions and of enhancing lesions gadolinium (Gd+) ⁴⁷ . Moreover increased level of 25(OH)D related to less active rate of new lesions and relapse rate at 57% ⁴⁸ .

The receptors of vitamin D especially for 25(OH)D found in many cells of immune system like macrophages and ; and stimulation of these cells through the receptors can inhibit the immune response and cytokine production ; and in patients with MS , vitamin D supplements can the level of IL-2 mRNA in mononuclear cells ⁴⁹ . In patients with MS, the immunomodulation by 25(OH) D ,can increase the anti-inflammatory cells and inhibit the pro-inflammatory cells , which reduce the severity disease ; after the intake of vitamin D dietary(1000 IU/day) also the cytokine profile modification can reduce inflammation and this can be demonstrated in patients with MS ⁵⁰ .

As well as in the genomic level vitamin D receptor (VDR) gene polymorphisms have been demonstrated to be link to numbers of diseases such as MS ⁵¹ . Furthermore a similar result showed the significant differences between the patients and controls of genotype distribution of (VDR) genes ⁵² . On the other hand , Cakina *et al.* showed that , there is no significant differences between MS patients and control groups ⁵³ .

Conclusion

In spite of the controversy role of CMV in triggering

of MS ; this virus play a major role in this disease either by induction of disease by activation of immune system against the myelin of CNV by molecular and antigenic mimicry or by reduce the reactivity of disease and lesion formation due to evasion of immune system by periods of latency of these viruses. Vitamin D is not only act a vitamin it is a gene and cell regulator . It is play a crucial role in induction of many diseases like cardiovascular disease , diseases related with the nervous system and immune system . And its role in MS induction and activation is clear , and its role of it and its receptors need for more investigations.

Potential Factors Associated with Epilepsy among Epileptic Patients Attending Middle Euphrates Neurosciences Center - Al-Najaf City

Sahar Adham Ali ¹, Hayder Ibrahim Ali ², Hasan Alwan Baiee ³

¹University of Babylon –College of Nursing, Iraq, ²Higher Health Institute AL-Najaf Health Directorate, Iraq, ³University of Babylon –College of Nursing, Iraq

Abstract

Objective: To identify the some factors associated with epilepsy. A Case-control study was carried out at Middle Euphrates Neurosciences Center in An-Najaf City- Iraq, the study was conducted from mid of October 2016 until mid of March 2017. Participants recruited in the study were selected as conveniently, (74) of them were already diagnosed by neurologist as epileptics patients and considered as cases, while (140) were non-epileptic from same setting considered as control group. instrument structured for this purpose, data collection was done using pretested questionnaire which consist of two parts, first one included: biographical data (age, gender, marital status, level of education, occupation, and resident). The cases and control groups are age and sex matched. Epileptic patients had a significantly low level of education (Not read and write) 34.4% as compared to healthy control group 13,3% this difference is statistically significant $p < 0.05$ the Odds Ratio (OR) was 2.1., the following possible risk factors were significantly associated with epilepsy in this study; unemployment OR= 2.7 , positive family history OR=1.8, central nervous system lesions OR= 4.3 and natal defects OR=8.3.

Keywords: epilepsy, risk factors, Iraq

Introduction

Epilepsy is a common health problem that effect peoples and it is featuring as a seizure attacks with differences in clinical events, that need to be treated by use of medications ⁶. Epilepsy can occur at any age, race, ethnic ⁵. More than 10 % of people around the world were effected with single attack of abnormal movement, generally single attack not classified as epilepsy if not affected at least two unprovoked seizures attack separated by 24 hours, but the person at risk for recurrent and appear as epileptic patient ⁸. About 724,500 epileptic patients are distributed in Arab countries according to epidemiological review in Arab countries for epilepsy ¹. The risk evolving for epilepsy in life of person along life time is 1.4-3.3 % ¹³. Many factors are associated with occurrence of secondary epilepsy or considered as risk factors for it if present in person like family history, any brain lesion (tumor, trauma, and cerebrovascular accident), and central nervous system infection. Otherwise if not associated with any mentioned factor consider primary (unknown

cause) epilepsy ⁹. People who are affected with epilepsy are interesting to identify the risk factors related to underling health condition ¹¹, 25%-45% of epileptic patients, were affected with epilepsy related to many causes such as hereditary, brain structure lesion, or metabolically disturbances cause, while other peoples with epilepsy considered an idiopathic affect ⁴. Family history according to antecedent studies consider one of major risk factors affecting young age ⁸. It is important to predict the potential risk factor for epilepsy to take preparation of health planning contribution ³. This study was conducted to identify the risk factors associated with epilepsy.

Methodology

A Case-control design was carried out at Middle Euphrates Neurosciences Center in An-Najaf City which is the single specialist center established in (2010) to cover the needs of neurological consultations for population in south region of Iraq, the study period from 16 October 2016 until 16 March 2017. Data were

collected from (214) patients selected as a convenience sampling, (74) of them were already diagnosed with epilepsy considered as cases group, while (140) were non-epileptic from the same setting considered as control group. This data were achieved verbally by direct interview with both who attend as outpatients of the center, structured questioner was constructed for this purpose, the using form consist of two parts, the first one includes: demographical characteristics (age, gender, marital status, level of education, occupation, and residence), while the second part consists of questions about potential risk factors for epilepsy such as family history, history of central nervous system lesion that result from (infection, congenital defect, trauma, tumor, and other defects for CNS), pregnancy and delivery factors, other potential risk factors, and unknown risk factors for epilepsy. Reliability of the questions was (0.68) of the form were calculated after carrying out a pilot study which included (20) participants who excluded from the study sample, the validity of the study tool was done

through reviewing by panel of (10) experts. The selection of patients considered the clinical diagnosis of patients and using of chronic disease identification form which used for free medications and the diagnosis confirmed by electroencephalograph (EEG). Statistically analysis was done using Odds Ratio (OR) with measure the risk, OR more than one considered as a positive association.

Results and Discussion

The current case-control study includes 74(35.2%) epileptic patients and 140(64.8%) non-epileptic patients. Table (1) shows differences in distribution of socio-demographic characteristics among case and control group, males 117 (54.7%) more than females 97 (45.3%) in all sample. Most of them were married 128 (59.8%) and 86 (40.2%) were single. 45 (21.0%) were read and write, while 3 (1.4%) had higher academic level of education. The highest 77 (36.0%) were not working, 136 (63.6%) were living in urban area.

Table (1) Distribution of Socio-demographic characteristics of sample

Socio-demographic characteristics		Cases	Control
		No. (%)	No. (%)
(Age groups) years	(1-18)	40 (54%)	17 (12.2%)
	(19-36)	18 (24.3%)	60 (42.9%)
	(37-54)	9 (12.2%)	46 (32.8%)
	(55 and more)	7 (9.5%)	17 (12.1%)
Gender	Male	41 (55.4%)	76 (54.3%)
	Female	33 (44.6%)	64 (45.7%)
Marital status	Single	53 (71.6%)	33 (23.6%)
	Married	21 (28.4%)	107 (76.4%)
Levels of education	Not read and write	24 (32.4%)	20 (14.3%)
	read and write	14 (18.9%)	31 (22.1%)
	Primary school	19 (25.7%)	22 (15.7%)
	Secondary school	14 (18.9%)	30 (21.4%)
	Academic holder	3 (4.1%)	37 (26.4%)
Occupation	Not working	47 (63.5%)	30 (21.4%)
	Free working	10 (13.5%)	25 (17.9%)
	Office holder	15 (20.3%)	40 (28.6%)
	House wife	2 (2.7%)	45 (32.1%)
Place of Residence	Urban	40 (54.1%)	96 (68.6%)
	rural	34 (45.9%)	44 (31.4%)

Table (1) shows that (1-18) years were the highest age group in case, while in control group the age group (19-36) years was the highest.

In consideration of gender in case group the male were 41 (55.4%) more than female 33 (44.6%), like that in control group the male group was 76 (54.3%) more than female 64 (45.7%).

Regarding to marital status 53 (71.6%) were single case group, while in control group 107 (76.4%) were married.

The highest percentage were not read and write related to level of education in case group was 24 (32.4%), while in control group the highest were 34 (24.3%) for Academic holder.

Regarding to place of residence most of cases 40 (54.1%) were living in urban area in case group and control group 96 (68.6%).

Table (2) Distribution of the Associated Risk Factors Among the Study Group

Risk factors	Exposed	Cases	Control	OR
		F (%)	F (%)	
Family history	Not Exposed	39 (52.7%)	94 (67.1%)	1.83
	Exposed	35 (47.3%)	46 (32.9%)	
CNS lesion	Not Exposed	34 (45.9%)	110 (78.6 %)	4.31
	Exposed	40 (54.1%)	30 (21.4%)	
Antenatal def.	Not Exposed	45 (60.8%)	130 (92.9%)	8.37
	Exposed	29 (39.2%)	10 (7.1%)	
Others diseases	Not Exposed	70 (94.6%)	135 (96.4%)	1.54
	Exposed	4 (5.4%)	5 (3.6%)	

CI (confidence interval)=95%, OR= Odds Ratio

Table (2) presented the distribution of OR (1.83) for (74) epileptic patients in case group 35 (47.3%) patient exposed with family history and 39 (52.7%) are not exposed, in control group 46 (32.9%) exposed and 94 (67.1%) are not exposed, OR (4.31) for 40 (54.1%) exposed to CNS lesion and 34 (45.9%) are not exposed in case group, while in control group 30 (21.4%) exposed to same lesion and 110 (78.6 %) are not exposed, for 29 (39.2%) exposed and 45 (60.8%) not exposed to natal defects in case group, and 10 (7.1%) exposed and 130 (92.9%) not exposed the OR was (8.37). With history of other chronic disease potential risk factor the OR (1.54) for 4 (5.4%) exposed in case group and 70 (94.6%) are not exposed in same group, but in control group the exposed to these factors were 5 (3.6%) and not exposed were 135 (96.4%). The current study carried out to identify the risk factors for epilepsy in 74 participants who classified as disease compared with 150 participants no disease as control group. This study explain the association between different factors studies

such as family history, brain lesion, natal and postnatal defects, the Odds ratio in all these exposure are more than 1.5 this means the associations are positive and the factors studies are related to the development of this disease. Family history is one of the major risk factors for epilepsy as that found by ¹⁰. in their study in Iran at 2007, in current study family history had positive affect for occurrence of epilepsy. Central nervous system lesion included infection, congenital defect, trauma, tumor and other defects are positively associated with the study in occurrence of epilepsy in population, this finding is similar to Bhalla D. and Lotfalinezhad E. in their study at 2016 when presented that stroke is a significant risk factor for epilepsy. Wang H. et. al. in their study of Influential factors of epilepsy following aneurismal subarachnoid hemorrhage found that many aneurismal subarachnoid hemorrhage cases result in epilepsy that confirm the reality of brain lesion effect in occurrence of epilepsy. Prenatal, antenatal and post-natal defect history detect in this study have positive effects this defect distributed among (asphyxia, low weight, premature, trauma during delivery, jaundice, febrile seizure) this

finding agree with ⁷ who find in their study of Epileptic Encephalopathy in Children as Risk Factors for Brain Damage effect of prenatal and perinatal brain defect history on occurrence of epilepsy of many children. In view of point family history considered a risk factor in occurrence of epilepsy together with exposure to trauma and exposure to congenital anomalies and antenatal, post natal.

Conclusion

There are a strong association between epilepsy and family history, nervous system lesion, natal defect and other diseases.

Conclusion

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon –College of Nursing, Iraq and all experiments were carried out in accordance with approved guidelines.

Acute Infective Bloody Diarrhea in Children Below Five Years Admitted to Children Welfare Hospital in Medical City - Baghdad During 2015

Maral F. Thabit¹, Radhwan R Hussian²

¹Institute of Medical Technology, Baghdad/Head of Physiotherapy department, ²Baghdad Teaching Hospital

Abstract

Bloody diarrhea in young children is usually a sign of invasive enteric infection that carry a substantial risk of serious morbidity and death. Objectives : to identify the proportion of infective bloody diarrhea out of total number of gastro-enteritis cases ,also to identify the prevalence of different etiological agents and to find the relation between the main infective etiological types of bloody diarrhea and some sociodemographic factors of this study. Retrospective study was conducted in Children Welfare Teaching Hospital / Baghdad during period extending from 1st of January to 30th of June 2016. Information was collected by reviewing the records of patients with acute infective bloody diarrhea under 5 years of age admitted during 2015. The study revealed that the proportion of infective bloody diarrhea was 10. 9% out of the total gastroenteritis (788) cases admitted during 2015, and Entamoeba Histolytica was the most common isolated pathogen in the study 42 (48%) patients. followed by E.coli 15 cases (17.4%), shigella, salmonella 7(8%) and 4(4.7%) respectively . The most vulnerable age was those below 2 years (58%) and males were affected more than females (1.3:1), (37%) were bottle fed. The majority had chlorinated tap water supply (82.6%).

Key wards: *bloody diarrhea/children/under 5/children*

Introduction

Diarrhea is a preventable and treatable disease however it is still a major public health problem particularly in developing world It ranks as the third leading cause of both mortality and morbidity among infectious diseases, placing it above tuberculosis and malaria ¹. About 80% of deaths due to diarrhea occur in the first two years of life. The main cause of death from acute diarrhea is dehydration. Other important causes of death are dysentery, malnutrition and serious infections such as sepsis ². Bloody diarrhea in young children is usually a sign of invasive enteric infection that carries risk of serious morbidity and death. Non-infectious causes account for a very small proportion of episodes of bloody diarrhea ³ About 10% of diarrheal episodes in children under 5 years of age have visible

blood in the stool and these account for about 15% of diarrhea-associated death in this age group worldwide ⁴. Compared with the watery diarrhea, bloody diarrhea generally lasts longer, is associated with more complications, is more likely to adversely affect a child growth and has a higher case fatality rate ^(5,6,7). There is also a synergism between bloody and persistent diarrhea accompanied by malnutrition; therefore the control of bloody diarrhea will prevent most of deaths attributed to malnutrition and persistent diarrhea ^(2, 8, 9). According to WHO, in Iraq, the sanitary condition and general hygiene all over Iraq had been deteriorated during the last decade, particularly following the last war 2003 ^(2,10). However, only a few studies have described the epidemiology of bloody diarrhea among this age group.

Aim of Study

1. To identify the proportion of infective bloody diarrhea cases and their different etiological factors out of total number of gastro-enteritis.
2. To identify the predisposing factors of bloody diarrhea.

Corresponding author:

Maral F Thabit:

Institute of Medical Technology, Baghdad.

Email:maral.fthabit@yahoo.com

3. To find the relation between the main infective etiological types of bloody diarrhea of the admitted patients and some sociodemographic factors of this study.

Patients & Method

Study design: A Cross-sectional retrospective study.

Study period: it is carried out during the period extending from 1st of January to 30th of June 2016.

Study population: Children under 5 years.

Study place: Children welfare Teaching hospital/ Baghdad.

Study sample: (86) cases of bloody diarrhea out of (788) gastro-enteritis cases admitted in the above mentioned hospital during 2015.

Data collection method:

Patients with bloody diarrhea (three or more loose bowel motions / day with visible blood in stool)¹. Those with surgical conditions were excluded from the study (e.g. volvulus, intussusception), reports were reviewed and data collected from the case files of the patients (name, age, gender, address, type of feeding, type of water supply, boiling of drinking water, the presence of domestic animals).

Confirmation of diagnosis: for each patient the following was done by the same qualified laboratory personnel by stool culture and slide agglutination test was also done but it was not possible to identify the causative agents in 18 (21%), this could be due to infection with other organisms not routinely investigated in the stool samples or due to the lack of sensitivity of some laboratory procedures that used in this hospital or not present at all, this was similar to studies conducted in our country^(10,11).

Statistical Analysis

The data were analyzed statistically by using computerized SPSS system version (20). Descriptive statistics including observed frequencies and percentages. And Chi square test was used to assess the association between two categorical variables. P-value less than 0.05 was considered as a statistically significant, and value less than 0.01 was considered to be highly significant.

Results

Number of patients with bloody diarrhea was (86) from total number of patients of gastroenteritis (788) admitted to Children Welfare Teaching hospital during 2015 so the proportion of bloody diarrhea cases was (10.9%).

Results of examination and stool culture (86) patients identified as follows

Table (1): Isolation rate of enteropathogenes in children with bloody diarrhea:-

Enteropathogenes Isolated	Number and percentages of cases.
E. histolytica	42 (48.8%)
E. Coli	15 (17.5%)
Shigella	7 (8%)
Salmonella	4 (4.7%)
No isolate	18 (21%)
Total	86(100%)

The proportion of causative agents in descending order, E. histolytica 42 (48.8%), E. Coli 15 (17.5%), Shigella 7 (8%) . Salmonella 4 (4.76%) , & 18 (21%) of cultures showed no isolates.

Table (2): Age Distribution of the patients according to etiological agents:

Age(month)	Etiological agent			Number of patients
	Bacterial	Amoebic	Unknown	
1-12	4 (18.1%)	13 (59%)	5(22.7%)	22(25.6%)
13-24	9(32.2%)	17 (60.7%)	2(7.1%)	26(32.6%)
25-36	4(40%)	3 3(30%)	3(30%)	10(11.6%)
37-48	7(46.6%)	4(26.7%)	4(26.7%)	15(17.4%)
49-60	2(18.1%)	5(45.5%)	4(36.4%)	11(12.8%)
ToTotal	26	4242	18	86

X²= 20.95 ,P value = 0.001.

The majority of bloody diarrhea cases 50 (58.2%) found in those who were below 2 years. There is highly statistically significant difference (p value < 0.01) between different etiological agents and age group.

Table (3): Sex distribution of the patients according to the etiological agents :

Sex of child	Etiological agent			N. No of Patients
	Bacterial	Amoebic	Unknown	
Male	16(32%)	23(46%)	11(22%)	50 50(58.2%)
Female	10(27.8%)	19(52.8%)	7(19.4%)	36(41.8%)
Total	26	42	18	86

X²= 1.97, P value = 0.04

Males were more affected 50 (58.2%) than females 36(41.8%) There is significant difference between total number of cases and gender of the patients p< 0.05.

Table (4): Distribution of the patients and their etiology according to the type of feeding

Type of feeding	Etiological agent			No. of patients
	Bacterial	Amoebic	Unknown	
Breast	12 (46.1%)	9 (34.6%)	5 (5(19.2%)	26(30.2%)
Bottle	6 (18.7%)	20 (62.5%)	6 (6(18.7%)	32(37.2%)
Diet	4 (30.7%)	6 (46%)	3 (3(23%)	13(15.1%)
Mixed	4 (30.7%)	7 46.6%)	4 (4(26.6%)	15(17.5%)
Total	26	42	18	86

X² X²= = 12.47, P=0.002 .

There are statistically significant differences (P value < 0.05). Between number of cases of bloody diarrhea and different types of feeding showed more patients admitted with bottle feeding 37.2%.

Table (5): Distribution of the patients and their etiology according to the types of water supply:

Water supply	Etiological agent			NO. of patients
	Bacterial	Amoebic	Unknown	
Tap water	21 (29.5%)	36(50.8%)	14(19.7%)	71(82.6%)
Others like river, irrigation, canal, wells	5 (33.3%)	6(40%)	4(26.7%)	15(17.4%)
Total	26	42	18	86

X² X²= = 24.7., P value = 0.001

There is a highly significant (P value < 0.01) relationship between total number of patients and different types of water supply. 71(82.6%) of patients used tap water. There is also a relationship between different etiological factors and type of water supply. Tap water associated with more amoebic diarrhea 36 (50.8%) than bacterial 21(29.5%).

Table (6): Distribution of the patients and their etiology according to the habit of boiling water:-

Boiling of water	Etiological agent			NO. of patients
	Bacterial	Amoebic	Unknown	
Yes	7(46.7%)	5(33.3%)	3 (20%)	15(17.44%)
No	19(26.8%)	37(52.1%)	15 (21.1%)	71(82.56%)
Total	26	42	18	86

X² X²= = 5.6, P value = 0.001
 There is a highly significant P value < (0.01) relationship between total number of patients and habit of boiling water , showed more patients of bloody bl diarrhea were using un boiled water 71(82.5%) .

Discussion

The study revealed that the number of cases of bloody diarrhea was (86) cases from (788) cases of total gastroenteritis admitted during 2015, the percentage was (10.9%) this result is similar to ⁷ in Baghdad .

Entameoba histolytica was the most common isolated pathogen as it was detected in stool sample of the patients. This finding was similar to that observed in studies conducted in Basrah by (^{12, 13 , 14}) in Baghdad. Also in other studies done by (^{15, 16,7}).

The opposite finding was reported in many studies in different countries which showed that shigella species

were the most common agent associated with bloody diarrhea (^{5,6,17 ,18,19}) the reason for this difference could be explained by the fact that invasive amebiasis is an important public health problem and occur globally in endemic areas ³ . On the other hand, probably amebiasis is routinely over diagnosed and laboratory reports may be of little value, a study done by Walsh support that ²⁰ .

Entameoba histolytica cyst was found in (38 %) of bacterial bloody diarrhea. This means that more than one pathogen may be isolated from patients with bloody diarrhea. This is in agreement with studies done by (^{21,16}). ²² found that association of *E. coli* with *Entameoba histolytica* infection will enhance amebic virulence.

It was not possible to identify the causative agent in 18 cases (21%). This could be due to infection with other organisms not routinely investigated in the stool samples or due to the lack of sensitivity of some laboratory procedures, This is in agreement with other studies (10,6,18).

The age of the most affected children was between (7-12) months. A similar result was also found by (8, 23) . Susceptibility of this age group to bloody diarrhea may be explained by many factors such as declining level of maternal immunity , introduction of solid food which may be contaminated by enteropathogens , together with introduction of foreign material to the mouth of these children as they have learned to crawl up and pick subjects in their hands by this age ,which increases the risk of exposure to fecal pathogens (24,25) . Also most of the admitted cases were in this age group ,because of high worry of the families toward their children at this age group (2,10) .

Male sex was affected more than female with ratio of 1.6:1. This is agreement with other studies (10,6,17), while the opposite found by 18.

The significant difference in sex distribution was in those amebic dysentery, male to female ratio 2.2:1. This was also found by (25,26,27) in Ethiopia .

A high percentage were bottle fed 32 (37%) while breast fed is less 26 (30%) and this strengthen protective value of breast milk against diarrhea, weather bloody or watery. Similar results were found by (2,23,25,28)

The majority of the patients included in the study had tap water supply 71 (82.6%) while other sources is just 15 (17.4%).However, even chlorination of water cannot kill amoebic cyst or some other enteropathogenes this was aided by some studies (1,10), or it may be due to contamination of water system by ground water responsible for outbreak of amoebic dysentery 29.

Conclusions

1. The proportion of infective bloody diarrhea out of total gastroenteritis cases was relatively low .
2. Entamoeba histolytica is one of the most frequent offending pathogen in patients with bloody diarrhea in our society.
3. Children below 2 years are the main affected group and male sex affected more than females .

4. Bottle feeding preference, non-boiling of drinking water make children more prone to have bloody diarrhea.

5. Tap water use was associated with cases of bloody diarrhea.

Source of Funding: Self-funding.

Ethical Consideration:Approval to conduct this study was obtained from concerned authorities (Children Wefare Hospital in Baghdad),as well as the name of the participants was kept hidden.

Conflict of Interest: Nil

Comparison between Hypertensive and Non-Hypertensive Individuals in the Value of Response to Salt Administration

K.A Al-hilali¹, Layth Ibrahim AL-Shibbani¹, Ali Ayad Jabbar¹

¹Department of Nursing, AL- Safwa University College, Karbala province, Iraq

Abstract

Background: consumption of salt (sodium-chloride) causes increment of blood pressure (B.P) in both normal and hypertensive individuals, that is why, the use of diuretics which eliminate salts from the body decreases the B.P. and used as a line of treatment, in hypertension.

Objective: the study aims to know whether there is any difference in the increment of B.P. both systolic and diastolic between normal people and hypertensive people after giving salt orally.

Method: one hundred individuals were involved in the study, 50 patients were hypertensive, individuals (25 males and 25 females) and labelled as group A, and 50 persons (25 males and 25 females) were normal individuals and labelled as group B and played as control. After full physical examination including 3 times B.P. checking before and after giving 6 gm of sodium-chloride (table salt) orally ; after 2 hours the values of B.P. were recorded and statistical analysis was done to know the difference, between the two groups.

Results: in all individuals of both groups, the B.P. increased, after salt consumption. In group A (the hypertensive group) the mean increment, of systolic B.P. (S.B.P.) was (15.98) mmHg and the mean diastolic B.P. increment (D.B.P.) was (9.4) mmHg , while the mean S.B.P. increment, in group B was (8.7) mmHg and mean D.B.P. increment was (8.0) mmHg.

Conclusion: the study showed significant difference in the increment of B.P., both systolic and diastolic between the two groups, showing that hypertensive group is more sensitive to salt consumption than normal individuals (the control group).

Keywords: *systolic B.P. , diastolic B.P., increment, sodium-chloride.*

Introduction

Hypertension (HTN) is a major health problem world wide ¹. It is defined as chronically elevated blood pressure (B.P.) and the British hypertensive society defined B.P. as :1- optimal if the B.P. > 120 mmHg systolic, and less than 80 diastolic, 2- normal B.P. as > 130/85 mmHg and 3- high normal of 130/89 mmHg ².

Elevated arterial B.P. is a major cause of premature vascular disease leading to cerebrovascular events, coronary heart disease, and peripheral vascular disease ³.

In the past 1-2 decades, hypertension varied in prevalence, from western compared with eastern countries e.g. it was very high in Germany and lowest in China. Now a days, the differences are less ⁴.

Recently no much difference was found between developed, and developing countries, although it is still high, especially among black Africans (40-45-%) prevalence rate.

According to WHO reports in 2008, the prevalence, of high B.P. in Iraqi people was 40% among 25 years, old and above , in Oman also 40% (NCD/ Oman country WHO [https:// www. WHO. Int/ beat – ncd / countries/ Oman/ enl](https://www.WHO.int/beat-ncd/countries/Oman/enl)). In Indian WHO 2008 also reported a prevalence, rate of (32-5)% . In November 16, 2006 the largest rise in prevalence of adults has been in Canada & U.K.

It is documented that HTN immediately, rises after the age of 60 years ⁵.

Essential hypertension,has no single or definite cause, there are multiple factors e.g. heredity, environmental,factors e.g. obesity, alcohol, smoking,and high salt intake and,probably other factors³.The effect of salt,consumption on B.P. differs among different,people and high potassium intake does the opposite effect.

Japanese who live north east of Japan eat more apple,which is rich in potassium suffer from low,cardio-vascular hypertension complications e.g. apoplexy compared with other regions in,Japan⁶.

A positive linear correlation between,salt intake and B.P. which has been considered,since ancient times⁷.

Experimental observations over the,few past decades have indicated that B.P. can significantly be reduced with salt restriction,and enhancing sodium excretion in urine,with the use of diuretics (8, 9, 10).

Diner stein in August. 9. 2018 wrote that 1 gm of salt consumed,increases B.P. by 3 mmHg¹¹.

Patients and methods:

One hundred individuals were a dopted to this epidemiological,study. Fifty patient with hypertension,either having uncontrolled or controlled,B.P but should have BP less than 160/100 mmHg to avoid complication during the study.

This group is labelled as group A, they were 25 males,and 25 females. The same for normal individual, as control(group B) , for comparison they accepted to carry out the study,by their own wish (volunteers).

The study was conducted in the Al-Hussain teaching,hospital (Al-Hussain medical city), at the out patient medical,clinic. Hypertensive patients were labelled as group A and companions,of patient were labelled as control.

The study was conducted,from first February to first June 2019. For every individual after complete physical examination,including taking B.P at sitting position 3 times with 5-10 minutes,intervals in between, taking the mean B.P for both group, then 3 ml of blood was taken from each person for routine,blood test e.g.RBS, or (FBS) B. urea, S. creatine ,S. uric acid and CBP.

Blood pressure was taken,according to the strict B.P guide line, suspected white coat hypertension persons, pregnant,ladies and patient with renal failure were

excluded from the study as well as patient,with B.P higher than 160/100 mmHg.

Then each individual was given 6 gm. of pure salt (measured by gold balance). Two,hours later the B.P was re-measured as before taken the average B.P. finally all data were collected,and statistically analyzed.

Results and Discussion

One hundred,individuals were studied. Fifty hypertensives and 50 normals as group A and as group B respectively. Each group,contained 25 males and 25 females they were matched for age and sex. Their ages ranged from 35-78 years with a mean of 60 + 5 SD. The majority of individuals,lie in the age group 57-78 years (69%) , (table 1).

The prevalence rate of hypertension,for females and males differ slightly with 37.8% vs. 38.5% respectively – (table 2). The degree of increased,in S.B.P. among group A ranged from 1 to 20 mmHg with a mean of 15.98 - (table 3), while the degree,of increment of D.B.P. was also from 1-20 with a mean of 9.4 mmHg.- (table 4).

In group B the average,value of increment of S.B.P. was 8.2 mmHg and for D.B.P was 8.0 mmHg (table 6)

Table (1): Age distribution of both groups (n = 100)

Age groups in years	No. of individuals
35 – 45	11
46 – 56	20
57 – 67	33
68 – 78	36
Total no.	100

Table (2): Prevalence to Hypertension in both groups matched with age

Sex	Prevalence rate
Males	38.5
Females	37.8

Table (3): value of increment of Systolic B.P. in group A in mmHg (patients)

Value of increment	No. of patients	Average
0 – 5	1	15.98
6 – 10	8	
11 – 15	23	
16 – 20	15	
< 20	3	
Total no.	50	

Table (4): value of increment of Diastolic B.P.in group A in mmHg (patients)

Value of increment	No. of patients	Average
0 – 5	18	9.4
6 – 10	20	
11 – 15	11	
16 – 20	1	
Total no.	50	

Table (5): value of increment of Systolic B.P. in group B in mmHg (control)

Value of increment	No. of individuals	Average
0 – 5	25	8.7
6 – 10	15	
11 – 20	10	
Total no.	50	

Table (6): value of increment of Diastolic B.P.in group B in mmHg (control)

Value of increment	No. of individuals	Average
0 – 5	22	8.0
6 – 10	23	
11 – 20	5	
Total no.	50	

In industrialized societies the high degree of inter-individual variability or difference of sodium intake compared to much smaller inter individual difference may obscure potential biological association probably better solved by quantitative, statistical method using urinary sodium estimation¹². The age distribution in the study (table 1) showed higher prevalence, value as the age advances. It is reported that the average systolic, B.P (SBP) rises with age while the diastolic, B.P. (D.B.P.) rises up to the age of 50 years and then declines¹³. The sex difference in prevalence, rate also showed little difference with slight male preponderance. After adjusting for age no significant difference between sexes in mean prevalence except for higher prevalence among men in developed, countries¹⁴. The average male prevalence rate in developed, countries is 40.8% VS 32.2% in developing countries, while in female the prevalence rate was 33.0% VS 30.5% respectively, these figures are not far away from the study figures (table2). High salt intake is the major cause of raised B.P and, accordingly leads to cardiovascular disease as well as, recently showed association with increased risk of obesity through sugar- sweetened beverage, consumption¹⁵. Uptill now the exact pathophysiology, of how increased salt intake, increases B.P is unknown, but the known fact is that high salt intake, increases B.P, while reducing daily, salt intake reduces B.P, as well as by using diuretics¹⁶.

Conclusion

The study showed that salt intake, increases both S.B.P. and D.B.P., but the increment is different in the two groups (A & B) e.g the value of increment is more obviously higher in group A (the hypertension, group), than group B (the control group) as shown in, tables from 3 to 7. especially noted by highly significant increment

of the S.B.P. in group A compared,with group B but to a lesser extent regarding,increment in DBP between the two groups.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the AL- Safwa University College, Karbala province, Iraq and all experiments were carried out in accordance with approved guidelines.

Effect of Lactic Threshold Exercises using us Ginseng in the Development of Some Functional Variables of the Lungs and Lactic Tolerance and the Performance of Complex Offensive Skills in Basketball Youth

Rasha Abdul Ameer Jawad¹, Rana Fadhil², Hussein Menati Saget³, Jaafer Ahmed Mahdi⁴

¹ University of Kerbala /college of Education for pure Sciences, Iraq, ² University of Kerbala/College of veterinary Medicine, Iraq, ³ University of Kerbala / College of Physical Education and Sports Sciences, Iraq, ⁴ Directorate of Education Karbala, Iraq

Abstract

The aim of the study is to prepare the lactic threshold exercises using US ginseng in improving some functional variables of the lungs and the lactate tolerance and performance of the offensive skills of the young basketball players. The researcher used a curriculum Alter Webby B test kisses me and posttest of the two groups of experimental (Experimental and first trial) . Dosages of US ginseng were used in the form of capsules (400 mg) and 5% ginsosides, equivalent to 20 mg. Thus, the total US ginseng for the program is 60 g, Sexosides. The superiority of the first experimental group was determined by the second experiment with all the research variables. Effect of lactic threshold exercises using American ginseng in the development of some functional variables of the lungs, lactation and complex offensive skills in basketball for youth.

Keywords: *Lactic threshold exercises, Lungs, Lactic tolerance*

Introduction

The modern sports training depends on the concentration of its objectives for the development of energy production systems and the associated functional changes. The more aerobic or anaerobic exercise is possible, the more direct it will be on the level of physical and professional performance. Training also leads to many changes, whether physical, functional or chemical. The most important chemical changes that are affected by the training is the concentration of lactic acid in the muscles and blood as the anaerobic training, which lasts for (1-3) minutes, oxidizes the sugar to anaerobic, which leads to the production of acid. The higher the duration of the anaerobic action, the higher the ratio of the accumulation of lactic acid in the muscle, which in turn leads to slower other chemical processes. As the game of basketball is a game in which the work of the anaerobic system (Lactic) high rate and this is a sign that during the games there will be accumulation of lactic acid in large quantities so players have to bear this accumulation in the muscle and blood and not stop

the player and work fatigue early. This is also related to the functional variables of the lungs, which work on many important functions of runners, including oxidation of oxygen through the vesicles pulmonary. , Nutrition science is now one of the applied sciences that depend on it in the field of physical education and sports. Nutrition has been associated with exercise for health because it has an important role in weight control and control of body composition. Nutrition has also been linked to the competitive sports field during its various stages. In training or in competition, nutrition plays an important role in the ability to tolerate training, delay the onset of fatigue, as well as the speed of recovery, as evidenced by its important role in the competition to raise the level of performance.

Methodology and field procedures

Research Methodology

The researcher used a curriculum Altger Webby B) Pre and post test for the experimental groups (first and second

experimental) to suit the nature of the research.

The research community and its design

It was identified research society my players basketball youth belonging to the Sports Club MAHAWEEL ages (16-18 years) training for the season 2018-2019 and the 14 players. The sample was selected in a comprehensive inventory method and the sample was divided into two experimental groups with seven players per group.

Homogeneity and equivalence of the sample:

In order for the work of the researcher to proceed in the right direction and the objective of the work of the researcher , he found the homogeneity and equivalence between the two groups of research in terms of physical measurements (length, mass, and training age and time as well) on the functional variables of the lungs and lactic endurance and offensive skills complex using the appropriate statistical treatments to know the truth Differences between the two research groups as shown in Table (1, 2).

Table (1) Shows the homogeneity of the sample

T	Variables	measruing unit	Test Phrase Leven)		Indication of difference
			Calculated	Standard error	
1	Age	Year	1, 6 46	0, 4 22	Not significant
2	Training age	Year	0.3 9 2	0, 5 29	Not significant
3	Bloc	Kg	0, 089	0, 9 71	Not significant
4	Length	cm	1, 5 70	0, 4 20	Not significant

Table (2) It shows circles and standard deviations and the values of (t) And the significance of differences in the tests examined between the experimental groups in the pre- test

Variables	measuring unit	The second experimental group		First experimental group		Values t Calculated	mistake percentage	Significance of differences
		s	P	s	P			
Compulsive dynamic capacity	L / d	3.64	0.6 67	3.535	0.347	0.542	0.5 31	random
Forced volume is one second	L / d	3.566	0.3 87	3.387	0.382	0.1 87	0.3 22	random
Maximum lung ventilation volume	L / d	102.9	12.201	100.9	12.68	0.2 83	0.3 43	random
Pick up and jump by 2 points	Degree	4.2 71	1.6 67	4.267	1.318	0.1 42	0.4 22	random
Pick up and jump 3 points	Degree	1.1 48	0.7 93	1.9 59	0:561	0.0 7 7	0.3 0 1	random
Receiving and high-pitched finished pacification	Degree	5.3 91	1.9 63	4.891	0.8 29	0.1 41	0.2 06	random
Hold the locket	Accurate	1.331	0.1 19	1.410	0.1 11	0.5 87	0.4 73	random

* Significant at the level of significance (0.05) if the error level is less than (0.05).

Determination of measurements and tests used :

1/ measurement of lung function variables.

Functional variables of the lungs were measured through a device Vica test Spirometer. The variables are:

- 1- Compulsive dynamic capacity Forced Vital Capacity .
- 2- The expiratory volume is forced for one second Forced Explorative Volume in one Second
- 3- Maximum lung ventilation volume Maximum Voluntary Ventilation .

Measuring tolerances Lactic :

The researcher has access to a lot of scientific studies concerned with the physiological domain where Kojnham and Vlawkins test run for carrying lactic ² . Where a questionnaire was distributed to a number of experts to clarify the validity of the tests and their suitability to the sample and after a statistical analysis proved to be valid for measuring the variables under study .

Measuring offensive basketball skills:

Through the researcher’s knowledge of many sources and scientific studies in the field of basketball has been identified offensive skills compound is : (receipt + jump correction / two points) . (Receiving + jump correction / three points) and (receiving + high pitched + peaceful correction). And have been identified for offensive skills tests the vehicle surveyed by seeing a lot of references and scientific studies Ot three tests churned the nomination (Faris Sami) ³ . Where were distributed a questionnaire to a number

of gentlemen experts form to clarify the extent of the validity of the tests and the suitability of the sample after it was found statistically analyzed in his favor to measure the variables under study.

Determination of US ginseng doses:

The US was determined Alzhinsnj doses used in research where the researcher reference studies, research and scientific references survey ⁴ Which dealt with the use of US ginseng to identify the permissible and effective doses in the human body, where it was found that:

- 1- Effective doses of adults aged 20-30 should be between 50-75 g and 2 to 8 g for a period of 8-12 weeks maximum.
- 2- American ginseng should be taken every 12 hours, twice a day.
- 3- It is best to take the American ginseng before eating to increase the absorption speed of the food and to take advantage of it more.
- 4- Use of US ginseng should not exceed 3 months because it leads to vitamin deficiency B6 In the body leading to feeling numbness and depression.
- 5- The good product for American ginseng is the one that contains ginsocide Ginsenoside By between 4 and 7 percent.

On this basis it was used doses of American Alzhinsnj in the form of capsules (400) mg and Psonbh Jnsosadat 5% is equivalent to 20 mg, bringing the total US Alzhinsnj program completely is (60 g), and the equivalent of (3 g) of Gansusaadat, table The following illustrates this.

Table (3) US ginseng dosages used in research

Subject	size Capsule	The dose Per day the one	The dose the college Of the program (10)weeks	The dose the college Of the program (G)
Ginseng American)capsule (400milligrams	800 mg (2 capsules)	800 x 75 days = 60,000 mg	60 g
Sexesides	20 mg	40 mg	40 x 75 days = 3000 mg	3 g

8 - reconnaissance experience:

The researcher conducted the pilot experiment on a sample of (5) players on 5/12/2016 at 3:00 pm in the stadium of Al Mahaweel Sports Basketball Club. The exploratory experiment led the researcher to identify:

- 1- The validity of the equipment and tools used in the research.
- 2- The time taken to perform the tests.
- 3- Stand on the difficulties that may be exposed to it when the researcher giving a C of the President tests.

1/ scientific transactions for testing:

I. Honesty:

The researcher concluded the validity of the tests in question through the questionnaire distributed to the experts and specialists who indicated its validity to measure the (tactical endurance and complex offensive skills).

2 - Persistence: The researcher tried to find the coefficient of stability of the tests, by finding the correlation between the results of the first and second test after retesting on the survey sample after three days of the first test, and after calculating the coefficient of correlation (Seberman) of the ranks between the results of the first and second test and As shown in Table (4), the correlation coefficients were extracted by T-law. It was found that the correlation was significant at the degree of freedom (3) and the significance level (0.05). The calculated value (T) was greater than the maximum scale (2.11) The test has a high degree of stability.

III. Objectivity: The objective researcher concluded by finding the correlation between the results of two judgments. The correlation coefficient (Siberman) for the rank between the results of the two sentences confirms that the test is highly objective, since the value of (T) (2,11), at the degree of freedom (3), and the level of significance (0.05), see Table (4).

Table (4) Shows the value of the coefficient of stability and objectivity and statistical significance of the tests examined

the test	measuring unit	Stability coefficient	Values(T) calculated	Statistical significance	Subjectivity coefficient	Values(T) calculated	Statistical significance
Lactic endurance	Accurate	0, 897	4 , 221	moral	0, 878	3 , 998	moral
Pick up and jump by 2 points	Degree	0. 889	4.229	moral	0. 889	3. 987	moral

* Significant at the level of significance (0.05) if the error level is less than (0.05)

Show me from the table (3) The level of error ranged from (0.00 to 0.023) For all search variables which is smaller than (0.05) b , indicating the significance of the differences between the tribal and remote tests at the level of error (0.05) in front of the degree of freedom (6) and for the post-test.

b- display the results of the differences between the pre and post tests of the experimental group second in the surveyed variables and analysis.

Based on the above results (Table 5 . 6 . 7) is clear we have significant differences in the number of lung function variables between pre and post tests for the two sets of research for the benefit of the post test, attribute the researcher the reason for this to the evolution in the level of players through the use of threshold training The importance of physiological abilities in improving construction and development as a natural result of training that contributed to the development of lung variables. The researcher also attributed this improvement to the improvement in the lungs by increasing the capacity of the vital, and increase the strength of breathing muscles and large volume of breath, To Zia The exchange of gases with the blood more after the training of the threshold of Latakia differential (8) weeks with (3) weekly training units. He confirmed (Mohamed Osman , 1990 “The world has started to rely entirely on energy systems in sports training. This has been demonstrated by the field experiments that have emphasized the need to match the special performance requirements during the exercise with the energy system working during the competition to ensure the largest percentage of the contribution of special exercises in refining the athlete and achieving the required achievement “⁵.

CONCLUSION

Lactic threshold exercises using ginseng have contributed to the development of the investigated variables (combined offensive skills, lactation tolerance, and functional variables of the lungs) by: The results showed a superior superiority between the tribal and remote measurement in the (combined offensive skills) of the players of the first experimental group and for the benefit of the post measurement. The results showed a superior superiority between the tribal and remote measurement in the (non-tactical endurance) of the players of the first experimental group and for the benefit of the telemetry. The results

showed a superior superiority between the pre - and post - natal measurement in the functional variables of the lungs for the first experimental group and for the post - measurement . The first experimental group is superior to the second experimental group in the telemetry of the investigated variables and for the benefit of the first experimental group .

Preoperative Anxiety and Fears among Adult Surgical Patients in Baghdad Teaching Hospital, Iraq

Kawther Salman Dawood

PhD. / Psychiatric Mental Health Nursing /lecturer / Institute of Medical Technology - Baghdad / Middle Technical University, Iraq

Abstract

Background: Surgery was suggested as a major life change that negatively affects the patient's recovery and post-operative pain.

Objectives: The study aims to assess the preoperative anxiety levels among surgical patients, to determine the fears related to surgery and to find out the relationships between some variables; age, sex, marital status, educational level and experience of previous surgery and level of anxiety.

Methodology: a cross-sectional study was conducted on patients undergoing surgery under a general anesthesia in general surgery unit of Baghdad Teaching Hospital from 1st August 2018 to 30th May 2019.

Results: the current study indicated that all patients 80 (100%) were experience a preoperative anxiety in different levels; 36.2% of them had a high level of anxiety, 32.5% had a moderate level of anxiety and (31.2%) had a low level of anxiety. The main source of patients' fears was; fear of death (51.2%), post-operative wound pain (48.8%), and fear of post-operative nausea and vomiting (47.5%) There was a significant relationship between age and level of anxiety. No difference in level of anxiety in respect to gender and previous surgery.

Key words: *preoperative, anesthesia, anxiety, surgery, patients.*

Introduction

Anxiety has been described as a normal psychological response to stress. It is uneasy and unspecified feeling. The preoperative period is a worrying event for surgical patient. Patients may perceive the day of surgery as the largest and most dangerous day in their life ⁽¹⁾. The psychological symptoms of anxiety can be observed during preoperative period which may include increased tension, irritability, apprehension, aggression, nervousness and insecurity ⁽²⁾. Many studies suggested that factors of pre-operative anxiety depend on age, sex, marital status, educational level, uncertainty of the precise day of operation, the pre-operative patient anxiety caused by many fears which include; fear of unknown, fear of medication, concern about pain, loss of control, and fear of death ⁽³⁾. The extent of anxiety levels differs from person to person, it varies over time; different patients respond perioperative period in different ways, some of them experienced it as a stressful event; they

were concerned about their distress or concerned about the achievement of the operation ⁽⁴⁾. The anxious patient response differently to anesthesia and analgesia when compared with non-anxious patient; patient who experience high level of anxiety requires more anesthetic to achieve sedation and needs to increased doses of analgesia to relief pain. Research studies suggested that pre-operative anxiety increased post-operative pain, fatigue, nausea, delay recovery period and depression ⁽³⁾. Provide patients with appropriate information during the period prior to anesthesia will decreases patient's anxiety. Many studies suggest that patients receiving pre-anesthetic information experience low levels of anxiety ⁽⁴⁾. **Objectives of the study:** To assess the preoperative anxiety levels among patients undergoing a surgery. To determine the fears related to surgery. To find out the relationships between some variables (age of patients, sex, marital status, level of education and experience of previous surgery) and level of anxiety.

Methodology

A descriptive study was conducted on patients undergoing surgery under a general anesthesia in general surgery unit from 1st November 2018 to 30th April 2019. A purposive (non-probability) sample of 80 adult patients from both sexes who were admitted for semi-elective surgery in Baghdad Teaching Hospital from 1st December to 31 December 2018. A questionnaire was constructed to achieve the study objectives, it consists of 3 sections:

- 1- The socio-demographic characteristics of patient.
- 2- The data related to previous surgery and fears about anesthesia.
- 3- Assessment the level of anxiety using the (STAI) scale: State Trait Anxiety Inventory for adults of Spielberger, 1977 which contain (20) items ⁽⁵⁾. The

researcher translated the scale to Arabic language. Some items reflect a positive response while others reflect a negative response, so the scoring and rating for negative items is (not at all=1, sometimes=2, moderately=3, very much=4) and positive items is (not at all=4, sometimes=3, moderately=2, not at all=1). The levels of anxiety measured according to cut to off point and the range of scoring is: 0-20 = no anxiety, 21-35= low anxiety, 34-51= moderate anxiety, 52-77= high anxiety.

The questionnaire was presented to (5) experts in psychiatric mental health nursing in order to test its validity. For the purpose of measuring the reliability of the questionnaire the Cronbach's alpha (coefficient alpha) used to estimate the internal consistency for the level of anxiety scale which= 0.746. The data has been collected by interviews the patients before 1/2 an hour of surgery after obtaining oral consents in the preparatory room.

Results and Discussion

Table (1): The demographic characteristics of surgical patients

No.	Variables	f	%	
1	Age	18-27	30	37.5
		28-37	20	25
		38-47	16	20
		48-57	8	10
		58-67	6	7.5
	Total	80	100%	
2	Sex	male	47	58.8
		female	33	41.2
	Total	80	100%	
3	Marital status	married	44	55
		divorced	8	10
		widowed	6	7.5
		single	22	27.5
	Total	80	100%	

Cont... Table (1): The demographic characteristics of surgical patients

4	Educational level		8	10
		Read & write	9	11.2
		Primary	12	15
		Intermediate	8	10
		Secondary	9	11.2
		≥ Bachelor	34	42.5
		Total	80	100%
5	Employment	employed	44	55
		retiree	5	6.2
		not employed	31	38.2
		Total	80	100%
6	previous surgery experience	Yes	39	48.8
		No	41	51.2
		Total	80	100%

Table (1) revealed that the patients aged between (18-67) years old with mean of age around 35 years and Standard Deviation (SD) = 12.482. More than half of them are males (58.8%) and married (55%). As regarding to their level of education, the highest percentage of them were had a bachelor degree (42.5%). And 55% of patients were employed. Approximately half of them were not experience a previous surgery (51.2%).

Table (2): Distribution of patients according to fears related to anesthesia and surgery

No	Items	Yes		No		Total	
		f	%	f	%	f	%
1	Fear of being unconscious as a result of anesthesia	31	38.8	49	61.2	80	100%
2	Fear of postoperative wound pain	39	48.8	41	51.2	80	100%
3	Fear of not wake up again next the operation	37	46.2	43	53.8	80	100%
4	Fear of an inadequate anesthetic effect and stay conscious during surgery	32	40	48	60	80	100%
5	Fear of post-operative Nausea and vomiting	38	47.5	42	52.5	80	100%
6	Fear of death	41	51.2	39	48.8	80	100%

Table (2) indicated that the main source of patients' fears were; fear of death (51.2%), postoperative wound pain (48.8%), fear of post-operative nausea and vomiting ((47.5%), fear of not wake up again next the operation (46.2%) and (40%) of them were fared from staying conscious during surgery and (38.8%) of them were afraid from unconsciousness results from effect of anesthesia .

The result of the current study was congruent with Mavridou et al, (2013) and Biro and Maurer, 2015 who reported in their studies that patient's fears of anesthesia mostly focus on post-operative wound pain, post-operative nausea and vomiting, not waking up after surgery and that they might stay conscious during surgery that they might not wake up again after the operation ^{(6) (7)} . Nigussie et al, 2014 mentioned that the most common pre-operative fears were fear of death, financial loss, result of surgery and awareness during surgery ⁽¹⁾.

Table (3): Distribution of patients according to Level of anxiety

No.	Level of anxiety	f	%
1	Low anxiety	25	31.2
2	Moderate anxiety	26	32.5
3	High anxiety	29	36.2
Total		80	100%

Table (3) indicated that all patients 80 (100%) experience a preoperative anxiety in different levels; (36.2%) of them had a high level of anxiety, (32.5%) had a moderate level of anxiety and (31.2%) had a low level of anxiety.

This result was congruent with Mavridou et al (2013) who reported that (81%) of patients experience preoperative anxiety ⁽⁶⁾. Bakr et al (2014) mentioned in their study that most patients had moderate to severe anxiety levels and others had mild anxiety levels. Ramesh et al (2017) reported that most of patients had increased preoperative anxiety ⁽⁸⁾.

Table (4): Analysis of variance for level of Anxiety among Patients with their Demographic Characteristic (N=80)

Anxiety Characteristics	Source of Variance	Sum of Squares	df	Mean Square	F	P-value (Sig.)
Age	Between Groups	1796.988	4	449.247	2.766	.033 (S)
	Within Groups	12182.562	75	162.434		
	Total	13979.550	79			
Marital status	Between Groups	952.429	4	238.107	1.371	.252 (N.S)
	Within Groups	13027.121	75	173.695		
	Total	13979.550	79			
Educational level	Between Groups	1072.174	5	214.435	1.229	.304 (N.S)
	Within Groups	12907.376	74	174.424		
	Total	13979.550	79			
Employment	Between Groups	52.568	3	17.523	.096	.962 (N.S)
	Within Groups	13926.982	76	183.250		
	Total	13979.550	79			

(df: degree of freedom, S: significant, N.S: non-significant)

Table (5) revealed that there is a statistical significant relationship between the age and level of anxiety while there is no statistical significant relationship between marital status, educational level and employment with the level of anxiety. This result was supported by Bakr et al (2014) and Almalki et al (2017) who founded in their studies a highly significant relationship between age of surgical patients and anxiety levels ⁽⁸⁾⁽⁹⁾.

As regards to other socio-demographic characteristics variables the current study revealed that

there is no significant relationship between anxiety level and marital status, educational levels, employment and income. These findings were consistent with a study of Ramesh et al (2017) who reported that was no association between socio-demographic variables such as education and occupation with the level of anxiety ⁽¹⁰⁾. Woldegerima et al (2017) found that no statistical significant relationship between anxiety and level of education ⁽²⁾. In a study of Matthias and Samarasekera (2012) reported that there was no relationship between the anxiety level and educational level and marital status ⁽¹¹⁾.

Table (5): Significant Difference for level of Anxiety among Patients with respect to their Gender and Previous Surgeries (N=80)

Anxiety Variable			Independent t-test					
			M	SD	t	df	P ≤ 0.05	Sig.
Gender	Male		43.212	13.411	-.369	2	.713	N.S
	Female		44.333	13.324				
Previous Surgery	Yes		41.962	13.543	1.306	2	.195	N.S
	No		45.561	12.951				

Table (5) indicated that there is no difference between males and females in level of anxiety while there is no statistical significant association between presence of previous surgery and anxiety level. This result was congruent with a result of the study of Nigussie et al (2014) who reported that there was no variance between males and females in anxiety level ⁽¹⁾. Some studies have discovered that women experience elevated rates of anxiety compared to men. The results also supported by Almaliki et al (2017) who were found that no significant relationship between exposure of previous surgery and pre-operative anxiety level ⁽⁹⁾.

Conclusions

All patients were experience a preoperative anxiety in different levels; the highest percentage had a high level of anxiety. The main source of patients’ fears was; fear of death, post-operative wound pain, fear of post-operative nausea and vomiting. There was a significant relationship between the age and anxiety level while there was no significant relationship between level of anxiety and the demographic characteristics of patients; level of education, marital status and employment. There was no difference in anxiety level among male and

female patients and there was no significant relationship between level of anxiety and the experience of previous surgery.

The Prevalence of Parasitic Infection in Domestic Chicken: A Review

Yassir Dakheel Kremsh Alasadiy¹, Arshad Naji Alhasnawi¹, Farhan AlaAllah Eabaid¹

¹Department of Biology, College of Education for Pure Sciences, AL- Muthanna University, Samawah, Iraq

Abstract

The relative contribution of poultry to total animal protein production in the world is increasing, the major increase in developing countries. Many types and species of ectoparasites and Endoparasites are known to infect chickens; one of the actual problems that cause economic bias in animal farms and rural areas that raise chickens annually is parasitic diseases. The common parasitic infections that occur in poultry can be divided into External parasites include arthropods Lice, Mites, Fleas and Ticks which are isolated from skin and feathers. Internal parasites include protozoa, cestodes, nematodes, trematodes which are isolated from the digestive tract, blood and pooled poultry droppings. The external and internal parasites that infect hosts possess features such as small size, cylindrical body, hook and hard body, which enhance their adaptation to the long life and effect on the poultry industry by affecting the growth rate of chickens, leading to little egg production, and death in severe infections. Prevalence of helminthic infection (cestodes and nematodes infecting the digestive tract) was high in farms and rural areas of chickens from the different studies in different sites in the world, followed by protozoa infection by blood, followed by arthropod infection by skin and feathers and followed by prevalence by trematodes.

Keywords: Prevalence, Chicken, Helminthes, External parasites, Internal parasites

Introduction

The history of chickens (*Gallus domesticus*) is still a bit of a puzzle. Scholars agree that they were first domesticated from a wild form called red junglefowl (*Gallus gallus*), a bird that still runs wild in most of southeast Asia, most likely hybridized with the gray junglefowl (*G. sonneratii*), that occurred probably about 8,000 years ago¹. Recent research suggests, however, there may have been multiple other domestication events in distinct areas of South and Southeast Asia, southern China, Thailand, Burma, and India. Since the wild progenitor of chickens is still living, several studies have been able to examine the behaviors of wild and domestic animals. Domesticated chickens are less active, have fewer social interactions with other chickens, are less aggressive to would-be predators, are less susceptible to stress, and are less likely to go looking for foreign food sources than their wild counterparts. Domestic chickens have increased adult body weight and simplified plumage; domestic chicken egg production starts earlier, is more frequent, and produces larger eggs². Parasites are organisms that live on or in another organism, referred to as the host, and gain an advantage at the expense of the

host³, the internal and external parasites that infect hosts possess physiological and morphological features for example lesser size, shape of the body, hook and tough body, add to their adaptation to the long life also presence of hordes, these organisms are a major factor controlling of the fowl industry by affecting the rate of growth in the host, leading to organ dysfunction and ultimately death⁴. Parasitic infection or their concurrent infections also result in immunosuppression, especially in response to vaccines against some poultry diseases⁵. Parasitism has resulted in reduction of weight gain (17%) in growing chicken and reduction in egg production (12.5%) in laying hens in Bangladesh⁶. Chickens can carry ectoparasites; such as ticks, lice, mites, and Endoparasites, such as protozoans, cestodes, nematodes and trematodes. It has been recorded that they are considered a most important source of transmission of diseases and infection. Poultry has been accepted as one of the most important sources of animal protein for humans in the world, as well as consumers have high preferences for poultry products particularly during festivals. Furthermore, it is that poultry products provide proteins of high biological value⁷.

The protozoan parasites

There are many external parasites that attack poultry by either feathers or feeding on the skin or sucking blood, in small herds it is problematic to prevent contact with external environment, The protozoan parasites encountered were *Eimeria tenella*, *E. brunetti*, *E. mitis*, *E. acervulina*, *E. necatrix*, *E. maxima* and *E. mivati*. *E. tenella* was the most prevalent, while the parasite belonging to species *Eimeria mivati* the minimum abundant, the most parasites belonging to protozoa indicated the highest predominance through the wet period than the waterless period, telling us this warm environmental conditions and lower humidity favor the development of this parasite, clinical signs of parasitism are lack of development, feed conversion and poor growth, low egg production, and even death in severe infections. Moreover, the parasites can make the herd less resistant to disease and exacerbate existing of disease in herd⁽⁸⁻¹⁰⁾. Cryptosporidia are protozoan parasites classified within the class sporozoa and the subclass coccidian, They inhabit the brush border of the small intestinal mucosa of a variety of mammals¹¹. Cryptosporidiosis is a disease or infection caused by cryptosporidia. This parasite is not confined to the cryptosporidia of birds and can infect other animals, even mammals and chickens. Cryptosporidia is often spread from one animal to another on the feet of people and animals and can be borne by overland birds. Cryptosporidia is common, and symptoms are usually mild. Often, the only symptom is pale skin in yellow-skinned breeds. Cryptosporidiosis can be contracted by inhalation, leading to more severe respiratory inflammation of the intestinal form. There are no drugs for this parasite of cryptosporidiosis. Providing supportive treatment and protection from secondary infection are the only workflows. Once recovered, the birds are immune to future infections, There are a great diversity of *Cryptosporidium* species and genotypes recorded from fish, amphibians, reptiles, birds and mammals^(12,13) Haemosporidians are intracellular protozoan parasites found within the blood cells and tissues of their avian hosts, they are worldwide distributed and occur in a variety of avian species, including domestic chicken, the avian haemosporidian parasites (Phylum Apicomplexa) are taxonomically diverse and cosmopolitan in distribution infecting most bird families¹⁴. "The most commonly recorded parasites in smears of peripheral blood are unicellular eukaryotic parasites of the genera, *Haemoproteus*, *Leucocytozoon* and *Plasmodium*"¹⁵.

The greatest important groups of haemoparasites that infected chickens are *Leucocytozoon*, *Haemoproteus* and *Plasmodium*. The chickens haemoparasites have been recorded in the different countries of the world such as Bolivia, Pakistan, Italy, Czechoslovakia, Nigeria, Tanzania, Kazakhstan, India and South and East-Southern Asia,^(16,17).

Helminth parasites

A-The cestode parasites

Chickens is greatly susceptible to the contagion by a multiplicity of intestinal helminthes which leads to severe commercial losses during meddling with fit development in the system of late growth chiefly the chickens, making adult chickens exposure to secondary contagions, actually reduced chickens production¹⁸. Parasitic worms are common in large-scale poultry, while intensive infections are common in heavily managed stocks that cause severe pain that affects the natural activities of birds that lead to death. The cestode parasites encountered were *Raillietina tetragona*, *R. echinobothrida*, *R. cesticillus*, *Choanotaenia infundibulum* and *Hymenolepis carioca* out of which *R. cesticillus* was the least prevalent while while the parasite belonging to species *Hymenolepis carioca* was the most prevalent, cestodes are known to interfere with the metabolisms of certain compounds: they absorb glucose and galactose and stored them as glycogen as well as absorbed amino acids, polypeptides and proteins, the clinical signs include loss of ruffled feathers, drooping wings, appetite, increased mortality and decreased egg production, although with less pathogenic species, the only signs will be poor growth, weight loss paralysis, leg weakness, and a sudden raise in mean of mortality, Also stated that it is every so often possible to talk if a chicken is infested by cestodes simply by observing at the droppings. Egg of Tapeworm is observable white pellets struck in its feces^(19,20).

B- The nematode parasites

recovered included *Ascaridia galli* Shrank 1788, *Heterakis gallinarum* Shrank 1788, *Hartertia gallinarum* Theiler 1919, *Gongylonema ingluvicola* Ransome 1904, *Syngamus trachea* Montagu 1811 out of which only *A. galli* and *H. gallinarum* were most prevalent and the remaining rare⁴.

These helminthes affect on the metabolism of the host, causing in lowly feed utilization, thus impairing

growth and production ²¹.

The Arthropoda parasites

Common ectoparasites of village chickens range from lice, mites, fleas and ticks ⁶. They may constitute a clinical problem and transmit a number of infectious diseases and can also act as transport/ intermediate hosts of a range of helminth parasites ⁽²²⁻²⁵⁾. Some of the ectoparasites, especially tick and mites acts as vectors of poultry diseases such as Pastuerellosis, Fowl Pox, Newcastle disease and possibly chlamydia ^(26,27).

Table (1): shows the local studies on parasitic infection in domestic chickens.

Hygienic Practices of Street Food Vendors and Schools in Some Iraqi Governorates

Luay S. Khaleefah¹, Hayder N. Salman¹, Sadeq Muneer Shawkat²

¹Asst. Lect., Dept. of Food Sc. & Tech., ²Lecturer Dept. of Dairy Sc. & Tech.,
College of Food Science /Al-Qasim Green University

Abstract

“The study was conducted during the period from December 2018 to May 2019, to assess hygiene practice in schools and street food vendors inside two Iraqi cities (Babylon and Thiqr). The Codex code for practice of general principles on food hygiene, observations and other relevant documents to provide information that may clarify certain misconceptions on hygienic practices related to street food vendors. 110 street food vendors and schools were studied in all Babylon and Thiqr. Specially designed questionnaire form was used, allowed fast data collection. Many noncompliance was found in the hygienic practices and requirement, personal hygiene, hygiene of equipment, food preparation and food service. Babylon Governorates in term of hygiene of equipment and food preparation generally showed higher conformity than in Thiqr Governorates. The level of fulfillment of the hygienic requirements was most strongly influenced by the type of schools and street food vendor in both section of personal hygiene and hygiene of equipment and food preparation and serving for Babylon and Thiqr. The results of this work should not discourage to eat street food, but to minimize food poisoning risk, support the reasonable choice of eating-places according to basic food hygiene knowledge.”

Key words: food safety, schools, street food, food hygienic practices.

Introduction

Food poisoning is still causing a growing risk to public health. European Food Safety Authority (EFSA) indicated that foodborne diseases raising also in the EU European union. EFSA reported that in year 2010 about 48.7% of foodborne illness were associated with catering establishments ^{5,7}. Significant part of the foodborne probably result of inappropriate hygienic practices of food service sector. The safety of street vended food in countries where such a food plays an essential part of life and culture is of particular concern ^{16, 4}. According to the WHO, worldwide epidemiological studies showed that, in the majority of cases, outbreaks of foodborne diseases are due to the incorrect handling of food by food workers. “Causes of foodborne disease by food handlers include cross contamination between

raw and processed food items; “storage and cooking of food in adverse conditions; and utilizing contaminated utensils and equipment. Food handlers are defined as “employees who are employed directly in the production and preparation of foodstuffs. Those include employees in the manufacturing, catering and retail industries as well as those who are undertaking maintenance or repair of equipment in food handling areas, whether permanent staff, workers on contract or visitors to food handling areas ¹. Food handling, comprises all stages of food treatment from farm to fork ^{8,1} probability that food handlers could carry pathogens while not showing any symptoms and transmit those pathogens in food such as salmonella, staphylococci, and E. coli ⁶. A new concept called Street Food Safety Objective (SFSO) was also introduced by ² in an effort to approach the safety of street food with the FSO concept. In order to achieve the SFSO a well-planned programme of good hygiene practices should be applied starting from the safety of the ingredient and raw materials entering the street food chain. In particular, there is a special provision setting down requirements for street food vendors. The

regulation is based on Codex Alimentarius (CA) general principles of food hygiene (CCFH, 2003). And this basic code of practice is used also by the CA for publication of regional codes of practice pertinent to street foods e.g. for Asia (CCASIA, 2017). Those requirements comprise willingness to abide by food hygiene requirements and may reflect lack of knowledge about transmission of microorganisms¹⁷.

Materials and Method

Sampling Plan

“The information was collected from 110 food vendors in two governorates (Babylon and Thiqr) having either direct or indirect contact with food in Iraq restaurants through a questionnaire. “The field period of the survey lasted from December 2018 to May 2019”. “The information was collected through questionnaires and face to face interviews to ensure the accuracy of responses”. “Participation by respondents was voluntary and sufficient time “20-30 minutes” was allowed to answer the questions”. The general characteristics of the vendors were analyzed according to Governorates of vendor’s placement their location in the city, type of facility, type of food sold or served and number of employees in premises,

“Observations”

“Inspections were carried out by direct and discreet semi-structured observation using a specially determined questionnaire which allowed fast evaluation and observation. Interviews with respective food handlers were not carried out”. “The food handlers were also not aware of the observation carried out to minimize influence on food handlers’ attitudes during inspection”. “Each observation lasted for about 20 min”.

Statistical analysis

“ Analysis of such a large number of variables required using several statistical methods”. “To characterize the level and distribution of scores the mean scores, median, mode, standard deviation, coefficient of variation, skewness and kurtosis coefficients were used”. To investigate the dependence of country, vendor’s location, type of food sold and number of employees on the obtained scores, a variance analysis - SPSS - was used. for Windows, version (24.0) . Two analyses were conducted: “for the first and for the second part of questions was performed using Spearman’s

correlation coefficient”. The two-sided p-value of < 0.05 was applied and considered to be statistically significant

Results and Discussion

Overall characteristics

“The socio characteristics of one hundred and ten (n=110) food handlers in restaurants in Iraq the first one grouped vendors selling fresh fruit, vegetables, fish, meat, eggs . “The second one grouped higher rated vendors which were vendors selling meat and fish meals, falafel and other dishes such as shakes, ice cream, coffee, tea”.” The first analysis, concerned the hygiene of equipment, personal hygiene and food preparation indicate that, The largest groups were small street restaurants “30.3%” followed by food kiosks “25.2%”. mobile food vendors for example food cart bike “21.7%” and stands selling street food “20.7%”. The smallest group was food trucks “2.3%”. In most street food vendors meat or fish meals were produced and popularly sold “44.6%”. fruit and vegetable meals for example squeezed juices and pilled and sliced fruits and vegetables “22%” fresh fruits vegetables meat fish and eggs “19.8%” and others “10%””. The largest group of street food vendors that appointed one employee “61%” next with two employees “24.1%” and the smallest group was vendors with three or four employees “14%”. “Most of the street food vendors were located in the outskirts and suburbs of the cities “45.5%” city center “28.6%” and tourist sites “25.9%”. (40.9%) of them have an education at College/ University level”. “Approximately (55.4%) of food handlers with direct or indirect contact with food have 1-6 years of experience in the food sector”.” More than half (75.0%) of the respondents have not participated in any food safety training program”. “From these respondents, only (1.3%) have attended a food safety course more than two years ago”. “ (54.9%) of the total number of respondents had a medical examination card by the Ministry of Health, Iraq.

Hygiene of equipment and food preparation

“The analyzed data, which concerned the hygiene of equipment and food preparation presented in Fig.1”. “The Mean scores, SD and values of statistical coefficient in street food vendors’ hygiene of equipment and food preparation”. “The distribution of questionnaire scores of all street food vendors on two group, the first one grouped vendors selling fresh fruit, vegetables, fish, meat, eggs”. The second one grouped higher rated vendors which were vendors selling meat

and fish meals, falafel and other dishes such as shakes, ice cream, coffee, tea. The degree of compliance i.e. fulfillment of requirements, in hygiene of equipment and food preparation was differentiated the Mean score was 2.7 The mean scores for all questions were below the suppositional Mean score 3.5, with Standard deviation 0.91 , degree of compliance was 68 %. The Mean score level Is not equal mode and median, which confirmed that the distribution of scores for each question was left asymmetric negative skewness. :Negative skewness indicated a greater dispersion and variability in the lower scores As indicated value of Skewness and Kurtosis coef. were (1.66 , 1.39) respectively” . “Indicating that the answers of street food vendors and the low level of assessment, do not give high attention to the Hygiene of equipment and food preparation. Which indicates the cleanliness of food production and preparation equipment in Babel governorate is very low”.

“The data revealed the hygiene of equipment and food preparation the SPSS analysis indicated that the level of assessment of street food vendors in the significant and consistent manner was strongly influenced by three characteristics, Insects, Unnecessary things, and Water supply”, “The other characteristics i.e. location of facility and other variables, had a lesser impact on the assessment scores”. “Statistically there are no significant relationship between other variables and location of facility”. “Also, there was a statistically significant relationship between type of food and Water supply only, other variables are having no significant relationship”. “There was a statistically significant relationship between Location of facility in the city with Insects, and Water supply and there is a very low significant relationship between the other variables which makes it reflect negatively on the hygiene of equipment and food production-preparation and serving in Babel governorate”.

“Fig 1 Questions abbreviation according to the hygiene of equipment and food production-preparation and serving (Part I of the questionnaire) in Babel governorate”.

The analyzed data, which concerned the hygiene of equipment and food preparation presented in Fig.2. The Mean scores, SD and values of statistical coefficient in street food vendors’ hygiene of equipment and food preparation”. The distribution of questionnaire scores of all street food vendors on two group, the first one grouped vendors selling fresh fruit, vegetables, fish, meat, eggs. The second one grouped higher rated vendors which were vendors selling meat and fish meals, falafel and other dishes such as shakes, ice cream,

coffee, tea. The degree of compliance i.e. fulfillment of requirements, in hygiene of equipment and food preparation was differentiated the Mean score was 2.88. The mean scores for all questions were below the suppositional Mean score 3.5, with Standard deviation 1.07, degree of compliance was 72 %. The Mean score level is not equal mode and median, which confirmed that the distribution of scores for each question was left asymmetric negative skewness. Negative skewness indicated a greater dispersion and variability in the

lower scores. The value of Skewness and Kurtosis coef. (0.91 & 1.15) respectively. Indicating that the answers of street food vendors that the level of assessment low, Do not give high attention of “Hygiene of equipment and food preparation Which indicates the cleanliness of food production and preparation equipment in Thiqr governorate is very low”.

The data in Fig 2 revealed the hygiene of equipment and food preparation The SPSS analysis indicated that the level of assessment of street food vendors in

the significant and consistent manner was strongly influenced by three characteristics, Insects, unnecessary things and food separation. Statistically there are no significant relationship between the other variables and location of facility. There was a statistically significant relationship between Food separation with Type of food, Type of facility and Insects. There is a very low significant relationship between the other variables which makes it reflect negatively on the hygiene of equipment and food production-preparation and serving in Thiqr governorate”.

Fig 2 questions abbreviation in the evaluation of street food vendors hygiene of equipment and food preparation according to the hygiene of equipment and food production-preparation and serving (Part I of the questionnaire) in Thiqr governorate.

“Personal hygiene”

fig 3 shows that the Mean score of this part was 2.65. The mean scores for all questions were below the suppositional Mean score 3.5, with Standard deviation 0.86,” “degree of compliance was 64 % The Mean score level indicated that The mean scores Is not equal to mode and median, which confirmed that the distribution of scores for each question was left asymmetric negative skewness”. “Negative skewness indicated a greater dispersion and variability in the lower scores as indicated value Skewness coef. 1.72, Kurtosis coef. 3.58 . In other words, data Skewness coef. Towards the right of the normal distribution curve. Indicating that the answers of street food vendors that the level of assessment low, Do not give high attention of Hygiene of equipment

and food preparation Which indicates the cleanliness of food production and preparation equipment in Babel governorate is very low”.

the SPSS analysis of personal hygiene. there was a statistically significant relationship between Jewelry and Visible cuts with Location of facility in the city”.” Also, there Is no statistically significant relationship between other variables and location of facility”. There was a statistically significant relationship between Washing hands with Type of food only. there was a statistically significant relationship between Location of facility in the city with Visible cuts, and Gloves with Location of facility in the city, and Touching face with Type of food and there is a very low significant relationship between the other variables which makes it reflect negatively on

the hygiene of equipment and food production-preparation and serving in Babel governorate”.

“Fig 3 Questions abbreviation according to personal hygiene (Part II of the questionnaire). in Babel governorate”.

“Fig4 questions scores in the evaluation of street food vendors personal hygiene according to the vendor's characteristics (Part II of the questionnaire)”. in Thiagar governorate.

Fig 5 Comparison between Babel and Thiagar according to the hygiene of equipment and food production-preparation and serving.

“Fig6 Comparison between Babel and Thiagar according to the personal hygiene”.

Conclusion

The level of fulfillment of the hygienic requirements was most strongly influenced by the type of schools and street food vendor in both section of personal hygiene and hygiene of equipment and food preparation and serving for Babylon and Thiagar. The results of this work should not discourage to eat street food, but to minimize food poisoning risk, support the reasonable choice of eating-places according to basic food hygiene knowledge.”

Estimation of Serum Lipid Profile among Pre and Post-Menopausal Women in Baghdad City

Athraa Fouad Kadhuim

Middle Technical University, Institute of Medical Technology/Baghdad/ Nursing Department, Iraq

Abstract

This study aimed to determine the lipid profile concentration in the sera of women before and after the menopausal age in Baghdad city, since it is one of the main causes of cardiovascular diseases. The study included 100 women (40 premenopausal women with their ages ranged between (25-45 years) and 60 postmenopausal women with their ages ranged between (50-65 years). Blood samples were collected and total serum cholesterol (TC), S. triglycerides (TG), S. high density lipoprotein (HDL), S. low density lipoprotein (LDL) and S. very low density lipoprotein (VLDL) were measured. The results showed no significant difference ($P>0.05$) in the level of total cholesterol (TC) between the two groups of women, while there was a statistically significant increase ($P<0.05$) in the level of serum triglyceride (TG) in postmenopausal women (144.32 ± 43.16) mg/dl when comparison with premenopausal women (101.92 ± 32.44) mg/dl, and a significant decrease ($P<0.05$) in HDL level in postmenopausal women (33.56 ± 10.65) mg/dl when compared with premenopausal women (43.13 ± 14.23) mg/dl. The results of LDL level also showed a significant increase ($P<0.05$) in postmenopausal women (107.57 ± 21.28) mg/dl when compared with premenopausal women (77.23 ± 30.40) mg/dl, and a significant increase ($P<0.05$) in VLDL level in postmenopausal women (31.86 ± 8.16) mg/dl when compared with premenopausal women (21.32 ± 7.12) mg/dl.

Key words:-*dyslipidemia, postmenopausal, premenopausal, lipid profile.*

Introduction

Menopause is the period of absence of the menstrual cycle for more than six months, and it is a natural phenomenon that occurs in all women and represents a transition from the age of fertility to the stage of inability to reproduce (childbearing). It is often caused by the termination of ovarian eggs, and thus ovaries stop producing estrogen hormone, and this stage is accompanied by many symptoms that vary in severity between one woman and another ¹. Women often reach the menopausal age gradually, where the menstrual cycle becomes irregular in the year before the menopausal age, where the menstrual cycle occurs frequently and then begins spacing every two months or more, but sometimes women reach the menopausal age suddenly where the menstrual cycle stops suddenly after months or years of regular cycles ². The menopausal age period is of two types: the first period is the premenopausal, which represents the reproductive period, i.e before the absence of the menstrual cycle ³, while the second type is the post menopause, which is the period of the

woman's life that comes after the last menstrual cycle, where the ovaries stop functioning for whatever reasons whether natural or pathological ⁴. Hyperlipidemia is a major cause of cardiovascular diseases and is the most common cause of death for females after the menopausal age ⁵.

Cholesterol is an organic molecule found in food, and can be absorbed slowly from the digestive system. It plays a vital role and found in the membranes of all eukaryotic cells ⁶. While LDL carries the largest part of cholesterol and represents the bad cholesterol. Cholesterol is carried in blood by low density lipoproteins. LDL carries cholesterol from liver to tissues, and represents cholesterol ester-containing globular particles. HDL is the good cholesterol which carries cholesterol from the vessels to the liver to get rid of it, thereby it prevents cholesterol precipitation on the walls of the arteries ⁷. Triglycerides act as essential sources of energy in the body. They are organic compounds composed of glycerol bound to three fatty acids. Triglycerides move in blood and stored in fatty cells. Triglycerides have

an important function in the body, since they provide the body with activity and energy. Studies have shown a link between triglycerides and heart diseases ⁸, and even most studies indicated the risk of triglycerides increase on cardiovascular diseases ⁹. The current study aimed to estimate the lipid profile levels in the sera of postmenopausal age women and compare them with the premenopausal age women.

Materials and Method

This study was performed on randomly-selected healthy women before and after menopausal age who visited Baghdad teaching hospital and some health care centers in Baghdad city during the period from (October 2017 to February 2018).

After blood sample collection, laboratory tests were performed on the study groups which included 100 women (40 premenopausal women with their ages ranged between (25-45) years and 60 postmenopausal women with their ages ranged between (50-65 years). Data on age, weight, life style, demographic and menopausal status were recorded precisely in a questionnaire form for each of the study samples, who were selected according to selection and investigation criteria. Women with dyslipidemia, Diabetes mellitus, hypertension, kidney diseases, cardiovascular diseases, acute infections, liver diseases and other chronic diseases were excluded from our study.

Serum levels of cholesterol, triglycerides, HDL, LDL and VLDL were estimated by enzymatic method. Data obtained from our study were analyzed using the SPSS program according to the (T-test) by which means and standard deviations were obtained, and ($P<0.05$) was counted as significant while ($P<0.01$) was counted as a highly significant.

Results and Discussion

In this study, the lipid profile concentration including total serum cholesterol (TC), S. triglycerides (TG), S. high density lipoprotein (HDL), S. low density lipoprotein (LDL) and S. very low density lipoprotein (VLDL) were estimated for women before and after the menopausal age. The study included 100 women (40 pre-menopausal women with their ages ranged between (25-45) years and 60 post-menopausal women with their ages ranged between (50-65) years.

Results in table and figure (1) showed an increase in the level of lipids in the sera of pre-menopausal women in comparison with their levels in the sera of pre-menopausal women. There was a remarkable but non-significant increase in serum total cholesterol level among post-menopausal women (167.63 ± 43.16) mg/dl when compared with its levels among pre-menopausal women (138.85 ± 38.31) mg/dl.

There was a statistically significant elevation ($P<0.05$) in the level of serum triglyceride (TG) among post-menopausal women (144.32 ± 43.16) mg/dl as compared with pre-menopausal women (101.92 ± 32.44) mg/dl, and a significant decrease ($P<0.05$) in HDL level in post-menopausal women (33.56 ± 10.65) mg/dl when compared with premenopausal women (43.13 ± 14.23) mg/dl. The results of LDL level also showed a significant increase ($P<0.05$) in post-menopausal women (107.57 ± 21.28) mg/dl when compared with pre-menopausal women (77.23 ± 30.40) mg/dl, and a significant increase ($P<0.05$) in VLDL level in post-menopausal women (31.86 ± 8.16) mg/dl when compared with pre-menopausal women (21.32 ± 7.12) mg/dl.

Table (1): Lipid profile levels in pre and postmenopausal age women

Lipid profile	Mean \pm SD (mg/dl)	
	Premenopausal women (25-45) years	Postmenopausal women more (50-65) years
S.TC	138.85 \pm 38.31	167.63 \pm 43.16 Ns
S.TG	101.92 \pm 32.44	144.32 \pm 43.16**
S.HDL	43.13 \pm 14.23	33.56 \pm 10.65*
S.LDL	77.23 \pm 30.40	107.57 \pm 21.28*
S.VLDL	21.32 \pm 7.12)	31.86 \pm 8.16*

TC(total cholesterol). TG (triglyceride), HDL (high density lipoprotein), LDL (low density lipoprotein), VLDL (very low density lipoprotein).

** Highly significant $P\leq 0.01$, * Significant $P\leq 0.05$, Ns: No significant.

Results obtained from our study regarding cholesterol levels agreed with other studies such as Igweh et al ¹⁰, who found a non-significant increase $P>0.05$ in total cholesterol levels. Our results also were in agreement with Fatma et al ¹¹, who demonstrated a

non-significant increase in cholesterol levels.

Our findings were consistent with the study conducted by Swapnali et al, who indicated a significant increase in the mean levels of TG, LDL-C and VLDL-C during the postmenopausal age, and a significant decrease in the mean levels of HDL-C in postmenopausal age women in comparison with its levels in premenopausal women, while their results regarding TC levels did not agree with our findings when they found a significant increase ($p<0.05$) in TC levels in postmenopausal age ¹².

Our current results disagreed with those of Kalavathi et al and Muzzio et al who found a significant increase in TC levels in the postmenopausal age due to estrogen hormone deficiency after the menopausal age ^(13,14).

In a study conducted by Kanwar et al, it was shown that the mean and standard deviation differences of TG were non-significant between the pre and postmenopausal women, with a significant decrease in VLDL-C levels ($P<0.05$) in postmenopausal age women in comparison with the premenopausal women. However, their results agreed with our findings in regard to HDL-C and LDL-C and TC ¹⁵.

Table (2): Lipid profile levels in premenopausal age women

Lipid profile	Mean \pm SD (mg/dl)		P value
	Premenopausal women 25-34 years	Premenopausal women more than 35-44 years	
S.TC	146.04 \pm 48.05	128.95 \pm 32.59	NS
S.TG	109.65 \pm 42.06	95.23 \pm 22.59	
S.HDL	43.05 \pm 18.02	44.48 \pm 11.96	
S.LDL	82.50 \pm 32.16	64.49 \pm 28.09	
S.VLDL	23.02 \pm 9.23	17.96 \pm 4.92	

TC(total cholesterol). TG (triglyceride), HDL(high density lipoprotein), LDL (low density lipoprotein), VLDL (very low density lipoprotein).

Table (3): Lipid profile levels in postmenopausal age women

Lipid profile	Mean \pm SD (mg/dl)		P value
	Postmenopausal women 50-59 years	Postmenopausal women more than 60-65 years	
S.TC	156.95 \pm 38.75	176.23 \pm 23	NS
S.TG	138.23 \pm 35.43	148.15 \pm 35.85	
S.HDL	35.68 \pm 10.96	34.5 \pm 8.73	
S.LDL	93.92 \pm 19.04	117.02 \pm 27.82	
S.VLDL	26.85 \pm 6.87	28.98 \pm 7.01	

TC (total cholesterol). TG (triglyceride), HDL (high density lipoprotein), LDL (low density lipoprotein), VLDL (very low density lipoprotein).

The premenopausal age women group (40 samples) whose ages ranged between (25-45) years was also subdivided into two groups: the first group (25) women whose ages ranged between (25-34) years, and second group (15) women whose ages ranged between (35-44) years.

There was a very little and non-significant increase ($P>0.05$) in the levels of TC, TG, HDL, LDL and VLDL among the second group of women at premenopausal age whose ages ranged between (35-44) years (146.04 ± 48.05), (109.65 ± 42.06), (43.05 ± 18.02), (82.50 ± 32.16), and (23.02 ± 9.23) mg/dl respectively when compared with their levels among the first group of premenopausal age women (128.95 ± 32.59), (95.23 ± 22.59), (44.48 ± 11.96), (64.49 ± 28.09) and (17.96 ± 4.92) mg/dl respectively as shown in table (2).

While the postmenopausal age women group (60 samples) whose ages ranged between (50-65) years were also subdivided into two groups: the first group (40) women whose ages ranged between (50-59) years, and second group (20) women whose ages ranged between (60-65) years.

There was a little and non-significant increase ($P>0.05$) in the levels of TC, TG, HDL, LDL and VLDL among the second group of women at postmenopausal age whose ages ranged between (60-65) years (176.23 ± 23), (148.15 ± 35.85), (34.5 ± 8.73), (117.02 ± 27.82) and (28.98 ± 7.01) mg/dl respectively when compared with their levels among the first group of postmenopausal age women whose ages ranged between (50-59) years (156.95 ± 38.75), (138.23 ± 35.43), (35.68 ± 10.96), (93.92 ± 19.04) and (26.85 ± 6.87) mg/dl respectively as shown in table (3).

The study performed by poonam, showed coincident results with our findings as they found no change in TC levels between the pre and postmenopausal age women ¹⁶.

Results obtained by Yassin et al were in agreement with our results regarding HDL and LDL levels, while their results did not agree with ours regarding TC and TG ¹⁷.

Our findings also agreed with those of Anthony et al in regard to TC, HDL, TG and VLDL, while they did not agree with us in regard to LDL levels ¹⁸.

It is worth mentioning that the absolute value of total

cholesterol is not the most important factor to identify cardiovascular diseases, but the abnormal levels of the cholesterol types TG, HDL-C and LDL-C are the most important factors in such disease, and this is attributed to the variation in races and genetic types as well as other interfering factors. The values of lipid profile obtained in our study match with women in Baghdad city with all the similar statistical differences of the racial and genetic variations in other parts of the world. It is estimated that an increase of 1 mg/dl in HDL-C level leads to a 3% reduction in the risk of the coronary artery diseases and a 4.7% reduction in the risk of death and cardiovascular diseases ¹⁹. In our study, the level of HDL-C decreased, while the level of LDL-C increased, which is a great and important indicator of cardiovascular disease development, and this finding was reported by many studies ²⁰.

Undoubtedly, the postmenopausal changes in lipid profile levels in our study are unhealthy changes and can be harmful to the cardiovascular system.

Conclusion

Menopause causes lipid profile alteration through increasing the levels of Tc, TGs, LDL, VLDL. Therefore the risk of cardiovascular disease will be higher. Post-menopausal women are always at highly risk of cardiovascular disease development, due to the change in their lipid pattern and loss of estrogen effect in protecting the cardiovascular system.

²College of Education for Pure Sciences / Department of Biology / University of Kerbala

Abstract

The plant was selected as the source of the nanoscale study because it possesses more chemical compounds than the other plants, ZnO nanoparticles (ZnONPs) were prepared from the plant *Artemisia herba alba* extract and from the flavonoid compound. The samples were diagnosed by Atomic Force Microscopy (AFM) and Fourier transform infrared (FT-IR) spectroscopy, and effect ZnONPs the synthesis from *Artemisia herba alba* extract, from the flavonoid compound, *Artemisia herba alba* and flavonoid on the criteria for oxidative stress (Malonaldehyde MDA, Lipid peroxidation level LPO) and antioxidants (GSH glutation) were determine effective time and effective dose. The results showed that MDA and LPO showed a significant decrease compared with the control group, while the period of 32 days showed a significant decrease compared to 62 days. The analysis of GSH found that the coefficients of the study showed a significant increase compared with the control, while the period of 32 days showed a significant decrease compared with 62 days.

Key words : ZnO Nanoparticles, *Artemisia herba alba*, Flavonoid, MDA, LPO, GSH

Introduction

Nanoparticles is one active modern science, rapid growing field with technology and science for the purpose manufacturing new materials at nanoscale level ¹, The term nanotechnology was first used by Norio Taniguchi, using the word to describe tools that use nanoparticles, Nanotechnology is defined as the ability to monitor, measure, process and manufacture nanomaterials, and the nanometer-nm is one billionth of a meter, which is very small ². ZnO nanoparticles was one of the most nanoparticles used for used make ointments and cosmetic creams, etc.. which protect skin from cancerogenic and burns of ultraviolet radiation ³ Free radical generation is a natural consequence of living in an oxidising environment, cells generate small amount of free radical or reactive oxygen species (ROS), accumulation of ROS may damage biological macromolecules such is DNA, carbohydrate, protein, lipid ⁴, External factors such infection, radiation, heat, toxins and exercises can lead to increase free radicals and other ROS ⁵, oxidant damage may be minimised by antioxidant defence mechanism that protect the cell

against cellular oxidant and repair system that prevent the accumulation of oxidatively damaged molecules, antioxidant enzyme play a vital role in protecting cellular damage from harmful effect of ROS ⁶ plants contain phytochemicals are any compound such as phenol, terpenoid, polysaccharide and flavone that contribute in reduction and stabilizing nanoparticles ⁷, plants are natural antioxidant sources which are used in traditional medicine for healthy of many disease ⁸ as *Artemisia herba alba* plant (Asteraceae family commonly known as annual wormwood) is a plant used many centuries in medicine treatment of many of disease ⁹, moreover, *Artemisia* leave a high content of cineole, *Artemisia* ketone, camphene ¹⁰ being a rich source of various phenolic compounds as a source of natural antioxidant ¹¹. Such flavonoid have great potential to inhibit the generation of reactive oxygen species (ROS) and once they are formed perform antioxidant function, flavonoid are found in the chloroplast which play role as scavenger of oxygen and stabilizers of chloroplast outer envelope membrane ¹² Since our food is rich in antioxidants, including flavonoids, and the current time research

has been manufactured with some caveats and that nanoparticles have taken into account the application of biological, industrial and medical in an attempt to reduce the oxidant stress, so the study aimed at:-1- synthesis ZnO nanoparticles from *Artemisia herba alba*, 2 - preparation best of ZnO nanoparticles,3- studying evaluation properties antioxidant – oxidant of *Artemisia herb alba* extract Flavonoid,4- analysis oxidant strese Malonaldehyd (MDA) and Lipid peroxidase (LPO). 5-analysis antioxidant glutation GSH.1: Materials and method

1-1-plants collection: *Artemisia herba alba* obtain from karbalaa city in 2018 during the flowering stage the plant were air dried and at oven degree 45c° and powder.

1-2-Soxhlet Extraction : 50 gm of fin powder was plased in to an extraction thimble and extracted with 50 ml of (80%) methanol in flask round volum (500 ml) for 24 hours, (Iqbal, 2012) then evaporated at (45C°) by a rotary evaporator and using freez drayer (lyophilizer) to dried crude extract.

1-3-Exrtraction of total flavonoids from *Artemisia herba alba* : Material has been according to this method ¹⁴.

1-4: preparation ZnO nanoparticles from the extraction *Artemisia herb alba* and flavonoid. Material has been done according to his method ¹⁵.

1-5: Diagnosis using FT-IR infrared spectrum: Work has been done according to his method ¹⁶

1-6-Diagnosis using Atomic Force Microscope AFM:

1-7 Design experiment: Atotal adult male rat , weight (200-320) gm, age (8-10) weak , wer used in this study and were isolated in a relatively controlled environmental at temperature of about 25C° in animal house , rats were divided in to 5 groups , G1-the control group has given normal saline (0,9%) only, G2- injection 150 mg/kg B.W of *Artemisia herb alba* extracted , G3- injection 150mg/kg B.W of Flavonoid extracted, G4- injection 0. 4 mg/kg B.W ZnO nanoprticles synthesis from *Artemisia herba alba* extract, G5- injection 0.2 mg/ kg B.W ZnO NPS synthesis from Flavonoid.

1-2- Oxidant -Antioxidant analysis :

1-2-1 : Malondialdehyde (MDA) U/ L: Work has been done according to his method ¹⁷

1-2-2 Lipid peroxidation : Work has been done according to his method^(18, 19).

Results And Discusion

Identification of nanoparticles :

Atomic Force Microscopic (AFM):

The topography of surface was studied using AFM , Fig (1) showed two dimention image semispherical and spherical of ZnONanoparticles synthesis extract of *Artemesia herb alba* and Flavonoid compounds , nano particles high to the ZnO show 33.33nm , 18.00 for ZnONanoparticles synthesis extract *Artimesia herb alba* and Flavonoid in tabl 1,

comparison with study of ²⁰ the morphological character of ZnO nanoparticles by flavonoid was analysis by SEM which showed spherical shape and cluster.

Tabl (1) show shape , nanoparticles , size particles , diameter average of ZnONPS *Artimesia herb alba* and ZnONPS Flavonoid.

Sample	Sample	Nanoparticles	Size particle	Diameter average
ZnO Artimesia herb alba	Semispherical	33-33 nm	55-100.00nm	80-55 nm
ZnONPS Flavonoid	Spherical	18.00 nm	55-85.00 nm	75-04 nm

Fourier Transform infrared (FT-IR) analysis: The FT-IR spectra of the four samples are shown in figure (1), The results of FTIR spectrum of ZnONPs A.herba alba presence of alcohols and phenols with a peak at 3411.19 , 3344.68, 3300.31, 3219.30 , 3173.01, 3117.07 , 3057.27 cm-1 , The peak at 2960.83 , 2883.68 and 2883.68 cm-1 to the C-H stretching presence some, fatty acid , alkene compounds, wax, carotenoid and phytosteroil are present. The peak 17570.21 cm-1 presence to the C-C stretching which means that some glycoside, The peak value at 1614.47 cm-1 assigned to the C=O stretching which means the presence of some Flavonoid, polyphenol and catechins. The peak value at 1508.38 cm-1 assigned to the C=C stretching which means that some aromatics , flavonoid . The peak values at 1396.51, 1332.86 cm-1 assigned to the C=N stretching confirms aromatic

amines. The peak value at 1274.99 cm-1 assigned to the C-N stretching confirms aliphatic amines, The peak value at 1168.90 , 1111.03 cm-1 assigned to the C-O stretching which means that Alcohols , ester, carboxylic acids, and the peak value at 852.56, 781.20 , 617.24 cm-1 assigned to the C-N stretching which means that Aliphatic amines and secondary alcohols , the absorption at in peak 478.36 cm-1 identifies the presence of ZnO nanoparticles , compared with result of ²¹ which indicate the presence of ZnO nanoparticles at peak 450-540cm-1 that synthesized from aqueous leaf extract of coriandrum sativum using zinc acetate sodium hydroxide as in Figure 1 and Table 3 . the studies (^{22,23}) at peak between 1543-1028 cm-1 the affinity of the confirmed material of the nanoparticles of ethylene glycol and ethyl alcohol .

Fig (1) FTIR ZnO synthesis from *A. herba alba*.

The results of FTIR spectrum of Flavonoid at peak 3205.80 cm⁻¹ the presence of alcohols and phenols The peak at 2993.62 cm⁻¹ and 2071.62 cm⁻¹ presence to the C-H stretching alkene compounds , fatty acid , carotenoid and phytoSteroil are present. The peak value at 1633.76 cm⁻¹ assigned to the C=O stretching which means that Flavonoid , polyphenol and catechins , The peak value

at 1396.51, 1332.86 cm⁻¹ assigned to the C=N stretching which means aromatic amines. The peak value at 1274.99, 1238.34 and 1047.38 assigned to the C-O stretching which means alcohol, ester, carboxylic acid , the peak values at 985.66 and 729.12 cm⁻¹ assigned to the C-N stretching which means Aliphatic amines as in Figure (6) (24, 25,26, 27)

Discussion

The experiment result show that (*A. herb alba* , flavonoid ,ZnONPs) improved antioxidant enzyme activity and effectively free radicals scavenger that can enhance the antioxidant capacity ,because *Artemisia* contained bioactive substance such polysaccharide and flavonoid which has very good radicals scavenging capacity and antioxidant effect. Because flavonoid have antioxidant effect at extracellular or intracellular antioxidant substance levels and act inhibition xanthine oxide activity is free radicals defense mechanism .that has conversion of xanthine oxide product to xanthine dehydrogenase so that decrease free radicals substance produce. ZnO nanoparticles is able to protect cell membrane against radical ferr damage , increase antioxidant enzymes and decrease MDA level and decrease level ROS.

Molecular Identification of Sarcocystis Species Infection in Sheep in Karbala Governorate – Iraq

Saja A. M. Al-Saadi¹, Kawther A.M. Al-Mussawi¹, Hayder A. Muhammed²

¹Department of Biology, College of Education For pure Science, University of Kerbala,

²Department of Microbiology, College of veterinary medicine, university of Kerbala

Abstract

Sarcocystis spp. are causative agents of ovine muscular stiffness, myopathies and/or inflammations of the mucosa of the intestine, diaphragm Heart and skeletal muscles, which are generate important economic loss when causing clinical and subclinical cases, ovine Sarcocystis spp. are a protozoan parasite of worldwide distribution transmitted by canids, most commonly associated with subclinical infection in sheep, our study were described in unorganized five different localities in Karbala governorate for sheep Sarcocystis spp. investigation and classified in to two ages groups, less than 18 months-old and over 18 months-old, Macroscopic and microscopic and certain biochemical tests were used for parasite observation, Molecular assay PCR assay was used to confirm this protozoan, Currently, PCR assay based on certain regions of the cytochrome oxidase 1 sequences is considered and used widely as an inexpensive, rapid and precise molecular approach to identify the Sarcocystis spp.

Keyword: Sheep Sarcocystis, PCR, Macrocyts and microcyts.

Introduction

Sarcocystis is anobligatory intracellular protozoan that belongs to the phylum apicomplexan and has the ability to infect a broad spectrum ofvertebrates' poultry, livestock, and humans with more than 150 knownspecies¹⁶ and⁷. It is a heteroxenous parasite that has anobligatory two host's life cycle in order to thrive, one host,being an intermediate onewhich is usually herbivores or omnivores in which the parasite will have its merogonystage and results in cyst formation inside the skeletal muscles of these hosts which are commonly referred to as (sarcocysts). The other host is the definitive (final) host which in turn would usually be a carnivores or omnivores in which the parasite undergoes it's sporogony and gamogony stages of development that leads to shedding of infective sporocysts and oocysts in the stool of these animals¹⁴. The same animal species can be infected with more than one species of Sarcocystis, for example, sheep as intermediate hosts, can be infected with more than four different species of Sarcocystis and are intermediate hosts these are *S. gigantea*(*S. ovifelis*), *S. tenella* (*S. ovicanis*), *S. arieticanis*, and *S.medusiformis*¹. The prevalence of Sarcocystis varies with respect to its species were *S.gigantea* is known

to have a global distribution whereas *S.medusiformis* on the other hand has been only reported in only a few parts of the world like Australia, New Zealand²³. The pathogenicity of Sarcocystis varies with respect to its species. The inspected sheep meat which turns to be heavily infested with macrocysts in Iraqi abattoir most of the time will be condemned as unfit for human consumption .Another point of concern involves the fact that nearly all investigations on ovine Sarcocystis infection are limited to just inspecting the carcasses at the slaughterhouse without paying attention to determine the exact species of Sarcocystis involved which may return harmless and fit for human consumption and thus reducing the economic losses²⁹ and¹⁹.

Materials and Method

Animals: During the course of this study which extended from December 2018 to May 2019, tissue samples involving the esophagus were randomly collected from 412 (289 male and 123 female) sheep slaughtered at five different localities in Karbala. Careful examination was conducted prior to slaughtering to make sure that all included sheep were healthy before being slaughtered. The estimation of sheep age was made on the basis of teeth examination to calculate the number of

temporary teeth as well as the erupted permanent incisor count ²⁶. The gender of each sheep was recorded. The animals were categorized into two groups according to their age (Table 1).

1- Group A: this group included all sheep 18-month of age irrespective to their sex. It included (211) sheep with (155) male and (56) female. The ages of this group of male members ranged from 10-18 month (16.8 ± 1.61) and that of the female group member ranged from 14-18 (15.38 ± 2.27) month.

2- Group B: this group included all sheep with an age of equal to or more than 18-month. It included (201) sheep with (134) male and (67) female. The ages of this group male members ranged from 18-32 (27.26 ± 2.03)

month and that of the female group member ranged from 18-38 (28.35 ± 2.46) month.

Macroscopic examinations.

After washing and removing of tunica adventitia, each collected esophagus underwent careful and thorough inspection in the search for macrocysts of the *Sarcocystis* parasite. Any specimens found to have macrocysts was isolated, its cysts were excised and liberated out of the esophageal tissue to be collected in a petri dish (Fig. 1), and underwent subsequent classification based on the physical features like shape, color, and size. The cysts ranged (3 -14 mm) in length (11.2 ± 1.3 mm). Their colors varied from opalescent white to pale yellow and their shapes included both round and oval forms.

Figure 1: Macrocysts of different sizes and shapes isolated from infected esophagi.

Microscopic examination:

Three samples were taken from each esophagus with an approximate weight of at least 25 g in order to be used for *Sarcocystis* bradyzoites that are harbored in the microsarcocysts which are typically banana shaped (Fig. 3) with a length of about 3.08 to 7.45 μm that were estimated using ocular micrometer. All parts were labeled with information representing the age, gender, and date of slaughtering. Each collected esophagus was examined with the following three methods:

Peptic digestion method.

For performing this procedure, a modified technique commonly used by similar studies was adopted ¹⁰ were 2 grams of pooled muscular tissue obtained from the esophagus after removing fat and tunica adventitia. The

extracted piece was in turn cut into smaller and smaller pieces using a scalpel after that it was placed into 10 ml test tube followed by adding 7 ml of peptic digestion solution and incubated at 40 C° for 30 minutes. The digestate was filtered through 3 layers of medical gauze into 10 ml centrifuge tube and centrifuged for 7 minutes at 2000 rpm. The supernatant was discarded and 0.5 ml of 0.9 % physiological saline was added to the precipitant, mixed thoroughly and a drop was taken and placed over a glass slide in order to be examined by microscope for the presence of bradyzoites under the power x 40 ¹⁷.

2- Meat mincing by garlic presser:

As described by ²¹, 4 grams esophageal muscle sample placed in a metallic garlic presser and firmly squeezed to extract a liquid from the meat from which a drop was taken via Pasture pipette and placed on a

glass slide, covered with a cover-slip and examined by microscope at force 40 X.

3- Slide squash method (Trichnoscopy):

A meat sample was cut into as small pieces as possible using a scalpel in a direction parallel to that of muscle fibers. 2 x 2 mm piece placed over a glass slide and covered with two coverslips. After placing the slide on a firm ground, it was pressed by thumb as hard as possible to crush the sample then the upper glass slide was removed and the sample examined at 40 X ²⁷.

Molecular study

For molecular analysis, soft cysts of the macrocysts were dissected, washed several times in 0.01 M phosphate-buffered saline (pH 7.2), and stored at -20 °C until DNA extraction.

DNA extraction

G-spin™ Total DNA Extraction Mini Kit, Korea was used for DNA extraction where according to provider’s protocol and after collecting extracted macrocysts in a Petri dish, 20 mg of macrocysts placed in 1.5 ml Eppendorf tube smashed into liquid state using a sterile wooden stick and mixed up with 200 µl of tissue lysis solution followed by adding 20 µl proteinase-K. The

mixture incubated at 60 °C in a water bath for 30 minutes with constant shaking using vortex every 5 minutes. 200 µl binding buffer added and mixture incubated at 60 °C for 10 min then 100 µl of absolute alcohol added. The mixture was transferred into a collection tube for centrifugation at 13000 rpm for 1 minute. 700 µl of washing buffer 1 solution added and another run of centrifugation at 13000 rpm was conducted. After discarding the supernatant, washing buffer 2 added and the mixture was replaced in 2 ml tube together with 200 µl of buffer and let dry at room temperature for 5 minutes. The tube was centrifuged at 13000 rpm for 1 minute then the DNA containing fluid was stored at -20 °C for further evaluation.

PCR-reaction.

PCR was conducted on all esophageal samples using *Sar* primers including *Sar-F1* Forward 5’GCACTTGATGAATTCTGGCA3’ and *Sar-R1* Reverse 5’CACCACCCATAGAATCAAG3’ (2, 12, 13).

PCR reaction was carried out in 30 µl of Premix (AccuPower PCR PreMix, Korea). Twenty-five microliters of TaqMaster Mix were used with 10 ng template DNA, 0.1 µM of each primer and distilled water. Cycles of PCR are summarized in (Table- 2):

Table 1: age, sex, and type of infection together with the detection method used for detecting prevalence of microcystic infection in sheep included in the study.

	Males		Females		Total

	Extension	72	30 sec	
	Terminal	72	10 min	

The amplified DNA obtained after PCR procedure was electrophoresed using 2% agarose gel, stained with Ethidium Bromide (0.5 µg/ml) and visualized under the UV light.

Statistical Analysis

Statistical analysis was done to evaluate the results with a confidence interval of 95% using non-parametric χ^2 test using SPSS (Version 22; IBM, USA). A probability values of $p < 0.05$ were regarded as statistically significant.

Results and Discussion

The results of this study concluded that after examining esophageal muscular tissue samples, sheep had been infected with both macroscopic and microscopic cysts figure (2 &3). With respect to infection with the macroscopic form of the parasite, it was found that among total of (N=412) examined sheep by naked eye, there was (n=23, 5.82 %) confirmed infections with macrocytic form, while the infection rate with the microscopic form of the parasite was (n=374, 90.78%). These finding are consistent with those of similar studies on prevalence of Sarcocystis in livestock in Iraq, were it was found that a prevalence rate for macrocysts of about (4.1 %) was reported in the south of Iraq²¹ likewise, a prevalence of (97.5%)for microcysts was reported in north of Iraq¹⁹.

Figure 2: Sarcocystis bradyzoites extracted from microcysts showing typical banana shaped appearance after staining with Giemsa stain and examining using x200 power

Upon comparing the prevalence of infection between both age groups, it was evident that infection rate was significantly higher from the statistical point of view in sheep with older age when compared to those with younger age (7.96% vs. 3.32%, $P < 0.05$) for the first and second groups respectively. It was also noticed that there was a statistically significant difference in infection prevalence between males and females members of both groups ($P < 0.05$). Infection rate was higher in females when compared to males (8.93% vs. 1.29%) respectively for the first group. The same was true with respect to members of second group (17.91% vs. 2.99%) for females and males respectively. It was found the females in both age groups were having the highest prevalence of infection with the macroscopic form when compared to

males ($P \leq 0.05$) as shown in table (1). The results also concluded that older sheep had more prevalent infection were there was a statistically significant difference ($P \leq 0.05$) upon comparing infections in both age groups.

Table 3: age, sex, and type of infection together with the detection method used for detecting prevalence of microcystic infection in sheep included in the study.

	Males		Females		Total
	< 18	≥ 18	< 18	≥ 18	
Age group (month)	< 18	≥ 18	< 18	≥ 18	
Number of sheep (N)	155	56	134	67	412
Macroscopic cysts (n1)	2	4	5	12	23 (5.58%)
Microscopic cysts (n2)					
Pepsin digestion	140	126	52	56	374 (90.78%)
Trichnoscopy	138	111	46	49	344 (83.50%)
Mincer	91	82	40	43	256 (62.14%)

N = total number of sheep in any subgroup.
n1 = number of sheep infected with macrocysts in any subgroup.
n2 = number of sheep infected with microcysts in any subgroup.
% = $(n/N) \times 100$.

Regarding infection with the microscopic form of the parasite, there was no seasonal variation in the rate of infection among study months ($P=0.41$). The results of this study which encompassed 412 esophageal samples from slaughtered sheep in Karbala/ Iraq, revealed that macrosarcocysts when compared to microsarcocysts had a lower prevalence in the examined sheep. On the other hand, PCR amplification of Sarcocystis parasite with mentioned primers revealed an electrophoretic bands (Fig. 3) but, in the same time our isolates demonstrated a Sarcocystis specific 600 bp band. We easy used molecular technique for detection of Sarcocystis compare with microscopic examination, it is take long time may be need more expertise for Ophthalmic screening, other wise it is an inexpensive, rapid and precise molecular approach to identify this parasite.

Figure 3: 2% agarose gel electrophoresis of DNA produced by PCR and stained with ethidium bromide showing bands detected at 600 bp region of 1100 Bp ladder.

At yet, special molecular procedures such as cytochrome oxidase 1, agarose gel electrophoresis staining with safety red DNA staining, have been employed for diagnosis of sarcocystosis in meat samples. These methods are genus no specific and just performable on slaughtered carcasses, so it is different with some researcher who have designed some nucleotides primer have ability to form genus-Specific PCR (28, 18).

International Crimes and the Legal Basis of the International Committee of the Red Cross in Armed Conflict

Heba Eidan Abd Ali Jassim¹, Sarmad Amer Abbas¹

¹University of Babylon / College of Law, Iraq

Abstract

International and non-international armed conflicts and other acts of violence are conflicts that cause death, persecution, suffering, internal displacement and destruction of the nation's infrastructure. These conflicts, with their various names, revolve around most of the world. There are international conflicts between two states and conflicts involving armed groups within the state known as armed conflicts Non-international, and there are internal tensions and tensions known as internal conflicts (other violence). International and non-international armed conflicts govern international law. International humanitarian law is the basis for the rule of these disputes, which is defined as the laws of war. The definition and classification of disputes and their conditions leads to the identification of serious violations of international humanitarian law and the applicable international law. Article 2 of the four Geneva Conventions of 1949, Additional Protocol I of 1977, which deals with international armed conflicts, and non-international armed conflicts apply Article III, in particular Additional Protocol II of 1977 Which complemented Article 3 common to fill the deficiency and imbalance in this article.

Key words: *Crimes, Legal Basis, International Committee*

Introduction

Armed conflicts are a reality and a legal issue, especially if we recognize that the United Nations since 1945 prohibits the use of armed force in relations between States, except in cases of self-defense or aggression¹. The definition of aggression as a crime under international criminal law was adopted only in 2010. In addition, there is no international legal definition of armed conflict per se. Since 1949, article 2 common to the four Geneva Conventions has defined the international armed conflict that² entails the application of humanitarian law. (Known as Common Article 3) to the minimum rules applicable to non-international armed conflicts, without giving a clear definition of this dispute, the expansion of Additional Protocol I to the Geneva Conventions of 1977, as well as the jurisprudence of the³ courts International standards in the definition of international armed conflicts and included the criteria for interpreting this definition. The problem entailed in those definitions lies in the obligation to respect the traditional and customary rules of humanitarian law⁴, which are particularly applicable to international armed conflicts, rather than the more restrictive rules applicable

to non-international armed conflicts⁵. The law applicable in armed conflict is international humanitarian law, which can be defined as “a branch of public international law whose customary and customary rules are intended to protect the affected persons in the event of armed conflict. This is done to protect the money that is not The armed conflict and the ensuing humanitarian suffering, destruction and long-term effects on the societies and individuals who are engulfed⁶ in it have created international mechanisms to limit and control violations and to assist victims of conflicts. An International Red Cross mechanism that has given confidence to its leading role in this field. The importance of this research lies in the knowledge of international crimes, the consequences of armed conflicts, their classification, and what may apply to each of these conflicts of international law⁷, the role of the International Committee of the Red Cross and its legal basis in international norms, the importance of this NGO and its humanitarian role in providing humanitarian response and clarification. Its international standing in accordance with international conventions⁸.

Methodology

This research is based on the analytical and

descriptive approach through which we analyze the legal texts that can be applied in armed conflicts and what international crimes are adopted by the ICRC in its humanitarian tasks.⁹

Definition of international crimes and armed conflicts

International crime has long existed. The United Nations has recognized the existence of violations against peoples, most of them war crimes, and there is a threat to the vital interests of the international community, the oldest of which is the crime of piracy. Some have argued that there is no international definition of armed conflict, since the circumstances that may or may constitute or constitute an armed conflict are different and different from each other. To know this, one must refer to each case of conflict to see whether it constitutes an international or non-international armed conflict and we will refer to international and non-international armed conflicts and internal conflicts in accordance with the opinions of jurists and international law in two sections:

Section I: Definition of International Crimes and International Armed Conflicts.

Section II: Definition of armed and non-international conflicts and internal conflicts.

Section I: Definition of International Crimes and International Armed Conflicts.

First, the international crime was defined by the jurist Glacier as “any act that violates the law because it harms the interests protected by this law within the scope of international relations and is described as a criminal act that requires the application of punishment to the actor.” This definition is not subject to the international criminal justice, As “acts contrary to the rules of international law, which entail international responsibility and are of such gravity that they may cause disturbance and disturb the public security of the international community.»¹¹

International crimes include three pillars: the physical pillar, the moral pillar and the international corner. International crimes under the Rome Statute are divided into four crimes: war crimes, genocide, and against humanity and aggression.

1. War crimes: Article 8, paragraph 2, which refers to war crimes:

a. Grave breaches of the 1949 Geneva Conventions

include acts against persons and property protected by the Geneva Conventions.

b. Serious violations of the laws and customs applicable in international armed conflicts.

2. Genocide: is defined in article 6 and any act specified in the Rome Statute (such as murder or causing serious harm) committed with intent to destroy, as such, a national, ethnic, racial or religious group, is wholly or partly inalienable.

3. Crimes against humanity: Article 7, any act prohibited and defined in the Rome Statute, when committed in the context of a widespread or systematic attack directed against any civilian population, including such acts as willful killing, extermination, rape, sexual slavery, deportation or Forced relocation of people, the crime of racial discrimination and others. Genocide and crimes against humanity are punishable regardless of their perpetration at the time of “peace” or war.

4. Crimes of aggression: The International Criminal¹² Court does not specify what is meant by this in article 5, paragraph 2, and once a definition has been defined, the Court exercises its jurisdiction.

Definition of International Armed Conflicts

Article 2 of the Geneva Conventions of 1949 states that the definition of international armed conflict as “declared war and armed conflict is between two or more High Contracting Parties, even if no one recognizes the state of war.” In addition to international armed conflicts,⁴ of Article 1 of Additional Protocol I of 1977 to the Four Geneva Conventions of 1949. Jurists have known international armed conflict with multiple definitions, including: Sadiq Abo Hafe defined it as “a struggle between the armed forces of each of the conflicting parties, each aiming to safeguard its rights and interests in the face of the other⁵ Muhammad Bashir al-Shafei defined it as “armed conflict between States with a view to imposing a political point of view in accordance with the means regulated by international law⁶

Jean-Baptiste defined it as “Any difference between states that leads to the intervention of members of the armed forces is an armed conflict⁷

Charles Rousseau defined international armed conflicts as “armed conflict is based on inter-State fighting with a view to giving preference to a political viewpoint according to the means of international law⁸

Third: Conditions of International Armed Conflicts:

1. Status of armed conflict.
2. International parties to the conflict.
3. Declaration of the parties to the conflict of armed conflict between them.
4. Achieving a national interest ⁹

Section II: Non-International Armed Conflicts and Other Acts of Violence.

First: Definition of non-international armed conflicts.

The armed conflicts that were not international were defined as “mixed war.” According to the definition of the jurist Grosius, Bovindov defined them as “wars in which members of one society are fighting among themselves.” Galvo defined them as “confrontations within a single state, Other against the central government) ¹⁰

The international armed conflict has been defined as “confrontations within the territory of a single State in which the armed forces of any other State do not engage this central Government¹¹

It was also defined that “every act of hostility directed against the legitimate government if it represents a collective character and a minimum of organization¹²

The four Geneva Conventions of 1949 are the subject of non-international armed conflicts of international humanitarian law. The 1949 Diplomatic Conference was an important and strategic step in addressing the problem of non-international armed conflicts, but it did not set a specific definition. However, the International Committee of the Red Cross the objective criteria were accepted in order to find an application to the Geneva Conventions on these disputes:

1. The possession of the rebel military force responsible for its actions and organization.
2. To control and work on parts of the Territory capable of respecting the Geneva Conventions. ¹³
3. The authority must be forced to fight with the official government forces.
4. Recognize them as combatants or declare them at war.
5. The inclusion of any dispute over the work of

the Security Council and the General Assembly as a threat to international peace and security or as a state of aggression, ¹⁴ but the Diplomatic Conference was unable to establish a specific definition of non-international armed conflicts¹⁵

The Second Additional Protocol of 1977 defined and defined non-international armed conflicts as (conflicts in the territory of one of the High Contracting Parties between the High Contracting Parties and its armed forces, dissident forces or other armed groups, and acting under the responsible leadership of a part of the Territory Of control, enabling it to conduct continuous, coordinated and capable military operations to implement this Protocol).

The International Criminal Court defined non-international armed conflicts in article (2/8/9) as “armed conflicts occurring in the territory of a State when there is a protracted armed conflict between the authorities .

Governmental organizations and organized armed groups), a definition similar to that of the International Criminal Tribunal for the Former Yugoslavia (ICTY).

Any non-international armed conflicts to which the State is not a party and which is conducted between armed insurgent groups that do not constitute a non-international armed conflict in accordance with Protocol II, because the most important feature that characterizes it and adds to it a non-international character is the State’s being a party of it. ¹⁶

Other violence.

Internal violence and internal disturbances are other violent acts known as internal disturbances resulting from violence but do not amount to armed conflict. This does not necessarily involve military action, but with long-term violence or widespread violence The description of a situation does not require internal tensions to be experienced by state repression, long-term internal tensions, short-term consequences, re-emergence from time to time, or affecting a part or all of the territory of the State or the motive behind it Religiously, ethnically, politically or socially Or other, and the law has distinguished between rebellion, disobedience and civil war.

The second requirement: the legal basis for the ICRC’s work in international and non-international armed conflicts and other acts of violence.

The International Committee of the Red Cross (ICRC) is a unique and unique place in international humanitarian conventions. The ICRC has been established for nearly a century and a half century. It carries a humanitarian message in the protection and assistance of all those who need the wounded, sick, refugees, internally displaced persons and other victims of armed conflict. To carry out its humanitarian work in two branches: its legal basis in international armed conflicts and its second legal basis in non-international armed conflicts and other acts of violence.

Section I: The Legal Basis of the International Committee of the Red Cross in International Armed Conflicts. The facilities used by protected persons and they can speak with them without a censor, with the assistance of an interpreter when necessary. The full freedom of representatives and delegates of the Protecting Powers is given in relation to the choice of places they wish to visit. The delegates of the International Committee of the Red Cross The appointment of such delegates to the consent of the States under whose jurisdiction the territories are to be exercised “, and these privileges for the International Committee of the Red Cross to facilitate their work, as set forth in article 126 Of the Third Geneva Convention, the privileges enjoyed by the ICRC when it visits protected persons, as well as the mandate granted to it under the Statutes of the International Movement in Article (5/2/D), Article 81 (1) of the Additional Protocol I (Right of Initiative), as follows: “Parties to the conflict shall be accorded all possible facilities by the ICRC to the International Committee of the Red Cross The International Committee of the Red Cross to enable it to carry out the humanitarian tasks entrusted to it under the agreements and this Protocol with a view to providing protection and assistance to the victims of conflicts. The ICRC may also carry out any other activity on behalf of these victims provided that the parties to the conflict concerned agree.

In view of the International Committee of the Red Cross (ICRC), it has been granted certain rights to visit prisoners of war or civilian prisoners, to deliver relief materials, to operate the tracing agency and to international humanitarian law of the Geneva Convention , Articles 76, 109, 137, 140, and 143 of the Fourth Geneva Convention, as well as the right to initiate in international and non-international armed conflicts in articles (Common Article 3, Articles 9 / 9 / 9 / 10) Geneva) in assisting victims of international armed conflicts, the ICRC is based on the ICRC The Geneva Conventions

of 1949, in particular the Third and Fourth Conventions and Additional Protocol I of 1977, Article 81, to carry out their work in international armed conflicts, the special status of the ICRC, its neutrality and its being the custodian and observer of the application of international humanitarian law by the signatories to these conventions, Which is the engine of these international conventions in providing services to the combatants of victims of armed conflicts, the right to visit detainees and prisons and to provide aid and humanitarian intervention and interview them unchecked, and has contributed effectively in this area, N talk about the Geneva Conventions without mentioning the International Committee of the Red Cross.

Conclusion

The role of international non-governmental organizations, especially those of a humanitarian nature, has an important role to play in ensuring human rights because this process requires continuity in the defense and sustainability of human rights. These are the International Committee of the Red Cross (ICRC). The ICRC is one of the most important mechanisms of international humanitarian law Which plays a key role in the implementation of international humanitarian law and is based on international law and its statutes, particularly the four Geneva Conventions which have given it an important mandate to carry out its humanitarian tasks.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon / College of Law, Iraq and all experiments were carried out in accordance with approved guidelines.

Physical Preventive Strategies Related to Children with Leukemia from Mothers' Perspective in Al.Basrah Province

Muntatdher Hasan Khalaf¹, Nuhad Mohammed Kassem²

¹Master student Child Health Nursing, Faculty of Nursing, University of Babylon

²Assist. Professor of Child Health nursing, Faculty of Nursing, University of Babylon

Abstract

Objectives: To assess mother's preventive strategies concerning physical complication for children with leukemia. A cross-sectional descriptive study consisting of (150) mothers were interviewed at Basrah specialist hospital for children in Basrah Province in a period from 3 February to 21 March 2019. Findings of the study revealed that the highest percent of studied mothers 73(48.7%) had high level related to physical preventive strategies and 74(49.3%) had moderate level related to chemotherapy physical preventive strategies. systematic application a protocol of home care for children having leukemia to help mothers to provide appropriate home care and reduce the incidence of physical complication in children undergoing chemotherapy.

Keywords: Mothers, physical, Preventive, Strategies, Leukemia.

Introduction

Leukemia is a rapidly progressive abnormal white blood "cells" formation that can result in severe scientific consequences such as life-threatening distress with infection and bleeding¹. Pediatric leukemia is one of the deadly malignancies with unusual white blood cells shape and stem cells turn into lymphoblast ("leukemia cells"), which lead to body reaction present by way of lowering the quantity of "red blood cells" and platelets². "Cancer is the second most common cause of death among children aged" between 0 and 14 years old, after accidents. Blood cancer is "one of the most common cancers among children", accounting for about one-third of all cancers in children. It is diagnosed about "3,800" children annually in the United States (United States). Small but steady annual increase between 1975 and 2012, the incidence rate of leukemia in childhood in the United States led to a rise in total by 55% in the annual number of cases during the past three and a half decades³. As long as treatment and management of "childhood acute lymphoblastic leukemia (ALL)" have been advanced, Is transferred from being "life threatening disease to chronic disease." In addition, it leads to the transfer child care from the hospital to the home, which imposes a change in family roles and interest in organizing social activities and work

commitments and all life features. This thorough change in the family life and the fear of losing the ill child has a great effect on the caregiver's health related quality of life^{4,5}. Mentioned that even today, family caregivers are perceived as a major resource for the profit of the child patient, when always present and participating in their treatment in the hospital. Therefore, "Professionals need to help family members acquire skills"; caregivers for "leukemia" children need information, abilities and judgment to take care of their patients, who reduce the burden on them. The capability of family caregiver to deliver excellence care and donate to the administration of prolonged illnesses is a vital source of health care. Health care providers must be reassuring of family caregivers and help them gain awareness and skills in order to maximize the quality of care. Providers need to help family caregivers develop and solve problems, organizational skills and communication skills^{6,7} has confirmed that leukemia requires long-term treatment with unexpected results, and the lack of caregivers of knowledge in providing care for leukemia patients in children with chemo therapy side effects with financial problems, which are issues in many Mainly causing stress and anxiety to patients and their families. Cancer is many times seen as a misfortune event, which is probable to attract additional attention and care from family members which considered A major duties

delivered by the nurses with unlimited such as personal hygiene of the patient, observation changes of patient situations, maintenance an eye “on“ the advancement of treatments such as iv drips, and providing foods ⁸.

Methodology

A cross-sectional descriptive study carried out between the periods of (30 July 2018 to 10 July 2019) in Al.Basrah province. A “non Probability purposive sample of (150)” mothers who have children under eighteen years was selected in “oncology” & hematology clinic and “leukemia” ward at the “Basrah” specialist hospital for children was selected as 10% of the “total” population of “leukemic” children under eighteen years to the main specialist hospital for children in the province after obtaining legal permission from sectors and ethical approval from the sample of study to participate in research. A data was collected through the used questionnaire, which is constructed and developed after a comprehensive review of related literature by the researchers, itis consists of three parts: Part-I the socio-demographical characteristics which comprise of three sections, part-II preventive strategies related to physical complications of leukemia which involves of (22) items and part-III Preventive strategies related to chemotherapy physical complications” which comprise of (25) items. The responses for these items are rated and scored on 3-level type Likert scale as; yes=3, uncertain=2 and no=1. Each mother needs to approximately (25-35) minutes for the answer on the items of the questionnaire. Data were analyzed through using the Statistical Package of Social Sciences (SPSS, version 24) performed with descriptive and inferential statistical data analysis approach.

Results

The uppermost proportion of children estimating as 92 (61.3%) are from early childhood class. Concerning their genders, it shows that 88 (58.7%) were male, while 52 (34.7%) were “4th” and above order among their families, besides, no other children affected with leukemia in the family as estimating in 150 (100%). That the highest percent of sample 49 (32.7%) aged (40-46) years old; 48 (32%) have a primary level of education; logically 136 (90.7%) are unemployed; 89 (59.3%) living in nuclear family type; as regards to economic status, approximating as 93 (62%) in satisfaction with some extend; majority of the population is living in urban estimating as 109 (72.7%). The figure (1) indicates that

the highest percent of study, mothers 73 (48.7%) had high level, while 65(43.3%) of them had moderate level and 12(8%) had low levels.

Figure (1). Preventive Strategies Related to Physical Complications of Leukemia

The figure (2) directly below indicated that the highest percentage of mothers involved in the current study had moderate level estimating as 74 (49.3%), while 67 (44.7%) of them had a high level and 9 (6%) had low levels.

Figure (2) Preventive strategies related to chemotherapy physical complications

Discussion

The uppermost of the studied children within the age groups (2-7 years) who considered as the earliest stage of childhood. More than one-half of those kids were male; with relation to the kid order, less than 0.5 were forth and higher than order within the family, besides, the bulk of those participants don’t have any alternative kids with the malignant neoplastic disease within the family. A study provided by ⁴ who carried out as a cross-sectional study involved parent of (299) children in Malaysia; targeting to assess the correlation between coping strategies and the health-related parental quality of life, who had kids suffering from “acute lymphoblastic leukemia”, reported that less than half

“145” (49.5%) of the studied population was in the age group (6-12 years). While a retrospective study directed by ⁹ about “Patterns of childhood cancer incidence in Saudi Arabia (1999- 2008)”, resulting in all cases under the age of 15 years and both genders. They found that elevated percent (43.1%) of kids studied were in the age group (0-4) years. According to the researcher opinion, based on the results of the study underhand which supported by various studies, reflect the risky age within the early and middle childhood who exposed to many influences that reassure the exposure to cancer including leukemia. While, in another study of (56) “children hospitalized in Pediatric Hematology-Oncology Unit in Athens” conducted by ¹⁰ around “assessment of quality of life of children and adolescents with cancer during their treatment”, findings indicated that 32(57.1%) of the studied subjects’ were male. Genetic differences in immune function or behavioral related factors might be responsible for such a difference between girls and boys ¹¹. In a cross-sectional study described by ¹² which recruiting all children on chemotherapy “attending the pediatric oncology service Zagazig University Hospitals and Tanta Cancer Center, Egypt”. The study aimed to “assess the self-esteem of pediatric patients on chemotherapy for acute lymphoblastic leukemia and the psychological status of their parents”. The results of the study show that about half (52.0%) of children were second in order. The feedback of the existing study showed that less than 0.5% of the intentional mothers (150) was the in age groups (40-46) years, about an educational level less than half were from primary education, with the majority of them were unemployed. More than half percent of the sample, their type of family was unclear. Also, the analysis of the same table revealed that more than sixty percent of mothers, their economic status was satisfied to some extent, more than seventy percent were living in urban as shown in Table (2c) A cross-sectional study support the result of the current study, which conducted by ¹³ in selected hospitals affiliated with the universities of medical sciences in Tehran, included all mothers of (200) children aging 1–15 years with leukemia who had experienced the recurrence of the disease at least one time and who visited blood clinics. The result indicates that “124” (62%) of mother’s age was (30-39) years, this means that the present study had a sample from early middle parenthood who take youngsters with cancer of the blood, additionally reflects that mothers of this age are mature enough to require responsibility for providing take care of their kids. In a quantitative non-

experimental descriptive study done by ¹⁴ “in selected cancer institute, Adyar, Chennai, India on (40) mothers of leukemic children about the knowledge of leukemia, the stress and coping strategies of mothers with leukemic children undergoing treatment”. This study found approximately half, 47.5% of the mothers were illiterate and 22.5% have a primary school education. According to investigator outlook, level of education associated with Iraqi society ladies tradition shaped that the studied sample was from primary education, this result are often true in Iraq wherever most females might solely have the chance to achieve primary education, additionally level of education was a tributary issue that helps the mothers to scan and perceive complication bar for his or her kid with leucaemia, use health data and build them ready to specific whether or not they yes, uncertain and no. A quasi-experimental study design conducted by ¹⁵ on (60) parents at daycare and outpatient “clinic in pediatric hospital of Ain Shams University” aiming to detect “the effect of a psycho-educational training program for Parent’s having children with leukemia on their experience and psychological well being”. The study revealed that 91.7% of the population included in the study were mothers and 50% of them were unemployed, with almost of participants 44 (73.3%) were living in urban. This outcome appears to be the same as the current results as the population included with common graduated from primary level 48 (32%), and logically without employment who, constituting 136 (90.7%), besides, 109 (72.7%) living in urban. Moreover, another study accompanied by ¹⁶ about “Types and Influence of Social Support on School Engagement of Young Survivors of Leukemia in the province of Quebec (Canada)”. They found that the high percent 41 (77%) of the study sample, family structure was consist of “two” parents. While, another study is provided by ¹² who carried out a cross-sectional study involved parents of (178) children “attending the pediatric oncology service Zagazig University Hospitals and Tanta Cancer Center, Egypt” in the direction of “psychological impact of chemotherapy for childhood acute lymphoblastic leukemia in patients and their parents”, who reported that approximately half 107 (59%) of studied parents were living in rural areas According to the researcher’s point of view, it can be explained in a way that people prefer to be within the areas where services are widely distributed primarily in urban areas and are easily accessible. A cross-sectional study conducted by ⁴ among (299) parents of kids with “Acute lymphoblastic leukemia” in Malaysia and Kuala Lumpur. They

found that high percent, 206 (70.3%) Of children were diagnosed as early within the first six months of age. Finally, according to the researcher opinion, this means that more common incidence in children less than one year, whether the first or second half. The result of present study demonstrations that less than half of the study, mothers 73 (48.7%) had a high level around preventive strategies related to physical complications of leukemia as shown in Figure (1). According to the researcher opinion, through the meeting with the sample, the researcher found that mothers are anxious to learn the issues or behaviors necessary to avoid the physical complications of their children with leukemia. The result of the existing study signifies that less than half of the studied mothers 74 (49.3%) had adequate levels around preventive strategies related to chemotherapy physical complications as shown in Figure (2). According to the researcher opinion, the observed physical look deteriorated over time. This result could be due to the side effects of therapy. However, additional research is wanted to know how to assist patients overcome this difficulty, so that they do not become active.

Conclusion

The study concluded that mothers' preventive strategies related to physical, complication of leukemia is perceived within a high level of knowledge, while, the moderate level towards preventive strategies related to chemotherapy physical complications.

Abstract

Trichomonas tenax, a commensal flagellated protozoan, inhabits in human oral cavity. This parasite is cosmopolitan and frequently found in patients with poor oral hygiene and advanced periodontal disease. By using wet mount smear and giemsa staining to detect the prevalence of oral protozoa in patients with oral diseases and a healthy control group. From October 2014 to April 2015, the subgingival dental plaques of 310 patients with gingivitis or periodontitis and 310 controls who attended to clinics periodontics, in Babylon province. 64 (20.6 %) of patients were positive (40.2 % periodontitis, 14.2 % gingivitis) by using wet preparation and Giemsa staining. The prevalence of oral *Trichomonas tenax* in our study (20.6%) and *Entamoeba gingivalis* was (42.9 %) was compatible with many other published reports which mostly has ranged from 12%-32%. The study revealed dependence between the frequency of occurrence of protozoa and the state of periodontitis. The age group (41-50)yr. Have high incidence of *T.tenax* compared with an other groups, as well as the males have high incidence (24.7 %) than females (16.8 %).

Key words: *Entamoeba gingivalis*, *Trichomonas tenax*, gingivitis patients.

Introduction

T. tenax is an anaerobic commensal of the human oral cavity. There are studies that relate to its prevalence in patients with Marginal Chronic Periodontitis^(4,6). Transmission is through saliva, droplet spray, and kissing or use of contaminated dishes and drinking water^(7, 14). World widely, its prevalence in the mouth ranges from 4 to 53%^(17,19,22). Since the organism is believed to enter the respiratory tract by aspiration from the oropharynx and then cause bronchopulmonary trichomoniasis, the importance of oral infections has been increased recently^(1,12, 13). Surprisingly in Iraq there is study of¹¹ which shows a prevalence of periodontitis 8.4 % with *Entamoeba gingivalis* and *T. tenax* by direct smear. The number of trichomonads found in oral washing is rather low, and detection by conventional methods such as wet-mount preparations or staining may be sensitive. In addition, staining is useful for species identification, and culture techniques are routine use^(2,5,15). This study was carried out to determine the prevalence of oral trichomoniasis by direct smear methods and giemsa staining with microscopic observation to detect of *T.tenax* and *E.*

*gingivalis*⁸.

Materials and Method

The *Study population* included 620 individuals; 310 patients (160 females and 150 males) aged ranged 18-60 years old with periodontitis or gingivitis who attended to periodontitis -clinics of periodontics- and 310 healthy controls, who were matched with case group. The kind of oral disease previously was established by periodontist. Direct observation For each patient a sample of subgingival dental plaque from deep pockets obtained and preserved in an individual container of 2 ml Ringer's solution. The containers of fixed plaques duly labeled and examined to the department of Microbiology for identification of oral parasites. Microscopic observations were made three times under dry magnification (400x) and then each sample stained with Giemsa. The identification of *T. tenax* was established as a pear-shaped flagellated trophozoite, about 5-13 μ long and with circular movement. Another oral protozoan, *Entamoeba gingivalis*, if present, was differentiated by its size (10-20 μ), presence of prominent pseudopodia, and sluggish

movement. The statistical analysis was performed by the Chi-square test (signification level 0.05) so as to study the correlation between the kind of oral disease, age and sex with the presence of parasite.

Results

Among the samples 33 (14.2% gingivitis) and 31 (40.2 % periodontitis) of those specimens were detected by wet preparation and Giemsa-stained smears. All the cases of oral trichomoniasis in control group were both

detected by direct smear. The infection rate among the patient with periodontitis and gingivitis was 40.2 % and 14.2 %, respectively (Table 1). There was a significant difference between two last groups [$P < 0.005$]. Oral trichomoniasis was prevalent at age ranged 31-40 yr, and in total males (24.7 %) than females (16.8 %) with no significant difference (Table 2, 3). *Entamoeba gingivalis*, the other oral protozoan, was found in 133 (42.9 %) distributed as 98(42.1%) in gingivitis patients and 35 (45.45 %) in periodontitis patients(Table 2).

Table(1): Prevalence of *Trichomonas tenax* according to type of oral diseases

Discussion

The prevalence of oral trichomoniasis in our study (20.6%) was compatible with many other published reports which mostly have ranged from 12%-32% (4,6,17,19,20,22).²¹ examined 700 patients with periodontitis and found a prevalence of 26.5%²².⁴ in France reported a prevalence of 28% among the 300 patients⁴. Mahdi in Iraq examined the saliva of 143 patients with poor oral hygiene and reported a prevalence of 8.4%¹¹, but further investigation showed that saliva was not a suitable media for detection of parasite⁸. In Iran 50 patients with periodontitis were examined by wet mount and 46% were found to be infected by *T. tenax* or *E. Gingivalis*¹⁶ but the prevalence of each parasite was not determined. In the most above- mentioned researchs, the methods for detection and identification of *T.tenax* from human oral samples have been based on conventional techniques, such as microscopic observation²² and cultivation²¹, which are poorly reliable in spite of being skill-requiring and time-consuming. Recently small ribosomal RNA (SrRNA) sequences or the corresponding genes have been utilized as targets for PCR³. Similar to our study,

Kikuta in Japan¹⁸ developed a PCR protocol for specific detection of *T. tenax* by using a pair of primers (PT3 and PT7 with nucleotide positions of 407 to 425 and 1164 to 1182, respectively). In his study 55.6% of patients were shown to carry *T. tenax* in subgingival- plaque but no parasites were observed by microscopic examination. Likewise, in present study, we were not able to detect *T. tenax*, using wet mount, in 9 cases that were positive by PCR. To find *T. tenax* in bronchoalveolar fluid, Mallat in France amplified the 5.8S rRNA gene. He suggested that the sequences of this gene presented the advantages of being present in multiple copies in the genome, even between very closely related species¹³. The occurrence of *T. tenax* was not correlated with the age in our study and this finding was not agree with some authors (4, 19,22) who found that the frequency of infection increased with age, while some were believed that oral protozoa were rarely found in children¹⁷. According to our experience, Ringer solution was better than normal saline for transportation and maintenance of samples. But¹⁰ recommended Safranin mixed with patient's saliva as fixative and emphasized that mishandling the plaque, use of different staining techniques, plaque other than

from the extreme base of the pocket, recent medication or hygiene and some types of food, did result in false negatives⁹. As in other reports^(10, 16,17,22) our results demonstrated a link between the presence of *T. tenax* and periodontitis in comparison with gingivitis and it seems that in each case, oral parasites were only found in diseased sites.

It is perhaps appropriate to note here that *T. tenax*, whilst seen less frequently than *E. Gingivalis* in patients with poor oral condition, but due to its role to produce pulmonary trichomoniasis, deserves much closer attention. Conclusively, with development of PCR for detection of *T. tenax*, we suggest an investigation to evaluate the pulmonary trichomoniasis in patients with cancer and chronic lung diseases.

Conclusion

The prevalence of oral *Trichomonas tenax* in our study (20.6%) and *Entamoeba gingivalis* was (42.9 %) was compatible with many other published reports which mostly has ranged from 12%-32%.The study revealed dependence between the frequency of occurrence of protozoa and the state of periodontitis.the age group (41-50)yr. Have high incidence of *T.tenax* compared with an other groups,as well as the males have high incidence(24.7 %) than females (16.8 %).

Iron Oxide Nanoparticles Induced Histological Alteration and Fetal Skeletal Abnormalities in the Embryo of Albino Rats

Reyim Hameid Kamel¹, Amel Ali AL-Tae²

¹Collage of Science, Babylon University, Iraq, ² Professor/Biology Dep., Collage of Science, Babylon University, Iraq

Abstract

The study was carried out to investigate the effect of iron oxide nanoparticle(NP) on the brain, liver, spleen and vertebral colum in the embryo of albino rats at the age of 19 day of pregnancy . The study included twenty (20) embryos divided into two groups ,treated and control group . The results of the histological study reveled the existence of histological alteration in the brain, liver, spleen and vertebral colum of treated groups compared with controls .

Keywords: *Histological Alteration, Fetal Skeletal, Abnormalities.*

Introduction

Nanotechnology is the mere controlling and invention of materials at nano scale level, where characteristics vary with different size, shape ,aggregation and surface area. This technological leads to a revolution in the field of electronics and communications, optics, chemistry, energy and biology ¹. Iron oxide nanoparticles(IONPs) have encouraging characteristics like biocompatibility and magnetic behavior that makes them perfect agents for magnetic resonance imaging, carriers for drug delivery, magnetic hyperthermia, tissue engineering, cell separation, enzyme immobilization, protein purification and biosensing ^(2,3). Moreover, IONPs offer significant improvements in water purification and environmental remediation because of low cost technology ⁴ . Iron and oxygen chemically combine to form iron oxides (compounds ⁵ . The general process of manufacturing nanoparticles include laser ablation, plasma synthesis, combustion, arc method, electrolysis, pyrolysis, diffusion flame synthesis, chemical precipitation and vapor deposition and mechanical processing, wet phase processing and high energy ball milling ⁶ .A recent study on mice reported size dependent bioaccumulation and transport of IONPs in the liver and spleen ⁷ . Pregnant mice treated with multiple doses of IONPs reported biodistribution of iron in the foetal liver, placenta and increased foetal deaths ⁸

Material and Method

This study was conducted in the studying of the effect of IONPs on the brain , liver, spleen and vertebral colum in the embryo of albino rats.

Animals: Thirty six healthy adult female albino rats weight (225±10gm), age (10-12)weeks were purchased from Iraqi Center for Drug Research/ Baghdad. All these animals were housed during the period of experiment in the animal house unit in science college of Babylon University, under controlled temperature (21 ± 1 C 0) and constant light-dark schedule (12 hours light and 12 hours dark cycle), food and water were available. The pregnant rats divided into tow groups:

Group1: administrated orally (150 mg/kg) of body Wight iron oxide NPs by gavage tube for 19 days of pregnancy.

Group2: administrated orally (1ml) distilled water by gavage tube for 19 days of pregnancy.

At 20 day of pregnancy the pregnant rats were killed and the embryo extracted for histological Alteration and Fetal Skeletal Abnormalities study.

Experimental Design:

Twenty embryos divided into two groups .

Group I: Control group (n=10).

Group 2: Treated group (n=10) .

Embryos Extraction and Reservation:

After dissecting pregnant females in the 20 days of pregnancy, the uterus horns were extracted which contain embryos. Then the embryonic membranes were removed surgically by fine surgical tools and dissection microscope and the embryos were taken and washed with normal saline (NaCl 0.9%) into a petri dish. The embryos were fixed directly by Aqueous Bouin's Fixative for 24 hours. After fixation, the embryos were washed several times by ethyl alcohol (ethanol) at concentration 70 % in order to remove the yellow color from embryos⁹ .

Histological Study:

After fixation, serial alcohol was used for dehydration of the tissue samples (brain, liver, spleen and embryo). Tissue specimens were cleared in xylene and embedded

in paraffin. The paraffin blocks were sectioned at 5 microns thickness by microtome. The obtained tissue sections were collected on the glass slides and stained by Hematoxyline and Eosin stain for histopathological examination by the light microscope¹⁰ .

.While the vertebral column of the embryo was prepared and stained by Alizarin stain according to⁹ .

Results

Histological study of the embryo

Histopathology of brain

The main histopathological changes of the brain sections show observed vacuolation and degeneration in the neuron cells with glial cells in the embryo at the age 19th day of pregnancy compared with control groups. Figure(1-1)

Figure(1-1): Cross section in the brain of the embryo.(A) showed sever Vocuolation in the nervous tissue(V) with astrocytes (astrocytosis)(A) (H&E 40X).(B) control group (control group) showed normal brain tissue with Normal neuron (N) . (H&E 10X)

Histopathology of liver

The main histopathological changes of the liver show degeneration of hepatocytes, hemorrhage in the hepatic tissue and infiltration of inflammatory cells and dilation of sinusoids compered with control groups. Figure (1-2)

Figure(1-2): Cross section of the liver of the embryo at age 19th day of pregnancy.(A) showed Degeneration of hepatocytes(D), hemorrhage in the hepatic tissue(H) and infiltration of inflammatory cells(M) and dilation of sinusoids(S) (H&E 40X).(B) (control group) showed normal hepatic architecture(R). (H&E 10X)

The histopathological changes of the spleen sections show depletion of white pulp and proliferation of red pulp with congestion of blood vessels in the lymphoid tissue compared with control group. Figure(1-3)

Figure(1-3): Cross section of the spleen in the embryo at 19th day of pregnancy (A) showed depletion of white pulp (W) and proliferation of red pulp with congestion of blood vessels in the lymphoid tissue (C) (H&E ,40X) .(B) (control group) showed proliferation of lymphocyte (L) and proliferation of red pulp(R). (H&E ,10X)

The histological change of skeletal malformation of embryo vertebral Column at the age 19th day of pregnancy show abnormalities in the vertebral column which include irregular and large vertebral with profuse calcification , colour compared with control groups.Figure(1-3)

Figure(1-4) :Cross section in the vertebral column of embryo at 19th day of embryo. (A) show irregular and large vertebral (V)with profuse calcification (CA).(B) (control group) show normal vertebrae (V) with normal proliferation of chondrocyte(CO) stain with Alizarin stain (10X).

Discussion

The cellular toxicity of iron oxide nanoparticle on organs were very clear in our study, NPs may cross the blood-brain barrier (BBB) and accumulate in the central nervous system (CNS), brain very important organs clinical signs in the animals its showed very hyper activity because the change in the brain tissue of treated embryo by iron oxide nanoparticle, the importance of the histological changes of the brain in the embryo the histological change of 19th day embryo include sever Vocuolation in the nervous tissue with astrocytes (astrocytosis) compered to the control groups. These results agree with anther study who recognized that iron oxide nanoparticles may induce damages to the neural tissues as results to accumulation of the iron oxide that induce the increases in levels of oxidative stress and ROS production that induce important roles in some critical diseases such as Alzheimer's and Parkinson's ¹¹. Anther study confirm that IONPs accumulation in tissues triggered ROS generation which significantly altered the antioxidant enzyme levels, the altered antioxidant status and bioaccumulation of IONPs caused histo morphological changes which demonstrate that increase in oxidative stress affects the cellular structure ¹².

The defect in liver tissue is very important and in the histopathological observation showed degeneration of hepatocytes, hemorrhage in the hepatic tissue and infiltration of inflammatory cells and dilation of sinusoids. Nanoparticles are initially reabsorbed by Kupffer cells, cell membranes will be damaged and toxic degradation products of iron oxide magnetic nanoparticles will be slowly imported to hepatocytes from macrophages ¹³. These findings are agreed with ⁴ who described damaging processes generated in the livers of rats after exposure to iron oxide nanoparticles. Another study referred that using of high concentration of iron oxide nanoparticles can caused undesirable effects in the liver with damage to the hepatocyte and elevation the level of liver enzymes, iron oxide nanoparticles (IONPs) can cause damaging in the liver-based presence of inflammation, congestion of the interstitial tissues, peri-central-vein-based fatty degeneration, and necrosis of hepatocytes ¹⁵.

Our study demonstration important change in the spleen, In embryo of 19th day reveled depletion of white pulpe and proliferation of red pulp with congestion of blood vessels in the lymphoid tissue. These results agree with ¹⁶ who found similar effects of the nanoparticles on the spleen of mice. Treatment with Fe₂O₃ caused series

effect in the spleen tissue include red pulp congestion and prominent white pulp in the treated rats ¹⁷.

For skeletal malformation changes, Our results inducted the presence of changes in the vertebral colum of rats embryos compared with control groups, these changes includes irregular and large vertebral with profuse calcification. Oral administration of iron oxide NPs caused some mild and severe defects in the skeletal formation (vertebral colum) in the developing fetuses. The current study indicated that the use of Alizarin Red-S was the best method to detect the osteogenesis in laboratory animals such rabbit fetus simulated that reported in mouse ¹⁸. Moreover the present result as well as that in mouse stated that the red color of the bones was due to the high affinity of the Alizarin Red-S to the calcium ions in the bones ¹⁹. In fact, there are some reports that show some nanoparticles can transfer through placenta and cause embryo toxicity, Iron oxide nanoparticles can accumulate in the sinusoids and hepatocytes of the fetus liver ^(20,21). This is in agreement with Bourrinet who mentioned that ferumoxtran-10 had major fetal skeletal malformations in both rabbits and rats ²². Tsay stated that bone loss has been detected after increased iron ions concentration in mice, Their results revealed dose-dependent elevation of iron content in tissue with bone composition alteration and thinning of trabecular and cortical bone accompanied by high bone resorption, this may be contributed to the increased reactive oxygen species (ROS) production ²³.

Conclusion

The study included twenty (20) embryos divided into two groups ,treated and control group . The results of the histological study reveled the existence of histological alteration in the brain, liver, spleen and vertebral colum of treated groups compared with controls .

Clinical Characteristics of Headache among a Sample of Iraqi Medical and Dental Students

Noor S. Mohammed Ali¹, Rasha Basim¹

¹Assistant Lecturer, department of oral diagnosis, College of Dentistry, University of Baghdad

Abstract

Background: Headache is a painful condition related to a major lack of productivity, limitation of social activities and impairment of quality of life.

Method: in this study a structured questionnaire was formulated in a form of multiple choices questions to gather information on the clinical characteristics, associated factors and the triggering factors along with the mode of treatment adopted by dental and medical undergraduate students of the University of Baghdad in the period from January to March 2019. Language of questionnaire was made simple and easily understandable to students. Students were assured of confidentiality and the participation was entirely voluntary.

Results: in this study a total number of 340 students participated, 170 of them were medical students 76(44.7%) males and 94(55.3%) females, and the other 170 were dental students 45(26%) males and 125(74%) females. It was found that 170 medical students had 161 associated symptoms with headache, the most common associated symptoms was scalp tenderness 44(25.9%), while the least common associated symptom was diarrhea 4(2.4%). While 170 dental students had 162 associated symptoms, the most common associated symptoms was scalp tenderness 46 (27.2%), while the least common associated symptom was seizures 2 (1.2%). 170 medical students expressed 385 triggering factors for causation of headache. It was found that the most common triggering factors was irregular sleep 118(69.4%). And 170 dental students expressed 437 triggering factors for causation of headache. It was found that the most common triggering factors was stress 136 (80.5%). In this study the percentage of medical students who taking self medications was 88.82% and 92.35% for dental students also it was found that both medical & dental students had the highest percentage for using Paracetamol as analgesic, 119(70%) for medical students, and 126(74.6%) for dental students.

Conclusions: the results of this study show that the majority of both medical and dental students suffer from headache with self medications used by the majority.

Key words: Headache, clinical characteristics, students

Introduction

Headache prevalence is 96%, with a female predominance. The global active prevalence of tension-type headache is approximately 40% and migraine 10%. Migraine occurs most commonly between the ages of 25 and 55 years and is 3 times more common in females^(1,2). Despite the fact that it causes significant disability, migraine remains under diagnosed and undertreated, trigeminal autonomic cephalgias are rare compared with migraine and tension-type headache. The most common trigeminal autonomic cephalgias is cluster headache, with

a population prevalence of 0.1% and a male/female ratio of 3.5-7:1^(3,4). Chronic daily headaches of long duration include chronic migraine, chronic tension-type headache. Hemicrania continua and new daily persistent headache, worldwide prevalence of chronic daily headache has been consistent at 3%-5% most of which likely represents chronic migraine¹. The International Classification of Headache Disorders (ICHD) was first published in 1988 and has now gone through two revisions, most recently in 2013. By convention, headache classification is based on the characteristics of the individual headache in the prior year, not the individual with the headache, though

features specific to individuals may be used in helping to differentiate between two close diagnostic matches. The ICHD is periodically reviewed and continues to evolve⁵. A primary headache has no known underlying cause. The most common primary headaches include migraine tension-type headache, and cluster headache⁶. Migraine is the third most prevalent disorder according to the Global Burden of Disease Survey and the seventh highest cause of disability worldwide⁷. Risk factors associated with transformation to chronic migraine include coexisting noncephalic sites of pain, mood and anxiety disorders, medication overuse, obesity, and lower educational status⁸. Tension-type headache is far more common, with lifetime prevalence in the general population of up to 80%. There is often a degree of associated disability, and this, combined with the high frequency produces significant socioeconomic impact². Tension-type headache is a dull, bilateral, mild- to moderate-intensity pressure-pain without striking associated features that may be categorized as infrequent, frequent or chronic and is easily distinguished from migraine. Although there may be a genetic element in the development of tension-type headache, environmental factors likely play a larger role than in migraine. Tenderness of pericranial muscles, co-existing mood disorders, and mechanical disorders of the spine and neck may be contributing factors⁹. Cluster headache, often referred to as “suicide headache” because the intensity of the pain, occurs more commonly in men and is usually episodic, characterized by “clusters” of from 2 weeks to 3 months. The pain is extremely severe, with 1 to 8 episodes per day, often awakening the patient from sleep shortly after falling asleep. Features are stereotyped with attacks of severe unilateral orbital pain lasting 15 minutes to hours, usually associated with ipsilateral autonomic symptoms increased lacrimation, nasal congestion/discharge, partial Horner’s and producing a characteristic restlessness^{3, 4}. The aim of this study is to evaluate the prevalence, clinical characteristic, and the use of self-medication of headache among a sample of Iraqi medical and dental students in the University of Baghdad.

Subjects, materials and methods:

Subjects: Total of 513 structured questionnaires were distributed to the 5th class which were (195) undergraduated dental students, and 6th class which were (318) undergraduate medical students. The questionnaires were distributed through the class, in the period from January to March of the year 2019.

Questionnaire: a formulated questionnaire in a form of multiple choice questions was structured to gather information on the prevalence of headache, clinical characteristics, associated symptoms and the triggering factors along with the mode of treatment adopted by dental & medical undergraduate students of the university of Baghdad. Language of questionnaire was made simple and easily understandable to students. Students were assured of confidentiality and the participation was entirely voluntary¹⁰. Severity of headache was assessed by Numeric Rating Scale (NRS). Headache was graded as mild, moderate and severe as per the numerical value marked from 0-10 on NRS by each participant¹¹.

Statistical Analysis: Statistical analysis were performed by the SPSS software version 18.0 (SPSS Inc, Chicago, IL). Results are expressed as mean SD, percentage; Fisher exact and Chi square were used to assess the significance of any differences between the two groups. The statistical significance was set at $p < 0.05$ as significant and $p < 0.001$ as highly significant.

Results

Total of 513 structured questionnaires were distributed to the 5th, and 6th years of undergraduate dental and medical students respectively in Baghdad university.

The total number of the students whom participated in this study were (340) students, for medical students information was provided by only 170 students from total 318 students (53.45%) which were 76 (44.7%) males and 94 (55.3%) females, with mean age = 23.36 ± 0.497 . And for dental students: information was gathered from 170 students from total 195 students (87.17%) which were 45 (26%) males and 125 (74%) females, with mean age = 22.42 ± 0.496 , with females predominance (64.41%) while males were (35.59%). Headache experienced by majority of medical students was frontal 67 (39.4%), dull pressing 80 (47.1%) with moderate intensity 75 (44.1%), duration < 4 hours 119 (70%) and 85 (50.3%) had no impairment of routine activity, 74 (44%) of medical student had family history of headache. While in dental students Headache experienced by majority of dental students was bilateral 64 (37.9%), Pulsatile (throbbing) 83 (49.1%), moderate intensity 91 (53.8%), duration > 4 hours 98 (58%) with no impairment of routine activity 91 (53.8%) and 72 (39.9%) of dental student had family history of headache (Table 1).

Table 1: Headache characteristics of medical & dental students

Characteristics	Number of medical students (%) N=170	Number of dental student (%) N=170
Headache side		
• Unilateral	53(31.2%)	48(27.8%)
• Bilateral	50(29.4%)	64(37.9%)
• Frontal	67(39.4%)	58(34.3%)
Quality		
• Pulsatile (throbbing)	62(36.5%)	83(49.1%)
• Dull pressing	80(47.1%)	78(46.2%)
• Sharp stabbing	28(16.5%)	9(4.7%)
Headache intensity		
• Mild	72(42.4%)	67(39.6%)
• Moderate	75(44.1%)	91(53.8%)
• Sever	23(13.5%)	12(6.5%)
Duration		
• >4 hours	51(30%)	98(58%)
• <4 hours	119(70%)	72(42%)
Impairment of routine activity		
• Complete impairment	17(10%)	7(3.6%)
• Incomplete impairment	68(40%)	72(42.6%)
• No impairment	85(50.3%)	91(53.8%)
Family history		
• Yes	74(44%)	72(39.9%)
• No	96(56%)	98(60.16%)

170 medical students experienced 161 associated symptoms, the most common associated symptoms was scalp tenderness [n=44 (25.9%)], followed by nausea/vomiting, photophobia, vertigo, diplopia and paresthesia, while the least common associated symptoms was diarrhea [n=4 (2.4%)]. While 170 dental students experienced 162 associated symptoms, the most common associated symptoms was scalp tenderness [n=46 (27.2%)], followed by photophobia, nausea/vomiting, vertigo, diplopia and paresthesia, while the least common associated symptoms was seizures [n=2 (1.2%)]. In this study it was found that there is significant difference between the two groups regarding to nausea/vomiting and photophobia as the p value equals to 0.03 as shown in (Table 2).

Table 2: associated symptoms with headache

associated symptoms	Medical students N (%)	Dental students N (%)	P value
Nausea\vomiting	41(24%)	25(14.8%)	0.03*
Scalp tenderness	44(25.9%)	46(27.2%)	0.78
Vertigo	25(14.7%)	26(15.4%)	0.86
Photophobia	28(16.5%)	44(26%)	0.03*
Diplopia	10(5.9%)	7(4.1%)	0.46
Seizures	0(0%)	2(1.2%)	0.155
Paresthesia	9(5.3%)	5(3%)	0.28
Diarrhea	4(2.4%)	5(3%)	0.73
Other	0(0%)	2(1.2%)	0.155
No symptoms	66(38.8%)	59(34.9%)	0.46

* significant p<0.05

In this study 170 medical students expressed 385 triggering factors for causation of headache. It was found that the most common triggering factors was irregular sleep [n=118(69.4%)] & stress [n=105(61.8%)], followed by exertion [n=71(41.8%)], flashing lights[n=31(18.2%)], hunger [n=30(17.6%)], weather changes [n=23(13.5%)], menstruation, specific smells, specific food [n=11(6.5%)], while 170 dental students expressed 437 triggering factors for causation of headache. It was found that the most common

triggering factors was stress [n=136(80.5%) & irregular sleep[n=105(62.1%)] which is a similar result to what we had with the medical students group, followed by hunger [n=57(33.7%)], exertion [n=30(17.8%)], flashing lights [n=29(17.2%)], weather changes [n=29(17.2%)], menstruation[n=18(10.7%)], specific smells[n=15(8.9%)], specific food [n=10(5.9%)], in this study there was high significance regarding to stress/exertion / hunger, as the p value was equal to 0.0002/0.0000/0.0007 respectively Table 3.

Table 3: triggering factors for headache

Triggering factors	Medical students N (%)	Dental students N (%)	p. value
Stress	105(61.8%)	136(80.5%)	0.0002 **
Flashing lights	31(18.2%)	29(17.2%)	0.7953
Specific smell	11(6.5%)	15(8.9%)	0.32
Specific food	11(6.5%)	10(5.9%)	0.83
Weather changes	23(13.5%)	29(17.2%)	0.35
Exertion	71(41.8%)	30(17.8%)	0.0000 **
Irregular sleep	118(69.4%)	105(62.1%)	0.16
Hunger	30(17.6%)	57(33.7%)	0.0007 **
Menstruation	11(6.5%)	18(10.7%)	0.17
Other	1(0.6%)	4(2.4%)	0.17
Nothing	1(0.6%)	3(1.8%)	0.31
** highly significant p<0.001			

In this study the percentage of medical students who taking self medications was 88.82% and 92.35% for dental students also it was found that both medical & dental students had the highest percentage for using Paracetamol as analgesic, 119(70%) for medical students, and 126(74.6%) for dental students (Table 4).

Table 4: Medications used by medical and dental students

Medications	Medical students N(%)	Dental students N(%)
Paracetamol	119 (70%)	126 (74.6%)
Paracetamol+ibuprofen	20 (11.8%)	20 (11.8%)
Paracetamol+propyphenazone	4 (2.4%)	3 (1.8%)
Aspirin	7 (4.1%)	0 (0%)
Diclofenac	3 (1.8%)	4 (2.4%)
Migranil	1 (0.6%)	4 (2.4%)
other	48 (28%)	20 (11.8%)

Discussion

In this study it was shown that high prevalence of headache among both medical and dental students and this agree with previous studies ^(10, 12); with female predominance and this agree with other studies that demonstrated high prevalence in females ^(10,13).

In this study the prevalence of positive family history was 42.9%, in other previous studies like Oman study reflect 58% of students ¹⁴ while in an Indian study only 20.16% of students had positive family history ¹⁰.

The most common associated symptoms in this study was scalp tenderness for both groups, while the most triggering factors for the causation of headache were stress and irregular sleep and this agrees with other study that found similar results ¹⁰. It is being widely reported that medical students undergo major stress. Causes for the same are varied, from their interpersonal problems to their course overload to uncertainties of future career prospects, in this study dental students had shown high level of stress than medical students and that in concordance with other study ¹⁵. In this study the percentage of medical students who taking self medications was 88.82% and 92.35% for dental students and this can be reasonably explained by the fact that being in medical profession, students possess theoretical knowledge about the medications, for this reason they prefer to seek self medications using over the counter drugs ¹⁰. The most self medications used by both groups was paracetamol due to be a simple analgesic and reachable.

Conclusion

In this study the results showed that both medical and dental students had high prevalence of headache and scalp tenderness was the most associated symptoms with headache for both groups, stress and hunger most significant triggering factors for causation of headache among dental students, while exertion was most significant among medical students. The majority of both medical and dental students used self medications for treating headache. The improvement of the academic performance of the students needs the precise diagnosis and proper treatment for headache among them.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the department of oral diagnosis, College of Dentistry, University of Baghdad and all experiments were carried out in accordance with approved guidelines.

Antioxidants Activity of Date Seed Extraction of Some Date Varieties

Nareeman Adheem Shnaa Al Ghezi¹, Aum El-Basher H. J. Al-Mossawi¹, Ali Khudhair Jaber Al-Rikabi¹

¹ Department of Food Technology, College of Agriculture, University of Basrah , Basrah, Iraq

Abstract

The study included preparing aqueous , alcoholic, and oil extractions of date seed power of (*Phoenix dactylifera*) Al Hillawi, Al Khadrawi and Al ZAHDY date varieties estimating its total contents of phenol and flavonoids, and then it is studied its antioxidants activity, reduction strength and ability to bon Ferrous ion. The results showed that total contents of phenolic compounds are ranged from 56.16 to 67.32 mg/ml for the ethanol extraction, 56.6 to 65.6 to 65.32 mg/ml for methanolic extract and 27.88 to 40.06 mg/ml for aqueous extraction. While the total contents of flavonoids of aqueous extract is ranged from 22.12. to 33.32 mg/ml, 40.21 to 52.16 mg/ml in the ethanolic extract and from 35.11 to 46.16 mg/ml in the methanol extraction. Indeed, aqueous and alcoholic extract of (*Phoenix dactylifera*) Al Hillawi, AlKhadrawai and Al Zahdy give Antioxidation activity are ranged from 37.50% to 88.70%, reduction strength is ranged from 0.895 to 2.63 and the value of Ferrous ion bon is ranged from 41.92% to 60.93%.

Keywords: Date seed, antioxidants and phenolic compounds

Introduction

Dates seeds are deemed of the most important waste of date industry representing very important economical resources and at same time may cause environmental problem if it is accumulated considerably in the nature²². The new studies reported that dates seeds have high level of phenolic compounds, Flavonoids, antioxidants, Dietary fibers higher than those are reported in flesh part. there are high levels of α -Tocopherol, Ascorbic acid and Glutathione and of polyphenol compounds such as Sinapic acid , Caffeic acid with quantities of protocatechnic acid¹¹, also it is diagnosed multi-aromatic in dates seeds includes alcohols, citrates, aldehydes, Ketones, saturated and unsaturated hydrocarbonates¹⁵. The study discussed Phenolic , Flavonoids contents and Antioxidant of date seed extracts, it is also observed that Dietary fiber extracted from date seed are Polyphenoles-riche¹⁹.⁹ suggested that the date seed contents in Phenolic compounds are ranged from 21.0 to 62.0 mg Gallic acid/100g . In addition to studies that was made to extract oil from date seed and use it in food, Pharmaceutical, Plastic industries¹⁰. Whereas date seed is rich source of important components such as oil, protein, dietary fibre, carbohydrate are deemed source of phenolic compounds and antioxidants; and to exploit these materials which respecting a valuable by-

product of date fruit processing industries and there was no local study approach this matter in detail; therefore, we found that it is necessary to perform this study to extract bioactive compounds from date seed powder and to estimate of Phenolic and Flavonoids compounds and their antioxidant activity.

Method and Materials

(*Phoenix dactylifera*) Halawi , Khadrawi , Zahdi date seed were obtained from Local market , Basrah . Separate seed from date , then their wishes , drier and milling to smooth powder then care in sterilize and close cups to uses then .

2-Preparation of Date seeds Extract s

A- Aqueous Extract

By applying method of¹⁴, be weighed 20g from date seed powder and their add 500ml of distilled aqueous , drop out in Shaking incubator for 24 hours at 28C° then centrifuged at 2500 Round/min for ten minutes , then filtration by Whitman No1, concentrated of filtrate by Rotary Vacuum Evaporator to thick liquid then placed in incubator at 37C° for 48 hours get at dry powder of extract , take care in showdown and obscured glasses package and cured in refrigerator at 4C°.

B- Ethanolic Extract

Ethanolic extract were prepared by weighting 100g of date seed powder dissolved in 500ml ethanol (98%) and mixed well , left for 24hours at laboratory temperature (25-30C°), filtration by Whatman No1 , concentrated by Rotary Vacuum Evaporator at 40C°and left at laboratory temperature to get at dry powder , take care in showdown and obscured glasses package and cured in refrigerator at 4C°⁸. .

C- Methanolic Extract

Two steps applied in paragraph A to extract Methanolic date seed powder.

D- Oil Extracts

It is extracted date seed oil from seed powder to study variety according to ⁵ using mixture of aqueous , methanol and chloroform solvents.

Determination of total phenols*

It is estimated total phenolic compounds in date seed extracts by using (Folin –Ciocalteu) received in ²¹, and uses Standard curve from Gallic acid in concentration between 10 to 200 mg/ml to calculating phenolic amount in extracts depending the scatter graph between acid concentration and absorption at 760 nanometer .

Fig 1: Standard curve of Gallic acid

*** Determination of total Flavonoids**

It was solved of 1gm from date seed extract in 1.5 ml ethanol, add it Aluminium chloride AlCl₃.6H₂O (2%) this perpetrated in 100ml methanol , mixed well, after 10 minutes calculate Absorption at 367 nanometer, and preparation to concentration of Flavonoid compound (Rutin) from 0 to 100 mg/ml, then determination of Flavonoids depending on correlation between concentration of rutin standard solution and Absorption at 415 nm.

.Fig 2: Standard curve of Rutin

Antioxidant activity

1-Scavenging of free radical ability

it is assessed ability to date seed extracts for scavenging of free radical according to ¹⁷, and used the equation for calculate activity:

$$\text{Scavenging of free radical \%} = \left[1 - \frac{\text{Sample absorption}}{\text{Control absorption}} \right] \times 100$$

2-Reducing power

It is applied the method by ¹³, the increase of absorption to mixture interaction it was indicator stating high reduction power.

3-Chelating of ferrous ion

Followed the method Decker and Welch (1990), calculated of chelating ability by next equation :

$$\text{Chelating of ferrous ion \%} = \left[1 - \frac{\text{Sample absorption}}{\text{Control absorption}} \right] \times 100$$

Results and Discussion

1-Total Phenolic Content

Results of the total phenolic compounds on Halawi, Khadrawi, Zahdi date seed is presented in Figure 6 below, the result of Statically analysis showed presence Significant differences (P<0.05) in phenolic contents by difference solvent extracts and seed source, Alcoholic extracts (Ethanolic and Methanolic) exhibited the highest content of phenolic compound compared with aqueous extracts .

Fig 3: Total phenolic content of date seed extracts

The results is in agreement with ⁶ and ¹⁸ as it is found that e phenolic content in aqueous extract lower than ethanolic date seed extract, and the Statically analytic showed Significantly affected ($P < 0.05$), the higher content of phenolics in Zahdi date seed that all extracts reach 67.32 , 65.32 , 40.06 mg/ml for ethanolic , methanolic, aqueous respectively, and then Khadrawi 60.11 , 62.33 , 33.34 mg/ml for 3 extracts respectively and the lower content of phenolic compound was Halawi date seed 56.16 , 52.11 , 27.88 mg/ml respectively, as it is agreed with same results of ⁶.

2-Total Flavonoids content

Figure 7 clarified Flavonoids content in date seed extracts as the result showed that there is important differences between aqueous and alcoholic extracts ($P < 0.05$), ethanolic extract of Zahdi seed excellence in Flavonoids reach to 52.16 mg/ml and ethanolic extract of Khadrawi 50.11 mg/ml then ethanolic extract of Halawi seed 40.21 mg/ml , followed methanolic extracts , Halawi extract was the lowest in flavonoids 35.01 mg/ml , then Khadrawi 40.83 mg/ml and methanolic extract of Zahdi reach to 46.16 mg/ml , then aqueous extracts 22.12, 27.00 , 33.32 mg/ml of Halawi ,Khadrawi , Zahdi date seed respectively, the central reason in differences of Flavonoids return to growth condition, maturity stage,

geographic location , manuring method , soil disease types, storage conditions and extracts system ⁴ . .

Fig 4: Total Flavonoids content of date seed extracts

Antioxidant activity of date seed extract

It is determined antioxidant activity by measure of date seed ability to free radical scavenging by uses(DPPH reagent) Diphenyl-1-Picrylhydrazyl compared to(BHT) Butylated Hydroxy Toluene , explain to Figure 8 A,B,C , the result of Statical analysis showed Significantly differences ($P < 0.05$) of antioxidant activity to extracts as difference of seed source , and there were noticed the antioxidant activity increasing when concentration increased for all extracts , As Halawi

date seed (A) the methanolic extract showed the higher antioxidant 83.20% at 1.25 mg lml , when antioxidant activity of BHT 88% as the same concentration , then oil extract of antioxidant activity reach to 83.10% and ethanolic extract 61.2% , while the aqueous extract reach to 37.5% as the same concentration. The antioxidant activity of Halawi date seed differs at solvent extract of differences , it was posses the highest of scavenging of free radical DPPH compared to BHT , this due to presence bioactive compounds these posses antioxidant activity

to responsible to termination oxidation reaction by presence hydroxyl group donate hydrogen and reaction with free radical their convert to stable products, and the result is shown in Figure B antioxidant activity (DPPH) to Kadrawi date seed extracts, when ethanolic extract give a higher activity than methanolic, oil and aqueous reach 88% at concentration 1.25mg/ml it was equal BHT activity 88%, these results is in agreement with¹² when they found ethanolic extract of date seed give a higher antioxidant when uses DPPH radical as compared with aqueous extract, that return to a high content of phenolic compound and flavonoids which posses scavenging free radical due to presence hydroxyl group which donate electron to free radical, then oil extract of Khadrawi seed reach 85.2% and methanol extract 85%, while aqueous extract of Khadrawi seed gives the lowest antioxidant reach 42.4% as the same concentration because of a little content of phenolic compounds due to a limit ability of water to extract phenolics 162g/kg and flavonoids 17 g/kg from date seed due to a low solubility to these compounds in water², in addition of the uses of water alone induce to extraction other compounds such as protein, polysaccharides and induce to appearance inclusions through filtration and hardness to disposed³.

Reducing power

The result of statical analytic showed height significantly ($P < 0.05$) in reducing power values as increasing of extracts concentration to all types of seed, in Figure A4 Halawi date seed gives clear reducing power compared with α -tocopherol which reach to 2.689, and noticed the methanolic extract appear the higher reducing power compared with other extracts through Absorbance values when increase Absorbance that mean a higher reducing power reach to 0.864 for methanolic extract as concentration 0.25 mg/ml and increase when concentration increasing reach to 2.527 at 1.25mg/ml, while ethanolic extract reach to 0.4, 0.7, 1.09, 1.513 and 1.733 at concentrations 0.25, 0.5, 0.75, 1 and 1.25mg/ml respectively when reducing power reach to 0.762, 0.822, 0.94, 1.223 and 1.552 for oil extract at concentration 0.25, 0.5, 0.75, 1, 1.25 mg/ml respectively. were aqueous extract appeared the lowest reducing power ranged from 0.362 to 0.895 when concentration increase from 0.25 to 1.25 mg/ml. Also, the result showed in Figure 9 B reducing power of Khadrawi date seed, ethanolic extract appeared the higher reducing power compared with methanolic, oil and aqueous reach to 2.650, while reducing power for other extract reach to 0.8, 1.223, 1.534, 1.923 and 2.223

for methanolic extract at concentration 0.25, 0.5, 0.75, 1, 1.25 mg/ml, and 0.223, 0.433, 0.622, 0.792 and 0.834 for aqueous extract and 0.752, 0.866, 0.993, 1.523 and 1.690 for oil extract as the same concentration, in Figure C noticed reducing power for ethanolic extract of Zahdi date seed 2.632 equal reducing power α -tocopherol at concentration 1.25 mg/ml followed methanolic extract reach to 2.342 then oil extract reach to 0.821, 0.892, 1.003, 1.45, 1.732 at concentration 0.25, 0.5, 0.75, 1, 1.25 mg/ml, and that were the lowest reducing power for aqueous extract reach to 0.432, 0.634, 0.793, 0.875 and 0.993 at concentration 0.25, 0.5, 0.75, 1 and 1.25 mg/ml.

Chelating of ferrous ion

The percentage of date seed extracts ability to chelating of ferrous ion compared with Ethylene Di-amine Tetra acetic acid Di-sodium, the statical analytic showed significantly differences ($P < 0.05$) among prepared extracts of chelating ability, in Figure A that the higher ability to chelating of ferrous ion were ethanolic and oil of Halawi date seed reach to 53.56% and 51.22% at concentration 1.25 mg/ml respectively then methanolic extract and aqueous extract, while Khadrawi date seed (B) the ethanolic extract appeared a higher chelating than previous extract 59.32% and lower than ethanolic extract of Zahdi date seed 60.93% at concentration 1.25mg/ml, while oil extract reach to 56.00% for Khadrawi, followed methanolic extract that appeared chelating ability reach to 48.03% then aqueous 42.97%, also ethanolic and methanolic of Zahdi date seed appeared chelating ability (C) a highest compared with previous two types reach to 60.93% at concentration 1.25% followed oil extract 52.75% then methanolic extract 52.23%, this values were less compared with EDTA-2Na reach to 92.00%, while aqueous extract appeared less ability 41.92% at concentration 1.25mg/ml, this results agree with¹² were found that aqueous extract chelating ability was less than ethanolic extract at concentration 20% and the chelating of ferrous ion return to phenolic compounds that a manner role of chelating ions that oxidation catalyst such as iron and copper¹⁶.

Conclusion

Capability to benefit from date manufacturer by product to produce natural antioxidant alternative to artificial antioxidant that highly effective side. Alcoholic extracts give the higher of phenolic and flavonoids content than aqueous extract. Alcoholic extracts posses

the higher antioxidant than aqueous extracts while the antioxidant of oil extracts higher than aqueous extracts

Unemployment and Its Role in Increasing Crime Rates within the Iraqi Society

Ammar Ghali Abdulkadhim El-Eisawy

Faculty Member, Faculty of Law, University of Babylon

Abstract

Unemployment is a complex problem whose dimensions and effects are not confined to the economic aspect solely, but also extend to the political, social, cultural and security aspects. It has great consequences, the first of which is crime and the increase of its rates. Perhaps there is a big difference between the developing communities that are still suffering from economic crises and instability in most fields of life, and suffer from chronic unemployment, which almost takes the form of the heavy legacy passed down from one generation to the next and the developed communities that are thinking of the need to exploit leisure time ideally through the creation of more future job opportunities and the importance of providing generous pensions for aged groups, not to mention the development of service sectors, especially health services and increasing the percentage of those covered by health care and health insurance services. Perhaps the difference between these and those is the attraction factor of security stability, which is the most effective tool for crime prevention and control, rather than the huge money spent by developing communities in building and arming the security

Keywords: *Unemployment, Crime Rates, Iraqi Society*

Introduction

Criminologists explain to us that criminal conduct is the result of two types of factors: the first of which is known as internal (personal) factors ¹. This means everything related to the individual criminal himself, such as biological factors like genetics, physical, mental and psychological construction, and they eventually conclude that there are people that are naturally more prepared to commit the crime compared to others without denying the possibility of committing crimes by others, who do not have the of criminal predisposing factors ². The other type of crime-producing factors in communities are (environmental) external factors, which mean the external pressures to which the individual is exposed ³, which ends up drawing him to commit the crime, and as far as the topic in question is concerned, these factors are going to be the focus of such research to the extent to which they are related to the issue of unemployment and its role in increasing the crime rate in communities in general and in the Iraqi society in particular.

2- The external environment factors are varied, and each of them has a role in the crime and who commits it. We can mention, for example, the following factors:

- Physical environment factor, which means living conditions in terms of housing, daily activities and population density.
- The political environment factor, which means the political conditions of the society in which he lives in terms of the type of government, how it deals with citizens, the amount of freedom enjoyed by the individual, the duties inflicted thereupon, and the amount of authority and control of public life.
- Cultural environment, which means community culture as if the community were tribal, liberal, civil, or Islamic.
- The social environment, which means the family institution, the educational institution, and the media foundation.
- Economic environment which means the economic conditions, unemployment rates and living standards, This is the essence of the study under consideration as far as the crime is concerned.

3- We find through study and research that crime and delinquency in general are significantly associated with the economic environment. Unemployment comes at the forefront of the economic effects that affect the individual and his conduct. you can find in an unemployed person nothing but a negative personality, pervaded by despair and frustration, lost personal balance in terms of relationship with the community in which he lives, and hence comes the risk if this person is drawn to deviation and crime.

Methodology

1- Analytical approach to identify the explicit positions of criminologists, economists and specialists in studying the phenomenon in question and linking it to the reality of Iraqi society, and to reveal the negative aspects of this phenomenon and identify the faults related thereto.

2- The objective approach in studying the phenomenon by recognizing and identifying it as a reality that imposes itself on the developing communities in general and the Iraqi society in particular, while moving away from the personal and subjective tendencies in order to reach the abstract real knowledge of the research problem.

Study Objectives

This study aims to ascertain whether there is an inevitable correlation between unemployment on the one hand and crime on the other, identifying the forms of crimes in which the correlation with unemployment is deeper and greater than others, giving them statistical significance based on the evidences and past experience that are clearly unambiguous or skeptical in Iraq at the very least.

Study Plan:

The research treatment of the subject under study takes place on two topics, the first of which addresses what unemployment is in general in two themes. The first theme introduces the definition of unemployment, and this theme comes in two sections, the first of which deals with the linguistic definition of unemployment, while the second section introduces its conventional definition. The second theme includes the types and causes of unemployment, and this theme comes in two sections, the first of which deals with the types of unemployment, while the second section introduces its causes. The

majority of applicant currently lack the qualifications that enable them to compete for vacant positions because of the incompatibility of their qualifications and experiences with the high ceiling of qualifications in the labor market, which ends with increased unemployment and the delay, if not to say failure, of many applicants to get jobs. The previously above mentioned is simply the general meaning of unemployment in its modern sense, even if the term “unemployment” contains many details and interventions, which in turn leads us to delve into the linguistic and conventional definition of the term “unemployment” as follows.

The Linguistic Definition of Unemployment:

Unemployment is derived from the infinitive form “employ”. Disguised unemployment means: The surplus number of employees in governmental bodies and departments, and the day of unemployment means: any day off, while the unemployment rate is: (Economy) the economic measurement in which the people that are unemployed, capable of working, want to work are represented compared to the already employed population in a certain community. Unemployment as the noun of “unemployed” refers to a person that has been unemployed for one month or more, who does not have a job and do not work.

Types and causes of unemployment

There are many forms of unemployment by reference to its causes. Economic studies have depicted multiple forms of unemployment, and this is what this research is going to introduce in the followings two sections.

Types of unemployment

1- Regular (cyclical) unemployment: - It means unemployment that appears in the cases in which markets suffer from recession and poor performance, despite the availability of job vacancies, but in most of the cases, the job itself is not beneficial, such as workers⁴ who quit their jobs or are dismissed from work, and fail to get another job. This type also includes young people, women who work from their homes and their work involve just simple tasks that can hardly be called jobs or work in the true sense of the work.

2- Temporary unemployment: by which people work for temporary periods such as seasons while they remain unemployed for the rest of the year, and this is often found in rural areas with regard to the work of

agriculture and livestock, as well as for the classes of students who work during the summer holiday.

3- Partial unemployment:- In which individuals work for a number of hours less than the regularly known working hours or work in part-time jobs. Therefore, there is an ⁵ abundance of labour force available compared to the actual employment rate.

4- Frictional unemployment: - it refers to the movement of workers between professions and regions along with the lack of stability in the amount of labour force, where there is no match between the labour force and job opportunities available in one region and another because of the ill- considered professional mobility due to the lack of information available to job seekers on the one hand and employers on the other hand.

Crime and Unemployment

The crime is one of the remnants of poverty and unemployment, and whatever its type, size and gravity is, crime remains a dangerous phenomenon that threatens the humanitarian community. It has a serious negative impact, either on individuals ⁶, communities or on the economy as a whole, since it is considered the scourge that kills economic and human resources.

Crimes related to Unemployment in Iraq

First: Terrorism Crimes: The positive economic factor plays an important role in creating the appropriate environment for the elimination of terrorism. On the contrary, stagnation and unemployment are a suitable environment for the maturity and spread of terrorism. It is natural that when the individual is able to fulfil his needs and ⁷ satisfy his family needs, this can ensure that he will be satisfied with the community in which he lives and feel stable and secure.

Second: Drugs Crimes: Drugs trafficking is considered one of the highways for quick and substantial financial gain. it is almost the most attractive element for the unemployed, where they find an opportunity to provide them with ⁸ enough money to meet their needs, forgetting or ignoring the great risk they are exposed to as a result of such trafficking.

Third: Organs Trafficking Crimes: There is no doubt that poverty, the need for money and the lack of job opportunities that can provide it are the reasons behind this crime. In an official report issued by the British website ?????, it was stated that unemployment

and poverty alone are the reason behind this crime, which made Iraq the hub of human organs trafficking. It is worth mentioning that the Iraqi legislator addressed the ⁹ crime of human organs trafficking by several laws dealing with different forms of human organs that can be traded, its owners can be exploited or that can be taken by force, including law no. (60) of the year 1981 which prohibits human kidneys trafficking, law no. 113 of the year 1970, which prohibits human eyes trafficking. We also refer here to the Minors' Welfare law no. (78) of the year 1980, which includes the protection of minors from any form of exploitation and the Juvenile Welfare Act no. (76) of the year 1983, providing for the protection of juveniles from all forms of exploitation. I cannot fail to mention the provisions of Article (37) of the Iraqi Constitution of the year 2005, which prohibits the trafficking of forced labour, slavery, slave trade, trafficking in women or children, and sex trade.

Conclusion

Unemployment is a negative social and economic phenomenon, from which suffer all communities of different political and economic aspects, regardless of the extent of their progress or regress in keeping pace with modernity and development, although the percentage is quite different between the problem in developing countries and in developed countries. However, the specter of this problem remains existent in both cases, and this is the crux and gravity of the problem. The analysis and study of the problem of unemployment is not limited to the importance of human resources and the fact that it occupies an important place, but is also due to the important fact that human capital is the basis of development, in addition to the danger posed by the continuous increase in the number of unemployed and the subsequent complications thereof in the social and political consequences that accompany the situation of unemployment, where unemployment represents the fertile environment conducive for the expansion of crime, extremism, violence and terrorism. The lack of income, which is synonymous with unemployment, leads to a drop in the standard of living and an increase in poverty along with the accompanying deterioration in the humanitarian situation, which are one of the most encouraging factors of delinquency and crime in the future. Unemployment has its causes, which are almost common and similar wherever it occurs, whether in developed or developing countries. The issue of unemployment in Iraq is one of the thorniest and most complicated issues, as its rates continue to rise due to

the large changes in the economic structure of Iraq and the inability of the state to retrench its increasing expenditures. Despite the importance and gravity of this large problem facing Iraq and the Iraqi people, there are no official statistics until now concerning such problem. The aggravation of unemployment and its negative impact on Iraqi society are due to a number of reasons related to the nature of Iraq and the rapid events it has experienced.

Conclusion

Perhaps there is a big difference between the developing communities that are still suffering from economic crises and instability in most fields of life, and suffer from chronic unemployment, which almost takes the form of the heavy legacy passed down from one generation to the next and the developed communities that are thinking of the need to exploit leisure time ideally through the creation of more future job opportunities and the importance of providing generous pensions for aged groups, not to mention the development of service sectors, especially health services and increasing the percentage of those covered by health care and health insurance services. Perhaps the difference between these and those is the attraction factor of security stability, which is the most effective tool for crime prevention and control, rather than the huge money spent by developing communities in building and arming the security and police services and ultimately stand unable to put an end to the growing crime rates day after another.

Treatment of Congenital Capillary Hemangioma: Review of 30 Cases in Nasiriyah (2013-2018)

Ahmed Abdulhussein Kawen¹, Ahmed Abdulameer Daffar²

¹ Department of Dermatology, ²Department of Surgery, College of Medicine / University of Thi-Qar, Iraq

Abstract

The study is designed to identify the peak age of incidence of hemangioma and the most common site of involvement, presentation, different types, types of surgical procedures and the perioperative complications as well as the variation of sizes in hemangiomas. A retrospective study was done on a sample size of (30) persons. They were selected from Al_Hussein teaching hospital in Nasiriyah between (2013-2018) which included 13 males and 17 females starting from age of less than 6 months til the age of more than 3 years. The peak incidence was in those aged more than 6 months and up to three years (66%). The most common place involved being the trunk (50%), then the lower limb (16%), upper limb (16%), the the face and neck (16%). The most common presentation was increment in size in 50% of patients, recurrent ulceration in 20% and recurrent bleeding in 16% of patients. The patients in the study had three types: capillary hemangioma (66%), cavernous hemangioma (20%) and combined hemangioma (14%). The size of hemangioma varied from smaller than 5 cm (33%), 5-10 cm (33%) and larger than 10 cm (33%).

Key Words: capillary Hemangioma, surgical treatment , Nasiriyah

Introduction

A **hemangioma**, its most common vascular tumor regarded as benign tumors of infancy and it has been reported in 5–10% of the infants.⁽¹⁻³⁾, may be appear post infancy in rare conditions .this vascular tumor it contain an abundant type of endothelial cells covering the vessels wall of human .⁴The female, premature and low birth weight infants are frequently affected by such tumor .^(5,6) they usually seen during early weeks of life

and began to increasing in size abruptly with in the early three to six months after delivery.⁽⁷⁻¹⁰⁾ In good number of cases of this vascular tumor , 80% of its size is generally completed by third months.¹¹ Most of the cases, targeting its growth with stage of involution at one year of life. meanwhile, the growth can be occurred over many years and large number of tumor regression happened by five years.^(12,13) though this lesion disappeared naturally with time, few of them can precipitate and causing stigma of lax skin, small dilated vessel , or color remnants.

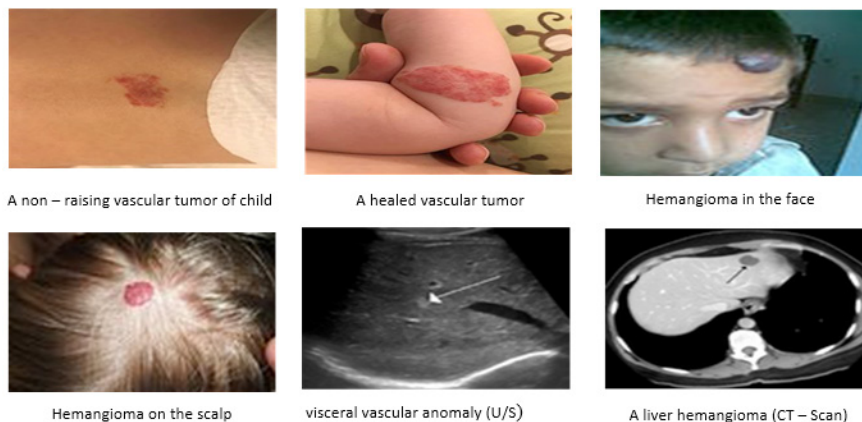

Figure (1) Types of Hemangioma

Corresponding author:

Ahmed Abdulhussein Kawen

Email: ahmedpath.@yahoo.com

Diagnosis:

Most of the cases of vascular tumors of infancy easily discovered from patient history and direct physical examination.⁶ In certain conditions need assisted measured like imaging (US) with Doppler, (MRI) and/or other confirming tools are needed like cytology or histopathology.¹⁴ This vascular tumor (infantile hemangioma IH) are not present at birth in most of cases or faint area, small dilated blood vessel, or dark area may be present. A well developed lesion after delivery predict other diagnosis. The type of vascular tumor with faint red strawberry color it's a Superficial type that occupied the upper dermis, while the blue and firm textured lesion which occupying the deep dermis and subcutis that indicates deep type of this vascular tumor. Mixed type of lesion contain both proliferative IH which do not substantially proliferate¹⁵ and pig endophytic IH in which obvious increment in size began later and continue for extended period.¹¹ A good history of the unique growth of a such condition its very important in the detection of the lesion. In the early weeks of after delivery this vascular abnormality proliferate very abruptly with increasing mass more than its size. After that accompanied by a decreasing growth for t up to 6-9 months, while the majority of growth about 80% is achieved by 3 months. Lastly, this lesion regressed over a period of years.¹¹ If the diagnosis is not reached from physical examination, so other added measures like imaging or histopathology is helpful.^(4,14) On Doppler ultrasound the diagnosis is achieved by showing a high flow soft-tissue mass usually without direct arteriovenous shunting for the proliferative phase. On MRI, showing the increased signal intensity and increase up take after gadolinium injections. There are fast flow vessels.^(14,15) specimen for diagnosis can be taken from the lesion by different invasive methods for microscopic evaluation.¹⁶ Under the microscope and tissue can be processed for the detection of this tumor cells, abundant well capsulated endothelial cell.¹⁷ The GLUT-1 histochemical marker also may be help full in differentiation from other vascular abnormalities.¹⁸

Results

Table (1) Frequency of age groups in patients and site of hemangioma

Variable Age group	Frequency	Percent
Smaller than 6 Months	5	16.6%
6 Months - 12 Months	10	33.3%
1 Year - 3 Years	10	33.3%
Older than 3 Years	5	16.6%
Total	30	100%

Site	Frequency	Percent
Face	2	6.66%
Neck	3	10.0%
Trunk	15	50.0%
Lower Limb	5	16.6%
Upper Limb	5	16.6%
Total	30	100 %

More than 10 cm	10	33,3%
Total	30	100 %

Discussion

At present work the female to male ratio was 1.3:1 unlike the study done in Goldenberg DC, et al. *Plast Reconstruct Surg.* 2016 which showed that the female-to-male ratio was 5.7:1.

In our study the most common site was the trunk then limbs followed by the face and neck unlike the study done in Goldenberg which showed that the face and limbs are the most common site .The presentation differed in our study from recurrent bleeding to increment in size to recurrent ulceration like the study done in Goldenberg DC and in Department of Pediatric Surgery, La Paz Children ´s Hospital, Spain .

in our present study, the most common type is capillary hemangioma and this is similar to the study

in Department of Pediatric Surgery, La Paz Children ´s Hospital.

The size of hemangioma ranged from less than 5 cm in one third of patients to more than 10 cm in one third of patients who underwent surgery and this is similar to the studies made by others.

Conclusion

Hemangiomas actually resolve spontaneously and only the rare and exceptional cases who needed surgical intervention were mentioned in our study. Surgical intervention was more commonly carried out in the trunk and very rarely in the face.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of dermatology / College of Medicine / University of Thi-Qar, Iraq and all experiments were carried out in accordance with approved guidelines.

Is Glycosylated Hemoglobin A Marker of Infertility? Prospective Analytic Study

Sahar Hamzah Ali Al-Tameemi¹, Azhar Mosa Al-Toriahi²

¹Maternity and children hospital in Al- D iwaniayah,² Collage of Medicine-Kufa University

Abstract

Infertility: Is the inability of a couple to naturally conceive, carry or deliver a healthy child after a year of unprotected intercourse⁽¹⁾. Causes: Female factors :- Problems with ovulation. Blocked fallopian tubes; this can happen as the result of pelvic inflammatory disease, endometriosis, or an ectopic pregnancy. Hormonal problems such as polycystic ovarian syndrome (pcos). In ability of the fertilized egg to implant in the uterus. Cervical hostility. Premature ovarian failure. Age; A women's fertility decline after the age of 30, both in her ability to conceive and her ability to carry pregnancy to term. Male factors: The chief factor in male infertility is sperm quality, the man may have poor motility < affecting its ability to reach ovum. Alcohol, marijuana and other drug abuse can affect sperm quality. Other possible factors include erectile dysfunction and retrograde ejaculation. Female infertility account for one third of infertility cases, male infertility for another third, combined male and female infertility for another 15%, and the remainder of cases are " un explained".

Keywords: Hemoglobin, Marker, Infertility

Introduction

Poly cystic ovary syndrome(PCOS):- Is a common endocrine disorder in women of reproductive age with primary manifestation of infertility¹. menstrual dysfunction, and clinical or biochemical hyperandrogenism (hirsutism, acne, and elevated androgens), obesity². Its other associated with hyperlipidemia and impaired glucose tolerance³. The ovaries in woman with PCOS are usually large⁽³⁾ and full of cysts, although they may not have symptoms. About 6%-10% of women have PCOS .To be diagnosed with PCOS, a women must have at least one of the clinical signs mentioned above. It is generally believed that PCOS has a genetic⁴ compenent that is influenced by environmental factors such as diet and exercise. Obesity increase the insuline resistance that often occure with women who have PCOS a hormonal imbalance⁶. Their ovaries and adrenal glands produce more androgens, specifically testosterone, and often less estrogen and progesterone than normal.

Pathophysiology: The frequency of obesity in women with anovulation and PCOS has been reported to be from 35%-60%^{6,7}, obesity is associated with three alterations that interfere with normal ovulations , and

weight loss improves all three:

- 1- Increased peripheral aromatization of androgens to estrogens.
- 2- Decreased level of sex hormone-binding globulin(SHBG), resulting in increase levels of free estradiol and testosterone.
- 3- Increased insulin level that can stimulate ovarian stromal tissue production of androgen⁵.

The ovary does not secrete increased amounts of estrogen and estradiol level are equivalent to early follicular phase concentration, circulating estrone levels are slightly elevated. The increased total estrogen is due to peripheral conversion of the increased amount of androsteredione to estrone. Both estrone and estradiol continue to be secreted in significant, although low amount. The level of sex hormone binding globulin(SHBG) are controlled by a balance of hormonal influences on its synthesis in the liver ; testosterone is inhibitory, estrogen and thyroxine are stimulating. In an ovulatory women with POCS, there is an approximately 50% reduction in circulating levels of SHBG, a response to the increased testosterone, and in patients with hyperinsulinemia due to direct insulin

effect on the liver⁷. There is increase insensitivity of the pituitary to releasing hormone stimulation, manifested by an increase in LH pulse amplitude and frequency, but mainly amplitude, this can be attributed to increase level of free estradiol because of the significant decrease in SHBG. The increase LH secretion as expressed by the LH:FSH ratio is positively correlated with the increased free estradiol^{8,9}. The lower FSH levels represents the sensitivity of the FSH negative feed back system to the elevated estrogen, both free estradiol and estrone formed peripheral conversion of androstendones. Because the FSH levels are not totally depressed, new follicular growth is continuously stimulated, but to the point of full maturation and ovulation¹⁰, follicular life span may extend several months in the form of multiple follicular cysts, 2-10mm in diameter (some can be as large as 15mm). these follicles are surround by hyperplastic theca cell, often lutenized in response to the high LH levels. As various follicles undergo atresia, the tissue derived from follicular atresia is also sustained by the steady state and now contributed to the stromal compartment of the ovary. It is not surprising that this functioning stromal tissue secrete significant amount of androstendione and testosterone, the usual production of theca cells. In response to the elevated LH, the androgen production rate is increased.

Insulin Resistance:

Is defined as a reduced glucose response to a given amount of insulin⁽¹¹⁾. There are several mechanism for the state of insulin resistance: peripheral target tissue resistance, reduced hepatic clearance, or increased pancreatic sensitivity⁽¹²⁾. The clinical presentation of patients with insulin resistance⁽¹³⁾ (whether they have impaired glucose tolerance or diabetes mellitus) depend on the ability of the pancreas to compensate for the target tissue resistance to insulin. At first, compensation is effective and the only metabolic abnormality is hyperinsulinemia. In many patients, the beta cells of the pancreas eventually fail to meet the challenges, and decline insulin levels lead to impaired glucose tolerance and type II non insulin-dependent diabetes mellitus.

Indeed, Beta cell dysfunction can be detected in women with PCOS even before the appearance of glucose intolerance.

Overall Goals of Treatment

- 1- Induction of ovulation to achieve pregnancy.

- 2- Protect the endometrium against the effects of unopposed estrogen.

- 3- Reduce the production and circulating levels of androgens.

- 4- Support life style changes to achieve normal body weight.

- 5- Avoid the effects of hyperinsulinemia on the risks of cardiovascular disease and diabetes mellitus,

- 6- Lower the risk of cardiovascular disease.

The clinical consequences of persistent anovulation

- 1- Infertility.

- 2- Menstrual bleeding problems, ranging from amenorrhea to dysfunction uterine bleeding.

- 3- Hirsutism, alopecia, and acne.

- 4- An increase risk of endometrial cancer and, perhaps, breast cancer.

- 5- An increase risk of cardiovascular disease.

- 6- An increased risk of diabetes mellitus in patients with insulin resistance.

Glycosylated haemoglobin (HbA1c)¹⁴.

Is found by covalent binding of glucose to the N-terminal Valine of the β -chain in the haemoglobin molecule throughout the life time of the erythrocyte.

In the clinical control of diabetic patients, HbA1c serves as an estimator of the time-averaged blood glucose concentration in the proceeding 3-12 weeks.

As a diagnostic tool, HbA1c may have advantage in relation to other methods, and a glycosylated proportion of 7.0% or higher has been proposed as indicative of the need for pharmacological intervention.

Subjects and Method

This is a prospective study carried out at the Maternity and Paediatrics Teaching Hospital in Al-Najaf, during the period between first January 2004 to 30th September 2004. A total of 50 patients were included in this study. They were selected from patients consult out-patient unit as first time planning for pregnancy without previous reproductive experience and patients consult infertility unit after one year of primary infertility for

the first time. 20-30 years old subjects who living with a partner were weighed in light clothes with no shoes and height has been measured ; body mass index was calculated by weight(kilograms) divided by squared height(meters). 6-months retrospective menses calendar was obtained to define of an approximated menstrual irregularity. A serum sample was frozen for later analyses of prolactin.

The measurement of HbA1c was included in the protocol from Jan 2004.

HbA1c was determine in capillary whole blood or venous blood using an immunoturbidmetric assay.

Those whom excluded from the study:

- 1- Those women had diagnosed diabetes mellitus.
- 2- Weight greater than 140 Kg.
- 3- Smoker.
- 4- Those on hormonal therapy.
- 5- Those with insulin sensitizing agents.

Results

A total of 60 patients were available for analysis. Independent t-test had been applied in statistical analysis

at level of significance P,0.05.

SPSS statistical process used V.10.

P>0.05 not significant.

P< 0.05 significant differences.

Table (1):Relationship between Body mass index of 50 subjects with their mean glycosylated haemoglobin.

Group	Number of subject	Mean value of HbA1c	SE mean	Sig. (2-tailed)
BMI<25	13	6.3538	0.6233	0.021 *
≥25	37	8.8973	0.5909	0.006

* significant at P value <0.021

50 subject were weighted in light clothes no shoes and weight(kilograms) divided by squared height(meters) with measurement of HbA1c. A high body mass index was significantly associated with high HbA1cas been shown in table (1) with P. value<0.021.

Table (2) : Relationship between regularity of the menstrual cycle and the mean value of HbA1c.

Regularity of menstrual cycle	Number of subject	Mean value of HbA1c	SE mean	P.value
Regular	22	5.8773	0.2417	0.0001
Irregular	28	9.8926	0.7900	

6-months retrospective menses calendar was obtained to define an approximated menstrual irregularity.

Irregularity of the cycle was significantly associated with high HbA1c With P.value<0.0001.

Table(3): Relationship between the ultrasound finding which related to PCOS and the mean value of HbA1c

PCOS u/s finding	No.	Mean	SE mean	Sig. (2-tailed)
Not present	29	7.7862	0.5258	0.496*
Present	21	7.2381	0.4940	0.494

* no significant association at P.value>0.05.

(Independent sample Test)

Ultrasound examination of those 50 subject reveal presence of ultrasonic finding of polycystic ovary syndrome in (21) of the subject (27 of the total with history of primary infertility not receive treatment till now).

Table (4): Relationship between S.Prolactin level and mean value of HbA1c

S.prolactin level	Number of subject	Mean value of HbA1c	SE mean	Sig. (2-tailed)
Normal	17	8.5059	0.9150	0.272 *
Abnormal	10	9.3900	1.4794	

* no significant association at P.value>0.05.

A serum sample was frozen for later analysis of prolactin for those 27 subjects (whose had history of primary infertility) show 10 of them only presented with biochemical prolactinemia while the rest 17 with normal level. There is no significant association between high prolactin level and high HbA1c with P. value of 0.272.

Discussion

The results indicated that females HbA1c may be a marker of infertility. The level of HbA1c differed significantly between the East and West centres (mean 4.83 versus 4.65 P<0.0005). All couples at the East centre were interviewed at the hospital and HbA1c was measured simultaneously from a capillary blood sample, while for the majority of samples at the west

centre(70%), a sample of various blood sample obtained for later analysis at the laboratory, this may explain the observed differences between the centres.

Possible Physiological mechanisms: Polysystic ovary syndrome(PCOS) is characterized by enlarge ovaries containing an increased number of follicles, and a hyperandrogenic hormone profile involving increased plasma concentrations of testosterone and luteinizing hormone(LH), decreased serum hormone binding globulin(SHBG) and hyperinsulinism¹⁵⁻¹⁷. The prevalence of PCOS syndrome among premenopausal women has been estimated as 5-8%, but usually PCOS diagnosed only when women seek medical advice for hirsutism, oligomenorrhea or infertility¹⁷, using ultrasound detection methods, the prevalence of an ovarian morphology typical of PCOS was shown to be approximately 20% in population samples of adult women and a considerable proportion had a hyperandrogenic hormone profile^{18,19}. These women generally have a normal menstrual and normal body mass index. PCOS has no single organic aetiology, but chronic overstimulation of ovarian steroid synthesis caused by insulin or insulin-like growth factor secondary to decrease insuline sensitivity may be a central feature of the complex hormonal dysregulation leading to this syndrome¹⁶. In this present study only a single blood sample was obtained, irrespective of the timing with respect to the menstrual cycle. A high concentration of HbA1c was associated with a high body mass index. A high concentrate of HbA1c was associated with irregularity of cycle and this differ from the result obtained by Niels Henrick I Hjollund , Tina Kold Tensen, Department of occupational Medicine, Aarhus University Hospital,Norrebrogade, a following study of first time pregnancy planners. HbA1c was not related to ultrasonic finding of PCOS, s-prolactin level. This similar to the result obtained by Department of Gynecology and Obstetrics, Aarhus University Hospital , Aarhus , Denmark,a following study of first pregnancy planners.

Conclusion

Female infertility account for one third of infertility cases, male infertility for another third, combined male and female infertility for another 15%, and the remainder of cases are “ un explained”.

Serum Salusin- α and Salusin -b levels with some Biochemical Parameters in Patients with Major Thalassemia

Hiba Ali Numan¹, Hanaa Addai Ali¹

¹College of Science, University of Kufa, Iraq

ABSTRACT

Thalassemias are a heterogeneous group of genetic disorders in which the production of normal hemoglobin partially or completely is suppressed because of defective synthesis of one or more globin chain. It is sometimes called Mediterranean anemia. Many biochemical changes in the blood accompany this disease. In this research, some biochemical parameters were measured in thalassemic patients and compared with healthy control group. These parameters include serum Iron, ferritin, TIBC, transferrin, transferrin saturation percentage, Salusin- α , salusin- β , insulin, and lipid profile. The aim of this study was to Measuring the level of cytokine(salusin- α and salusin -b) lipid profile, blood sugar level and resistance to insulin in serum of thalassemia patients and Find interconnectivity between cytokine(salusin- α and salusin -b), iron, lipid profile, blood sugar level and insulin resistance. The results of the research showed that there is a significant increase ($P < 0.05$) in BMI, serum iron, ferritin, TIBC, TS%, FBG, Insulin, HOMA- β , TG, cholesterol, HDL-C, LDL-C, and salusin -b in thalassemic patients group in comparison with healthy control group. A significant decrease ($P < 0.05$) in HOMA-IR and salusin- α . There is no significant difference ($P > 0.05$) in Age, TIBC, Transferrin, and VLDL-C.

Key words : Major thalassemia, salusin alpha, salusin beta, HOMA-IR.

Introduction

The thalassemias are inherited anemias caused by mutations that affect the production of the globin chain, the protein elements of the hemoglobin. Thalassemias produce a enormous public health problems in many parts of the world²⁴. These hereditary anemia caused by reduced or absent production of one type of globin chain either α or β globin chain. These disorders range from asymptomatic to severe

anemia that can cause significant morbidity and mortality¹⁵.

Major morbidity and mortality can result from iron overload, liver dysfunction and failure, pan- endocrine failure, heart failure and fatal cardiac arrhythmias, which establish the main concerns in weakly chelated patients¹⁸. Thalassemias are classified according to which specific globin chain(s) is/are produced in a reduced amount, which may lead to an inequality in globin chains synthesis, unproductive erythropoiesis, hemolysis, and ultimately to a variable degree of anemia. The chief types of Thalassemias are the a, b, db, d, and gd. The

a and b thalassemias are the most common types, and b thalassemia is the most important and broadly spread type which causes severe anemia in the homozygous and compound heterozygous states^(27,26,9). The typical treatment of severe beta-thalassemia is at this time based on medical treatment, and a blood transfusions, iron chelation and splenectomy, permitting an increased being alive and improvement of the patients' quality of life²³.

In 2003, salusins was defined as a new class of vasoactive peptides by Shichiri et al. Salusin-alpha (Sal- α) and salusin-beta (Sal- β) are peptides composed of 28 and 20 amino acids, correspondingly. Preprosalusin is mostly excreted from vascular smooth muscle cells and endothelial cells.²⁰ Salusins are synthesized and released from the renal system, central nervous system and vascular system of human²² While salusins are expressed from coronary atherosclerotic clots, expression of Sal- α is detected at a lower ratio when associate to that of Sal- β ²⁵. In an in vivo study, it was exposed that Sal- β was synthesised by fibroblasts in the vascular smooth muscle cells of the media layer and by the media layer of aorta during coronary artery bypass graft surgeries in patients

with coronary artery disease². Salusins have differently effect on haemodynamic activities⁶. In the present study, detection of low salusin-alpha and high salusin-beta levels in major Thalassemia patients suggest the possible effect of decreased salusin-alpha and increased salusin-beta levels in rapid reactionary responses. We detected significant differences between groups regarding salusin levels on TM. This supports the idea that low levels of salusin- alpha and high levels of salusin-beta levels differ significantly in patients with Major Thalassemia to healthy people. In this study, we detected that salusin levels were increased an average of 2 hours after onset of chest pain.¹⁶.

Materials and Method

A case-control study was conducted in "Thalassemia Unit" at "AL-Zahra'a Teaching Hospital" in Najaf city-Iraq, during the period from September to December 2018. The present study included of Sixty Iraqi thalassemia major patients. Their ages ranged 1-28 years old and Thirty apparently healthy subjects were selected as control group. Their age ranges were similar to that of patients. None of these subjects was anemic or has an obvious systemic disease or any chronic diseases. The Body Mass Index was measured by dividing weight in kilograms by length of individual in square meter: $BMI = (\text{weight in kg}) / (\text{height in meters}^2)$.¹³. Fasting venous blood samples were collected from patients and control group and the serum was separated and stored at - 20 °C until they were for analysis. Serum Iron was estimated by using colorimetric method¹⁹, TIBC were estimated by using colorimetric method. The Ferritin were determined by ELISA assay (Elabscience,USA). The percentage of transferrin saturation was calculated by using the formula: $\text{Transferrin (g/L)} = \text{Serum iron } (\mu\text{mol/L}) / (3.98 \times \text{TS}\%)$ (Morgan, Dean, & Davies, 2002). Fasting investigation of Serum glucose, and lipid profile (TC, TG, LDL-C and HDL-C) levels were estimated by the colorimetric method for the quantitative in vitro diagnostic measurement using a kit. Insulin were measured determined by ELISA assay (CALBIOTCH Company,USA) Insulin resistance index (Homeostatic model assessment-insulin resistance, HOMA-IR) was estimated as follows: $HOMA\ IR = [\text{glucose (in mg/dl)} \times \text{insulin (} \mu\text{U/ml)}] / 405$ $HOMA\ \beta\ \% = 360 \times \text{insulin} / (\text{Glucose} - 63)$.⁸. Salusins (Sal - α and sal - β) were determined by ELISA assay (Elabscience,USA).

Statistical Analysis

Statistical analysis was performed using two statistical software, the Statistical Package of Social Science (SPSS ver. 21) and Graphpad Prism ver.5. Continuous variables were expressed as mean \pm standard deviation (SD). Significant differences were assessed using Paired t-test and independent t-test for variables with equal and unequal frequencies respectively. Bivariate correlations were assessed using standardized Pearson coefficients. The *p* values obtained of less than 0.05 and 0.01 were considered as statistically and highly statistically significant respectively.

Results and Discussion

The anthropometric and biochemical variables of the Thalassemia patients and healthy control group was summarized their statistical significance in Table 1. The present study demonstrated Non significant difference in age of thalassemia patients when compared to those of control group. The results of BMI revealed a significant decrease ($p < 0.05$) in groups of thalassemia patients compared with healthy group

On the other hand, found a significant increase in serum iron, ferritin, UIBC, TS%, FBG, Insulin, HOMA- β , TG, cholesterol, HDL-C, LDL-C, and salusin - β in patients with Major Thalassemia compared with healthy group but significant lower in HOMA-IR and salusin- α , ($p > 0.001$) while TIBC, Transferrin, and VLDL-C non-significant.

In Table (2) found a Correlation between Salusin α and studied variables in Major Thalassemia patients. Age, TIBC, and UIBC, have a positive correlation, and significant with *P* value ($P < 0.05$). while Salusin β , FBG and Transferrin are a negative correlation and significant.

In Table (3) found a Correlation between Salusin β and studied variables in Major Thalassemia patients Salusin α are a negative correlation and significant with *p* value ($P < 0.05$).

Homeostatic model assessment (HOMA) is a moderately simple method of estimating insulin resistance and beta-cell function by using the fasting plasma measurements of glucose and insulin¹⁷ Patients with Thalassemia major present decreased HOMA-B and elevated HOMA-IR levels compared with healthy people²¹ or displayed decreased HOMA-B and elevated HOMA-IR levels after follow-up¹⁴ Similar to previous studies, we demonstrated decreased HOMA-B in

patients without diabetes. Studies in patients with thalassemia and hereditary hemochromatosis who had chronic iron overload showed that glucose dysregulation occurred as a result of insulin resistance followed by β -cell dysfunction¹² Excessive iron causes insulin resistance and subsequently, pancreatic β -cell apoptosis and insulin deficiency⁴.

Table(1):The anthropometric and biochemical variable of major thalassemia patients and control

Parameter	Patients (n=58) Mean \pm SD	Control (n=30) Mean \pm SD	P-value
Age(Yrs)	17.28 \pm 5.758	17.97 \pm 6.990	N.S
BMI (kg/m ²)	17.67 \pm 3.73	29.11 \pm 14.46	0.000**
Ferritin(ng/ml)	3472.22 \pm 2356.84	123.70 \pm 48.05	0.000**

Salusin α is associated with renal dysfunction in patients with chronic renal failure¹¹. It was concluded that renal disorders are not rare in patients with beta-thalassemia major, iron and oxygen radicals may play a key role in the progression of chronic renal failure, the fact

that may be related to the changes in kidney excretion of different substances. Patients with Hemoglobinopathies including thalassemia would develop albuminuria and this may affect the blood concentration of albumin.⁷

Salusin is expressed not only in peripheral tissues but also in the central nervous system including neuronal cells of the hypothalamo-pituitary tract²². Intravenous administration of salusin- α or salusin- β was shown to cause a rapid decrease in arterial pressure; however, the depressor response of salusin- β was greater than that of salusin- α . Moreover, these depressor responses were concomitant with a decrease in heart rate²⁰.

Salusin-beta has been shown to have effects on heart through cholinergic mechanisms and cause hypotension, bradycardia, and cardiac dysfunction without affecting systemic vascular resistance ¹⁰

Thalassemia patients developed heart complications represent significant morbidity and remain the leading cause of mortality in transfusion. Cardiac structure and function in thalassemia are mainly affected by two competing factors: iron overload and increased cardiac output (CO). The cardiac iron deposition results in a decrease of left ventricular function. The anaemia together with marrow expansion leads to volume overload and increased CO that then demands increased contractility adding additional stress to the heart (Starling’s Law). Cardiac dysfunction in thalassemia manifests with congestive cardiac failure (CCF), arrhythmias and ultimately.

Premature deaths, in some cases, because of the difficulty in accepting the chelation treatment, which was cumbersome, but also occurred even in some patients who accepted the chelation therapy well.^(5, 1)

New results for major thalassemia patients in salusins levels in the current study found that serum salusin alpha levels are significantly lower and salusin beta are significantly higher in patients with major thalassemia compared to healthy as a control group.

Conclusion

In conclusion, the current study have demonstrated that salusins, newly identified bioactive peptides with potent hemodynamic activities, Measurement of serum, Salusin α and Salusin β levels may provide a novel approach to identify patient with major Thalassemia. , our results demonstrated the decrease in serum salusin- α levels in patients with major thalassemia .further,

this study confirmed previous finding reporting that its decrease plays a role in the development and progression of heart disease and renal system . The present study suggests that salusin- α may be a novel therapeutic candidate for the treatment mainly effect the cardio vascular system and further insulin and Salusin β levels increase in serum of major Thalassemia patients.

Isolating Liver abnormalities in CT Scan Images Using Enhancement Based Technique

Rabab Saadoon Abdoon¹, Zahraa Ali Khudair¹

¹Department of Physics, College of Science, University of Babylon, Hilla, Iraq

Abstract

One of the most dangerous diseases that causes death is liver cancer. As faster as detection of liver tumors and other abnormalities, as chances of survival will be increased. There are many modalities of medical scanning such as CT scan can be adopted for early detecting of the presence of any liver abnormality. In this study many CT scan liver images were adopted to investigate the robust performance of the proposed segmentation method. The proposed technique is an enhancement histogram based method employed here for segmentation purpose. The results of the presented technique showed the success of the technique in isolating and extracting the abnormal regions adequately. As well as, the implemented segmentation technique succeeded to extract the approximated whole liver regions according to the consultation of the radiologist. The processed technique was evaluated by calculating its accuracy to extract abnormal regions and it was 100%, whereas for extracting the whole liver regions the accuracy was 90%. In this study, the percent relative surface area of the abnormal regions were calculated as well.

Keywords: contrast adjusting, liver cancer, segmentation, enhancement, morphological operations.

Introduction

Liver locates at the upper right side of the human abdomen and it occupies the largest area among the various organs within the abdomen image ¹. It is well known that liver is built up of different types of cells, all types of liver cells are susceptible to many types of tumors, cancerous or noncancerous ². Computed Tomography, CT and many other modalities of medical imaging represent essential tools for fast diagnosis of the presence of any abnormal case within any member or organ of the body including the liver ³. Identifying liver on CT abdominal image is a challenging task due to the similarity of the intensity of other organs with the liver's intensity, and this makes the segmentation process more difficult ¹. According to the importance of detecting tumors and other abnormalities of liver, many researchers dedicated their efforts to process the medical images of liver in order to determine the site, area, volume and the shape of the abnormal regions as well as any other meaningful information to facilitate accurate diagnosis. One of the most principal processes,

is segmenting of the medical images to isolate or extract the abnormal regions. Several segmentation techniques were presented to handle this task, and many of these techniques gave promising findings ^(3, 4). Some researchers adopted and implemented clustering algorithms to segment medical images, while others proposed texture based methods and other researchers implemented neural network approaches and many other methods, see for examples ^(1, 3, 5-11). In this work a simple and accurate technique is presented. The proposed technique is an enhancement histogram based method employed here for segmentation purpose to isolate and extract liver abnormalities.

Enhancement Contrast based Technique

The objective of enhancement techniques of digital images is to improve the quality or the characteristics of the processed images, in such a way that, the resultant images become better than the original ones if they compared according to a specific criterion ¹². When the contents of the processed image are difficult to identify, contrast adjustment becomes essential, especially due to its ability to enhance the details in dark and bright regions ¹³. There is no general theory of image enhancement. When an image is processed for visual interpretation,

the viewer is the ultimate judge of how well a particular method works¹⁴. Enhancing an image in spatial domain depending on the image’s histogram, which is adopted in this work, is well explained in details in (14-16).

Experiments Procedure

The procedure of this work can be summarized as follows:

1. Input liver images.
2. Test many gray level ranges of the input images to be the whole intensity.
3. Select the proper range that differentiate the liver region upon other parts.
4. Utilize different morphological operations to get the liver region only.

5. Repeat steps 2 &3 to differentiate the abnormal regions upon other parts of liver.
6. Use different morphological operations to isolate the abnormal regions only
7. Calculate the surface area of the extracted liver regions as well as the abnormal regions.

Experimental Images

Many CT scan liver images were adopted to investigate the performance of the proposed technique, Figure (1) presented five of them as examples. These five images are of (992x866, 1080x731, 1280x1066, 1280x1134 and 1280x858) pixels of size from first image to the fifth one respectively. All the adopted images were acquired from the internet websites. According to the consultation of the radiologist, these images are for patients suffer from Haydatid cyst, Haydatid cyst, tumor, bloody hematoma and Hydro. cyst for the five images from the first to the fifth one respectively.

Figure (1): Input medical liver images.

Experiments and Results

The steps of fulfilling this work are presented as follows:

Suitable Intensity Ranges

Many gray level ranges of the input images were tested to be the whole intensity of the experimental images to select the proper range that enable isolating the liver regions and the abnormal regions within the input images. These ranges are ranged from [0.1- 0.3] to [0.5-0.8]. Figure (2) shows samples of the contrast adjusted images

for the five tested images.

Figure (2): Contrast adjusted images for different selected gray levels for the adopted medical liver images.

In Figure (2), the contrast adjusted images for different selected gray levels for five liver images from first line to the fifth one to highlight the abnormal regions ones . To extract abnormal regions, it is found that, the ranges $[(0.2-0.5), (0.1-0.3), (0.3-0.7), (0.2-0.5)]$ for the first four images respectively, were the most proper ranges to highlight liver regions desired regions. While for the whole liver regions isolation, the ranges $[(0.3-0.6), (0.2-0.3), (0.5-0.8)]$ and $(0.2-0.4)$ for the five images respectively are the suitable ranges to highlight the

Isolating and Extracting of Liver Regions

By adopting the proper gray level rang to be the image whole range and by the aid of the morphological opening process with disk shaped structure elements, as well as implementing area selector, the liver regions could be extracted. Figure (3) showed the results of this step for four liver CT images. The selected gray level range and the radii of the structure element depend on the processed images and differ from image to another. The approximated extracted live regions are presented in second line, while the third line shows the gray images

of the liver after convoluting the B/W images of second line with the original input images.

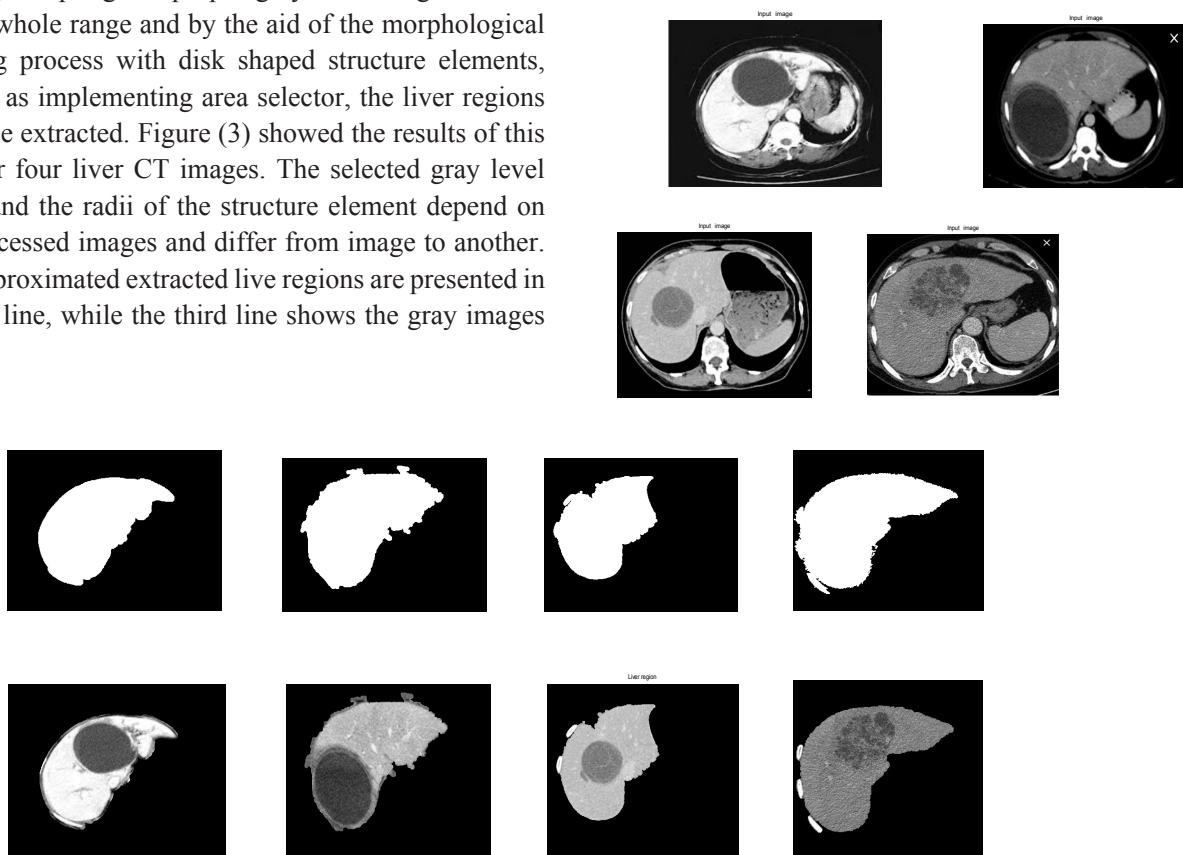

Figure (3): Results of extracting approximated final liver regions for the adopted medical liver images.

Extracting the Liver Abnormal Regions

From different gray level ranges, the suitable ones that enable isolating abnormalities upon other liver regions, were adopted to extract the abnormal regions. Opening morphological process and selecting areas function were applied to achieve the extraction process completely. The adopted radius of the structure element depends on the

processed image and it differ from image to another. Figure (4) presents the results of this step, the refined extracted abnormal regions are shown in the third line.

Figure (4): Results of extracting refined abnormal regions for the adopted medical liver images.

The surface area (white pixels in B/W image) of the approximated extracted liver regions and the surface area of the refined extracted abnormal regions were calculated, as well as the percent relative surface area of the extracted abnormal regions with respect to the surface area of the extracted live regions was calculated also and presented in Table (1). The proposed segmentation

technique was evaluated for its accuracy by calculating the number of succeeded cases to the total number of the processed images, and it was found that the accuracy equals 100% for extracting the abnormal regions and the accuracy equals 90% for extracting the whole liver regions without extra portions of other organs within the abdominal.

Table (1): Calculated surface area of the extracted approximated liver regions and the refined extracted abnormal regions as well as the percent relative surface area of the extracted abnormal regions.

Image	Image1	Image2	Image3	Image4	Image5
Surface area of extracted liver region (pixel)	164833	247427	332568	488607	*
Surface area of extracted abnormal regions (pixel)	49178	67002	54861	78723	110048
Percent relative surface area of extracted abnormal regions (%)	29.8400	27.0795	16.4962	16.1117	*
*Liver region of this image could not extract without extra portions of other organs.					

Conclusion

It is known that CT scan can be adopted for early detecting liver abnormalities. In this study, many CT scan liver images were adopted to investigate the robust performance of the proposed technique which is an enhancement histogram based method employed here for segmentation purpose. The results showed the success of the presented technique in isolating and extracting the abnormal regions adequately. As well as, the proposed segmentation technique succeeded to extract the approximated whole liver regions. The processed technique was evaluated by calculating its accuracy to extract abnormal regions and it was 100%, whereas for extracting the whole liver regions the accuracy was 90%. In this study, the percent relative surface area of the abnormal regions were calculated as well.

Factors Affecting Self-Care Behaviors of Patients with Heart Failure

Zeena Q. Abdulhussein¹, Diaan K. Abd-Ali¹

¹Adult Nursing, University of Kufa. Faculty of Nursing, Iraq

Abstract

A Descriptive Correlational Design is carried out in Al-Najaf City/Al-Najaf Al-Ashraf Health Directorate / Al-Sadder Medical City, from October, 17th, 2018 to June, 13th, 2019, in order to assess Self-Care Behaviors of Heart Failure Patients, and to assess the factors affecting patients with heart failure. A Non-Probability (Purposive Sample) of (110) patients who had heart failure, those who visit Al-Sadder Medical City for follow up, treatment, or both. Reliability of the questionnaire is determined through a pilot study and the face validity is determined through a panel of experts. The data are collected through the utilization of the developed questionnaire after the validity and reliability are estimated, and by means of interview technique. The data are described statistically and analyzed through use of the descriptive and inferential statistical analysis approaches. The findings of the present study indicate that the overall assessment for the patients' self-care behaviors is fair. In addition, the overall assessment of patients' self-efficacy toward self-care behaviors is fair, and the overall assessment of patients' attitude toward self-care behaviors is good.

Keywords: *self-care behaviours, heart failure, factors*

Introduction

Cardiovascular disease is presently one of most prevailing cause of death within world. In the 19th century, poor diet and infection disease were the reasons of most deaths and morbidities. Nowadays, Cardiovascular disease accounts for around 30% of completely deaths in more than 35 years old. concurring to statistical of 2008 mortality, over 2200 Americans die of Cardiovascular disease daily ¹⁹. Cardiovascular diseases is the essential cause of death in different created nations. In 2000, CVD is responsible for over 1.9 million of them within European Union, about 4.35 million deaths in Europe, accountable for 43% of totally deaths in men and 55% of totally deaths in women ^(1, 13). In addition to CVD is developing to become the biggest killer in the developed countries since the early 1900 ⁷. whereas the hazard of cardiovascular mortality was once moderately low in youth, collecting evidence recommends that CVD has its roots in childhood ¹⁶. Furthermore various hazard components have been connecting to the advancement of cardiovascular disease involving: poor dietary habits, weight gain, high blood pressure, diabetic mellitus, alcohol utilization, tobacco use, & impaired physical activity levels. Of relevance, numerous of these risk

factors are linked and reversible through a healthy diet and increased physical movement. ²¹. Universally, cardiovascular diseases are the number one cause of death and they are anticipated to stay so. An evaluated 17million individuals died from cardiovascular disease in 2005, representing 30% of all worldwide deaths, of these deaths, 7.2 million were due to heart attacks and 5.7 million due to stroke. Almost 80% of these deaths happened in low- and middle-income nations. If current trends are allowed to proceed, by 2030 an evaluated 23.6 million individuals will die from cardiovascular disease (basically from heart attacks and strokes). Cardiovascular diseases include: Coronary heart disease, valvular heart diseases, hypertension, peripheral artery disease, rheumatic heart disease, congenital heart disease, and heart failure ^(9, 2). In the middle east, in hospital mortality was 5.3% among acute HF patients, increasing to 7.5% at 30 days. However, the study was based in Riyadh, the capital of Saudia Arabia. A Yemeni study indicated that in hospital mortality was 9% (Al-Shamiri, 2013). Heart failure, frequently referred to as congestive heart failure (CHF), is when the heart is incapable to pump adequately to preserve blood flow to meet the body's needs. Signs and symptoms commonly include shortness of breath, excessive tiredness, and leg swelling. The shortness of

breath is usually worse with exercise, while lying down, and may wake the person at night. A limited ability to exercise is also a common feature. Chest pain, including angina, does not typically occur due to heart failure. HF can be caused by coronary artery disease, heart attack, cardiomyopathy, high blood pressure, atrial fibrillation, valvular heart disease, and infection ²⁰.

In addition, heart failure can influence the right or left side of the heart, or both at the same time. It can be either an acute (short-term) or chronic (continuous) condition. In acute heart failure, the symptoms appear abruptly but go away reasonably rapidly. This condition frequently happens after a heart attack. It may moreover be a result of a problem with the heart valves that control the flow of blood in the heart. In chronic heart failure, however, symptoms are continuous and don't improve over time. The vast majority of heart failure cases are chronic. HF is a chronic, quickly quickening disease that currently has no cure ²⁰.

Methodology

Design of the Study:

A Descriptive correlational Design is adopted in the current study to achieve the study objectives. The study started from October, 17th, 2018 to June, 13th, 2019.

Ethical Considerations and Administrative Agreements:

This is one of the most essential principles before data collection, to preserve the participants' principles and self-esteem. The researcher gets an agreement from the Faculty of Nursing / Kufa University to conduct the study, another agreement is gotten from the Ethical Committee in Faculty of Nursing, Also, an official agreement is taken from the Ministry of Planning/ Central Council for Statistics in order to accept the study questionnaire. Another agreement is gotten from Al-Najaf Al-Ashraf Health Directorate/ Al-Sadder Medical City/ CCU Unit, Medical Emergency Department, and Medical Wards, to interviewing each subject. And lastly, subject's agreement also was gotten from the patient him/herself after the researcher clarified the purpose of the study, seeks informed consent; and offered a respect to participants confidentiality in addition to making the participation voluntary to answer the questionnaire items.

Setting of the Study

The study is conducted in Al-Najaf Al-Ashraf City/Al-Najaf Al-Ashraf Health Directorate / Al-Sadder Medical City/ CCU Unit, Medical Emergency Department, and Medical Ward.

Sample of the Study:

A Non-Probability (Purposive Sample) of (110) patients who had heart failure, those who visit Al-Sadder Medical City/ CCU Unit, Medical Emergency Department, and Medical Ward for treatment, follow up, or both.

Sample Size :

The researcher utilized the power analysis method(Cohen's method) to determine the study sample size. This method can be clarify through its factors which involve: power, effect size, and level of significance. Power is an important factor to determine an adequate sample size for descriptive correlational study. Power is the capability of the study to determine the relationships between causality variables. The less acceptable power level factor for nursing studies is 80%, and the larger the power, the bigger the sample size that is required. The effect size was determined based on three levels of effect size: large effect (0.10), moderate effect (0.30), and small effect (0.50). The significance level or alpha (α) for this study was 0.05, because 0.05 means that the accepted chance of being wrong is only 5% of the time or less after infinite frequent sampling ⁴. Hence, based on the following factors (power = 90, α = 0.05, and effect size = 0.30), the adequate sample size that was needed for this study was a minimum of (N =91). Nevertheless, to increase sample size that was wanted increase the power level of the study, and use more than 90% of power level and have become a total of (N = 110).

The Study Instrument:

An assessment tool is adopted and developed by the researcher to assess the patients' self-care behaviors, and factors affecting self-care behaviors. The complete instrument consists of four parts: demographic data, clinical data, patients' self-care behaviors, and the factors affecting patients' self-care behaviors instrument.

Validity of the Study Instrument:

The validity of the study instrument is used to determine the study instrument will measure the data that

is intended to measure. The Face Validity is determined through the use of panel of experts to investigate clarity, relevancy, and adequacy of the questionnaire to measure the interested concepts.

A draft of questionnaire is designed and presented to (15) experts, who have years of experiment more than 10 years in field of nursing and medicine (appendix A).

Also, the experts’ suggestions have been taken into consideration. The final copy of the study instrument is accomplished to be valid tool to measure the study phenomena.

Clark and Creswell,(2014) mention that the panel typically comprises of at least three experts, but a more number may be suitable if the construct is complicated.

Reliability of the Study Instrument:

Reliability is concerned with the consistency and dependability of a research instrument in order to measure a variable of interest. Determination of reliability of the questionnaire is depending upon the reliability of internal consistency / Alpha Cronbach technique.

Data Collection

The collection of data is done by application of the developed questionnaire with aid of structured interview technique with the subjects as they are individually interviewed and the researcher use Arabic version of the questionnaire, by the same questionnaire for all study subjects who are involved in the study sample. The data collection process started from January 8th , to 17th February. Each subject spends approximately (15-20) minutes to complete the interview.

Statistical Analysis

The following statistical data analysis approaches is used in order to analyze the data of the study under application of the statistical package (SPSS) ver. (24), and the Microsoft excel (2010):

1. Descriptive Data Analysis:

- a- Tables (Frequencies and Percentages).
- b- Statistical figures (Pie Charts).
- c- Statistical mean and standard deviation.
- d- Pearson’s Correlational Coefficient (r).

e- Measures of central tendency: Mean, Mean of scores (MS)And the assessment by cutoff point (0.66) due to the three points likert scales with three levels of assessment, poor (1-1.66), fair (1.67-2.33), and good (2.34-3)for assessment of the levels of the patients’ self-care behaviours.

Determine the range and some of scores for the sample size(110) with four points Likert scale, scored as 1 for(poor), 2 for(fair), and 3 for(good). assessment of the levels of the patients’ self-care

2. Inferential Data Analysis:

This approach is used to accept or reject the statistical hypothesis, which includes the following :

- a- Chi-Square test for testing the independency distribution of the observed frequencies, and for measuring the association between the studies variables according to its type.
- b- ANOVA test to find out the variance between variables
- c- Independent t-test to find out the different between variables

Results

Table (1) Overall Assessment of Patients’ Self-Efficacy Toward Self-Care Behaviors

	Rating	Frequency	Percentage
Assess self-efficacy	Fair	50	45.5
	Good	30	27.3
	Poor	30	27.3
	Total	110	100.0

n (110); M.S 1.67-2.33 (fair))

Shows that the overall assessment of patients’ self-efficacy toward self-care behaviors is fair (45.5%).

Table (2) Overall Assessment of Patients’ Attitude Toward Self-Care Behaviors

	Rating	Frequency	Percentage
Assessment patients’ attitude	Fair	18	16.4
	Good	91	82.7
	Poor	1	0.9
	Total	110	100.0

Cut off point (0.66), M.S(mean of scores), poor (mean of score 1-1.66), moderate (mean of score 1.67-2.33), high (mean of score equal or more than 2.34)

Shows that the overall assessment of patients' attitude toward self-care behaviors is good (82.7%).

Table (3) Correlation Between Patients' Self-Care Behaviors and their Self-Efficacy and Attitude Toward Self-Care Behaviors

Studied domains	Statistical parameters	Self-care behaviors	Self-efficacy	Patients' attitude
Self-care behaviors	Pearson Correlation	1	.759	.354
	P-value		0.00	0.00
	N	110	110	110
Self-efficacy	Pearson Correlation	.759	1	.416
	P-value	0.00		0.00
	N	110	110	110
Patients' attitude	Pearson Correlation	.354	.416	1
	P-value	0.00	0.00	
	N	110	110	110

** . Correlation is significant at the 0.01 level (2-tailed).

Shows that there is a positive and high significant correlation between the patient's self-care behaviors domains and the patient's self-efficacy and patients' attitude domains at p-value > 0.01 (i.e. when the patient's self-efficacy and attitude increased, the self-care behaviours also increased and vice versa).

Table (4) Relationship Between Patients' Self-Care Behaviors and their Demographic Data

Demographic Data	Chi value	Df	P. value
Age	5.988	8	0.64 (NS)
Gender	2.437	2	0.29(NS)
Educational level	16.852	10	0.07(NS)
Monthly income	11.312	4	0.02(S)
Residence	8.093	2	0.01(S)
Marital status	10.354	8	0.24(NS)
Occupation	20.086	10	0.02(S)

n (110); Non-significant at p-value more than 0.05; S, significant at p-value less than 0.05; HS, highly significant at p-value less than 0.01

Shows that there is a significant association between self-care behaviors and monthly income, residency, and occupation at p-value less than 0.05, and there is a non-significant association with the other demographical data at p-value more than 0.05.

Discussion

Table (1): The study results indicate that the overall assessment of patients' self-efficacy toward self-care behaviors is fair (45.5%). These results are in agreement with (14, 17), that patients with higher self-efficacy feel less obstructions against self-care and have hence more activities of self-care, therefore, agreeing to the evidence gotten in this study and past studies, it can be understood that self-efficacy is an important determinant of self-care behaviors in patients with cardiac disease 3. Table (2): Shows that the overall assessment of patients' attitude toward self-care behaviors is good. These results are in agreement with (14, 17) There is a positive attitude towards self-care in heart failure patients and this will make them consistent 24. Generally, positive attitudes were expected about self-care describing it as vital to controlling symptoms. Individuals who had positive evaluative and experiential attitudes toward self-care employed that tactic to manage their symptoms 12. Table (3) indicates that there is a high significant correlation between the patient's self-care behaviors domains and their self-efficacy and patient's attitude.

Conclusion

Based on the study results and discussion, the study concludes that there is a deficient in self-care behaviors of patients with heart failure. In addition, the patients self-efficacy, attitudes, occupation, residency, monthly income, and smoking are the common factors affecting their self-care behaviors.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Kufa. Faculty of Nursing, Iraq and all experiments were carried out in accordance with approved guidelines.

The Prevalence of Sperm Parameters for Infertile Males in Thi-Qar City

Sumeya Ghanawy AL-Najjar

College of Medicine, University of Thi-Qar, Iraq

Abstract

Objective Male infertility is a term in which the male is not capable to attain pregnancy in a female. It occurs due to a lack of semen and low-quality semen. Semen Quality is referred to as a surrogate measure of male fecundity. This study aims to assess the frequency of sperm factors in infertile men in Thi-Qar City. **Materials and Methods:** This study involved an infertile couple, seminal fluid analysis (SFA) was done to evaluate male factors. Males with normal seminal fluid parameters were excluded. Regarding male, SFA was examined according to WHO 2010. Information such as age, duration of infertility and type of infertility were taken **Results** Among the percentage of abnormal sperm parameters for infertile couples in which the largest percentage was for asthenozoospermia that represent 66.70% of all infertile males. The second sperm abnormality is 12.13% for oligoasthenozoospermia. Asthenoteratozoospermia and oligoasthenoteratozoospermia have the same percentage (4.4). Azoospermia represents 6.7% while the lower percentage for teratozoospermia. **Conclusions** largest percentage was for asthenozoospermia that represents 66.70% of all infertile males .

Keywords: Seminal fluid analysis (SFA), sperm parameters

Introduction

Infertility is a different type of medical care as it relies on both male and female. Infertility is a unique medical condition because it involves a couple, rather than a single individual. In this condition, a couple fails to conceive after 1 year of intercourse without the usage of contraception in females less than the age of 35 years; and after the duration of 6 months of intercourse without the usage of contraception in females less than the age of 35 years and older (clinical definition) ¹. This is a very disturbing medical condition as the couple cannot have children if they are suffering from infertility. This further causes depression, psychological distress, and low self-esteem in the couple ^(2,3).

Types of male infertility

Asthenozoospermia

This term is described as the total sperm motility (non-progressive and progressive), non-progressive motility is less than 40 percent and progressive motility is less than 32 percent.⁴

Oligozoospermia

A few months ago, the World Health Organization reevaluated the sperm criteria and announced a lower reference point which is less than 15M sperm/ML. (WHO 2010) ⁴

Azoospermia

This term is described as the full absence of sperms from a minimum of 2 individual samples of centrifuged semen ⁴.

Teratozoospermia

Teratozoospermia; normal sperm morphology is <4% Kruger strict criteria ⁴

Male infertility

There is a common misunderstanding that the female is responsible for infertility but, it has to be understood that male is equally responsible for this severe medical condition ⁵.

Materials and Method

The study was carried out at infertility unit in Thi Qar city patient. From February 2015 to July 2017. This study involved an infertile couple, SFA was done to evaluate malefactors. Males with normal seminal fluid parameters were excluded. Regarding male, SFA was examined according to ⁴. Information such as age, duration of infertility and type of infertility were taken

Seminal fluid analysis

The seminal fluid sample was taken in a clean,

sterile, and dry disposable Petri-dish after three to five days of sexual absence. This was done by masturbation in a quiet room near the laboratory of semen analysis. The dish was a label with the name of the male, his age, sexual intercourse absence period, and the exact time of sperms collection. The sample was liquified using an incubator at the temperature of 37 °C for half an hour. It was then mixed and analyzed by microscopic and macroscopic tests. To note the results of seminal fluid analysis, the standard form of (WHO 2010) was used (Table 1).

Table 1: Normal values of semen variables ⁴

Sperm parameters		WHO Criteria
Sperm concentration millions/mL		15x10 ⁶ spermatozoa/mL or mor
Total sperm motility (%)		>40%
Sperm Grade Activity	Progressive motility (%)	>32%
	Non Progressive motility (%)	
	Immotile sperm(%)	
Normal sperm morphology (%)		>30%*

Results

Figure 1 shows the percentage of abnormal sperm parameters for infertile couples in which the largest percentage was for asthenozoospermia that represent 66.70% of all infertile males. The second sperm abnormality is 12.13% for oligoasthenozoospermia Asthenoteratozoospermia and oligoasthenoteratozoospermia have a same percentage (4.4). Azoospermia represents 6.7% while the lower percentage for teratozoospermia.

In our study table, 2 show the effect of male infertility duration on sperm parameters. Regarding

sperm concentration there is a significant decline at 5-10years, also there is a significant decline in sperm morphology when duration more than 10 years.

Table 3 discuss the effect of male infertility type in sperm parameters whether primary or secondary. There is no significant difference between primary and secondary types for all sperm parameters (sperm concentration, motility, and morphology).

Table 4 shows the distribution into primary and secondary fertility among infertile couples, 60% of them with primary infertility and 40% with secondary infertility.

Figure 1. sperm parameters

Table2: Effect of male infertility duration on sperm parameters.

Infertility duration Parameters	1-5 years	5-10 years	≥10 years
Sperm concentration	44.417±4.10a	38.375±4.92b	46.944±5.74a
Progressive motility %	11.763±2.21a	8.081±2.58a	12.300±3.42a
Non-progressive motility %	28.383±2.69a	29.425±3.23a	32.178±4.17a
Immotile sperm	43.615±2.79b	44.813±4.38b	52.439±5.34a
sperm morphology %	52.944±3.67a	43.188±3.64b	45.468±2.47b

Means with similar letters are nonsignificant different (P>0.05).

Means with different letters are significant deferments (P≤0.05).

Table3: Effect of male infertility type in sperm parameters.

Age groups Parameters	Primary	Secondary
Sperm concentration	42.459±3.59a	43.649±4.41a
Progressive motility %	10.298±1.80a	11.254±2.69a
Non progressive motility %	28.984±2.38a	30.141±2.93a
Immotile sperm	44.633±3.11a	47.265±2.84a
sperm morphology %	44.567±2.30a	48.595±3.05a

Means with similar letters are non-significant different (P>0.05).

Means with different letters are significant deferments (P≤0.05).

Table 4: Distribution into primary and secondary fertility among infertile couples.

Infertility	Frequency	Percentage (%)
Primary	60	60%
Secondary	40	40%
Total	100	100%

Discussion

Moreover, the sperm parameters correlate negatively with increased period of infertility 7 . These findings are in agreement with the results of the present study that the male patients with duration of infertility (1-5) years were with the lowest percentage of sperm motility. The results of this study showed that primary infertility (60%) was more than secondary infertility (40%) as it is obvious from table 4. But, in men having primary infertility, genetic and chromosomal factors have a vital role in the presence of primary infertility than secondary infertility 8. A retrospective study, conducted between 1992 to 1999 highlights the occurrence of asthenozoospermia as 18.71% and for asthenozoospermia, it was 63.13%, linked with oligo- or teratozoospermia. So, 81.84 percent of the investigated samples indicated altered motility. 9 In research conducted in Nepal, 20% of the couples indicated semen abnormality. 47% indicated oligospermia while 39% indicated azoospermia. Moreover, 14% of males had asthenormia. 10. Socioeconomic, environmental, and nutritional aspects are responsible for compromising the health of the male reproductive system 11. Chemotherapy, radiation, and surgery may have an impact on spermatogenesis 12 . A research conducted in Senegal to check this abnormality, oligoasthenoteratonecrozoospermia showed the highest percentage that is 20.2 percent while azoospermia showed 14.5 percent and asthenonecrozoospermia and astheno-necrozoospermia both showed the occurrence as 10.3% 13 . However, Pontonnier indicates that oligoasthenoteratozoospermia is the chief abnormality that is usually found in the general population and particularly in varicocele 14 .

Conclusion

Largest percentage was for asthenozoospermia that represents 66.70% of all infertile males.

Histological Study of Pregnant albino Rat Treated with Nickel Oxide Nanoparticles

Haneen M. Alsoltane¹, Amel A. Altaee¹

¹University of Babylon, College of Science, Iraq

Abstract

The present study was aimed to elucidate the effect of Nickel oxide nanoparticles (100 mg / kg b.wt) on some parameters in pregnant Albino rats, in both period of pregnancy (12 and 14 days). 30 albino rats were used; 20 female and the rest 10 were fertilized male rats which were used insemination only, the study including, maternal relative body weight, weight gain measurements and relative organ weights and histological study. Relative body weight of mothers showed decreases in both period of pregnancy. Body weight gain of the pregnant rat show decreases in 14 days of pregnancy in treated group as compared with control group while in 12 days of pregnancy showed increases in treated group as compared with control. Relative organ weight showed increases in (Lung, Uterus, kidney) in treated group and decreases in (Heart, Liver, Eye, Spleen, Brian) in (12) day of pregnancy. In (14) day of pregnancy showed decreases in (Heart, Liver, Eye, Brian , Kidney) and increases in (Lung, Spleen, Uterus) in treated group as compared with control group Histological study included some organ (liver, spleen, kidney, lung brain, eye and heart) for different period (12, 14) days of pregnancy.

Key words: NIO, nanoparticles, albino rats, histology.

Introduction

Nickel (Ni) is a silvery-white, hard metal. Although it forms compounds in several oxidation states, the divalent ion seems to be the most important for both organic and inorganic substances, but the trivalent form may be generated by redox reactions in the cell¹. Water-insoluble nickel compounds may dissolve in biological fluids². Particles of the same chemical entity (oxides and sulfides) have different biological activity depending on crystalline structure and surface properties^(3,4). Inhalation of all types of nickel compounds induces respiratory tract irritation, chemical pneumonia, emphysema and varying degrees of hyperplasia of pulmonary cells, and fibrosis (pneumoconiosis)⁶. Nickel may precipitate autoimmune phenomena and induce immunosuppression in vitro; the clinical importance of such effects has not been reported⁷. The histological changes noted in the lungs of this case included alveolar wall damage with fibrotic changes and oedema in the alveolar space. A statistically

significant increase in the incidence of deaths from respiratory disease was found in welders in some studies⁸. Studies in rats and mice demonstrate that chronic active inflammation in the lungs is the most prominent effect following inhalation exposure to nickel sulphate, nickel subsulphide, or nickel oxide⁹. In acute exposure, however, chronic lung inflammation was observed at the lowest concentrations of nickel sulphate and nickel subsulphide (ATSDR¹⁰). Chronic exposure for 2 yr to nickel (6 h/day, 5 day/wk) resulted in active lung inflammation in mice at 0.06 mg Ni/m³ and in rats at 0.11 mg Ni/m³ and higher.⁵

Materials and Method

Experimental Design

20 female albino rats were used in this study (in addition to 10 males in this study for mating only). Pregnant albino rats were divided into five groups (n=4), each group was subdivided into control (2) and treated groups (2). Pregnant rats were arranged into groups according to the period of treatment for 12, 14 days of pregnancy.

Corresponding author:

Haneen M. Alsoltane

Relative and Body Weight Gain

Weight of pregnant rats for both control and treated groups for 12 and 14 days of pregnancy were calculated by using electronic sensitive balance in the beginning and the end of experiment to calculate the Relative Body Weight as following:

$$\text{Relative body weight (\%)} = \frac{\text{final body weight} - \text{initial body weight}}{\text{initial body weight}} * 100$$

, while body weights gain of animals was calculated according to the following equation:

$$\text{Animal weight gain (g)} = \text{animal weight} - (\text{uterus weight} + \text{embryo weight})$$

Organs Weight: the liver, kidney, heart, brain, lung and spleen were removed, cleaned from adherent tissues, drying by filter paper and weighted immediately.

Histological Study: Tissue specimens of liver, kidney, heart brain, lung and spleen were fixed in 10% formalin. Trimming was done on the fixed tissue specimens. Tissue sections was prepared and stained by hematoxylin and eosin stain for histopathological examination by the light microscope.

Statistical Analysis

Results were shown as Mean ± Standard deviation (SE) for each group. Statistical analysis was performed by using SPSS 23. One-way analysis of variance (ANOVA) was used for multiple comparisons. The $p \leq 0.05$ was considered to be statistically significant.

Results

Body Weight Gain:

The oral administration of NIO at all treated group (100mg/kg/b.wt) periods showed significant increase ($p \leq 0.05$) in relative body weight in comparison with control group for 12 days of pregnancy, while it was decreases for 14 days of pregnancy as compared with control group (Figure -1).

Figure (1): Effect of Nickel Oxide nanoparticles (100 mg/kg b.w.) on Body weight gain (gm) in Pregnant Albino Rats for 12 and 14 days of Pregnancy.

Relative Body Weight.

The result in the present study showed that significant ($P \leq 0.05$) decreases in the treated group of (12, 14) days with NIO (100 mg / kg b.wt) in relative weight (12, 9.26) respectively , as compared with control group (14.56,22) respectively , (Figure 2).

Figure (2):: Effect of Nickel Oxide on Relative Weight of Pregnant Albino Rats for 12 and 14 days of Pregnancy.

Relative Organs Weight

The result of the present study showed that the organ weight means (heart ,liver , eye, spleen , brian) decreases significantly ($P \leq 0.05$) in treated group for (12days) with NIO (100 mg / kg b.wt) (0.436±0.05 ,9.36±3.16, 0.173 ±0.064,1.703 ±0.433,1.683 ±0.077) respectively , as compared with control groups (0.473±0.049, 11.16±2.54, 0.313±0.023, 1.896±0.17, 2.74±1.124) and increases significantly ($P \leq 0.05$) in weight of (lung , uterus and kidney) in the same treat group (3.16±0.497, 12.99±13.365 , .963±.155) respectively as compared with control group (1.56±0.062, 8.83±0.361, .783±.461) respectively (Table 1).

In the other hand in treated group of (14 day) there were significantly decreases ($P \leq 0.05$) of the organs weight

(heart, liver, eye, brain and kidney) (0.376±0.064, 8.4±1.93, 0.70±0.40, 1.9±0.697, 1.28±0.23) as compared with control group (0.403±0.066, 13.93±3.53, 0.466±0.152, 2±0.264, 1.56±1.28) respectively. and increases

significantly (P≤0.05) of the organs (lung, spleen, uterus) in the same treat group (3.066±0.152, 1.566±0.635, 14.80±19.40) respectively as compared with control group (1.54±0.096, 0.466±0.152, 7.866±0.503).

Table (1): Effect of Nickel Oxide on Different Relative Organs Weight (Heart, Lung, Liver, Spleen, Eye, Uterus, Brain and Kidney) in Pregnant Albino Rats for 12 and 14 Days of Pregnancy.

Peiods Organs weight	12 day		14 day		Sig. level p≤0.05

Histopathological Study for pregnant albino rat

12 days of pregnancy.

Light microscopy micrographs in 12 days of pregnant, the tissue of liver, kidney, brain, Spleen, Eye, Heart and Lung of experimental groups showed regular appearance as in control tissue groups (Fig. 3, 4, 5), while the lung section showed abnormality in the treated group with NIO (100 mg / kg b.wt), it showed thick alveolar septæ due to the presence of fibrinous exudate and chronic inflammatory cells as compared with control group.

14 days of pregnancy.

Light microscopy micrographs in 14 days of pregnant, the tissue of liver, kidney, brain, Spleen, Heart and Lung of experimental groups showed regular appearance as in control tissue groups, while the eye section show abnormality in the treated group with NIO (100 mg / kg b.wt), and in the section of Retina with Retinal tissue with atrophy of ganglion cell layer as compared with control group Retina with normal histological appearance during 14 days of pregnancy

(Fig.15). Also the lung showed abnormality in the treated group the tissue showed focal areas of moderate chronic inflammatory cell infiltrate of the perivascular areas. as compared with control group.

Figure (3): Cross section in the liver of pregnant rat (12 days) of pregnancy (A) control group, (B) treatment group, Liver tissue showed intact lobular architecture, hepatic plates and sinusoids (H&E x400).

Figure (4): Cross section through pregnant rat kidney at (12 days) of pregnancy, (A) control group, (B) treatment group, Renal tissue with normal glomerulus (blue arrow) and proximal and distal convoluted tubules (black arrow). H&E

Figure (5): Cross section through pregnant rat Brain at (12 days) of pregnancy (A) control group, (B) treatment group, Brain tissue with normal histological appearance (arrows). H&E. x400.

Discussion

Relative Weight of Pregnant Albino Rats for 12, 14 days of Pregnancy.

The results showed significant ($P \leq 0.05$) decreases in the treated group of (12, 14) days with NIO (100mg / kg b.wt) in relative weight, as compared with control group the decreases of the body weight in the cumented study is correlated to the toxic effect of NIO on the female rat and decreases in diet consumption and water in take¹² The weight decrease can be correlated to decrease in diet consumption and water intake¹³ The administration of NIO could be associated with weight loss and several side effects¹⁴ . The weight parameter considered as important indicator for the progress of biological activities and its affected by external effectors. Decrease of body weight may be attributed to anabolic metabolism in body of treated animals, or as a result of anti-digestion effect, or due to the loose of appetite in treated animals as a result of nanoparticles administration³² . It could also possibly be due to increased degeneration of lipids and proteins leading to decreased organ weight. Other factors may also be responsible for the reduced maternal body weight, may be due to mucophylline-induced resorptions, decreased weight, and growth of the fetus³¹ . It is well known that body weight and organ weight coefficients are sensitive indicators of potentially toxic chemicals in general toxicity studies¹⁵ , repeated gavage administration of Ni NPs to rats caused a significant suppression in body weight gain in the male 45 mg/kg group¹². Other study which indicate the negative effect of Zinc oxide nanoparticles on animal's structure, which represent the vital efficacy of its internal organs .This suggests that exposure to metallic nanoparticles, including silver nanoparticles, could cause gastric intestinal trace GIT disturbances in animals, loss of appetite and decrease fatty tissue in organs, and eventually decrease animal's body weight¹⁶ , The effect of different ZnO-NPs concentrations was

obvious on lowering animals' weights, especially with increasing the ZnO-NPs concentration into 200 mg/kg, and duration of exposure from 7 to 14 days¹³ . Other study showed different effect of NIO on the kidney which is correlated that the kidney was the major organ of nickel accumulation, and minor renal tubular damage at the corticomedullary junction was observed in rats exposed to NIO for 13 week to a significant decrease in urine volume and urine glucose levels and an increase in relative kidney weight were also observed^(17, 27).

Potential Risk Factors of Breast Cancer among Women Attending Teaching Hospitals in Babylon Province

Hasan Alwan Baiee¹, Zainab Fadhil Kizar², Huda salman Jasim² Suha Sheehan Jasim², Liala Qies Raheem²

¹Professor of Community Medicine – Babylon University-Hammurabi College of Medicine,

²Ministry of Health – Babylon Health Directorate

Abstract

Background: Breast cancer is the most common cancer among women worldwide and the leading cause of cancer deaths among Iraqi women.

Objective: To determine the potential risk factors associated with breast cancer.

Methodology: This was a hospital based case control study which was conducted at Merjan and Al-Hilla teaching hospitals. A sample of three hundred women participants who were selected and divided into 100 patients with established breast cancer (cases) and 200 healthy women without breast cancer who were considered as healthy control group. Data were collected by interviewing both groups using a structured questionnaire which includes information about (tobacco smoking, economic status, age of menarche, age of menopause, use of contraceptives level of education, family history of breast cancer). Medical records of patients and control group were reviewed to complete the data needed, chi square statistical test and Odds Ratios were calculated.

Results: Results of this study showed that the following factors like low economic status, late age of menopause, positive family history, use of contraceptives were significantly associated with breast cancer (Unadjusted Odds Ratios more than one, p values <0.05). Exposure to cigarette tobacco smoking, levels of education, and age of menarche did not show significant association with breast cancer in this study.

Conclusion: Breast cancer was associated positively with the presence of positive family history, Low socioeconomic status, late menopause and using contraceptive pills regularly.

Keywords: Potential risk factors, breast cancer, women, teaching hospitals, Iraq.

Introduction

Breast cancer is the most common cancer among women worldwide⁽¹⁻⁷⁾, and the leading cause of cancer death in women worldwide^{2,6} and the second leading cause of females' deaths after lung cancer². Globally, breast cancer is the commonest cancer among women, comprising 23% of the 1.1 million female cancers that are newly diagnosed each year⁴. It was estimated that 1.7 million people were diagnosed with breast cancer, accounting for around twelve percent of all new cancers.

Statistics shows between 2008 to 2012 a brisk increase in the incidence of morbidity and mortality of breast cancer among women⁸. Breast cancer was the most common cancer in 2012 with incidence of 43.4% and a mortality rate of 12.9%⁹. Incidence rates vary widely across geographic regions, with the highest rates in North America, Australia, and northern and western Europe and the lowest rates in large parts of Africa and Asia. Mortality rates do not differ as much due to better survival in developed countries, where incidence rates are also the highest³. In Iraq, breast cancer is very common type of malignancy among the population in general; responsible for about one third of the registered female cancers and almost one quarter of females' deaths from the disease^(2,4). The peak age incidence rates are

Corresponding Author:

Hasan Alwan Baiee

email:hassanbaey@yahoo.com

noted among middle aged women who often present with advanced stages documenting high mortality incidence ratios¹⁰. Breast cancer is a multi-factorial disease where genetic susceptibility, environment, and other lifestyle risk factors interact. Better identification of modifiable risk factors and risk reduction of breast cancer may allow implementation of useful strategies for prevention. In Iraq, there is a continuous rise in the incidence rate which is associated with an obvious potential risk factors which may act together or in sequence to initiate or promote carcinogenesis¹. This study was conducted to determine potential risk factors associated with breast cancer.

Method

This hospital based case control study was conducted at oncology units in Merjan teaching hospital and Al-Hilla teaching hospital. A sample of Three hundred participants was conveniently selected and divided into 100 patients with confirmed breast cancer(cases) and 200 women without breast cancer who were considered as a healthy control group. Data were collected by interviewing participants (both cases and control groups) using a structured pretested questionnaire which includes information about (tobacco smoking ,economic status ,age of menarche ,age of menopause ,use of contraceptives ,level of education ,family history of breast cancer), women with primary school level and below considered as women with low educational level. Women who use oral contraceptive pills for more than two years are considered (contraceptive users). Data collection from medical records were reviewed to confirm the diagnosis. Control group was selected from women who were examined in the mammogram unit ,and from women attending primary health care centers or hospitals .

The data were obtained from patients with breast cancer who were registered in breast tumor center/ Merjan teaching hospital and Al Hilla teaching hospitals from different age group and selected according to these criteria:

- 1-Women who have cancer according to confirmed diagnosis based on pathological diagnosis.
- 2-Patients who agreed to participate in the study and give verbal consents .

Statistical Analysis

Data analysis was done by using Spss version 21 to calculate Odds Ratios(OR) and chi square , p.value< 0.05 was considered to be statistically significant.

Ethical considerations

- 1- Approval of ethical committee in Babylon university- College of Nursing was obtained.
- 2-Acceptance of ministry of health(ethical committee of Babylon Health directorate was taken) ,together with the acceptance of authorities of the teaching hospitals.
- 3-Verbal consents of all participants were obtained after explaining the objective of the study ,the privacy and confidentiality issues.

Results

Table (1) shows that the percentage of tobacco smoking habit among cases and control group were (6% and 3.5% respectively the un matched Odds Ratio was (1.78) this means that there is a weak positive relationship between smoking and breast cancer the difference did not reach significant level $p > 0.05$.

Table (1) Frequency distribution of cases and control group by cigarette smoking.

Groups	Case(n=100) Number (%)	Control(n=200) Number (%)	Chi-square	OR	P-value
cigarette smoking	6 (6 %)	7 (3.5%)	1.005	1.759	0.3161
Not cigarette smoking	94 (94%)	193 (96.5%)			
Total	100 (100)	200 (100)			

Table (2) reveals that there is a highly significant difference between cases and control groups, regarding the income level cases with not enough income (poor) they constituted (47%) while the low economic level among healthy control is (23.5%) $p < 0.001$.

Economic status	Case(n=100) Number (%)	Control(n=200) Number (%)	Chi-square	OR	P-value
Not enough	47 (47%)	47 (23.5%)	17.112	2.88	0.0000
Enough	53 (53%)	153 (76.5%)			
Total	100 (100)	200 (100)			

Table (3) shows that the age of menarche has no significant association with breast cancer $p > 0.05$.

Table (3) Frequency distribution of cases and control group by age of menarche.

Age of menarche	Case(n=100) Number (%)	Control(n=200) Number (%)	Chi-square	OR	P-value
<12 year	45 (45%)	80 (40%)	0.686	1.22	0,4076
12 year Or More	55 (55%)	120 (60%)			
Total	100 (100)	200 (100)			

Table (4) depicts that there is a significant association between late age of menopause and carcinoma of the breast $p < 0.05$, the Odds Ratio (2.48), this means that those with late menopause are three fold more liable to have breast cancer than those with menopausal period of less than (45) years of age.

Table (4) Frequency distribution of cases and control group by age of menopause.

Age of menopause	Case(n=100) Number (%)	Control(n=200) Number (%)	Chi-square	Odd Ratio	P-value
>45 year	45 (45%)	44 (22%)	3.483	2.48	0.05
45 year & Less	7 (7%)	17 (8.5%)			
*Below the age	48 (48%)	139 (69.5%)			
Total	100 (100)	200 (100)			

Table (5) explains that the positive family history of carcinoma of breast is significantly associated with the development of this disease $p < 0.05$, OR= (2.25).

Table (5) Frequency distribution of cases and control group according to the family history of breast cancer.

Family history	Case(n=100) Number (%)	Control(n=200) Number (%)	Chi-square	OR	P-value
Positive	20 (20%)	20 (10%)	5.769	2.25	0.0163
Negative	80 (80%)	180 (90%)			
Total	100 (100)	200 (100)			

Table (6) reveals that level of education has no significant relationship with breast cancer in this study $p > 0.05$, OR= (1.27).

Table (6) Frequency distribution of cases and control group by the level of education.

Level of education	Case(n=100) Number (%)	Control(n=200) Number (%)	Chi-square	OR	P-value
Not educated	32 (32%)	54 (27%)	0.815	1.27	0.3666
Educated	68 (68%)	146 (73%)			
Total	100 (100%)	200 (100%)			

Discussion

The problem of breast cancer was studied through identifying some risk factors (both modifiable and non-modifiable ones) to pay attention to the prevention actions of this high priority public health problem in our country .The findings of this study show that tobacco smoking habit was not associated significantly with breast cancer ,this finding is in agreement with a study conducted among Jordanian Women during the year 2017 ¹¹ ,but disagrees with the finding of a local study done in Baghdad province /Iraq during 2013 ¹ This disagreement may be due to the small sample size of this study or due to embarrassment of women during the interview to speak about smoking habit which is considered as social stigma among women in our society, this finding is also disagreed with the finding of other reporters such as the work done in 40 clinical centers in the United states which showed that active smoking was positively associated with an increase in the incidence

breast cancer among postmenopausal women ¹².

Regarding economic status , this study reveals that low family income status was more prevalent among cases as compared to control group ,this finding is similar to the finding of other study conducted in Missan province /Iraq during the year 2012 ¹³ , and in a study done in Eastern India ¹⁴ and disagrees with the finding of other study in jordan ¹¹ .

The current study depicts that early menarche is not association with breast carcinoma, this finding goes in lines with the finding of other studies ^(1,15,16) but disagreed with a study done in Eastern India ¹⁴ and other study conducted in Dhaka city ¹⁷.

A high proportion of cases in this study were having their age at menopause more than or equal to 45 years, compared to controls, this result is statistically significant and agree with other study conducted in India that showed higher risk was found for women who

experienced menopause after 45 years of age ^(14,8) this can be explained by the long period of exposure of cases to estrogen hormone which is blamed as a potential risk factor ⁽¹⁸⁻²⁰⁾.

There is a statistically significant association between positive family history and breast cancer, this finding is similar to the findings reported by other local and international studies ^(1, 17, 8,21-26).

This indicates the importance role of genetic factors (inheritance) in the etiology of breast cancer among Iraqi women.

The finding of this study explains that the level of education of patient has no significant relation with breast cancer, this finding agrees with the finding of other local case control study conducted in Al-khadumia district /Baghdad province ¹⁶ and disagrees with the study done in Baghdad during the year 2013 ¹ and other studies conducted outside Iraq ^(11,14,27,28).

Conclusion

The current data support that various factors like economic status, late age of menopause, family history, use of contraceptives, are significantly associated with breast cancer among women in Babylon province. Exposure to cigarette tobacco smoke, women levels of education, and age of menarche, do not show a significant association with breast cancer in this study.

Epidemiological Aspects of Attention Deficit Hyperactivity Disorder among pupils in Al-Hilla City – Babylon Province –Iraq

Adnan H. ALjothery¹, Hasan Alwan Baiee¹

¹University of Babylon – Hammurabi College of Medicine, Iraq

Abstract

Background: Attention Deficit Hyperactivity disorder was an important issue of mental health and welfare affecting pupils at the primary school specially in conflict affected areas including Iraq.

Objectives: To identify the prevalence and the epidemiological profile of ADHD among pupils in Al-Hilla city –Babylon province/Iraq.

Methodology: This was a cross sectional study which was conducted in 4 randomly selected groups by lottery , the pupils at the primary schools located in AL-Hilla city center, the study was conducted during the academic year 2016-2017 , 100 children were randomly selected from the first three primary school grades. A structured questionnaire was used to assess the behavior of pupils by both teachers and parents after obtaining their verbal consents. The questionnaire was designed according to the formula of diagnostic criteria of attention deficit and hyperactivity disorders used by American Academy of Pediatrics.

Results: The overall prevalence of ADHD in the study group was 14%,.The male to female ratio was 3.5:1, there was a highly significant association between this disorder and the presence of family history of this health problem $p<0.001$, parents tobacco smoking habit was significantly associated with the presence of attention deficit hyperactivity disorder among their children (the combined type) $p<0.05$, there was significant relationship between poor school achievement and this behavioral problem $p<0.05$.

In conclusion, ADHD is an important health problem among pupils in Hilla city . Intervention should be made to improve health care providers and teachers' knowledge about this problem and control the modifiable risk factors.

Keywords: Attention Deficit Hyper activity Disorder , prevalence, primary school children, Babylon province

Introduction

Attention deficit/hyperactivity disorder is defined as one of the neuropsychiatric disorder occurred among children ¹. The neurodevelopmental process of childhood-onset is mostly attacked by this disorder, leading to induce the neurodevelopmental disorder among them ². Symptoms usually take place before 7 years of age , this disorder varies in prevalence in different countries. The nature for these discrepancies

across different countries is unknown. However, the differences in terms of demographical, cultural aspects and parameters used for the diagnosis in the studied countries could partially explain this . Pervious research indicated that the prevalence for this disorder was ranged from 5.4%-8.7% in most of African countries ⁴, however, 3.2% in Nigerian community ³. This trend of variations was also found in another continent like Asia. In one of the epidemiological studies conducted in Iran mention prevalence 13%, while (2.7%) among the pupils in Saudi Arabia ⁵. Results also came from a comprehensive study that was included 21 different countries demonstrated that the children who were from Japanese and Finnish populations had the lowest scores, while the score was

the highest among those from Jamaica and Thailand ⁶. In general, the symptoms for ADHD may be decreased when the person get older ⁷. This could be stemmed from the fact that the self-control and neural connections in the brain are seen to be more developed and less influenced during puberty ⁸. Many environmental factors and other factors like life style, mother's smoking during pregnancy or an early life of childhood, stress among pregnant, and low birth weight (<1.5kg) have been implicated with incidence of ADHD. Moreover, other medical problems such as hypoxemia, encephalitis, trauma, and brain injury could increase the incidence of ADHD ⁹. There was also a considerable evidence from a study that indicated that the incidence of ADHD was higher among first-degree family members of ADHD, suggesting that this disorder could be the most genetic psychiatric disorder ¹⁰. A study conducted in Jordan revealed that teachers perception was medium, no significant differences based on specialization and years of teaching experience, and suggests the importance of training teachers on enhancing their knowledge to identify students with attention deficit hyperactivity disorders ¹¹. A recent study conducted in Iraq shows that there is an association between computer-based video games, or mobile device use and behavioral changes like hyperactivity, attention deficit disorder among Iraqi children in Diyala province ¹². Studies showed that more difficult children are likely to be particularly vulnerable to higher levels of media exposure ^{13,14}, few studies were conducted in Iraq about the ADHD problem that affecting children and adolescent ¹⁵. ADHD children are more likely to have nocturnal enuresis, daily injuries, poor school performance and sleep problems ¹⁶. A study indicated that the drug abuse among adults was found to be linked with the cases of ADHD ¹⁷. This study was carried out to identify the prevalence and the epidemiological profile of ADHD Iraqi children at Al-Hilla city –Babylon province.

Methodology

One hundred primary school- age children were randomly selected by systematic random technique {50 males and 50 females), from four primary schools which were selected by simple random sampling from 48 elementary schools in Al Hilla city - Babylon province during the academic year 2016-2017. A random sampling was used among all students from grade 1 to 3 in the 4 elementary schools A structured questionnaire was used to assess the behavior of school children by both teachers and parents after obtaining

their verbal consents. The questionnaire was translated into Arabic language by 3 well known translators. This questionnaire was designed according to the formula of diagnostic criteria of attention deficit and hyperactivity disorders used by American Academy of Pediatrics (AAP).

The questionnaire included 18 items ; 9 of them are for information about attention deficit disorder and the other 9 are for information about hyperactivity and impulsivity disorders. Each item has 4 grades : nil – sometimes – usually – always. The way used in dealing with the data in the questionnaire is by giving score for each grade such as 1 ; 2 ; 3 ; 4 respectively and the diagnosis is made when the marks of child score for each type of the disorder is equal to or more than 22.5 marks. The child was considered as ADHD pupil when diagnosed by both teachers and parents for each type :attention deficit , hyperactive or both (combined). School children were considered as low school performing when they fail one academic year or more according to teachers and school records. Regarding tobacco smoking , smoker are those who currently smoke more than five cigarettes per day or at least one water pipe per week, while nonsmokers are those who never smoke or had quitted smoking since two years from the time of the study. Descriptive and inferential statistical analysis were applied using statistical package for social science (SPSS).Chi square test was used to assess the statistical difference between variables, $p < 0.05$ was considered as a level of statistical significance.

Results

Table (1) shows that the overall prevalence of ADHD among elementary school children in their early year is 14%,the males are highly predominant 22%. The male to female ratio is 3.5:1. Table (2) explains that this behavioral problem is more common in young age (7 years) and less among older children but this difference does not reach significant level , chi-square is 2.8251. The p -value is .243527. The result is *not* significant $p > .05$. Table (3) reveals that there is a statistically significant association between parents tobacco smoking habit and having children with ADHD problem $p < 0.05$. Table (4) depicts the very high significant statistical association between ADHD and the presence of positive family history of this behavioral problem among Iraqi children

Chi square= 34.9045 df=1 $p < 0.001$.

Table (5) shows that there is a statistically significant association between poor school achievement and development of attention deficit hyper activity disorder among the study group $p < 0.05$.

Table 1 (Distribution of ADHD among the study group by gender

Gender	Healthy NO (%)	ADHD NO (%)	Total NO (%)

Low school performance	8 (57)	16 (18)	24 (24)
Normal	6 (43)	70 (82)	76 (76)
Total	14 (100)	86 (100)	100 (100)

* Chi square=9.8036

* df=1

* p<0.05

Discussion

The overall prevalence of ADHD (combined type) among school children in early years in the current study was 14%. This prevalence was less than that reported by other study conducted on Iranian children of the same age group in which the incidence was 25.8% when the parents' evaluation was considered, while it was when their teacher's evaluation was taken into account.¹⁸ The prevalence of this study is higher than that observed in pupils ranged between 6 until 12 years old in AL-Saudi Arabia (11.6%)¹⁹. and higher than the prevalence

reported in Egypt (12.6%) which was measured among children in four primary schools in AL- Mansura province²⁰. And even lesser than that reported that among primary school children in Egypt which was reported to be 6.9%²¹ ADHD is more prevalent in male children in this study with ratio 3.5:1.

This finding was in the line with previous studies²¹⁻²⁴. The study reveals that there is a significant association between having ADHD problem and positive family history, ADHD is a condition that results from the interaction among three premises, namely, genetic, environment, and developmental traits. However, the genetic promise could cover most of the cases²⁵. A relationship is identified between ADHD and parents tobacco smoking habits this finding depicts the possible role of the environmental pollution. A study reported the

role of Research indicated that mother's smoking during pregnancy or an early life of childhood had increased the incidence of ADHD for a child¹¹. In addition, a study indicated that the born girls who were exposed to nicotine in their prenatal life had higher chances to develop hyperactivity and/or impulsivity symptoms^{26,27}

Zhu and his colleagues demonstrates that the born babies came from smoker mums and non-smoker dads had higher risk of ADHD than those came from the vice-versa, highlighting the role of mother's smoking in the development of ADHD²⁸. The adverse effects of tobacco smoke could be derived from their ingredients that are accounted to be more than four hundreds molecules. Nicotine is among them that was shown to be closely related in the neurodevelopmental disorder²⁹ De Zeeuw et al³⁰ investigated the brain volumes using the imagining scan from anatomic magnetic resonance indicated that the patients with ADHD that was prenatally exposed to the smoking from their mums had smaller cerebellum volume compared to those had no smoking .This study shows a significant association between poor school achievement and having Attention Deficit Hyperactivity Disorder this may be related to poor attention, this finding goes in line with findings of other researchers who explain many reasons for poor school achievement. Good education could be one of the effective approaches that enhance the development of our children. In addition, Schools with poor educational programmers do not only influence on our child's self-esteem, but it could increase the stress of the child's parents³¹

Conclusions

the findings of this study indicated that the prevalence of ADHD is relatively high ; it is associated with low school performance , ADHD is more prevalent in boys, the prevalence is high among children with positive family history of this disorder and those whom parents are tobacco smokers therefore, considering the importance of students' mental health, the urgent needs of early diagnosis, effective prevention and management at least of high risk group, training of teachers and school health staff using a bottom line approach(District Team Problem Solving approach), Further comprehensive large scale analytic studies are suggested to deal with this neglected mental health problem. A close collaboration between schools' authorities and parents is recommendable, and the early diagnosis is crucial.

An Accurate Breast Cancer Detection System Based on Deep Learning CNN

Kian Raheem Qasim¹, Alia Jumaa Ouda¹

¹University of Information Technology and Communications, Baghdad, Iraq

Abstract

Deep learning of multilayered computational models allowed processing to recognize the representation of data at multiple levels of abstraction. These technologies have significantly improved to identify breast cancer. Convolutional Neural Network (CNN) is a type of radiological basis for classification problems and is based on the Bayes decision-making base, which reduces the expected error in classification. In this paper, it is proposed to detect breast cancer using CNN of the mammography system to classify the mammogram to noncancerous abnormality and cancerous abnormality. The goal of Breast Cancer Detection based on CNN for speeding up diagnosis by helping a particular diagnose and classify breast cancer. A set of images of a mammogram is used to perform the pre-processing of the histogram equalization and adjust the appropriate parameters for the CNN work. Then, the whole changed images are set in CNN to classify as a training source. A CNN classifies can be produced as a model for identifying the mammogram. the BCDCNN method with the mammography classification utilizing MCCANN comparison with BCDCNN improved the classification accuracy on mammographic. Therefore, the results showed that the proposed system has a higher resolution than the other recently existing systems, and the only mass containing all was maximized from 0.84 to 0.88 and 0.70 to 0.82 accuracy.

Keywords: Breast Cancer, Convolutional Neural Network, Artificial Neural Network, Mammography Classification, Histogram Equalization.

Introduction

All over the world, the most common causes of many women deaths are breast cancer, the widespread type of cancer impacting women. In 2017, the estimates indicated that there were more than seventeen thousand five hundred women and one hundred and forty-four men with breast cancer. As an average, forty-eight of people with breast cancer were diagnosed daily. In Australia, the number of men and women affecting breast cancer has been increasing; as yet, the number of dead people because breast cancer is decreasing. The widespread type of cancer among women is breast cancer, which accounts for about 28.3% of all new cancers in women in 2017. The risk of this type of cancer at the age of 85 is 1 in 8 for women and 1 in 631 for men. If breast cancer is known to occur of younger women. In 2017, it was also estimated that 841 women aged between (twenty and thirty-nine) years were diagnosed with breast cancer. This represents 4.7% of all types of breast cancer diagnosed in Australia ¹.

According to the Breast Cancer Study, we found that 50% of NHS say they do not have the particular staff to recruit individuals with a limited nurse specializing in breast cancer². This is the most significant cause that may result a low-rate of survival of breast cancer worldwide. because of the lack of a nurse or breast cancer doctor, this will result in delayed diagnosis of breast cancer, lack of compliance with detection or optimal treatment, and unequal access to optimal treatment. Thus, detection of breast cancer has been developed to perform effectively both an anomaly and breast screening classification. This is to help and diagnose breast cancer. New proposal for image recognition system with detection of breast cancer. Image recognition utilized NN (Neural Network), a type of ANN that is designed and utilized successfully to determine visual images. This framework utilized a neural network, a kind of artificial neural network constructed and used effectively to identify visual images. This system is capable of classifying and detecting abnormalities in the image of mammograms. In general, the image of a mammogram may be categorized

as normal or cancerous abnormality (malignant), non-cancerous abnormality (benign) ³. In this paragraph, some previous researchers will be reviewed that have used various types of the neural network to depict mammograms into breast cancer as shown below:

In ⁴ (2009), Bozek et al. presented an indicator of breast cancer, such as architectural distortion but these are less important. The mass may be each non-benign. The variation between malignant and benign tumors is that tumors of benign have an oval or round shapes, whereas malignant tumors have a partially round shape of irregular outlines. Therefore, the malignant mass can seem whiter than other surrounding tissue.

In ⁵, (2011), Sharkas, Al-Sharkawy and Ragab presented discrete wavelet transformations (DWT), conversion of contour, and principal component analysis methods (PCA) to extract the feature. The system was the capability of detection and classification of abnormal and normal tissues. In addition, MC tumors were classified as malignant and benign. The rate of classification was nearly 98%.

In ⁶, (2013), Jawad Nagi presented Detection Breast Cancer (DBC) in Mammogram Images, achieved in four stages. The first phase was preprocessing and improved mammogram using global morphological techniques to reduce the image of the marker. The second phase was the process of segmentation using two techniques. Seed and growing the region and multiple OTSU threshold techniques. The third phase was the extraction of texture-based features and extracted fluorescence features. The last phase is passed by training and testing classification, and for the process of the training, the artificial neural network (ANN) was proposed.

In ⁷, 2015, W. Peng, R.V. et al. presented seeded region growing (SRG) and median filter using the 2D algorithm, improved image contrast, noise removal, deletion of radiology artifacts and elimination of chest muscle reduction from digital mammography, and ANN technology to classification the mammogram as follows: Normal Indicates a benign tumor or a malignancy. Here, 222 random images from the Breast Image Analysis Society database.

In ⁸, (2016), Jain, A, Levy D. presented Convolutional neural networks will be utilized to classify breast-segmented mammalian directly into mammography as benign or malignant, utilizing a combination of transport learning, pre-processing and increased data to overcome

limited training data. We deliver the state-of-the-art result on the DDSM data set, surpassing the performance of human, and demonstrate the viability of our model.

In ⁹, (2018), Saira Charan et al. presented neural networks to classify abnormal and normal detection of breast cancer. Convolutional neural networks (CNN) can be utilized in this detection. The dataset of mammograms-miss is utilized for this purpose system, containing 322 mammogram images of about 189 natural images and 133 abnormal breast images. A promising trial has been obtained that demonstrates the effectiveness of deep learning to detect breast cancer in mammograms and encourages the using of new methods of extracting and classifying features based on deep learning in different applications of medical imaging, essentially in the detection of breast cancer.

CONVOLUTIONAL NEURAL NETWORKS (CNN)

A Convolutional neural networks (CNN) is a special case of the neural network and a main tool of deep learning. CNN is perfect for pattern recognition for images. It includes more than convolutional layers, overwhelmingly in a subsampling layer, followed by more than connected layers just as in a Standard Neural Network (SNN) ¹⁰. The designing of CNN is derived behind the discovery of an optical mechanism, the visual cortex, into the brain. The visual cortex contains many cells in charge of light detecting in the small, overlapping subfields of the visible field, called the receiving fields. These cells act as local filters on the input area, while more complex cells contain more receptive fields. The torsion layer in CNN performs the function performed through cells into the visual cortex ¹¹.

The architecture of CNN

The primary focus of CNN is on the input basis which is comprised of images. This will give a focus on the architecture that will be set up in the best way that is required for handling data of specific type ¹². CNN consists of three types of classes. These are convolutional layers, pooling layers, and fully-connected layers. When these layers are stacked, CNN architecture has been formed. The simple architecture of CNN for classification of Breast cancer is shown in Figure (1).

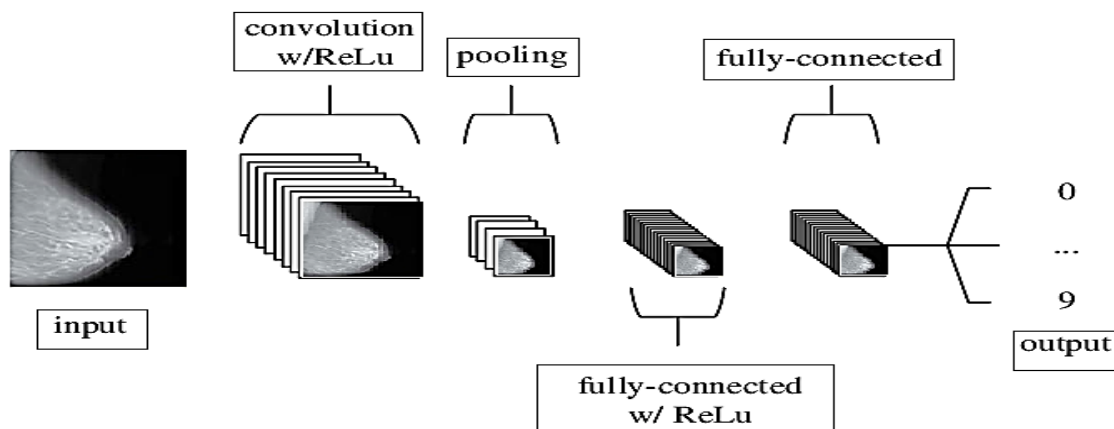

Figure (1): A simple architecture of CNN ¹² .

The basic function of CNN above will be divided into four major regions.

1. As found in other forms of artificial neural network (ANNs), the input layer can contain pixel value into image.

2. **Convolutional Layer** will be determined the yield of the neurons that are connected to the local input areas by calculating the product of scalar between its weights and the region related to the input volume. The aims of the rectified linear unit (ReLU) apply the “initial” activation function, like the sine, to the activation outputs produced through the previous layer.

3. **Pooling Layer** simply reduces the samples with the spatial dimension of the selected inputs, minimizing the number of parameters in that activation.

4. **Fully Connected Layers** can perform the same duties as the standard artificial neural network (ANNs) and try to produce the activation grades for classification. Also, it is suggested to use ReLU between these layers, for performance improving.

V. EVALUATION PERFORMANCE OF CNN

In any field of science, it is almost a necessary requirement that the performance of classifier must be evaluated to understand and measure the suitability of classifying a given problem. The classification of binary predicts all instances of data for the test data set either negative or positive. This classification or prediction results in four outcomes - true or false (positive and negative).

1. **True positive (TP):** Correct of Positive Prediction
2. **False positive (FP):** Incorrect of Positive Prediction
3. **True negative (TN):** Correct of Negative Prediction
4. **False negative (FN):** Incorrect of Negative Prediction

One of the most common measures is the confusion matrix it will be explained in the next section.

I. Confusion Matrix

The Confusion matrix is consisting of a two by two (2 x2) Table that contains four outcomes produced by a classification, these are essential performance measures, like accuracy, specificity, and sensitivity which are derived from the confusion matrix. The confusion matrix is utilized to represent the test of the result prediction model. Each of rows stands for the predicted class which means the (Output Class), and the columns stand for the true class which means the (Target Class). In Table (1), The matrix of confusion is displayed, which is described as the different values and equations associated with them. Few of these equations are closely related to performance analysis.

Table (1): A Typical Confusion matrix ¹³ .

Confusion matrix		Predicted	
		Negative	Positive
Actual	Negative	TN	FP
	Positive	FN	TP

The inputs of the confusion matrix have meaning in the context of the problem of data mining:

1. TN is the number of the prediction of true that in the case is negative,
2. FN is the number of predictions of false that a case positive,
3. TP is the number of predictions of true in which a positive instance,
4. FP is the number of predictions of false of negative instance.

The following are the Basic measures derived from the confusion matrix:

1) Accuracy

Accuracy (ACC) is determined as a number for all predictions of correct (TP + TN) divided by the total number of data sets (P + N). The best of accuracy equal to 1.0, while the worst equal 0.0. It can likewise be determined by 1 - error (ERR) as shown in equation (1).

$$ACC = \frac{TP + TN}{TP + TN + FN + FP} = \frac{TP + TN}{P + N} \quad (1)$$

2) Sensitivity (Recall or True Positive Rate)

Determined the number of predictions of true positive (TP) divided by a total number of the positives (P) this method called Sensitivity (SN) or likewise Recall or the True Positive Rate (TPR) (REC). The sensitivity equal to 1.0 is best, whereas the worst equal 0.0 as shown in equation (2).

$$SN = \frac{TP}{TP + FN} = \frac{TP}{P} \quad (2)$$

3) Specificity (True Negative Rate)

Determined the number of predictions of True

Negative (TN) divided by the total the number of negatives (N) this method called Specificity or True Negative Rate (TNR). The specificity equal to 1.0 is best, whereas the worst equal 0.0 as shown in equation (3).

$$SN = \frac{TN}{TN + FP} = \frac{TN}{N} \quad (3)$$

VI. The Proposed Method

The proposed method consists of three main stages, in the first stage is the acquisition of the image, second stage extraction features from the mammograms, selecting more optimal features, classifier to identify an appropriate classification of mammogram utilized CNN classification accuracy mainly depend on careful selection of features. In the finally step mammograms are classified, for this Convolutional neural network is used as a classifier to distinguish mammogram and classified it into malignant and normal classas shown in this Figure (2).

Figure (2). the main proposed system.

A. Dataset

The dataset used for this paper is a known Mammographic Database. Convolutional neural networks require a large amount of training data to realize height accuracy. Because of less accessibility of the dataset of enormous, testing and training were

done from the most accessible dataset on the web. In this paper were utilized 322 full images. The actual size of the images was 1024- 1024. It contained about 133 images that were abnormal and 189 of the regular category. The images of abnormal are included an inconsistency in which one breast increased density, 21 of which were included. The architectural deformity was the second types of abnormal, showing the arrangement of abnormal tissue on the breasts. This was included about 22 images. The small calcium deposits in breasts can be developed, where 24 of these images were found to contain calcification, which is irregularly shaped in the breast and can be malignant and some have not been ascertained if they are malignant. Data were randomly training by 70% and 30% were tested by CNN technology.

B.Equalize Histogram

In order to eliminate the effect of different illumination conditions, where images are taken in, the color histogram of the grayscale image is equalized, so that, the features are more distinguishable by the classifier, the overall effect of the lighting in the environment is removed.

Results

In this paragraph will illustrate the results obtained using the proposed method for a range of breast cancer images. The results of the proposed algorithm CNN are the best for detection of breast cancer.

Dataset: Mammographic Database is used in this proposed system. breast images Include both sides arranged in pairs, where each pair represents the right and left mammograms for 161 patients that mean 322 images as shown in this Figure (3).

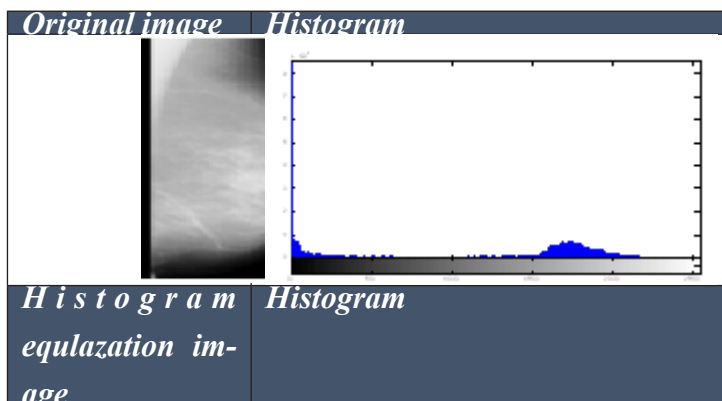

Figure (3): Mammographic Database

Histogram Equalization: Real life images are taken under different illumination conditions, which may affect the distinguishing ability of the patterns and features in the image. Thus, it is important to adjust the intensity of each pixel image through histogram equalization as shown in this Figure (4).

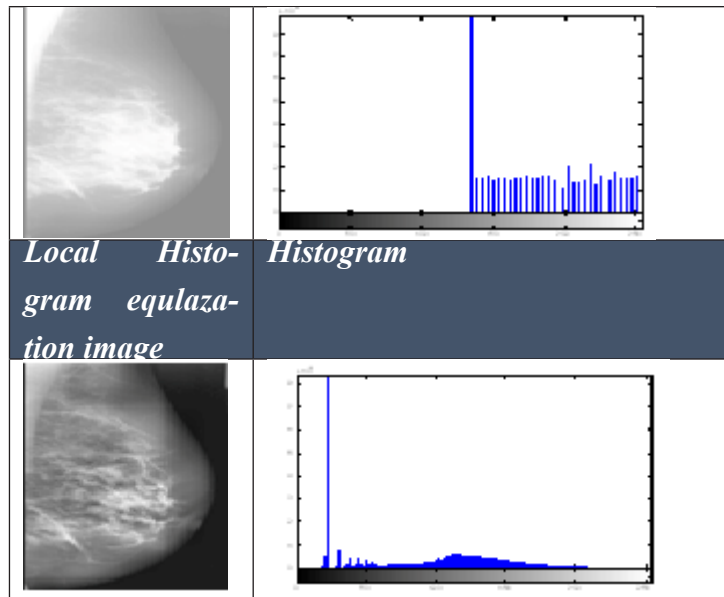

Figure (4):Histogram Equalization

• **CNN Classification:**The result of CNN detection of breast cancer divided three phases malignant, benign and normalas shown in this Figure (5) and Table (2) as shown Evaluation performance of CNN.

Figure (5): Breast cancer (malignant, benign and normal)

Table (2) Evaluation performance of CNN

breast cancer (malignant, benign and normal)
--

Sensitivity	45.32%	63.32%	95.1%
Specificity	45.43%	63.35%	99.3%
Accuracy	48.45%	63.40%	99.4%

Conclusion

To reduce the mortality rate because of breast cancer, it is very important to identify cancer in the initial phase.

Mammography from the mini-MIAS database is used in this paper. This database consists of 322 mammograms images, of which 52 are cancerous and 270 are normal. Ten texture features from CNN were calculated along 0°, and the feature space is reduced to six features using the Classification Features method. Results show 100% accuracy for validation and test data, and total accuracy achieved using the proposed method is 99.4%.

The Efficacy and Safety of Cinnarizine in the Treatment of Vertigo in a Sample of Iraqi Patients in Al-Diwaniyah Province

Ali Najm Abdullah¹, Qatarulnada Khudhair Abbas²

¹ ENT Specialist / Al-Diwaniyah Teaching Hospital / Department of Surgery / Al-Diwania / Iraq,

² Gynecology specialist / Al-Diwaniyah child and maternity hospital / Department of Obstetrics and gynecology / Al-Diwania / Iraq

Abstract

Background: Vertigo is a common vestibular disorder in daily clinical practice that is frequently described as rotational sensation by patients and caused by a variety of causes that can be central or peripheral in origin. Treatment should be directed toward underlying etiology, but symptomatic relief is required to improve patients' quality of life. Cinnarizine is frequently prescribed to relieve symptoms associated with vertigo; however little is known about its efficacy in daily clinical practice in Al-Diwaniyah province.

Aim of the study: To evaluate the safety and efficacy of cinnarizine in the treatment of vertigo in patients visiting ENT unit at Al-Diwaniyah teaching hospital.

Patients and method: The present cohort study included 66 patients of vertigo who were treated medically by cinnarizine (stugeron) and followed up for treatment response evaluation. The study was carried out in Ear Nose and Throat (ENT) unit in Al-Diwaniyah Teaching Hospital, Mid-Euphrates region, Iraq. The study started on June 2018 and ended on July 2019. The main variables included in the study were age, residency, level of education, occupation, other associated ENT manifestations and chronic illnesses. The primary outcome was response to treatment classified into satisfactory and unsatisfactory.

Results: Mean age of patients with satisfactory response was significantly less than that of patients with unsatisfactory response, 45.73 ± 13.31 years versus 54.95 ± 15.67 years, respectively ($P = 0.016$). Response to treatment was not significantly associated to gender, residency, occupation and education ($P > 0.05$). Response to treatment was not significantly associated to bilateral ear wax, acute otitis media, chronic suppurative otitis media, Meniere's disease and common cold ($P > 0.05$); however, it was significantly in the absence of hearing impairment and tinnitus ($P < 0.05$). Response to treatment was not significantly associated to uremia, trauma, anemia, hypothyroidism, anxiety, hypotension, arthritis and urinary tract infection (UTI) ($P > 0.05$), but significantly better in the absence of diabetes mellitus and hypertension ($P < 0.05$).

Key words: efficacy, safety, cinnarizine, vertigo, Iraq

Introduction

The problem of vertigo is among common clinical issues that are daily seen in emergency department and primary health care centers as well as private Ear Nose and Throat (ENT) clinics ¹. It is frequently described as sensation of motion by patients and mostly as rotational sensation ². It should be differentiated from lightheadedness or near syncope ². Vertigo is often due to abnormalities affecting vestibular system and the lesion could be peripheral or central ³. Vertigo is most often the

result of peripheral lesion such as Meniere's disease and benign paroxysmal positional vertigo (BPPV) ⁴. BPPV is caused by precipitation of calcium deposits in the posterior semicircular canal leading to recurrent attacks of vertigo that often extend for a few minutes ⁵. Meniere's disease is characterized by the presence of tinnitus, aural fullness and hearing impairment in addition to vertigo ⁶. The cause of Meniere's disease is attributed to increase in the volume of endolymph inside semicircular canal ⁶. Viral infection also causes peripheral vertigo due to acute vestibular neuritis of acute labyrinthitis ⁷. Ramsay Hunt

syndrome is another cause of peripheral vertigo caused by reactivation of latent varicella zoster virus in the geniculate ganglion with subsequent vestibulocochlear neuritis⁸. This syndrome is usually associated with signs and symptoms attributed to facial nerve involvement⁸. Other less common causes of peripheral vertigo are cholesteatoma, perilymphatic fistula and otosclerosis⁹. Central causes are due to involvement of cerebellum or vestibular nuclei by ischemic or hemorrhagic stroke¹⁰, tumors of cerebellopontine angle¹¹, vestibular migraines and multiple sclerosis¹². Other causes of vertigo include certain medications¹³, anxiety and other systemic chronic illnesses¹⁴. Vertigo is a frequent problem daily faced in clinical practice and estimated to affect about 10 % of population. It is more frequent in women than in men and its incidence increases with age. It causes significant impairment of quality of life; therefore its cause must be searched and treated properly¹⁵.

Management should be directed toward identification of the cause of vertigo because once the etiology is resolved symptoms disappear¹⁶. However, a number of medications are used to suppress vestibular symptoms for a while till identification of the cause. These medications include anti-histamines, benzodiazepines and antiemetics¹⁷. Cinnarizine (stugeron) is a calcium channel blocker with antihistamine properties is frequently used in clinical practice to relieve symptoms of vertigo arising from a variety of causes¹⁸. In the current study, the efficacy and safety of cinnarizine has been evaluated in a number of Iraqi patients presented with vertigo in Al-Diwaniyah province, Mid-Euphrates region of Iraq.

Patients and Method

The present cohort study included 66 patients of vertigo who were treated medically by cinnarizine (stugeron) and followed up for treatment response evaluation. The study was carried out in Ear Nose and Throat (ENT) unit in Al-Diwaniyah Teaching Hospital, Mid-Euphrates region, Iraq. The study started on June 2018 and ended on July 2019. The main variables included in the study were age, residency, level of education, occupation, other associated ENT manifestations and chronic illnesses. The primary outcome was response to

treatment classified into satisfactory and unsatisfactory. The study was approved by institutional ethical approval committee and a verbal consent was obtained from every participant after full illustration of the study aim and procedures. Obtained data were transformed into SPSS (version 23) spread sheet. Numeric data were expressed as range, mean and standard deviation, whereas, categorical data were expressed as number and percentage. Independent sample t-test was used to evaluate mean difference between two groups; while chi-square and Fisher exact tests were used to study association between categorical variables. The level of significance was considered at $P \leq 0.05$.

Results

The demographic characteristics of patients participating in the current study were demonstrated in table 1. According to response to cinnarizine treatment patients were categorized into two groups, satisfactory response group ($n = 45$) and unsatisfactory response group ($n = 21$). Mean age of patients with satisfactory response was significantly less than that of patients with unsatisfactory response, 45.73 ± 13.31 years versus 54.95 ± 15.67 years, respectively ($P = 0.016$), table 1. There was no significant association between gender and response to treatment ($P = 0.772$). There was also no significant association between residency and response to treatment ($P = 0.547$), table 1. In addition, there was no significant association between occupation and response to treatment ($P = 0.499$), table 1. Moreover, there was no significant association between education and response to treatment ($P = 0.542$), table 1. Regarding other ENT manifestations, response to treatment was not significantly associated to bilateral ear wax, acute otitis media, chronic suppurative otitis media, Meniere's disease and common cold ($P > 0.05$); however, it was significantly in the absence of hearing impairment and tinnitus ($P < 0.05$), as shown in table 2. Regarding other associated diseases and comorbidities, response to treatment was not significantly associated to uremia, trauma, anemia, hypothyroidism, anxiety, hypotension, arthritis and urinary tract infection (UTI) ($P > 0.05$), but significantly better in the absence of diabetes mellitus and hypertension ($P < 0.05$), as shown in table 3.

Table 1: Other ENT manifestations

Characteristic	Total n = 66	Satisfactory response n = 45	Unsatisfactory response n = 21	P
Bilateral Ear wax, n (%)	5 (7.6 %)	5 (11.1 %)	0 (0.0 %)	0.169 F NS
Acute OM, n (%)	4 (6.1 %)	4 (8.9 %)	0 (0.0 %)	0.289 F NS
Chronic suppurative OM, n (%)	4 (6.1 %)	4 (8.9 %)	0 (0.0 %)	0.298 F NS
Meniere's Disease, n (%)	3 (4.5 %)	2 (4.4 %)	1 (4.8 %)	1.000 F NS
Common cold, n (%)	2 (3.0 %)	2 (4.4 %)	0 (0.0 %)	1.000 F NS
Hearing impairment, n (%)	45 (68.2 %)	27 (60.0 %)	18 (85.7 %)	0.037 C S
Tinnitus, n (%)	44 (66.7 %)	25 (55.6 %)	19 (90.5 %)	0.005 C HS

n: number of cases; OM: otitis media; C: Chi-square test; F: Fischer exact test; NS: not significant at $P \leq 0.05$; S: significant at $P \leq 0.05$; HS: NS: highly significant at $P \leq 0.01$

Table 2: Associated diseases and abnormalities

Characteristic	Total n = 66	Satisfactory response n = 45	Unsatisfactory response n = 21	P
Uremia, n (%)	1 (1.5 %)	0 (0.0 %)	1 (4.8 %)	0.318 F NS
Trauma, n (%)	3 (4.5 %)	1 (2.2 %)	2 (9.5 %)	0.236 F NS
Anemia, n (%)	10 (15.2 %)	6 (13.3 %)	4 (19.0 %)	0.714 F NS
Hypothyroidism, n (%)	1 (1.5 %)	0 (0.0 %)	1 (4.8 %)	0.318 F NS
DM, n (%)	25 (37.9 %)	13 (28.9 %)	12 (57.1 %)	0.028 C S
Anxiety, n (%)	2 (3.0 %)	2 (4.4 %)	0 (0.0 %)	1.000 F NS
Hypertension, n (%)	20 (30.3 %)	8 (17.8 %)	12 (57.1 %)	0.001 C HS
Hypotension, n (%)	4 (6.1 %)	4 (8.9 %)	0 (0.0 %)	0.298 F NS
Arthritis, n (%)	4 (6.1 %)	3 (6.7 %)	1 (4.8 %)	1.000 F NS
UTI, n (%)	3 (4.5 %)	1 (2.2 %)	2 (9.5 %)	0.236 F NS

n: number of cases; C: Chi-square test; F: Fischer exact test; NS: not significant at $P \leq 0.05$ S: significant at $P \leq 0.05$; HS: NS: highly significant at $P \leq 0.01$

Discussion

In daily clinical practice, particularly in the unit of ENT, vertigo is a common clinical problem. This problem arises from a variety of causes; however, it can be basically considered as one of two major issues. Either a peripheral cause involving the vestibular system, as is the case in most of patients or a central lesion affecting the cerebellum or vestibular system causing vertigo in addition to other localizing neurologic clinical signs⁽³⁻⁹⁾. It is, indeed, the diagnosis of the exact etiology of vertigo and removing the specific cause, the ideal way to get rid of vertigo; nevertheless, in most of cases this not amenable until a period of time during which the patients quality of life is severely affected^(16, 17). For that reason symptomatic relief is sought by almost all patients in order to improve their quality of life and get rid of that annoying symptom. Several pharmacological agents are nowadays present but the efficacy of which is still not investigated in our health institutes. We select cinnarizine because it is the most commonly prescribed agent by most physicians in Al-Diwaniyah province in order to evaluate its efficacy and safety. In the current study, cinnarizine was effective and safe with negligible side effects. Its efficacy was seen in 45 out of 66 (68.2 %) which is comparable to a number of reports of several previous authors⁽¹⁸⁻²⁰⁾. However, we found that its efficacy is low in patients with hypertension, diabetes, tinnitus and hearing impairments. Therefore, we believe, that the treatment of the exact cause is the best therapy for those patients. In addition, the search for central cause such as ischemic stroke in those patients is mandatory since cinnarizine mainly acts on peripheral vestibular apparatus. Our findings are in line with several other authors with respect to poor response in case of tinnitus and hearing loss¹⁹. Therefore, Cinnarizine is effective and safe in the treatment of majority of causes of vertigo; however, some cases need other than cinnarizine to control their symptoms especially those patients with tinnitus, hearing impairment, diabetes mellitus and hypertension.

Conclusion

Cinnarizine is effective and safe in the treatment of majority of causes of vertigo; however, some cases need other than cinnarizine to control their symptoms especially those patients with tinnitus, hearing impairment, diabetes mellitus and hypertension.

Catalase Gene Polymorphism in Patient with Diabetes Disease Type 1 in Karbala City

Abdulridha Mohammed Al-Asady¹, Farah A. Al-marzook², Thoalffakar A. ALhamed¹

¹ Assist.Lecturer, College of Nursing, University of Warith Al-anbiya'a , Iraq, ² Lecturer, College of Nursing, University of Warith Al-anbiya'a , Iraq

Abstract

Diabetes Mellitus (DM) is a collection of metabolic diseases categorized by hyperglycemia caused by insulin excretion deficiencies, insulin performance, or both DM are categorized into distinct kinds. Type 1 diabetes (T1D) is defined by breakdown of β -cells, generally resulting in complete insulin deficiency. Type 2 diabetes (T2D) is a consequence of peripheral tissue insulin resistance. a complete of fifty patients and fifty control subjects were collected between February to October 2018. The genotyping of catalase were attained consuming polymerase chain reaction (PCR) in addition to restriction fragment length polymorphism (RFLP). We tend to firm vigorous changes within the genotype occurrences of catalase between patients with diabetes and controls using the $P=0.038$, $OR =0.58$ (0.48-0.78).

Keywords: Diabetes, RFLP, catalase, SNPs. Polymorphisms.

Introduction

Type 1 diabetes mellitus (T1DM) is the greatest public metabolic disturbance in which together hereditary and environmental aspects were complicated ¹. It had been assumed that while kids had a hereditary predisposition to T1DM, there are expected to an environmental aspect that activates progress of T1DM. The initiates have proposed involve viral contagion, vaccines, vit D lack , and cow's milk ².

The corrosion of in elevation levels of glucose in diabetic cells products extra electron givers (NADH and FADH₂) and rises the electron transmission, thus generating superoxide, spare generation of ROS like superoxide (O₂ •₂), hydrogen peroxide (H₂O₂), and hydroxyl radical (•OH) and responsive nitrogen classes like nitric oxide oxidize aim cellular proteins, nucleic acids, or lipid layers and destruction their cellular arrangement and function ³.

Overproduction of free radicals i.e., oxidative stress may effect oxidative destruction to lipids, proteins and DNA, finally leading to several chronic diseases like diabetes, myocardial infarction, cardiovascular diseases, atherosclerosis, stroke and other degenerative diseases in humans ⁴. Moreover, hyperglycemia-induced generation of reactive oxygen species (ROS) on the

mitochondrial level is the original trigger of malicious rotation of oxidative stress in DM ⁵.

Catalase (CAT) is present in peroxisomes and occurs as a dumbbell-designed tetramer of 4 equal axillary units. CAT quickly catalyzes hydrogen peroxide breakdown into less proactive oxygen and water particles. Insufficiency of catalase has been identified to direct to T2DM improvement ⁶. Catalase gene is positioned on chromosome 11p13. Exon 2 and adjoining introns of the catalase gene were supposed to modification heated stains aimed at T2DM vulnerability ⁷. Adjustment of cysteine to cysteic acid to tyrosyl nitration of CAT and reduced activation in cases of oxidative stress ⁸. In type 1, 2 and gestational cancer (GD) and disorders such as diabetic retinopathy (DR), diabetic nephropathy (DN), ischemic heart disease (IHD) and CVD ⁹, the exon 9-262C / T polymorphism in the catalase gene was screened. In addition, this purposeful polymorphism funded T2DM's progress and its issues ¹⁰. The A / T polymorphism genotype of the CAT gene ' AT ' can elevate the hazard of T2DM in northern Indians ¹¹.

Methodology

Sampling

Fifty blood samples had gathered of patients with

primary diabetes whose visits diabetes Center /Hilla/Iraq and fifty samples as control.

DNA Extraction

Genomic DNA of complete blood cells was derived and filtered by Extraction and filtration Kit of Favergen Company (Taiwan).

Using RFLP- PCR amplification for Genotypic Identification

The directed positions of DNA were intensified using special primers was designed: collected of Bioneer, IDTDNA (USA). Primer: Frontward categorization was 5- CTGGGTATCTCCGGTCTTCA-3, and opposite categorization was 5- CCGCTTTCTAAACGGACCTT-3.

PCR was done in 20µl response measurements covering 1 µl of back and forward primers, 12.5 µl of Green Master Mix, 3 µl of Genomic DNA, and the reaction volume was finished up to 20 ul by containing with 2.5 µl of Nuclease allowed water. Intensification had been completed in a thermo-cycler customized at 94 ° C for 2 min ; 5 minutes at 94 ° C for 35 cycles, 1 at 57.8 ° C and 1 at 72 ° C; and a last five mins extension. PCR products were electrophoresed using 1% agarose gel electrophoresis at 75 V for one hour using ethidium bromide. Photographs had been obtained utilizing the context of gel documentation. Through the Promega Company Protocol, the PCR item became removed utilizing *HinfI* restriction endonuclease, the PCR-

RFLP technique achieved stable. The next ingestion of MSPI feedback was electrophoresis utilizing gel electrophoresis (Cleaver Scientific–UK) in 3% agarose gels at 75 V of one hour and 8% polyacrylmide gel electrophoresis control associated with the following: 75 V, 20 Am for 160 minutes. Gels pictured subsequently by ethidium bromide. Utilizing gel documentation system (EBOXCX–UK) photos were obtained.

Statistical Method

The SPSS applied mathematics software system (17 ; SPSS Inc., Chicago, IL) was finished with total practical math analysis, and P- values < 0.05 were thought to be statistically important.

Results

study Genotype result

Deoxyribonucleic acid had been extracted from the blood sample Figure (1) revealed the catalase gene amplifying consumer’s agarose gel electrophoresis shot, measuring up to 369 bp portion. Issues of PCR-RFLP system catalase-related quality polymorphisms utilizing *HinfI* containment chemistry disclosed that there are three instances of genotype polymorphisms, which involve homozygous genotype (2 band, 200,175 bp), The second type was homozygous genotype (1 band 369 bp) and third example stayed heterozygous genotype (3 bands , 200,175 and 369 bp) which came about three DNA groups

Figure (3): Arrangements alignment ID: catalase gene fragment for *Homo sapiens* by use Bio Edit program

Discussion

Firstly, catalase gene polymorphism was studied in Diabetes conditions and controls. The spreading witnessed in catalase gene polymorphism in control set and conditions clusters are revealed into tab (1) maximum genotype in control group remained homozygote genotype 1 band (81.2%) followed by homozygote genotype 2 band (19.1%) and mutant heterozygote genotype 3 bands (0%) and. In Diabetes disease, peak genotype in Diabetes group was homozygote genotype 1 band (52.2%) followed by homozygote genotype 2 band (26.4%) and mutant heterozygote genotype 3 bands (20.58%). Sequencing findings proven haplotypes detected in our work. Various single nucleotide polymorphism (SNP), were taken between DNA polymorphisms (1, 2 and 3 bands) and Catalase NCBI Primer3^{plus} reference. Worldwide, DM is one of the maximum non-communicable diseases in the public. As per the International Diabetes Federation (IDF), they had 366 million persons among 20-79 years of age who had diabetes¹². IDF also reported that DM in 2011 culminated in as many as 4.6 million fatalities¹³. Among kids, T1D has the greatest prevalence of various kinds of DM, with the largest occurrence recorded in Finland and Sardinia and the lowest in China and Venezuela¹⁴. Among the youngest kids, particularly among the European population, the rise is the highest. “The number of children developing this form of diabetes every year has increased rapidly all over the world, except in Central America and West Indies where the trend is decreasing (14). However, latest research regarding incidence of T1D for children in Finland highlighted two significant changes in the trends between 1980 and 2011”. The study revealed up to 2005 an annual rise, accompanied by a plateau until the later part of 2011¹⁵. A comparable plateau incidence from 2005-2007¹⁶ and Norway from 2004-2012¹⁷ has also been recorded by Sweden. “Catalase is one of the main enzyme components of cell defense counter to oxidative stress and it had been hypothesized that the polymorphism CAT decreases the antioxidant capacity and can serve as a risk element for oxidative stress associated diseases. The association among SOD1-251 A/G, CAT-21 A/T, and GPX1-198C/T antioxidant gene polymorphisms in the risk of cataract was informed between Chinese population”¹⁸. Our results showed significant differences between patients and controls, Other results showed that CAT polymorphism was linked to enhanced hazard and began playing an essential role in diabetes pathogenesis¹⁹. On the other side, little

reviews had revealed the polymorphism of the catalase gene not related to the risk of cardiovascular diseases among type 2 diabetes mellitus in Finnish population²⁰ and also among type 1 diabetes mellitus patients in Czech population²¹. Other study exhibited No association between the catalase polymorphism and DM was detected in diabetic patients of type 2 Caucasian-Brazilian. That’s the earliest research planned for our data to investigate the relation between a polymorphism of the catalase gene and diabetic problems of patients with type 2 diabetes. Though catalase has mostly been researched, little studies have been specially examined relations of catalase polymorphisms through diseases²² To conclude, our findings provision the hypothesis which the polymorphism in the catalase enzyme connected to both the progress for diabetic retinopathy, diabetic nephropathy or ischemic heart disease popular Iraqis with type 2 diabetes.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Warith Al-anbiya’a and all experiments were carried out in accordance with approved guidelines.

²Assist. Professor; Psychiatric Mental Health, ³Lecture, Family and Community Health Nursing Department, College of Nursing, University of Kerbala, Kerbala City, Iraq

Abstract

Renal dialysis patients face many challenges during the treatment period and are subjected to many psychological stresses, but depressive symptoms of dialysis patients are associated with higher mortality. This study aims to assess the level of depression in patients with chronic renal disease undergoing haemodialysis treatment; 60 patients with chronic renal failure receiving haemodialysis treatment were recruited from Al-Hussain hospital in one of the religious cities in Iraq. Depression was assessed using the Beck Depression Inventory. The results showed that most participants had severe and extreme levels of depression, and higher scores were representative of somatic depressive symptoms. There was no significant association between depression and patient demographic data. Depression should be assessed by nurses, and patients should be referred for treatment to decrease mortality and improve disease outcome.

Keywords: Depression, Renal failure, Haemodialysis, Beck Depression Inventory

Introduction

Haemodialysis is a long-term treatment provided to patients with end-stage chronic renal failure. Patients suffer from this treatment despite it being a life-saving and irreplaceable treatment². Renal dialysis continues throughout the life of the patient, which changes the role of the patient in his or her family and increases his or her despair, feelings of hopelessness and fear of death, which affects quality of life³. Depression is one of the most serious psychological problems for a dialysis patient and has a serious impact on the quality of life of the patient and his or her family¹⁷. Depression has negative effects on all aspects of a patient's life, affecting social, economic, and physical aspects Kimmel, (2002) including increased incidence of illness and numbers of hospital admissions, reduced desire to take medication and, more importantly, increased desire to end life (24, 18). Patients lose control because of the inability to perform their role in their family and work, which increases their despair and hopelessness⁵. Symptoms of severe depression, such as sadness, anxiety, loss of interest in any activity, lack of self-esteem, pessimism toward the future, sleep disorders and lack of appetite during the period of dialysis, are found in many dialysis

patients⁷. Renal dialysis patients face many challenges during the treatment period and are subjected to many psychological stresses, but depressive symptoms represent the most common symptom of dialysis patients and are associated with higher mortality. Dialysis treatment changes the patient's role in their family and work and increases the patient's dependence on others; patients have feelings of fatigue and feel that the disease has overcome them¹⁹ because symptoms of severe depression may be misdiagnosed. From this point of view, it becomes necessary to evaluate depression in dialysis patients to help them think logically and to relieve their psychological stresses². Many studies have been conducted to assess the psychological condition and quality of life of a dialysis patient, and the results may vary because of differences in culture and differences in the social, economic and political status of the studied countries. Chronic renal failure tends to be an epidemic and a serious disease³. In Iraq the Ministry of Health announced in 2018 that there was an increase in patients with chronic renal disease needing haemodialysis treatment of approximately 20% each year in all of Iraq; however, there has been no precise study on the prevalence of depression in dialysis patients⁶.

Methodology

Design, setting and sample

A descriptive analytic study design was carried out to assess depression in patients with renal failure undergoing haemodialysis at Al- Hussain Medical City in Holy Karbala city. An official request was submitted to a health director (Training and Developing Center). Then, permission was obtained from Al Hussain Medical City in Holy Karbala city. The study was conducted in Karbala city. Karbala is a city in central Iraq located 100 km southwest of Baghdad and has an estimated population of 1,376,000 people. It is considered a Holy city for Shi'aha Muslims and is visited by many people, especially on religious occasions. The Chronic Renal Center is the only centre in Al Hussain Medical City, It is visited by 400-500 patients annually, some of whom were treated in the haemodialysis unit. A non-probability (purposive) sample of (100) renal failure patients was chosen; 40 patients refused to participate for different reasons, including family refusal of their participation and because of feeling too tired. Only the patients who agreed to participate and verbal consent were included in the study, and the rights of the participants were respected throughout the research process; confidentiality was ensured by not sharing any information with others. Only 60 patients gave their consent to participate. These patients were selected according to the following criteria after reviewing their medical records:

- a. Iraqi patients diagnosed with chronic renal failure by a consultant.
- b. Patients treated with haemodialysis at least twice weekly for more than 6 months.
- c. Patients of both sexes
- d. Patients at least 10 years old.
- e. Patients with no history of known mental disorder.

Procedure and Questionnaire

After receiving approval from the hospital where the patients were treated, the purpose of the study was explained to the potential study participants, and the questionnaire was distributed after the patients agreed to participate in this study. Patients were interviewed for 10-15 min before they started their haemodialysis. Some patients needed help from the researcher to

explain the Beck depressive items. The questionnaire consists of two parts, as follows: The second part of the questionnaire includes the 21 items of the Beck Depression Inventory BDI-II¹², which was revised in 1996 to be more consistent with the DSM-IV criteria for depression⁹ and was translated to the Arabic version¹. The questionnaire, which is believed to have the most sensitivity and specificity in making psychiatric diagnoses of depression in end-stage renal disease patients, was used to assess the level of depression. Each item consists of 4 choices to explain the patient's feelings and measures the level of depression. The evaluation of depression levels performed according to the table below.

Total Score	Levels of Depression
1-10	These ups and downs are considered normal
11-16	Mild mood disturbance
17-20	Borderline clinical depression
21-30	Moderate depression
31-40	Severe depression
over 40	Extreme depression

A cut-off score of 14 to 16 on the Beck Depression Scale is believed to be with a psychiatric diagnosis of depression³⁹. The reliability of the present study instrument was determined using the Alpha Cronbach approach²⁰. The result reliability coefficient for the patients was $r=0.73$, and the patient's agreement to participate was assigned; a private interview technique was used to ensure confidentiality during data collection.

Data Analysis

Data were analysed through the application of appropriate statistical methods by using the statistical package of social science (SPSS) version 22 to analyse and evaluate the results of the present study. Descriptive statistics were used (means, standard deviations, frequencies and percentages) to determine the patients' characteristics and levels of depression. One-way ANOVA was used to determine any significant association between the level of depression and the patients' demographic characteristics.

Results

Analysis of the results showed that 61.7% of the participating patients were female; 40% were 41-60 years old with a mean age of 47.96 SD(13.4), primary level of education(43.3%) and were often married and housewives, and more than two thirds suffered from hypertension(83.3%), while almost half of them reported

having diabetes(46.7%). Most of the haemodialysis patients had started their treatment within the last 6 years (1-3 years duration, 55%; 4-6 years duration, 31.7%) (Table 1).

Table (1): Sociodemographic characteristics of the sample

No			Frequency	Percent

		Widowed	1	1.7
		Total	60	100.0

Depression was found in all of our patients; 1.67% of patients were moderately depressed, 41.67% were severely depressed, and 56.66% were extremely depressed. These rates were higher than those in other studies, with a cut-off score of 14³⁹. The mean BDI was 41.2167(SD=5.45270), and the cut-off point was 1.963 (Table 2). When classifying BDI into somatic and psychological symptoms, it was observed that the mean somatic symptoms of depression score was 2.224, while the mean psychological symptoms score was 1.858. The somatic symptoms of depression were changes in sleep patterns(2.483), irritability (2.300), fatigue(2.233), changes in appetite (2.167), loss of energy (2.150), and loss of interest in sex(2.017). With regard to psychological depression symptoms, the results revealed that haemodialysis patients reported agitation, worthlessness, concentration difficulty, loss of interest, crying, self-dislike, sadness, self-criticism, pessimism, feelings of past failure, indecisiveness, loss of pleasure, feelings of guilt, feelings of punishment, and suicidal thoughts/wishes; the mean scores for these symptoms were 2.400, 2.217, 2.167, 2.083, 2.017, 1.883, 1.883, 1.850, 1.833, 1.767, 1.750, 1.717, 1.567, 1.433, and 1.300, respectively. However, there were no significant differences found between depression levels and the patients' demographic data.

Table(2): The level of depression among the sample

Items	Mean	Std. Deviation
Sadness	1.8833	.90370
Pessimism	1.8333	.76284
Feelings of past failure	1.7667	.85105
Loss of pleasure	1.7167	.76117
Feelings of guilt	1.5667	.74485
Feelings of punishment	1.4333	.74485
Self-dislike	1.8833	1.35411
Self-criticism	1.8500	.77733
Suicidal thoughts/wishes	1.3000	.74333
Crying	2.0167	.89237
Agitation	2.4000	.78546
Loss of interest	2.0833	.76561

Worthlessness	2.2167	.66617
Loss of energy	2.1500	.79883
Change in sleep pattern (Insomnia)	2.4833	.77002
Irritability	2.3000	.72017
Loss of appetite	2.1667	.84706
Concentration difficulty	2.1667	.90510
Tiredness and fatigue	2.2333	.76727
Loss of interest in sex	2.0167	.96536
Total	41.2167	5.45270

Total mean score = 41.2167 (SD=5.45270). The cut-off point (1.963)

Discussion

This study aimed to assess the level of depression in patients with chronic kidney failure treated with haemodialysis and to determine whether depression has any association with sociodemographic factors. Depression was found in almost all of the dialysis patients. Due to our result, depression was higher in our sample than in other studies that also used the BDI, such as those conducted by ²⁹ (45%), ⁵⁷ (42.7%), ²⁶ (30%), ³¹(39.3%), ²⁷ (42%), and ³(44%). These differences may be because most of our sample was female (61.7%); the majority were married and were responsible for a family, but because of the long-term haemodialysis treatment, which leads to a disturbance in family dynamics, they failed to play their role²¹. Our result corresponds to a study by ³, which found that 80% of haemodialysis patients in Baghdad had depression associated significantly with female sex and unemployment. In addition to the poor delivery of services in hospitals, there is an especially poor proportion of haemodialysis machines in the population, which causes a great burden on women and their families, ⁶. Additionally, there is no other treatment choice, such as transplantation, due to a shortage of kidney donors, and transplantation requires more social and governmental support in Iraq (⁷, ⁴). Therefore, patients need to remain on haemodialysis treatment for a long time; these two causes may be the only explanation for the increased level of depression in haemodialysis patients in Karbala. In the present study, somatic Beck depression symptoms had a higher mean score (2.224) than psychological symptoms (1.858) such as insomnia (2.48), irritability (2.30), fatigue (2.233), loss of appetite (2.167), loss of energy (2.150) and loss of libido (2.017). The higher psychological depression symptom scores were agitation (2.40), worthlessness (2.216), concentration difficulty (2.167), anhedonia (2.083) and crying (2.017). Haemodialysis patients in Karbala expressed depression with physical symptoms more than with psychological symptoms.

Conclusion

The study found that depression is at a high level in kidney failure patients treated with dialysis, is especially prevalent in females and is expressed by somatic symptoms more than psychological symptoms in a religious city; those of medium to old age, those with low education, and unemployed females were found to be more depressed, although there was no significant association among these patient demographic factors.

Depression should be treated to decrease morality and improve disease outcome.

Abstract

Diabetes is a predominant public health concern that has increased steadily worldwide . The disease causes substantial morbidity, mortality and long term complications. Herbs and natural products have been used in treatment of diabetes mellitus . Herbs and other plant products are considered more natural. They are a kind of home treatment and can be a part of home usual diet . Use of herbs is becoming popular more and more and is more appropriate for use in developing countries. The aim of this study was to examine the prevalence of use of herbal remedies among diabetic population in Nasiriya and to identify factors which might predict the likelihood of using herbal remedies. Cinnamon (Darcien) 12.3% and Black cumin(Habba soda) 11% . On univariant analysis , the factors which were found to affect the herbs use were education ,occupation , type of diabetes mellitus , duration of diabetes ,marital status and age . Using data analysis ,the significantly associated factors were occupation type of treatment and drug regularity . Health care providers should respect patients' wishes to use herbal remedies and should provide advices about treatment by herbal remedies.

Keywords: *Alternative medicine, diabetic, patients*

Introduction

Despite recent advanced in care and management, diabetes mellitus continues to be an important public health concern, causing substantial morbidity, mortality and long term complications. ¹ with increasing rates of childhood and adult obesity, diabetes is expected to become even more prevalent in coming decades, and its remains a significant risk factor for the Development of cardiovascular disease. ² The care of persons with diabetes has been influenced by a growing interest in complementary and alternative medicine (CAM).The use of alternative medicine (AM) has increased recently and attracted the attention of many researchers all over the world. (3,4)

Definition of diabetes mellitus

Diabetes is a chronic disorder in metabolism of carbohydrates , proteins and fat due to absolute or

relative deficiency of insulin secretion ,insulin action or both . ⁶ According to American Diabetes Association ,diabetes is defined as fasting plasma glucose value of at least 126 mg/dl (7mmol/l) or post glucose load of \geq 200mg /dl (11.1mmol/l)or both. ⁵

Diagnostic criteria for diabetes

The average plasma glucose level of a healthy man is 80mg/dl on fasting and up to 160 mg/dl in the postprandial state . Diabetes mellitus is characterized by recurrent or persistent hyperglycemia , and is diagnosed by demonstrating one of the following :

Fasting plasma glucose level at or above 126mg /dl (7.0 mmol/l)

Plasma glucose at or above 200mg/dl(11.1 mmol/l) two hours after a 75g oral glucose load in a glucose tolerance test.

Random plasma glucose at or above 200mg /dl (11.1 mmol/l).⁵

Tow fasting glucose measurement above 126mg/dl(7.0mmol/l)or random blood sugar level >200mg/dl (11.1mmol/l) on two occasions is considered diagnostic for diabetes mellitus. Patients with fasting plasma glucose between 110_125 mg/dl (6.1_7.0mmol/l)are considered to have impaired fasting glucose and patients with plasma glucose at or 140_200 mg/dl(7.8_11.1mmol/l) tow hours after a 75g oral glucose load are considered to have impaired glucose tolerance .⁶

Classification

Type 1 diabetes : it accounts 10% of diabetes patients, islet B- cell destruction usually leads to absolute insulin deficiency .patients are completely reliant upon exogenous insulin to prevent ketosis and other complications^(6,7) .

Type 2 diabetes : it accounts for more than 85% of cases worldwide. It is a heterogeneous type ranging from insulin resistance to insulin deficiency.

Type 2 diabetes is a multifactorial disease with both genetic and non genetic components^(6,7)

Other specific forms

Genetic defects of B cell function e.g. maturity onset diabetes of the young(MODY Syndromes)

Genetic defects in insulin action e.g. leprechaunism

Disease of the exocrine pancreas e.g. pancreatitis

Secondary to endocrinopathies ,e.g. acromegaly.

Drug or chemical induced , e.g. glucocorticoids

Infections , e.g. congenital rubella

Uncommon forms of immune_ mediated diabetes ,e.g. Stiff Man syndrome

Other genetic syndromes associated with diabetes ,e.g. Down ‘s syndrome.

Gestational diabetes : It is the diabetes which develops during pregnancy due to carbohydrates intolerance.⁶

Methodology

The overall study design

This study is descriptive cross sectional study , conducted in Nasiriya city from the period of 1st of January to the 30th of May 2010 on attendants of a diabetic center .

The study population

The participants were diabetic subjects of both gender attending diabetic center in Nasiriya city, who were aged 18 years and above.

Sampling and sample size

All diabetic patients who attending the diabetic center during the period of study were included. The total number was 885(516 females and 369 males). Data collected by direct interviewing, non-response was not reported.

The study tools

Interviewing (The questionnaire)

A structured questionnaire was used (Appendix 1), it was based on extensive literature review and it covers the following aspects :

A_ Sociodemographic data :age ,sex ,marital status ,educational status ,occupation ,monthly family income ,residence .

B_ Medical history of diabetes mellitus : including complication and control of DM depending on patients documents or reports ,types ,duration , Treatment and family history of diabetes .

C_ Information about the use of herbal or alternative medicine were acquired : use of herbal remedies in the last year , the type of herbal medicine ,duration of use ,cause of use and benefit from use .

D_ Type of treatment : Either on diet only ,oral anti diabetic drugs ,insulin alone and those on mixed treatment.

E_ Regularity of drug intake (anti diabetic drugs) : Regular or irregular .

Anthropometric measures :

A_ Height : Height was measured while the subject was standing without shoes with the heels touching the ground .

B_ Body weight : It was measured in (Kg)with the

subject wearing light clothes as possible , by portable weight balance to the nearest 0.5 kg .

C_ Body mass index (BMI) : Calculated by using Quetlet index ⁴⁰

BMI =weight in kg /height in square meter

Non obese : BMI < 25 kg /m²

Overweight : BMI 25 _29.9 kg /m²

Obese : BMI > or = 30kg/m²

Morbid obese : BMI > or = 40 kg/m²

Data collection

pilot study

The pilot study was carried out in diabetic center in Nasiriya city on 30 attendants who were included in the proper study . The aim was to asses the time required , the clarity and flow of the question and the expected response rate . In the light of this pilot study , the final proper study was prepared for .

The proper study :

The diabetic center was visited daily from 9_12 a.m. All the patients who visited the center at that time were interviewed in a quiet separate room after an informed consent was obtained. Each interview took about 15 minutes (on average 12 patient per day).

Statistical analysis

Data were analyzed using SPSS version 15 ,the data were tabulated and significant association between different variables .

Result

Table 1 shows the sociodemographic characteristics of the study population. Of the total participants,336(38.0%) were in the age group between 41-55 years , 356(40.1%) were in the age group \geq 56 years , 150(16.9%) were in the age group between 26-40 years and 43(4.9%) were in the age group 18-25 years.58.3% were females and 41.7%were males . The majority were married (77.7%). Most of participants were illiterate (51.3%), (72%)were un employed ,(65%) had intermediate monthly income, and most of them 65.5% were nonsmoker.

Table 2 presents the distribution of the study population according to diabetic and medical history. Regarding the duration of diabetes mellitus most of studied population had 1-5 years duration (48.3%), while those who had diabetes mellitus more than 5 years duration constituted (45.4%), and only 6.3% had a duration of diabetes mellitus less than one year. Most

of the patients were with type 2 diabetes (89.6%) , and only 10.4% were with type 1 diabetes . The percentage of those with diabetes complications was 58.9%. Most of the patients were on oral antidiabetic drugs which wae used in 70.8%, those who used insulin were 24.6% . The majority (89.9%) of them were on regular treatment.

The traditional medicine which include herbal medicine is an accessible and affordable health care resource for many countries including Eastern Mediterranean region .³³ In general people believe that herbal therapy is more modern pharmaceutical . The popularity of the herbs or the treatment of patients with chronic diseases may be attributed to the long standing suffering of the patients or failure of the medical treatment to bring a quick and long lasting .³⁴

Conclusions

Herbal remedies are 17.4% used by diabetic patients in Nasiriya. Many factors affect the use of herbal remedies such as occupation, antidiabetic treatment regularity ,educational level ,duration of diabetes and type of diabetes. Most diabetic patients in Nasiriya had a positive attitude with the use of herbal remedies .

Testosterone and Progesterone Levels, Gene Expression of Androgen and Progesterone Receptors in Albino Male Rats Treated with Phenolic Flower Extract of *Hibiscus Rosa - Sinensis L*

Rawaa S.A.AL-Azawi.¹ , Faris N. A. Al-hady²

¹Department of Physiology, College of Veterinary Medicine, AL-Qasim Green University- Babylon-Iraq.

²Department of biology, College of Science, University of Babylon, Babylon -Iraq

Abstract

Hibiscus rosa sinensis L. is one of medicinal plant and belongs to the family Malvaceae , *Hibiscus* species are used in the treatment of many disease, flowers are used to stimulate hair growth , wounds healing activity, anti-parasitic effect , Antidiabetic anti-hyperlipidemic activity. and have many pharmacological properties including anti-fertility , antipyretic, antispasmodic, antifungal, anti-inflammatory and many more. This study was conducted in the department of Biology /College of Science/University of Babylon/Iraq , to evaluate the Effect of Phenolic Extract of *Hibiscus rosa - sinensis L.* flowers on some biomarkers and gene expression in Albino male Rats .The overall number of animals used were 32 male rats aged 2-3 months. The results showed a significant decrease ($p < 0.05$) in the level of Testosterone and Progesterone in treated rats as compared with control groups for 30 and 60 days. Also the result revealed a significant decrease ($p < 0.05$) in the expression of the androgen receptors and progesterone receptor in the testicular cells treatment group with phenolic compounds of *H. rosa - sinensis* flowers at a dose of 300mg / kg /day of body weight for 60 days compared to control groups.

Keywords: Phenolic Extract, *Hibiscus rosa - sinensis L.* Testosterone, Progesterone, gene expression, androgen receptor, progesterone receptor

Introduction

Many plant extracts can be used as contraceptives by inhibiting the fertility of males and females ¹ however, those plant extracts, that have been developed into contraceptive are very few and have not been identified the methods of operation and effectiveness accurately because of the difficulty in finding out the active ingredients of the extract to be used as a herbal contraceptive² . Fertility in males is directly affected by the sex hormones produced in the testes, which are called androgens, testosterone is the main androgen of the males, which also produced by the cortex of the adrenal gland. Testosterone begins during embryonic development and last for a short period after birth and stops during the childhood and then produced very significantly at puberty. It is responsible for the growth and development of the male reproductive system, bones, muscles, enlarged throat, change of sound, hair growth and increased sexual desire ³ . Most plants

used in the regulation of fertility weaken the process of steroids synthesis by targeting the enzymes involved in this process at the level of leading cells or at the level of hypothalamus- pituitary gland- gonads, it has been shown that many botanical products targeting the Leydig cells and hindering their action ⁴.The medicinal plant extracts used in Chinese traditional medicine which containing alkaloids as one of the active compounds, caused a decrease in the level of gonadotropin hormones and testosterone which are caused edema in the interstitial tissue of mouse testis treated with these extracts ⁵. Gene expression is the process by which information from a gene is used in the synthesis of a functional gene product. These products are often proteins, but in non-protein coding genes such as transfer RNA or small nuclear RNA genes, the product is a functional RNA⁶. In genetics, gene expression is the most fundamental level at which the genotype gives rise to the phenotype. The genetic code stored in DNA is “interpreted” by

gene expression, and the properties of the expression give rise to the organism's phenotype, such phenotypes are often expressed by the synthesis of proteins that control the organism's shape, or that act as enzymes catalyzing specific metabolic pathways characterizing the organism. Regulation of gene expression is thus critical to an organism's development⁷.

Materials and Method

The flowers of *Hibiscus rosa-sinensis L.* were collected from nursery and agricultural areas in Babil province in April and May 2018. The plant was identified by Dr. Neddaa Adnan, plant herbarium/ Department of Biology/ College of Science/ University of Babylon. The flowers were collected in flowering stage after they were well cleaned and washed with water and left to dry in the air at room temperature for two weeks. After that the dried flowers were blended with a blender, until use.

Preparation of crud phenolic compounds of *Hibiscus rosa sinensis L.* flowers

The Crude phenolic compounds were extracted according to⁸ method putting 10 gm of powder flower in a flask (500 ml) and added 400 ml of acetic acid 2%. The phenolic compounds of the plant were extracted by using reflex condenser in water bath(70°C) for 8 hours. The solution was leaved to cool down after the completion of extraction. Filtrated by a separatory funnel, and added to it an equal volume of n- propanol and amount of sodium chloride until saturation. Two layers formed, the upper layer containing the phenolic compounds and neglected the lower layer, the upper part has been concentrated in a rotary evaporator then dried in oven (40°C), kept in refrigerator until use.

General phenolic Reagent

This reagent was prepared by mixing two equal quantities of aqueous solutions of 1% ferric chloride and 1% of potassiumic ferric cyanide. The extraction was derided after it was obtained by dry calcium chloride (CaCl₂) to get rid of any effect of the moisture which could affect the identification, then the compounds of *H. rosa sinensis* extract was identified by infrared spectrum by using Ft. Infrared spectroscopy³.

First experiment : Effect of *H. rosa- sinensis* flowers extract on hormones levels

This experiment include 32 male albino rats divided into two groups

1. Control (n = 16) treated orally with one ml of tap water .

2. Treated group (n = 16) treated orally with 300mg / kg /day of phenolic compounds of *Hibiscus rosa- sinensis* flowers extract .

After 30 days of treatment isolated 8 animals from each group (control and treatment) blood sample had been taken from animals for evaluated: Testosterone and progesterone hormones instruction of kits(Maglumi Testosterone CLIA/ China) .The other animals (included 8 control and 8 treatment) , was continue treatment for 30 other days , so that the treatment become 60 days . same biomarkers estimation were done like the first period (30 days) .

Second experiment : Genetic study

Control group : (n = 3) treated orally with 1 ml of tap water for 60 days

Treated group: (n = 3) treated orally with 300 mg/ kg /day phenolic compounds of *Hibiscus rosa- sinensis* flowers for 60 days .

Tissue preparation

Testis of each rat were collected immediately. Half of the sample had been frozen and stored at -80C until analysed.

Total RNA extraction and Real-Time PCR.

Total RNA was extracted from the samples according to the protocol of TRIzol™ Reagent (Thermo Scientific, USA).Complementary DNA (cDNA) was constructed by reverse transcription (Promega Corp., Madison, WI, USA) using the total RNA as a template .The primers used for rat AR,PR and glyceraldehyde 3-phosphate dehydrogenase (G3PDH) as a reference gene in RT-PCR were as follows : AR forward,5-TGTTATCTAGTCTCAACGAGC-3; AR revers,5-CATCATTTTCAGGAAAGTCC-3; PR forward, 5-CTCCTGGATGAGCCTGA TG-3; PR reverse,5-CCCGAATATAGCTTGACCTC-3,G3PDH forward,5-TCCCATCACCATCTTCCA-3 and G3PDH reverse,5-CATCACGCCACAGTTTCC-3.The PCR system consisted of 5 µl of SYBR Green qPCR mix; 0.25 µl of cDNA,0.25 Mgcl₂,2.5 Nuclease Free Water and primer pairs (0.5 µM forward and 0.5 µM revers) in a total volume of 10 µl. PCR was performed using standard protocols using the annealing temperature for 30 s at

52 °C. A final extension cycle was performed at 72 °C for 30 s. The melting curve program was 72-95 °C, with a heating rate of 0.3°C/s and continuous fluorescence measurement, the expression level of these genes was evaluated by an image software.

Results and Discussion

The effect of phenolic extract of *H.rosa sinensis* L. on Testosterone, Progesterone hormones level :-

Table 1 showed that the treatment of Albino rats with a dose of 300 mg/kg/day of body weight of phenolic compounds of *H. rosa- sinensis* flowers caused a significant decrease ($p < 0.05$) in the level of Testosterone and Progesterone in treated rats compared with control groups. The level of these hormones in both groups in comparison study between 30 days and 60 days of treatment revealed insignificant differences ($P > 0.05$) between two periods for each hormone (Figure 1,2). These results are consistent with the results of (9, 10), which revealed that the phenolic compounds of *H. rosa- sinensis* caused a decreased level of testosterone in serum of treated rats. The reason for the low testosterone level may be due to the effect of *H. rosa- sinensis* extract reducing the level of cholesterol and low density lipoproteins (LDL) in the blood (11). As the cholesterol derived from LDL is the basic compound in the process of testosterone synthesis in Leydig cells (12). The phenolic compounds of green tea reduced the level of testosterone through their effect on the enzymes required for the synthesis of hormone such as P450 α and 5 β HSD (13). Also the low level of testosterone may be due to the effect of phenolic compounds of *H. rosa sinensis* flowers on Leydig cells, some plant extracts have a negative effect on the numbers and diameters of Leydig cells and their nucleus, causing a reduction in the production of testosterone (14,15).

The low level of testosterone may be due to the effect of extract on the metabolic pathways of testosterone resulting from the presence of secondary compounds, especially flavonoids found in the *H.rosa sinensis*, Ohno *et al* (5) pointed out that the Genistein compound, a type of

flavonoids found in ginseng plant leads to the reduction of testosterone in patients of prostate cancer, this effect has been attributed to the chemical composition of this compound which is similar to the steroid hormones such as estrogen, and thus it somehow affects the process of hormonal regulation in the body and leads to lower levels of testosterone (16). The exposure to high concentrations of external estrogen hormone can cause changes in the levels of gonadotropin hormones and reproductive function (17). The ingestion of phytoestrogen by experimental animals caused a significant reduction in LH and FSH secretion and decrease the level of testosterone (18). Progesterone enhances sperm count, libido and increasing muscle mass, it also increases testosterone levels in the body and enhances its effects, being that it's a precursor of the mineralocorticoid aldosterone, and androstenedione which can be converted to testosterone, estrone and estradiol (19). In current study showed significant decrease in the level of progesterone in treated animals with phenolic extract of *H. rosa*. The treatment of male rats orally at a dose of 500 mg/kg of body weight of aqueous extract of *H. rosa sinensis* flowers caused a significant decrease in the concentration of sperms in testes and epididymis (20). Progesterone in male produced from adrenal gland, adrenal steroid biosynthesis is regulated by a negative feedback system, in which corticotrophin-releasing hormone secreted from the hypothalamus activates adrenocorticotrophic hormone release from the pituitary, and ACTH then stimulates the zona fasciculata cells to produce cortisol (21). The reduction in Progesterone and Testosterone level in serum may be due to the inhibitory effect of the phenolic compounds of *H. rosa sinensis* flowers of the hypothalamic- pituitary- testicular axis, since some studies have indicated the effect of different plant extracts on inhibiting the secretion of hormones such as alcoholic extract of *Mentha arvensis* leaves, which caused a significant reduction in the level of LH in the serum of treated male rats due to the inhibitory effect of the extract of the hypothalamic – pituitary – testicular axis (22).

Table 1. The effect of *H.rosa sinensis L.* flowers extract on male rats for 30 and 60 days.

Parameters	30 days		60 days	
	Control (mean ± SE)	Treated (mean ± SE)	Control (mean ± SE)	Treated (mean ± SE)
Testosterone (ng/ml)	a 3.22 ± 0.12	b 2.02 ± 0.27	a 3.06 ± 0.13	b 1.66 ± 0.12
Progesterone (ng/ml)	a 1.53 ± 0.11	b 0.97 ± 0.22	a 1.35 ± 0.12	b ± 0.14

-Different letters mean a significant difference (p > 0.05) between groups .

The effect of phenolic extract of *H.rosa sinensis* on androgenn receptors AR and progesterone receptor PR.

The results of this study showed a significant decrease (p< 0.05) in the expression of the androgen receptors (AR) and progesterone receptor (PR) of the testicular cells in group of rats treated with phenolic compounds of *H. rosa- sinensis* flowers (300mg / kg /day of body weight) for 60 days compared to control groups(

Figure 3,5) .The AR is a ligand- dependent transcription factor that is activated when androgens were found , anti- androgens or AR antagonists cause prevention of androgens for carrying out their biological activity via directly binding and blocking the AR receptor ligand binding domain (LBD), and by inducing repressive activity ²³ . The mechanism of anti- androgens action begin when anti- androgens bind to the binding pocket of the AR and thereby its activation ²⁴.

Figure 1: Folding change in gene expression of androgen receptor gene in treated and control rats groups during 60 days .

Figure 2: Real-Time PCR amplification plot of androgen receptor in testis

Figure 3: Folding change in gene expression progesterone receptor gene treated and control rats groups during 60 days .

Figure 4: Real-Time PCR amplification plot of Progesterone receptor gene in testis .

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Veterinary Medicine, AL-Qasim Green university- Babylon-Iraq and all experiments were carried out in accordance with approved guidelines.

Nutritional Status of Primary School Children in Babylon Governorate

Ali Jaleel Asser¹, Hussein Jaseem Mohammed²

¹ Master Student Community Health Nursing, Faculty of Nursing, University of Babylon,

² Assistant Professor, Community Health Nursing, Faculty of Nursing, University of Babylon.

Abstract

Objectives: To assess the nutritional status of school children. To identify some associated factors of school children related to nutritional status. And To find out some associated factors of school children and their nutritional status.

Methodology: A cross-sectional descriptive study consisting of (1013) pupil, to assess nutritional status of primary school children in Babylon Governorate.

Result: Analysis of data reveals that there is a 47.4% of children have a normal body mass index, and 43.0% have underweight, 7.6% overweight, while 2.0% only have obesity. The study showed that 76.4% has normal blood hemoglobin, 21.2% low blood hemoglobin and 2.4% increase blood hemoglobin.

Conclusion: Just under half of children has a normal body mass index and about half of study sample have underweight this considered as a result of malnutrition of primary school children. And Observed there are high percentage of children have anemia this can be result from many factors contribute in children anemic

Keywords: Nutritional Status, Primary School, Children.

Introduction

School-age children constitute a little under one quarter of the world's population, and about three quarters of these children live in developing countries¹. School age children spend most of their time away from their parents, therefore, affected by friends as well as media further affect the formation and stabilization of their dietary practices. There is growing evidence indicate that young children from developing countries are increasingly making unhealthy food choices, especially because to lack of knowledge and wrong perception towards healthy foods². School age is the active developing phase of childhood. Primary school age is a dynamic period of physical growth as well as of mental development of the child. Research shows that health problems due to miserable nutritional status in primary school-age children are among the most common causes of low school enrolment, high absenteeism, early dropout and unsatisfactory classroom performance³. Growth and development are sometimes used interchangeably. But growth implies increase in size of organs while body development implies

differentiation and maturation of function. The former indicates quantitative growth as well the latter indicates qualitative growth. Development is influenced in the physical, emotional and social environment. In early childhood, cognitive growth and development are difficult to differentiate from neurologic and behavioral maturation. Factors affecting child development: genetic factors, physical factors, nutritional factors, emotional factors, sociocultural factors⁴. The processes of growth and maturation are related, and both influence physical performance. There are three broad phases of development: early childhood, middle childhood, and adolescence. The definitions of these phases are organized around the primary tasks of development in each stage, though the boundaries of these stages are malleable⁵. Point out that two major growth spurts happen in the brain of children in the middle and late childhood; the first happens between the age of 6 and 8 and the second between the ages of 10 and 12. State that the growth of the brain between the ages of 6 to 8 has an influence on sensory and motor areas. There is an improvement in fine- motor skills and eye- hand

coordination ⁶. Food is necessary for the proper growth and development of children. It is important for the support of oral and physical health, the enhancement of the powers of resistance and continued renewal of the substances in the cells and tissues in children ⁷. Undernutrition among children is a critical problem because its effects are long lasting and go beyond childhood. It has both short and long term consequences. For instance, undernourished as compared to non-undernourished children are physically, emotionally and intellectually less productive and suffer more from chronic illnesses and disabilities ⁸. Nutritional assessments among school children is very important as they constitute a potentially susceptible group. Growth assessment is an important tool for monitoring health and nutritional status of children, identifying deviations from normality, and also providing an indirect measurement of well-being for the entire population.

Methodology

Study Design: A cross –sectional descriptive study to assessment nutritional status of primary school children in Babylon Governorate. Randomly sample of (1013) pupil from primary schools were selected. All of these children were measured by their weight, height, body mass index, hemoglobin and blood sugar, a questionnaire was also completed which included demographic information and dietary habits for children. The questionnaire considered a means for data collection.

The content credibility of the instrument was estimated through a panel of (16) experts, the stability of the items was based on the internal consistency of the questionnaire was evaluated by calculating Alpha Cronbach' which as= 0.80.

Data Analysis

Through the used descriptive statistical (SPSS) version 24 analysis approach that includes, frequencies, percentages, mean of scores, standard deviation and graphical presentation of data; and inferential statistical data analysis approach that include correlation.

Correlation is used to identify the relationship between nutrition status of children and their demographic variables.

Result of the Study

Table (1): Socio demographic characteristics of the study sample (N=1013).

Age groups	Frequency	Percent
6-7	169	16.7
8-9	209	20.6
10-11	328	32.4
12-13	255	25.2
14-15	52	5.1
Total	1013	100.0
Gender	Frequency	Percent
Male	466	46.0
Female	547	54.0
Total	1013	100.0
Residence	Frequency	Percent
Rural	372	36.7
Urban	507	50.0
Peripheral Village	134	13.2
Total	1013	100.0
School Type	Frequency	Percent
Private	79	7.8
Government	934	92.2
Total	1013	100.0

Table (1) shows that (32.4%) of student were between (10-11) years old age, (54%) were females, (50%) were live in urban, (92.2%) were study in government schools and (7.8%) study in private schools. This table shows that (20.2%) of the student in the fourth class, (60.6%) of the student's family income were enough, (95.8%) of the student's fathers were alive and (99.1%) of the student's mothers were alive.

Table (2): Distribution of Study Sample by their Nutrition Status through Anthropometric Measurement and blood tests (Height, Weight, B.M.I. , Blood sugar level, Hemoglobin).

Students Height		Frequency	Percent
	Small	210	20.7
	Medium	524	52.0
	Large	276	27.3
	Total	1,013	100.0
Students Weight		Frequency	Percent
	Low weight	235	23.2
	Acceptable weight	499	49.5
	more than normal weight	276	27.3
	Total	1,013	100.0
Body Mass Index Level		Frequency	Percent
	Underweight	436	43.0
	Normal	480	47.4
	Overweight	77	7.6
	Obesity	20	2.0
	Total	1013	100.0
Blood Sugar Level		Frequency	Percent
	Hypoglycemia	18	1.8
	Normal	985	97.2
	Hyperglycemia	10	1.0
	Total	1013	100.0
Hemoglobin Levels		Frequency	Percent
	Low Blood Hemoglobin	215	21.2
	Normal	774	76.4
	Hyperhemoglobinemia	24	2.4

Table (2) shows that(52.0%) of study sample were medium height, (49.5%)of sample were acceptable weight, (47.4%) of the study sample were normal B.M.I, (97.2%) of the students have normal blood sugar, (76.4%) of the study sample were normal.

Table (3): The distribution of the study sample by their dietary pattern data.

Dietary pattern score		Frequency	Percent
	Meat eater	63	6.2
	Vegetarian	558	55.1
	Mediterranean-	392	38.7
	Total	1,013	100.0

The table showed that (55.1%) of the study sample have been vegetarian dietary pattern, (38.7%) was Mediterranean and (6.2%) was meat eater.

Table (4). shows the correlation between Body Mass Index and nutritional status. Body Mass Index Level * Nutritional Status

Crosstab					
Count					
		Nutritional Status			Total
		Unbalance Nutritional Status	Balanced Nutritional Status	Well Nutritional Balanced	
Body Mass Index Level	Underweight	45	227	164	436
	Normal	54	243	183	480
	Overweight	4	41	32	77
	Obesity	2	14	4	20
Total		105	525	383	1,013
Pearson's R		0.001			

This table shows there are weak positive relationship (Pearson’s R: 0.001) between body mass index and nutritional status.

Table (5) shows the correlation between blood sugar and nutritional status.

Blood Sugar Level * Nutritional Status

Crosstab					
Count					
		Nutritional Status			Total
		Balanced Nutritional Status	Well Nutritional Balanced		
Blood Sugar Level	Hypoglycemia	9	1	8	18
	Normal	95	516	374	985
	Hyperglycemia	1	8	1	10
Total		105	525	383	1,013
Pearson’s R		0.030			

This table shows there are weak positive relationship (Pearson’s R: 0.030) between blood sugar and nutritional status.

Table (6) shows the correlation between dietary pattern and nutritional status.

Dietary pattern score * Nutritional Status Cross tabulation						
Count						
		Nutritional Status			Total	
		Unbalance Nutritional Status	Balanced Nutritional Status	Well Nutritional Balanced		
Dietary pattern score	Meat eater	63	0	0	63	
	Vegetarian	33	525	0	558	
	Mediterranean-	9	0	383	392	
Total		105	525	383	1,013	
Pearson's R		0.916				

This table shows there are strong positive relationship (Pearson’s R: 0.916) between dietary pattern and nutritional status.

Discussion

Socio-Demographic Data of the Nutritional Status of the Primary School Children.

Finding of the study includes (1013) of pupils participate in this study, the most gender was female (547 at 54% female and 466 at 46% male), the most age group was between (10-11) years, this age group qualifies the student in fourth class of school this percentages consisting with hiyam and zeyneb (2016) who have been studied time of emergence of permanent teeth and impact of nutritional status among 4-15 years old children and teenagers in basrah city /iraq. Thier results depicts that consisted of 1807 children and teenaged between ages (4-15) years, 766 of the sample were boys (42.4%) and 1041 were girls (57.6%) collected from random areas of basrah city. Moreover, Abdul Razak, and others (2018) have been studied Breakfast consumption among Malaysian primary and secondary school children and relationship with body weight status, their finding indicated that the most of participants are girls (53.8%) and boys (46.2%), and more age group was (6–9)years. In current study, residence of the sample was (50.0%) urban, (36.7%) rural, (13.2%)peripheral village which disagree with Naotunna and others (2017) ¹⁴ have been studied the nutritional status among primary school children in rural Sri Lanka; a public health challenge

for a country with high child health standards. Their findings reveals that the rural schools most included in this study (701) schools from (802) total schools. Current study find most of the sample was in government schools by percentage (92.2% government schools, 7.8% private schools). This results disagree with study has been studied A comparative study of nutritional status between government and private primary school children of Mysore city(India). Their results show that 695 (44.3%) were from government school and 871 (55.6%) were from private school ¹⁵.This study show most of the sample has enough family income (60.6%enough),(32.0% not enough) and (7.4% enough and more). This findings similar Nabeela and others (2010) which studied impact of socioeconomic factors on nutritional status in primary school children. Their results indicate that 83 (51.6%) children from upper and 78 (48.4%) children from lower socio-economic class. The current study find most of mother’s and father’s children was alive (99.1% mothers alive, 0.9% mothers dead, 95.8% fathers alive, 4.2% fathers dead). This results agree with study conducted by Lilian and other in 2013 that showed (80.0%) of children alive with both parents, (15.0%) alive with mother alone and (5.0%) alive with father alone table (1). The present findings of body mass index locate that (47.4%)of the study sample were normal weight, (43.0%) were underweight,

(7.6%) were overweight and (2.0%) were obese. The results of current study agree with Katarzyna Dereń and others (2018)¹⁷ which studied the prevalence of underweight, overweight and obesity in children and adolescents from Ukraine. Their findings showed that most study sample were (boys: 75.4% normal weight, 11.5% overweight, 10.8% underweight, 2.3% obese) and (girls: 70.4% normal weight, 8.5% overweight, 19.3% underweight, 1.8% obese). Current study showed that most of study sample were (97.2%) normal blood sugar, (1.8%) hypoglycemia and (1.0)hyperglycemia. The results in this work agree with results obtained by other reports such as Marta Murillo and others (2017)¹⁸ has been studied health-related quality of life (HRQOL) and its associated factors in children with type 1 diabetes mellitus (T1DM). Their findings reveals that (97.8% no have hypoglycemia, 2.2% have hypoglycemia and 92.6% no have hyperglycemia, 7.4% have hyperglycemia). Study results depicted that the (76.4% normal blood hemoglobin), (21.2% low blood hemoglobin (anemia) and (2.4% hyperhemoglobinemia). These results are concurrent with study which has been studied anemia among primary school children in eastern Ethiopia⁹. Their results indicates that the (73.1% normal, 13.8% mild anemia, 10.8% moderate anemia, 2.3% severe anemia) table (2). Regarding dietary pattern of children in the present study were (55.1% vegetarian), (38.7% mediterranean), (6.2% meat eater). These results are disagree with study which has been clustering of dietary patterns, lifestyles, and overweight among Spanish children and adolescents¹⁹. Their findings indicate that the most dietary patterns of Spanish children were mediterranean by percentage (41.03%) table (3). In the current study it is found that weak positive relationship between body mass index and nutritional status. similarly, a study done in India which studied nutritional status and morbidity among school going children: a scenario from a rural India. Their findings showed here association of malnutrition with normal children was found statistically non-significant ($p>0.05$) Singh, (2014) table (4). In current study showed there are weak positive relationship between blood sugar and nutritional status.

Conclusion

According to the findings of this research and related to the discussion, the present study concludes that: There is a significant relationship between nutritional status and dietary pattern, whereas Pearson's R was (0.916) of primary school children in Babylon governorate. So,

theresearcherrejects the null hypothesis and accepts the alternative hypothesis which stated that there is a significant relationship between nutritional status and dietary pattern of primary school children in Babylon governorate. There is weak a significant relationship between nutritional status and age group whereas Pearson's R was (0.07).

Financial Disclosures: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Faculty of Nursing, University of Babylon, Iraq and all experiments were carried out in accordance with approved guidelines.

Prevalence Rate of Depression among Ischemic Heart Diseases Patients in Al-Diwaneya Province / Iraq

Abdul Zahra Mohammed Alkafaji¹, Assel Hamid Risun¹

¹College of Medicine/University of Al-Qadisiyah, Iraq

Abstract

Background: Cardiovascular disease is on the upraise in the industrialized and unindustrialized countries, which characterize at the present time one of the chief challenges for the health systems all the world. Depressed Ischemiac Heart disease patients may have a poorer outcome than non-depressed patients ,so this study was performed with the aim of finding the link between depression and ischemic heart disease and its association with demographic factors in Iraqi patients.

Patients and Method: The study was designed to be a case- control study involving 128 case of IHD patients and 120 apparently healthy individuals serving as control group, with an age range from 20y-80y in Al-Diwaniyah Teaching Hospital in Al-Diwaniyah province/ Iraq. were examined for the presence of depressive disorder using ICD-10 diagnostic criteria and then assessing the severity of the depression in the depressed group by using Beck Depressive Inventory(BDI).

Results: The prevalence rate of depression was 48.3% in IHD patients while 22.5% in control groups .

Conclusion: Because of high rate of depression among patients with different types of heart diseases, early detection and identification of as possible ,to improve outcome .

Key words: depression, ischemic heart disease(IHD), prevalence rate

Introduction

Depression and coronary artery (CAD) are both very widespread diseases . They are changing quality of life and life expectations ¹.It is extended to be predictable that minor type of depression are found in up to 2\3 of patients in hospital after acute myocardial infarction [AMI], with major depression generally being established in about 15% of CVD patients ². The linking between the CHD and major depression disorder (MDD) was studied generally over recent periods and the prevalence of both situations has grown all over the world. Many studies over the past 2 decades show depression disorder is the most significant world health problems according to the WHO reports ³. The association between the CHD and major depression disorder (MDD) was studied extensively over recent decades and the prevalence of both conditions has risen all over the world. Every disorder remainders a main supplier to the overall burden of disease ⁴. Depression is one of principal risk factor for IHD in several studies

⁵. In China a meta-analysis study based on 27 studies the prevalence of depression was 51%in cardiovascular patients ⁶.,However the aim of this study is to identify the prevalence rate and determine the severity of depression, and its socio demographic characteristics among patients with ischemic heart disease in Al diwainya city in Iraq .

Patients and Methods

This study was designed as a case-control study, the case group being chosen from Iraqi patients whose diagnosed as Coronary Artery Diseases .A 120 patients were randomly included in this study from patients admitted to AL-Diwaniyah Teaching Hospital in cardiac care unit and cardiac catheterization center in AL-Diwaniyah province whose IHD was diagnosed/ confirmed via angiography and by specialists and 120 healthy people as control group .

Only 8 of these cases were refuse to take part in our study ..Arking days were 5 days /week ,starting from The study was started from the 20th January 2019 and

ended on the 10th June 2019. The including criteria in the study were to be all patients with ischemic heart disease of any age and sex were included, age 20 year or older with no family history of depression. And the excluded patient were those with congenital heart disease and very tired patients and refusal from patient's side to be involved in the study. Any patient with previous history of depression before heart disease and patients who have depression secondary to any organic disorder or substance abuse.

The study was approved by the Committee of Ethical Approval at Collage of Medicine / University of AL- Qadisiyah. And Verbal consent was considered when patients were selected to be part in our study.

Data was collected using a designed questionnaire having of three parts. The first part involved detailed socio-demographic and clinical information got from patients', second part questioner for diagnosis depression according to ICD -10. The third part was for assess the severity of depression according to Beck Depression Inventory (BDI) score administered during a private interview. The questionnaire, including the apparatuses, was translated from English to Arabic and back-translated from Arabic to English by two fluent specialists.

BDI test This questionnaire contains 21 multiple choice questions, each adding 0-3 points to the final score depending on the choice designated by the patient. This questionnaire was studied for validity and reliability and the endpoint points were set as following: those patients who scored a total of 0 to 9 were considered "Normal (no depression)", 10 to 19 as "mild depression", 20 to 29 as "moderate depression", and 30 and above as "severe

Results

The prevalence rate of depression among patients and control subjects is shown in table 2. Total cases of depression among control subjects were 27 out of 120 (22.5%), whereas, there were 58 patients with depression accounting for (48.3%); there was highly significant difference in the prevalence rate of depression between ACS patients and control groups, 48.3% versus 22.5%, respectively ($P < 0.001$), as shown in table 1. The prevalence rates of mild, moderate and severe depression among ACS patients were 18.3%, 20.8% and 9.2%, respectively. On the other hand, the prevalence rates of mild, moderate and severe depression among control subjects were 15.0%, 5.8% and 1.7%, respectively, table 3.

Table 1: Prevalence rate of depression among control and Acute coronary syndrome groups

Depression	Control group n = 120		ACS n = 120		χ^2	P
	N	%	n	%		
Mild	18	15.0	22	18.3	17.506	<0.001 ¥ HS
Moderate	7	5.8	25	20.8		
Severe	2	1.7	11	9.2		
Total cases of depression	27	22.5	58	48.3		
Normal	93	77.5	62	51.7		

n: number of cases; ACS: acute coronary syndrome; ¥: Chi-square test

Patients with acute coronary syndrome were categorized into three groups, stable angina, unstable angina and acute myocardial infarction (MI). The frequency distribution of patients with stable angina, unstable angina and acute myocardial infarction (MI) according to 10 years age intervals is shown in table 2. The mean age of patients with acute MI was significantly

higher than both stable and unstable angina ($P < 0.05$). There was also no significant association between gender and type of ACS ($P = 0.516$), table 3. There was, in addition, no significant association between marital status and type of ACS ($P = 0.318$), as shown in table 4.

Table 2: Distribution of patients with acute coronary syndrome according to age

Age (years)	Stable angina n = 43		Unstable angina n =31		Acute MI n = 46	
	N	%	N	%	N	%
21_30	0	0.0	2	6.5	1	2.2
31_40	3	7.0	4	12.9	3	6.5
41_50	10	23.3	4	12.9	6	13.0
51_60	11	25.6	7	22.6	8	17.4
61_70	12	27.9	8	25.8	12	26.1
71_80	4	9.3	5	16.1	10	21.7
>80	3	7.0	1	3.2	6	13.0
Mean \pm SD	58.02	6.83	55.97	5.92	62.61	5.21

n: number of cases; SD: standard deviation; MI: myocardial infarction

Table 3: Distribution of patients with acute coronary syndrome according to gender

Gender	Stable angina n = 43		Unstable angina n =31		Acute MI n = 46		χ^2	P †
	n	%	N	%	n	%		
Male	25	58.1	19	61.3	32	69.6	1.325	0.516 NS
Female	18	41.9	12	38.7	14	30.4		

n: number of cases; MI: myocardial infarction; †: Chi-square tests; NS: not significant at $P \leq 0.05$

Table 4: Distribution of patients with acute coronary syndrome according to marital status

Marital status	Stable angina n = 43		Unstable angina n =31		Acute MI n = 46		χ^2	P
	N	%	n	%	n	%		
Single	0	0.0	1	3.2	3	6.5	4.713	0.318† NS
Married	33	76.7	25	80.6	30	65.2		
Widowed	10	23.3	5	16.1	13	28.3		
Divorced	0	0.0	0	0.0	0	0.0		

n: number of cases; MI: myocardial infarction; †: Chi-square tests; NS: not significant at $P \leq 0.05$

Table 5: Distribution of patients with acute coronary syndrome according to occupation

Occupation	Stable angina n = 43		Unstable angina n =31		Acute MI n = 46		χ ²	P
	N	%	N	%	n	%		
Unemployed	6	14.0	4	12.9	9	19.6	0.588	0.745 †‡ NS
Employee	3	7.0	7	22.6	8	17.4

Housewife	12	27.9	5	16.1	6	13.0		
Student	1	2.3	0	0.0	0	0.0		

n: number of cases; MI: myocardial infarction; †: Chi-square tests; NS: not significant at $P \leq 0.05$; ‡: comparison was made between those having job or student and those without job, retired or housewives

Discussion

Our study estimate about 128 cases of Ischemic heart disease (IHD) Diagnosed by cardiologists doctors admitted to Intensive care unit in AL Diwanayah Teaching Hospital and patients admitted to the center of cardiac catheterization in AL Diwanayah city, only 120 cases accept to sharing in our search, same number of cases taken as control group whose apparently healthy people. Our study shows response rate 93.75% and other 6.25%(5 of them refuse sharing in our search and other 3 cases were tired). It is good reaction rate for sharing . This equivalent rates of sharing with Iraqi family health survey (IFHS) 95%⁷, as well as similar to Salman study 2009 (93.6%)⁸ and equated to study conducted in Iraq in 2018 (94.1%)⁹. This high response rate because Iraqi's peoples want someone to take care for them and listening to their problems . In present study shows the mean age of IHD cases and control group were 59.25 5.97y Versus 55.92 3.78 y, respectively (P = 0.071),so there was no significant difference in the frequency distribution of mean age between control and patients groups. Moreover no statistically interactions was found in the frequency distribution of both groups according to others demographic features [gender , occupations , level of education and marital status] P 0.05.That is suggests demographic data not consider as risk factor of developing IHD. Furthermore our study's result

resembling another study conducted in Iran 2018 which found that no relationship between demographic features of IHD patients and control group¹⁰ moreover it is same result of study conducted in India¹¹.In our study from 120 cases of control were (27) cases have depression according to ICD10 diagnostic criteria of depression the prevalence rate was (22.5%), there were 58 patients of (IHD) have depression prevalence rate (48.3%) which it is highly significant difference (P 0.001). These results go with many studies one of them study conducted by Shalan *et al.* shows that prevalence rate was 45%, which was analogous to our study⁹. Other study prepared in Iran prevalence rate was (46.5%) in (IHD) patients, while controls cases (19.5%).¹⁰. Moreover our study results are analogous to other study showed in Poland, prevalence rate of depression was present in 46.3 % of IHD patient while control cases was (21.2%)¹². Additionally according to meta-analysis done in Iran found that prevalence rate of depression in IHD patients was 47%¹³. The present study result higher than results of study finished in Iraq, prevalence rate was 24% in different types of heart disease while in control group was 4%¹⁴. This difference may be due to small sample size and they take different types of heart disease; in Iraqi patients the stressful conditions are increased every day. Furthermore our result was higher than many studies, study done in Virginia in 2014 was 33%¹⁵, Iraqi mental health survey(IMHS)¹⁶, study done in Pakistan

the prevalence was 27%¹⁷ WHO educational program on depression was 33%¹⁸, study conducted in Iran on 300 patient show prevalence rate 38%¹⁹ and other study done in Germany prevalence rate was (22%)²⁰. The prevalence rate of depressed IHD patients in our study was lower than carney study (65%) and (51%) in study done in China and lower than Pena FM., *et al* results(67%)^(21,22,23). Other study on Iranian patients found prevalence rate of depression was 73.2%²⁴. The most important explanations for these dissimilarity in the results of prevalence rates among many studies were using different instrument (questionnaires) to evaluate the prevalence rate of depression²⁵. Regarding the severity of depression; the prevalence rate of mild, moderate and severe depression among IHD patients according to BID score were 22 (18.3%), 25 (20.8%) and 11 (9.2%) respectively while in control group show in mild, moderate, and severe type of depression 18 (15.0%), 7 (5.8%) and 2 (1.7%). The degree of severity of depression is statistically highly significant (P 0.001) in relation with coronary heart disease. Other study done in Iraq in 2018 by using HAMD – 17 and DSM-IV found (P = 0.003) highly significant correlation of severity of depression with Ischemic heart disease showed 14.9% for mild depression, 20% for moderate depression, 7.06% severe depression and 3.14% very severe depression⁹, while these results not go with study done in Iraq 2014 only 3% have mild depression and prevalence of moderate depression in IHD 8% while severe depression only 1%¹⁴. Patients with IHD divided in to 3 type's stable, unstable and acute myocardial infarction. The mean age in our study 59.25 5.97y and found that mean age in acute myocardial infarction 62.61 which was more than mean age in stable, unstable angina (58.02; 55.97).

Deposition of Ta₂O₅ Film on Commercial Pure Titanium Disk by Modified Reactive Plasma Sputtering Technique

Hassan Jawad Farhan¹, Raghdaa Kareem Jassim², L.Thair³

¹Assistant Lecturer Department of Prosthodontics. College of Dentistry. University of Karbala, ²Professor. Head of Department of Prosthodontics. College of Dentistry. University of Baghdad, ³Chief Researcher. Ministry of Science and Technology, Iraq

Abstract

Background: Now days the interest of implantology is to improve Osseo integration by find materials which accelerate bone formation at bone implant interface to provide immediate or early loading after placement of dental implant and eliminate waiting period which is un favorite and disturbs patients. Titanium is most common material for dental implant, but still need some modification for surface properties chemically and physically by using an other material such as tantalum which is gaining more attention as a new metallic biomaterial. Coating the surface of implant is an important way for development of surface properties of titanium. plasma Ta₂O₅ used for surface modification, which has several advantages such as increasing surface roughness, changing surface topography and increasing the wettability of the surface.

Aim of study: To evaluate the action of Ta₂O₅ coating by modified plasma sputtering technique of commercially pure titanium disk on surface roughness, wettability and surface chemical composition in comparison to non-coated surface.

Materials and methods: All tested group were two groups in this study which include un-coated commercial pure titanium disks and Ta₂O₅ coated commercial pure titanium. Modified reactive plasma sputtering technique was used to coat CpTi with Ta₂O₅ at 4,6,8, hr. Analysis of surface characterization by x-ray diffraction (XRD) analysis, scanning electron microscope (SEM), energy dispersive spectroscopy(EDS) were carried out on the coated surfaces of the disks, contact angle measurement was achieved by applying drop of saline on the surface of coated disks and compared to non- coated one.

Results: The result of Ta₂O₅ coated specimen at times (4,6,8) showed that 8 hr. coating time was the best time. X-ray diffraction analysis show new peak formation for CpTi coated with Ta₂O₅ disk which was not present in non- coated CpTi disk. The results showed that the rough surface was more and better distribution in CpTi coated with Ta₂O₅ disk than non- coated CpTi disk which improve by electron scanning microscope, wettability of Ta₂O₅ coated disk was more than wettability of non- coated CpTi disk.

Keywords: Ta₂O₅ film, commercial pure titanium disk, modified reactive plasma sputtering technique

Introduction

Surface improvement of dental implant become much advanced than it was earlier ¹. Titanium is material of choice for dental implant which shows a favorable combination of intrinsic properties for the fabrication of dental implants such as low modulus of elasticity, low specific weight, high strength to weight ratio, very high corrosion resistance, easy surface coating and excellent general biocompatibility ². Acceleration of the Osseo integration of Cp Ti results in reducing the non-functional

time period of the implant, increase its applicability in alveolar bone with low quality, minimize the failure rates, and cause minimum discomfort for patient. ³. Increasing roughness and change surface properties physically and chemically is one of the methods used in increasing and accelerating the Osseo integration process. Surface coating can be used for changing surface topography, increasing surface roughness and in increasing the wettability of the surface. ⁴ Chemically and physically reactive plasma discharges are widely

used to modify the surface properties of materials. ⁵ Tantalum (Ta) is stable chemical element can stably exist in the surface layers of the substrate materials. Ta is one of the promising materials in used in dental fields ⁶. The Ta components offer a low modulus of elasticity, high surface frictional characteristics, and excellent Osseo integration properties (i.e. Bioactivity and biocompatibility) ⁷ The stable Ta₂O₅ protective film can provide better bioactive property and corrosion resistance than that of TiO film. ⁸ Surface-coated implants are reported to have less failure and can support heavier and more dynamic forces. Several clinical studies have analyzed the success and failure of implants in diabetic patients. ⁹

Material and Method

Sample preparation

Disks of Titanium were prepared (5×2mm) diameter and thickness respectively which were cut from Cp Ti rod using Bench Nibbling machine (TAURUS 7000-W6 CNC, Italy). The specimens were abraded by using Si C grinding paper with different grits started from 80 grit, and continued by 120, 230, 400, 600, 800 and 1000 grit to get free scratch and flat surface. All disks were polished to obtain a mirror polished and smooth surface. After that all specimens cleaned by ultrasonic cleaner with ethanol 99.8%. was carried out.

Surface coating by Ta₂O₅

By using modify Dc glow discharge reactive plasma sputtering system, the sputtering technique was performed. Number of the total samples were 10 disk which divided as 1 un coated CpTi disk and 9 coated CpTi disk with Ta₂O₅ (3 disk for each time). Then the coated disks sub divided according to the times of coating (three times 4,6 and 8 hr.) into 3 groups. The cause of 3 disk coated in same time was to send each sample to specific test for time consuming.

The sputtering procedure started with placing the clean and polished samples on the center of base of anode electrode. evacuating process of chamber to high vacuum ($\approx 1 \times 10^{-5}$ mbar) using high vacuum system consist of rotary and turbomolecular vacuum pumps to ensure the complete removing of the heavy gases like hydrocarbons. Power supply (negatively charged voltage 3.5 kV). For sputtering process, the voltage was gradually applied using variac until the required energy achieved (applied voltage and current), The pressure was

2×10^{-2} to 7×10^{-2} mbar and this pressure was achieved by feeding the bombardment and reactive gases. The appropriate voltage and amper were adjusted precisely by regulator until intended sputtering glow (purple color, which standardized for each gas) is achieved. One of the most important modification done to convert normal plasma system to sputtering plasma system was replacement of electrode position, so the cathode placed in upper part and anode electrode placed in lower part of chamber. A Target (cathode) and anode disk of stainless steel. The cathode faced the anode with 7 cm distance between them, which provides electric field for the gas to be discharged. The electrical electrodes and the associated dc-power supply of 5kV. The bottom of the stainless steel disk cathode electrode are covered with tantalum sheet which regarded as target. The clean and polished samples were placed on the anode in the center of base which regarded as substrate. The cathode was connected to the D.C. power supply, while the grounded chamber served as anode. All the samples were cleaned by argon plasma sputtering for 15 min prior to the Ta₂O₅ coating process by applying a bios dc voltage of 100 Von the anode. For reactive plasma sputtering procedure, the following process parameters were used: argon was used as bombardment gas and oxygen as reactive gas. The process was carried out at various sputtering times (namely 4, 6 and 8 hours). The reactive gas oxygen was introduced into the evacuated chamber and the flow rate was adjusted until the pressure was stabilized at the desired pressure (1×10^{-2} mbar), then the argon gas introduced to the chamber until the sputtering pressure of 5×10^{-2} mbar achieved. After the sputtering process completed, the samples were kept until ambient temperature in the vacuum chamber was reached.

Phase Analysis by using X-Ray Diffraction

Surface analysis for Phase's distribution was performed for non-coated CpTi, CpTi coated with Ta₂O₅ it has been done by using X-ray Diffraction Facilities (SHIMADZU 6000, Japan) using Cu K α radiation. XRD analysis were performed at room temperature in the 2θ range from 30° - 80° with a 0.05° step and counting time of 5 secs per step. The indexing of the data and the diffraction peaks were identified according to the powder diffraction files. (PDF), received from ICDD (Intimations' Center for Diffraction Data).

Scanning electron microscope examination

All tested group were examined by using SEM

(JEOL-JSM-5600) for examinations of the changes occurs on the coated layer of Ta₂O₅ during the plasma sputtering technique. Samples for SEM were prepared as cross section and then mounted in double face metal tape (electrically conductive) to make the sample holder electrically conductive before entering the samples into the SEM Chamber. VEGA3 TESCAN, SEM HV: 20 KV, SEM MAG:7.50kx, VIEW FIELD:27.7

energy dispersive spectroscopy analysis

chemical structures and relative concentrations for non-coated CpTi and coated CpTi with Ta₂O₅ discs were assessed via energy dispersive spectroscopy (EDS). EDS use of the X-ray spectrum radiate a solid sample with a focused beam of electrons to obtain a localized chemical analysis. All elements from atomic number 4 (Be) to 92 (U) can be detected in principle. Qualitative analysis involves the identification of the elements in the spectrum and is fairly straightforward owing to the simplicity of X-ray spectra. Quantitative analysis determination of the concentrations of the elements. Finally, element distribution images or 'maps' can be produced.

Atomic force microscopy examination

Atomic force microscope able to detect both conductive and nonconductive surfaces on the atomic scale. The AFM relied on the scanning technique and provided a high-resolution 3D image from the surface of the sample. A sharp tip at the end of the cantilever is in contact with the surface of the development and the sample displaced with piezoelectric scanners. The force on the tip causes deflection to measure with tunneling capacitive or optical detectors such as interferometer laser in this technique, the standard pressure applied to the joint is zero (to prevent any surface deformation).

Wettability test

Non-coated CpTi and Ta₂O₅ coated CpTi (grade

2) disk 10×5 mm diameter and thickness respectively were used by dropping equal amounts of normal saline (0.25ml) from graduated container on each disk, non-coated CpTi and coated with Ta₂O₅ for (4,6,8 hr.) and measure the angle formed between titanium disc surface and drop of normal saline. The best wettability achieved for the sample was selected for the (8hr.) measurement done after 20 second from putting the drop on disk surface, and digital camera about 15 cm from disk. The images were analyzed using the program Image Tool version 5.02 for Microsoft Windows.¹⁰

Result

Surface characterization by using X-Ray Diffraction.

A: Before Heat treatment:

XRD patterns of the control CpTi specimen and Ta₂O₅ coated by modified reactive plasma sputtering after different sputtering time (namely 4, 6 and 8 hours) are demonstrated in Figure (1). and these data were indexed according to the Powder Diffraction Files (PDF) for the hexagonal α -Ti (JCPDS-ICDD file # 44-1294), Ta₂O₅ (JCPDS-ICDD file # 25-0922, 33-1391 and 33-1390), and Ta₂O₅ (JCPDS-ICDD file # 34-0977). The diffraction peaks of the uncoated CpTi were found to be corresponding to (100), (002), (101), (102), (110), (200), (112) and (201) α -Ti at 2θ values 35.00°, 38.30°, 40.05°, 52.9°, 62.8°, 70.6°, 76.25° and 77.35° respectively. The patterns of the plasma sputtered specimen for 4 and 6 hours show wide peak in the range of 2θ 20-30° which seems to be due to the formation of not fully crystallized Ta₂O₅, whereas the pattern of the specimen sputtered for 8 hours show clear and prominent Ta₂O₅ peaks indicating the formation of Ta₂O₅ corresponding to the reflections 001, 200 and 1117 at 2θ 22.90, 28.79 and 49.12. Also its very clear there are a shift in the 2θ position of the CpTi reflections towards the higher 2θ indicating the change in titanium crystal cell volume.

Fig (1): XRD patterns for uncoated CpTi and coated specimen with Ta2O5 at (4, 6, and 8 hr.)

B: After Heat treatment:

The CpTi specimen's coated with Ta2O5 for sputtering time 8 hours before and after heat treatment are shown in Figures (2). The pattern of the heat coated specimen show prominent new peaks indicating the formation crystalline tantalum pentoxide Ta2O5. The peaks are assigned to 001, 200, 270, 211, 3100, 092, 3111, and 3171 at 2θo 23.06, 28.79, 32.88, 37.12, 49.62, 50.98, 56.24 and 64.4 respectively. Also it's noticed that only one reflection belongs the tantalum monoxide Ta2O5 which are 621 at 2θo 52.52.

Fig (2): XRD patterns of uncoated Cp Ti and coated with Ta2O5 for 8 hours before and after heat treatment.

Surface characterization using Wettability test

From the result of wettability test, 8 hr. coated disk with Ta2O5 give more hydrophilic surface. Contact angle of fluid drop in plasma sputtering with Ta2O5 was less than non-coated disk. Un coated CpTi disk with contact angle 60°, Ta2O5 disk coated for 4hr with contact angle 65°, Ta2O5 disk coated for 6hr with contact angle 45° and Ta2O5 disk coated for 8hr with low contact angle 30°.

Surface characterization using SEM

A: Topographic

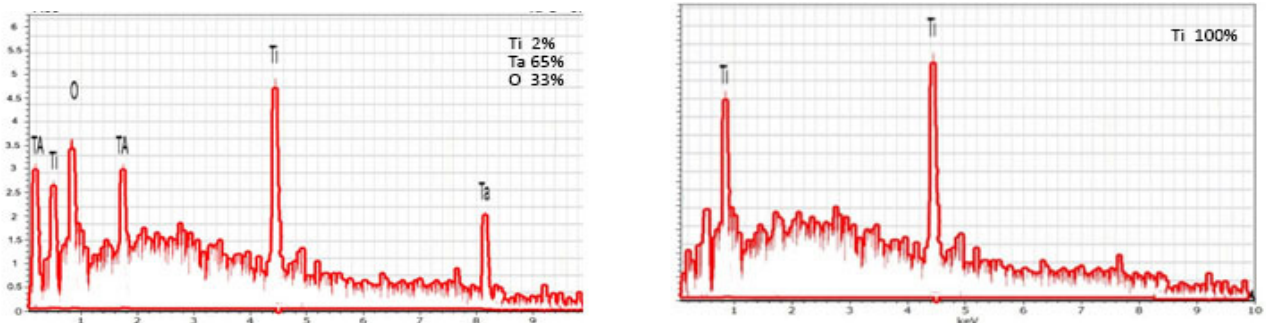

The scanning electron microscopy images of CpTi disk before coating in (figure 4a) revealed a relatively flat and smooth surface. While the surface morphology of CpTi plasma sputtering samples with Ta2O5 for 8 h showed a fully arranged nanochips and uniformly distributed in (figure 4b).

A: CpTi disk B: CpTi disk coated with Ta2O5

Fig (4): SEM.A/CpTi disk without coating B/CpTi disk coated with Ta2O5 for 8 hr.

B: chemical composition by EDS

chemical structures and elemental composition were assessed for all experimental groups which include CpTi and CpTi coated with Ta2O5. Regarding the chemical structure analysis for CpTi figure (5a) show tow titanium peaks with these value ($k\alpha$ 4.512 and $l\alpha$ 0.452) which resemble alpha phase of titanium. For second group of disk coated with Ta2O5, there were two peaks of titanium which resemble alpha phase, two tantalum

peaks and one peak of oxygen with following value ($k\alpha$ 4.512 and $l\alpha$ 0.452) ($l\alpha$ 8.146 and $m\alpha$ 1.712) ($k\alpha$ 0.525) respectively as shown in figure(5b). Elemental composition of tested group as follow in (fig a) titanium was 100%, in (fig b). percentage of titanium was 2%, tantalum was 65% and oxygen was 33%.

A: CpTi disk B: CpTi disk coated with Ta2O5

Fig (5): EDS.A/ CpTi disk without coating B/CpTi disk coated with Ta2O5 for 8 hr.

Discussion

The new trend in implant research is to increase and accelerate the osseointegration of Cp Ti which may result in decrease the non-functional time period of the implant, increase its applicability in alveolar bone with little quality, cause minimum discomfort to patient, and minimize the failure rates.¹¹ One of the methods used in increasing and accelerating the osseointegration process is to modify the surface properties of the implant¹². Chemically and physically reactive plasma is widely used to modify the surface properties of materials.¹³ In order to improve surface properties of CpTi, tantalum is a material with specific properties which is used in this research as a coat material with oxygen gas to develop Ta2O5 surface on CpTi disk by modified sputtering technique which has several advantages such as changing surface topography, increasing surface roughness, and in increasing the wettability of the surface.¹⁴ Reactive plasma coating constitutes a simple, dry technique, which does not harm the environment, of low cost and does not comprise the intrinsic properties of the biomaterial, affecting only its surface.¹⁵

Evaluation of the Effect of Endoscopic Sinus Surgery with Medialization of Middle Turbinate

Ahmed Adhab Mayan Alzubiadi¹, Laith ali Altimimi², Farah Salih Alaamiri³

¹Department of Surgery, College of Medicine, Kufa University, Najaf, Iraq, ²Ghazi Alhariri hospital, Baghdad, Iraq; ³Specialist Otolaryngologists, Teaching Hospital, Najaf, Iraq

Abstract

Background: The main goals and key points of endoscopic sinus surgery are providing a sufficient drainage and ventilation for the diseased paranasal sinus groups. **Method:** A total of 44 patients (males 22 & 22 females) were included in this study, all of them complaining of chronic rhinosinitsis with or without polyposis not responding to maximal medical treatment and were assigned for ESS. Patients were classified into three groups; Group A: ESS with bolgarization, Group B: ESS with suture medialization of middle turbinate, Group C: ESS without medialization Postoperatively, patients were followed up with subjective (nasal obstruction, nasal discharge, headache, fascial pressure and smell disturbance) and objective (endoscopic evaluation of middle meatal MM patency) parameters in 2 weeks, 1 month, 3 months, 6 months and 1 year. **Result:** There improvement in nasal obstruction was reported by patients in all the three groups. Improvement in other symptoms was significantly higher in group A as compared to other groups. MM patency was evaluated by endoscopy and showed improvement of 100% in group B.

Key words: Endoscopy, Rhinosinusitis, Bolgerization, Suturing, ESS.

Introduction

The main essential of endoscopic sinus surgery (ESS) is to open the passages of the sinuses allowing for proper drainage and ventilation to the nose. Through this technique new passages are created or existing ones are opened by removing thickened mucous, polyps and cysts, or membranes that's why endoscopic techniques are now routinely being applied to the management of many non-inflammatory sinonasal disorders.¹ Turbinate medialization techniques are often used for prevention of turbinate lateralization and middle turbinate (MT) medialization has no detectable adverse effect on olfaction.⁴ Medialization of the middle turbinate (MT) is an effective technique to prevent recurrent rhinosinusitis; but, could reduce olfactory function by interfering the odorants to reach the olfactory mucosae.⁵ Whereas, middle turbinate (MT) lateralization is a common complication of endoscopic sinus surgery (ESS) that occurs when opposing areas of denuded mucosa form a scar between them. This scar pulls the MT laterally to the lateral nasal wall and may cause obstruction of the middle meatus and the maxillary, ethmoid, or frontal sinuses, which can result in failure of the initial procedure and often necessitates revision surgery.⁴ Bolgarization

(Medialization) can also be achieved by creating a small scar band between the middle turbinate and the nasal septum. Packing in the middle meatus is necessary to keep the surfaces in contact long enough to heal together and create an adhesion (usually 5 to 7 days). The middle turbinate can also be suture fixated to the nasal septum using a dissolving suture (conchopexy). This technique can successfully secure a destabilized middle turbinate in most cases.⁶ The ethmoidal infundibulum is considered as a main draining space at the ostiomeatal complex that is bounded posteriorly by bulla ethmoidalis, anteromedially by the middle turbinate, and anterolaterally by an uncinat process, that's why it is also necessary to interfere with the middle turbinate to achieve enough ethmoidal infundibulectomy at the anteromedial aspect along with the uncinectomy^{8,9,10,11,12} when it comes to determine the recurrence incidence rate of sinusitis after middle meatal endoscopic surgery, the middle turbinate play a vital role.^{13,14,15} In most patients the middle turbinate is preserved and therefore it's vital to make it preserved during the surgery and not to destabilize. Fracturing anterior vertical insertion of middle turbinate from the skull base destabilize the MT. For posterior stability to the middle turbinate, which

is also important during surgery, could be achieved by preserving the horizontal portion of the ground lamella. However, excessive manipulation of the MT could fracture the turbinate's insertion on skull base and result in it becoming floppy. The frontal recess get narrower lateral dimension, which, ultimately, makes surgery very difficult and increases the risk of damage to the lateral wall of the olfactory fossa.

Methodology

The clinical trial was conducted in the department of otolaryngology, Head and Neck Surgery during the period from October 2015 to October 2017 at Al-Sader medical city, Al-Najaf governate. . All patients signed the informed consents, and the study conformed to the ethical principles set forth by the Declaration of Helsinki. A total of 44 patients (males 22 & 22 females) were included in this study, all of them complaining of chronic rhinosinitis with or without polyposis not responding to maximal medical treatment and were assigned for ESS.

Patients aged above 12 years and Patients complaining of chronic rhinosinitis with or without polyposis not responding to maximal medical treatment were included in this study while patients with sinonasal malignancy and middle turbinate resection and disturbed anatomy from previous surgery or trauma were excluded from the study.

The questionnaire survey methodology was used to collect the information from patients before operation for physical examination, anterior rhinoscopy, and nasal endoscopic examination and after survey all selected patients were subjected to detailed history, general examination, systemic examination and full head and neck examination and nasal endoscopic examination and divided into three respective groups, Group - A, B and C; details are given here under.

All patients were given a course of proper systemic oral antibiotic (patients with CRS) with local and systemic steroid and nasal douching for 2 weeks and then assigned for native computed tomography in axial, sagittal & coronal plane 1-2 mm thickness slices at level of the nose and paranasal sinuses was taken and the follow-up subjective (nasal obstruction, nasal discharge, headache, fascial pressure and smell disturbance) and objective (endoscopic evaluation of middle meatal MM patency) was performed after 2 weeks, 1 month, 3 months, 6 months and 1 year, respectively.

All cases were operated under general anaesthesia. The mucosa of the nasal cavity was decongested using nasal pledges with 1:80000 adrenaline and 2% xylocaine 15 – 20 minutes before surgery. After drapping, endoscopic examination with 0° rigid scope in the standard three passes to assess extent of the disease. Septoplasty was performed when necessary, removing the lateral part of concha bullosa when present. Classical steps of ESS including: unilateral or bilateral uncinectomy with MMA, anterior and posterior ethmoidectomy. sphenoidotomy and frontal recess interventions were done accordingly with the aid of microdebrider.

Patient Groups

Group A: the mucosa of medial surface of MT and the opposing septal mucosal surface were abraded with aid of sickle knife or rosen knife just posterior to the caudal end of MT (care must be taken that abrasion not extending through the whole length of MT otherwise postoperative anosmia and nasal obstruction ensure) with merocel meatal pack for 24-48 hrs to create iatrogenic synechia between MT and the septum (Fig 1).

Group B: 4-0 vicryl suture and tonsillar pillar needle were used to suture the MT to the septum. The needle passed through MT from lateral to medial through the septum to the other side and then passed in opposite direction just anterior to MT through the septum to be tied in the first side.

Group C: ESS without medicalization.

Endoscopic scoring depends on endoscopic evaluation of MM for presence of scarring or adhesion and it was graded as: 0 = 4 mm hopkin rigid 0 scope can pass freely at any point of MM. 1 = 4 mm hopkin rigid 0 scope can pass with freer used to medialize MT. 2 = 4 mm hopkin rigid scope can't pass at all.

Statistical Analysis

All collected data was then analyzed and compared on SPSS version 22.

Results

There were about three groups of patients i.e, Group A (Bolgazization group) which consisted of 13 patients, Group B (suturing group) which consisted of 9 patients, Group C (without medialization) which consisted of 22 patients. with no statistically significant differences had

been found neither in age nor gender among the three groups, ($P>0.05$). Nasal obstruction was the main chief complaint in all patients, and polyposis was the main finding in anterior rhinoscopy, with no statistically significant differences amongst the three groups neither in chief complaints nor the anterior rhinoscopy findings, ($P>0.05$) as given in Table- 1. As it shown in table 2 , there was a significant change (improvement) in nasal obstruction reported by patients in all the three groups, however, the change was significantly larger in suturing group, where the mean nasal obstruction score reduced from 5.89 at 2 weeks to reach 1.44 at the 12 month, with a mean difference of 4.45 and percentage change (improved) by of 75.5%, in bolgarization group the mean difference was (3.15) and in controls it was (3.0), by comparing the mean differences amongst the three groups it was statistically significant ($P<0.05$). In table 3 ,The changes in nasal discharge was insignificant in bolgarization group , the mean score for nasal discharge was 2.23 at 2 weeks relatively reduced at one month, three month and 6 month but return to its level at one year, ($P>0.05$). in suturing group the mean score was 2.22 reduced in the subsequent visits to reach 1.33 at the one year with a statistically significant difference of 0.89 and percentage change of 40.1% (improved), which was larger than the mean difference in control group, (-0.41) that increased at one year by 16.7% (worsening), ($P<0.05$), hence, the change (improvement) was in suturing group rather than Bolgarization and controls. . For the facial pressure, it was relatively and insignificantly reduced in bolgarization group, ($P>0.05$), but it was significant in suturing group where it reduced from 2.24 at two week to reach 1.33 at one year, with

a mean difference of 0.91 and 40.6% improvement, conversely, facial pressure get worse in controls; its score elevated from 2.5 at two weeks and to 2.81 at the one year, however it was statistically insignificant, i.e. it is the same, ($P>0.05$).

Smell was improved in both Bolgarization and suturing groups by an improvement rate of 23.7% and 50%, respectively, ($P<0.05$), compared to significant worsening in control group, ($P<0.05$). However, the larger difference and improvement rate was among suturing group , as shown in table 4.

Headache was improved significantly in both bolgarization and suturing group, ($P<0.05$) and the larger mean difference was 1.21 in suturing group with a percentage change of 52.4%, compared to 1.08 and 41.2%, respectively, in bolgarization group. While headache was relatively and insignificantly get worse in control group, ($P>0.05$) .

In figure (1)The mean MM score at two weeks was 2, 1.22 and 2.0 in bolgarization, suturing and control groups, respectively, at the one year it was improved by 57.7% in bolgarization group, reach zero (100% improved) in suturing group, also it was better in control group with improvement of 34.1, ($P<0.05$) . Middle turbinate plays an important role in ESS, extensive disease process or surgical resection may render the middle turbinate floppy and unstable with subsequent scarring and synechiae formation that result in middle turbinate lateralization and hence obstruction of OMC that impede drainage pathway and impair ventilation of the sinuses.²²

Table 1. Chief complaints and endoscopic assessment findings of patients in the studied groups

Variable		Bolgarization (n = 13)		Suturing (n = 9)		Control (n = 22)		P. value
		No.	%	No.	%	No.	%

Conclusion

The present study was conducted to perform Medialization of middle turbinate following conventional endoscopic sinus surgery to ensure widely patent middle meatus and osteomeatal complex to facilitate drainage, ventilation, mucosal healing and follow up with better access of topical medications to the mucosa and concluded that Medialization with trans-septal suture technique is an effective method in preventing lateralization of middle turbinate and subsequent OMC obstruction. It was also clinically and statistically better than other techniques of medialization namely bolgarization. The authors in present study recommended that Middle turbinate should be medialized and stabilized in FESS to ensure widely patent MM using 0-3 or 0-2 vicryl suture to avoid laceration of MT. There is a need for further studies with a broader population of patients and with longer periods of close endoscopic and symptomatic follow-up. Moreover, other techniques

of medialization including using of Gelfilm, bovine serum albumin tissue adhesive (BioGlue), bioresorbable implant (L-lactide-co-glycolide) may also be performed to check their effectiveness.

Determination Knowledge of Nurses' Concerning Measurement of Blood Pressure in Emergency Department at Al –Hussein Teaching Hospital in Al-Nasiriya City

Amer Muhasin Naser¹, Qassim Jawell Odah Abed²

¹Adult Nursing, Southern Technical University, ²Adult Nursing, Middle Technical University

Abstract

A descriptive study at Al Hussein teaching Hospital in AL- Nasiriyah city to determine the knowledge of nurses' in the emergency department. The most nurses working in this department after testing their information through the questionnaire prepared in calibrations did not have sufficient information about the pressure measurement. Nurses should enter courses on blood pressure measurement

Keywords: blood pressure, emergency, AL-Nasiriya City

Introduction

Accurate blood pressure is critical to patient order, to detect blood risk, and to monitor executives. The auscultatory procedure used in the medical profession is still used in decision-making to estimate the workplace, using the first and fifth periods of the Krotovov sounds, combined with the pregnant women.. The utilization of mercury is diminishing, and choices are required. [1] They have the benefit of having the capacity to take numerous reading . Appropriate preparing of spectators, situating of the patient, then choice of suitable cuff size estimate for the most part basic. It is progressively perceived that office measurement present inadequately with blood pressure measurement in different locations, and they can be enhanced without anyone else's can readings taken with approved blood pressure apparatus at home. There is expanding proof a disappointment of blood pressure measuring to fall the night might be related with expanded hazard. In obese patients and children, the utilization of a proper cuff size is of vital significance [2]. blood pressure is a critical value for cardiovascular risk factors and gives essential data on the hemodynamic state of intensely ill or harmed patients. blood pressure continually changes and ascends with stress , pleasure and environment. White-coat hypertension' happens in patients just after a patient is sighted a health care provider specialist. potable Blood pressure measurement apparatus , utilizing a convenient device at interval and typical daytime movement and during the evening, is better at deciding cardiovascular hazard [3]. The blood

vessels pressure are estimated in millimeters of mercury (mm Hg), systolic over diastolic. The ordinary normal range of systemic blood pressure is 120/80 mm Hg. Blood pressure diminishes in the arterioles and small blood vessels, and the systolic and diastolic reading converge two reading . As blood enters the veins, blood pressure diminishes further and approaches zero as it streams into the right ventricle. As referenced beforehand, the blood pressure in the small blood vessels has incredible significance, and normal blood pressure is sufficiently high to allow filtration for nutrition of tissues but, low enough to prevent rupture The arterioles (and veins throughout expanded sympathetic stimulation)) are more often than not in a condition of slight narrowing that keeps up typical blood pressure, particularly diastolic pressure. This is called peripheral resistance; it is managed [4]. Amazingly, even a little distinction in blood pressure reading can considerably affect the pervasiveness of cardiovascular disease occurrences and prospect [5]

Objectives of the Study

- 1- To determine nurses' knowledge about measuring blood pressure accurately.
- 2- To find out association between nurses knowledge toward blood pressure measurement and level of education of nurses.

Methodology

Design of Study: A descriptive study was carried

out through the present investigation in order to achieve the objects of the present study; the study was conducted in emergency department of AL-Hussein Teaching Hospital at Al- Nasiriya City. Randomize sampling of nurses selections in emergency department and in order to assess the blood pressure measurement by questionnaire consists of:

Part 1: Nurses socio demographic characteristics include (Age, Sex, Educational level and years of experience).

Part 2: Questionnaire:

It was found as examination sequences of blood pressure in text book Macleod's Clinical Examination [5] and was revised by the researchers. also, was adjusted by the analysts. This instrument was utilized to appraisal learning of assessment knowledge of nurses with exact blood pressure measuring , incorporates 15 items covering the accompanying: Resting the client for 5 minutes preceding examination, measure BP in the two arms (brachial arteries); the greater of the two is nearest to central aortic pressure and ought to be utilized to decide treatment, In the case of patient placement or rest,

the patient's arm is easily supported around the heart, with no tight clothing shrinking at the top of the arm, and can be measured on thin clothing, while the bladder width is 12.5 cm and 30 to 35 cm long. Place the cuff at the top of the arm, with the center of the bladder on the brachial artery, palpate the brachial artery, blow the cuff up to the point where the pulse is not felt, Puff up the cuff up to 30 mmHg and hear through the diaphragm of the headset installed on the brachial artery, Empty the cuff gradually (2– 3 mmHg/s) until the point that you hear is tapping sound (stage 1 Korotkoff sounds). Record read measurements for the nearest 2 mmHg. This is the systolic pressure, continue to empty the cuff gradually until you reach the point where the sounds go, the pressure record where sounds disappear just like diastolic pressure. Official permission was obtained from the Administrative of Thi-Qar health office and from the head nurses at the study settings to done the study. A verbal assent acquired from the respondents previously their incorporation in the study . Nature and goals of the study was clarified to every individual from the members. The information when gathered with questionnaire, through a use of indirect answers as mean of information gathering.

Result

Table (1): Show distribution of nurses' age groups that were cooperative in study.

Age			
		Frequency	Percent
Age of Nurses	21-25	59	59.0
	26-30	28	28.0
	31-35	11	11.0
	36-40	2	2.0
	Total	100	100.0

This table illustrates that the majority of (59.0%) of nurses' cooperative in study were at age group (21-25).

Table (2): Show Distribution of Nurses Gender that were Cooperative in the Study.

Gender of Nurses			
		Frequency	Percent
Gender	Male	30	30.0
	Female	70	70.0
	Total	100	100.0

This table illustrates that the majority of (70.0 %) that were females that cooperative in study.

Table (3): Show Distributions of Educational level among Nurses Cooperative in Study.

Educational Level of Nurses			
		Frequency	Percent
	Secondary	32	32.0
	Institute	51	51.0
	Colleague	17	17.0
	Total	100	100.0

This table illustrates that the majority of (51%) were graduated from medical institutes.

Table (4): This Table Show Distribution of Years of Experiences of Nurses Cooperative in This Study.

Years of Experiences of Nurses			
		Frequency	Percent
	2-5 years	59	59.0
	7-11 years	28	28.0
	12-16 years	11	11.0
	17-21 years	2	2.0
	Total	100	100.0

This table illustrates that the majority of (59%) were within from (2-5 years) of experiences.

Table (5): This Table Show Cooperative in Learning Session of Nurses that were Cooperative in Study.

Cooperative in Learning Session of Nurses			
		Frequency	Percent
	Yes	94	94.0
	No	6	6.0
	Total	100	100.0

This table illustrates that the majority of (94%) were cooperative in learning sessions.

Table (6): This Table Show the Number of Learning Sessions Cooperating by Nurses.

Number of Learning Sessions Cooperating			
		Frequency	Percent
	1-5	3	3.0
	6-10	97	97.0
	Total	100	100.0

This table illustrates that the majority of (97%) of all nurses cooperative in learning sessions that were cooperative number from(6-10) learning sessions class.

Discussion

At the state when blood pressure is measure and treated by medical guidelines, even modest decreases can have a clinically critical impact [7].The present study revealed that the majority of (59.0%) of nurses cooperative in study were at age group (21-25). The study results revealed that of (70.0 %) that were females that cooperative in study. The majority of (51%) were graduated from medical institutes the study results show (59%) of nurses cooperative in the study were from (2-5 years) of experiences. the majority of (94%) were cooperative in learning sessions. majority of (97%) of all nurses cooperative in learning sessions that were cooperative number from(6-10) learning sessions class^[8].The study result illustrates that the majority of (72%) of all nurses cooperative in this study have moderate knowledge toward blood pressure measurements. The results revealed that This outcome was in accepting for the result with [9] demonstrate that 35–60% of human services experts in the Departmentd States measure circulatory strain inaccurately. Highly significant ($P<0.00$) the highly statistically significance between Average of nurses knowledge toward blood pressure measurement and level of education^[10].

Conclusions

1- The correctness of blood pressure (BP) measuring is significant.

2- Organized minor errors can mislabel BP status in many persons.

3- Persistence retraining and assessment is an crucial step toward successful blood pressure measurement accuracy.

4- Quality enhancement sessions can assist healthcare teams to apply commended guidelines in everyday practice.

5- Numerous means in the blood pressure measuring process, it is useful to consider enhancing accuracy through a progression of little execution enhancement activities or quick enhancement cycles..

6- Give more attention for those patients with white coat hypertension.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Southern Technical University and all experiments were carried out in accordance with approved guidelines.

Abstract

The aim of this study was to determine the possible temperature increase on root surface of deciduous human teeth after intra-root canal laser irradiation with different chopped modes to clarify the thermal safety of these modes. fifteen freshly extracted unrestorable deciduous molars were used. Immediately after extraction, teeth cleaned, root canal perpetrated, laser irradiation was done in mesial root using dual wavelengths 980/810 nm InGaAs diode laser (using a 200 µm fiber, 800mW output power. Room temperature were raised in the laboratory to 37C to simulate body temperature, for each tooth three chopped program were used successively: 25ms on 75ms off, 50ms on and 50ms off, and 75ms on 25ms off. Each round laser irradiated for 5 seconds then 10 seconds pause. At the very last second temperature was measured using infrared thermometer. This procedure for the three groups was repeated but with non-stop laser irradiation with no cooling intervals.

It was concluded that 30/70 ms layout can be used safely to assist root canal disinfection.

Keywords: endodontic treatment, external root surface, laser

Introduction

Successful endodontic treatment mandate elimination of bacteria in root canal system ¹. Its well known that all available irrigation solution are not optimized to eliminate all bacteria due to surface tension of liquids, which prevent these liquids to penetrate more than 100 µm in dental tissue², whereas bacteria can do much more penetration in dentin which may reach ten folds of irrigation liquids depth ³. Therefor additional disinfection protocol is needed to eliminate microbes in dentinal tubules to increase success rates of root canal treatment ⁴.

The availability of diode laser in many dental clinics, the reasonable cost, and the quite rapid development of lasers technologies make them suitable aids to root canal disinfection ⁵. Diode laser had been vigorously studied and it was concluded that using it in combination sodium hypochlorite and/ or oxygenated water would obtain a

good outcome ⁶. The effect of diode laser on microbes in dentin is either photothermal or photo-activate. The effect of the formal is relied on heat generation which in turn will kill bacteria, and the latter is required presence of special dye ⁷. Beside photothermal effect cavitations generated by laser might assist in clearing smear layer and removing debris from dentin surface ⁸. Diode lasers of wavelengths between 600 and 980 nm, had been applied to disinfect root canal system, with special interest to wavelengths above 810, due to their high absorption by water. The efficiency of laser in endodontics are relied on several factors such as: wavelength, intensity, laser mode, and proper access cavity ⁹. The beneficial effect of laser photothermal of disinfection and cavitations of smear layer, may cause collateral damage to periodontal ligament and alveolar bone if the temperature on root surface increased more than 10 C for less than 60 seconds ¹⁰. To prevent or decrease this harmful side effect, the laser parameters should be optimized to a

precise level that can perform efficient disinfection and in the same time insure periodontal ligament health. For this purpose, this study was designed to investigate the thermal changes on root surface during application of laser irradiation through root canal.

Materials and Method

This study was performed in the secondary health center of Al_Dywaniya, from January 2019 to June 2019. In this study 15 freshly extracted unrestorable deciduous molars were used. Immediately after extraction, teeth cleaned with normal saline, carries removed, proper access opening were done by high speed hand piece (W&H), root canal instrumentation of coronal 2/3 of the canal using rotary endomotor (Eighteeth, China) and rotary files (AF Fanta 0/6, China), followed by clearing root canal using normal saline then dry it with generic paper points. teeth were hold using artery forceps from the distal root to fixing them, laser irradiation was done in mesial root using dual wavelengths 980/810 nm InGaAs diode laser (Quicklase, UK), using a 200 μ m fiber, 800mW output power. Room temperature were raised in the laboratory to 37C to simulate body temperature, for each tooth three chopped program were used successively: 25ms on 75ms off, 50ms on and 50ms off, and 75ms on 25ms off. Between each cycle teeth were cooled and cleaned with normal saline and dried. Laser fiber were inserted to the end of prepared canal then irradiation started, fiber was moved during the irradiation with speed of 3mm per second to avoid hot spot, Each round laser irradiated for 5 seconds then 10 seconds pause for six times and the total time of active irradiation was 30 seconds ¹. The temperature

on mesial root surface was measured at the last second of irradiation using infrared thermometer (generic) on the middle of the mesial aspect, the result was recorded. This procedure was performed for each tooth in the same manner. The exact procedure for each tooth for the same parameters were repeated but without pause intervals, 30 seconds of laser irradiation was given in the same speed of 3 mm per second, and the temperature was measured in the same spot of above-mentioned method, to clarify the effect of non-stop laser radiation on root surface temperature.

Statistical analysis was proceeded using SigmaPlot Version 12. mean and standard deviation for each Group (1–6).

To determine temperature differences between groups we used One Way Repeated Measures Analysis of Variance. Statistical significance was defined at $p < 0.05$. To isolate the group or groups that differ from the others we used all Pairwise Multiple Comparison Procedures (Holm-Sidak method). Comparison of groups of the same parameters was done using Paired T test.

Results and Discussions

Analysis data by one-way ANOVA revealed slight increase in root temperature in all groups (table 1), The Intermitted 70/30 groups showed the higher temperature raise (5C above the initial temperature), Intermitted 50/50 showed a lesser thermal change (~3C), and the Intermitted 30/70 revealed the least temperature raise (less than 1C as average).

Table 1. Analysis data by one-way ANOVA revealed slight increase in root temperature in all groups.

Treatment Name	N	Missing	Mean	Std Dev	SEM
Intermitted 70/30	15	0	42.000	2.803	0.724
Intermitted 50/50	15	0	39.767	1.770	0.457
Intermitted 30/70	15	0	37.093	0.139	0.0358

There was a statistically significant differences between these groups (table 2), thus post hoc test was performed to isolate group or groups that differ from the others.

Table 2. Statistically significant differences between groups.

Source of Variation	DF	SS	MS	F	P
Between Subjects	14	66.885	4.778		
Between Treatments	2	181.049	90.525	29.048	<0.001
Residual	28	87.257	3.116		
Total	44	335.192			

Post hoc analysis showed that Intermitted 70/30 had statistically significantly higher mean than Intermitted 30/70 (P= <0.001), and Intermitted 50/50 (P=0.002). lower mean was recorded in Intermitted 30/70 which was statistically significantly lower than other groups (P=<0.001) as shown in table 3.

Table 3. Statistically significantly lower than other groups

Comparisons for factor:					
Comparison	Diff of Means	t	P	P<0.050	
Intermitted 70/30 vs. Intermitted 30/70	4.907	7.612	<0.001	Yes	
Intermitted 50/50 vs. Intermitted 30/70	2.673	4.147	<0.001	Yes	
Intermitted 70/30 vs. Intermitted 50/50	2.233	3.465	0.002	Yes	

Data of non-stop irradiation showed higher means in all groups, both Nonstop 70/30 and 50/50 showed high temperature (table 4), which was exceeded the upper acceptable threshold of 7-10C (8, 11), on the opposite Nonstop 30/70 group showed slight increase within safe limits. One-way ANOVA analysis revealed as expected significant differences among groups (table 5), therefore post hoc test was done using Holm-Sidak method to isolate particular differences between groups (table 6), this test showed that both Nonstop 70/30 and Nonstop 50/50 had higher mean than Nonstop 30/70 (P=<0.001), also Nonstop 70/30 was higher than Nonstop 50/50 (P=<0.001).

Table 4. Data of non-stop irradiation showed higher means in all groups.

Treatment Name	N	Missing	Mean	Std Dev	SEM
Nonstop 70/30	15	0	58.053	1.743	0.450
Nonstop 50/50	15	0	47.847	2.093	0.540
Nonstop 30/70	15	0	37.387	0.344	0.0888

Table 5. One-way ANOVA analysis revealed as expected significant differences among groups.

Source of Variation	DF	SS	MS	F	P
Between Subjects	14	32.952	2.354		
Between Treatments	2	3203.494	1601.747	618.268	<0.001

Total	44	3308.986			

Table 6. Holm-Sidak method to isolate particular differences between groups.

Comparisons for factor:				
Comparison	Diff of Means	t	P	
70/30 vs. 30/70	20.667	35.164	<0.001	Yes
50/50 vs. 30/70	10.460	17.797	<0.001	Yes
70/30 vs. 50/50	10.207	17.366	<0.001	Yes

The aim of this study was to determine the possible temperature increase on root surface of deciduous human teeth after intra-root canal laser irradiation with different chopped modes to clarify the thermal safety of these modes.

It's important to mention that invitro circumstances are not always identical to vivo condition, thus the picture in real experiments may vary from this study results¹¹. In this study teeth temperature were raised to 37C by increasing room temperature to simulate the human body temperature, to avoid fast temperature loss during previous studies when using room temperature¹². Previous literatures had showed the safe threshold of root surface to be less than 10C to avoid periodontal and bone damage^(11, 13), although many authors considered 7C increases to be the safe threshold in human body due to slower cooling in comparing to vitro studies^(14, 15).

Under the condition of this study, it was observed that chopped intervals had intense influence on root surface temperature, and layout of both 70/30 and 50/50 ms on/off laser irradiated showed remarkable thermal raise which was exceed the safe threshold when it was used with non-stop mode, and in intermitted mode with cooling off intervals the raise was still within acceptable safe limits but both groups showed significantly higher temperature increase in comparing with 30/70 ms layout. It's important to mention that this study didn't examine the efficiency of laser on root canal disinfection, thus its not possible to give conclusion about the optimal laser layout, but we can conclude that 30/70ms layout can be used safely even if the laser used without cooling off periods, on the other hand its good to advice that laser layout of 70/30 and 50/50ms should use with precaution and always be used with cooling off period to avoid unintentional thermal raise which will exceed safe

threshold in less than 30 seconds.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under Al-Diwaniyah secondary dental health center, Al-Diwaniyah, Iraq and all experiments were carried out in accordance with approved guidelines.

Abstract

Objective: This research was carried out in rats in a special place of the laboratory of histopathological diseases in the period 6/9/2018 until 23/11/2018, this study to detect effect of the addition of the alcohol extract of ginger in the reduction of fat in liver tissue of rats.

Method: Eight groups and replicates for each group. The groups were homogenous in weights and were placed in 13 cages. Each group consisted of 10 rat and at 5 fares each. In the first treatment, rat were fed on regular feeding without adding and feeding rats in the second treatment sessions add to it the alcoholic extract of ginger in Turkey 150 mg / kg. The third group is the same as the normal food after adding the alcohol extract of ginger at a concentration of 300 mg / kg.

Results: The results of the study showed a high morale in the rates of reduction of fat in the liver tissue of rat fed on the alcohol extract of the ginger and improved the conversion factor of food by adding the extract of alcohol extract of each of the ginger.

Keywords: Cholesterol, liver tissue, alcohol extract of each of the ginger

Introduction

The cultivation of medicinal and aromatic plants and herbs has spread in most parts of the world and has been used for its medicinal effectiveness and quick cure for diseases which are used as whole herbs, powders, or aqueous or aquatic or oily extracts¹¹. Zingiber is a plant that is found in the hot areas. Rizhomes are used under the soil and contain volatile oils with pungent smells and pungent taste. They are also squirrels or yellowish white. They contain the ginger root nodes on resins, the most important of which are Gingerol¹¹

Methods

Preparation of the alcoholic extract of ginger

Get the ginger from the local markets and cut the raw

ginger into very small pieces. Solve 30 g of raw material in alcohol to get the ginger extract in 70 ml of ethyl alcohol at 96% concentration and place in a clean glass jar in a dark place, 4 times daily for at least two weeks. The solution is then filtered with Whatman1 filter paper²⁰. The solution is then placed in the rotary evaporator, at a temperature of 45 m for the purpose of extracting the solution. The solution was then placed in an electric oven at 45 ° C for 20 minutes to dispose of the remaining alcohol. After extracting the extract, it was weighed by a sensitive balance and stored in clean containers.

Histological study of light microscopy

For the purpose of studying the histological structure of the liver of mice, the following chemicals and colors were used⁷

Aqueous Bouin's Solution

I use this solution in the installation and have attended the accreditation⁷

Alcoholic alcohols

Attended progressive concentrations of ethanol alcohol 30%, 50%, 70%, 80%, 90% and

95% using distilled water¹⁶

Harris Hematoxylin Stain

This is a color of basal colors that are generally used for all animal tissues, especially when using the color of the Eocene⁷

Dissection of animals

At the fifth week of the rat’s lifetime, 8 rats were taken from each treatment. The total number of mice was 16 and then the animal was explained after anesthesia based the following¹²

-Place the animal in a Dissecting Tray.

- remove the skin, and then remove the sternum Caudal appendage until the area separated with the gravitational bone Coracoid bone Cranial.

- Make a cut in the skin in the lower abdominal region.

- Elevation of the liver after cutting the suture that connects it to the transverse septum barrier separating the pericardial cavity and the abdominal cavity.

- The samples were transferred to the installed solutions Formalin.

Preparation of histological slides

I attended paraffin slices based on¹⁶

. Fixation

Place a section of samples in a 10% formalin solution in time 24 hours. **Washing**

Samples installed with a formalin solution washed 10% concentration with tap water for half hour.

Dehydration

The samples were passed with an ascending sequence of ethyl alcohol for the purpose of drawing water from the sample, starting from 70%, 80%, 90%, 95% and 100% for half an hour per concentration.

Clearing

Sample samples with Xylene for 15 minutes to make samples more transparent.

Infiltration

Before the leakage, the samples were transferred to a mixture of xylene and paraffin wax, melting 58-56m at 1: 1 for half an hour, then placed in molten paraffin wax and repeated three times for half an hour each.

Embedding and making blocks

The samples were immersed in the same type of wax used for filtration. The molten wax was poured into special molds for this purpose. The samples were then transferred to the air bubbles to remove hot bubbles around the sample and leave the mold to harden.

Trimming and Sectioning

The molds were waxed using a sharp scalpel and mounted on a wooden stand. The mold was placed on the Rotary Microtome. The models were then cut into serial sections with a thickness of seven micrometers. The sections were then placed on clean glass slides coated with a thin layer of Mayer’s aluminum and distilled water. Hot plate temperature 37 m to dry

Staining

The textile slides were colored with their own colors and the following :

Harris hematoxylin and eosin

The sections were colored with hematoxylin Harris-eosin

- Histological sections were put in the xylene and in two stages for ten minutes for each stage
- The syllables underwent a downward chain of concentration of ethyl alcohol
- Rinse the sections with Hematoxylin Harris for 15 minutes and then wash with tap water for 2 minutes. After that, wash the sections in distilled water for 2 minutes.
- The sections were painted with the eosin coating for 3-4 minutes, transferred to ethyl alcohol 70% concentration for 2 minutes.
- Dry the sections with a series of progressive

concentrations of ethyl alcohol 70-100% and for 2 minutes per concentration.

- Raise sections by using xylene in two phases and for 2 minutes for each stage.

Mounting

The plates were placed using a Dextrin Plasticizer Xylene (D. P. X). Then, covered with glass cover and no bubbles, the glass slides were transferred to a 37 ° C hot plate and left to dry.

Microscopy

Microscope Photography Microscopic slides were examined using a light microscope and various magnification powers to suit the current study requirements. The microscopic slides were selected with a digital microscope equipped with a digital camera and a standard 12-megapixel Canon camera was used to visualize prototypes.

Results and Discussion

The Liver

The results of the current study showed the effect of alcohol extract of ginger in the morphological description and tissue composition of the rat liver and compared it with the treatment of control and the following.

The histological of the liver in the rat of the control treatment

The hepatic tissue in the rat appeared to treat the control of hepatic cells, which are covered with a Glisson capsule, composed of a thin layer of connective tissue that extends from deep inner barriers. Among the hepatic cells are a number of sinusoids that are lined with two types of cells They are endothelial cells that are flat cells that are not linked to each other. Their nuclei

are compressed and dark-colored and their cytoplasm is somewhat unnoticeable, while caper cells appear in the irregular blood cell cavity, and hepatic cords, The hepatic tissue in the mice appeared to treat the control of hepatic cells, which are covered with a Glisson capsule, composed of a thin layer of connective tissue that extends from deep inner barriers. Among the hepatic cells are a number of sinusoids that are lined with two types of cells They are endothelial cells that are flat cells that are not linked to each other. Their nuclei are compressed and dark-colored and their cytoplasm is somewhat unnoticeable, while caper cells appear in the irregular blood cell cavity, and hepatic cords appear around the veins He passed Central veins, as well as the portal area of the branch of hepatic portal vein, the hepatic artery branch and the branch of bile ducts, and occasionally the lymphatic cell branch (Fig. 1, 2 and 3) in their study on chickens⁸.

Sinusoids have appeared in narrow sinuses in mice and this is consistent with what has shown through their studies on chickens and ducks.

Polygonal shape (23.4 μm), a nucleus or two spherical nuclei, and one or more central nuclei, showed a cytoplasmic granularity, because it contains a diverse group of organelles. This result is consistent with what the researchers⁸ The branch of the hepatic portal vein located in the inner courtyard is characterized by the thinness of its wall and its large cavity. It is surrounded by endothelial cells surrounded by smooth muscle fibers, while the hepatic artery branch is characterized by its wall thickness, small cavity, limp, smooth muscular fiber^(8,21) referred to large bile ducts lined with simple epithelium based on the original lamina propria and surrounded by smooth muscle fibers covered with serosa. The primary bile ducts are lined with vertical epithelial cells.

The histological structure of the liver in rat treated with the alcohol extract of ginger at a concentration of 300 mg / kg:

The results of histological study showed that liver-fed rat on the standard diet plus her alcoholic extract of ginger concentration of 300 mg / kg in which distension may occur in the liver cells and the increase in the hepatic cells size as the diameter reached hepatic cell 30.4 micron and observed increasing the level of bilateral cells cores with expansion Central venous and get a blood congestion in the blood vessels and for the expansion of the bile duct branch (6 and 7 and 8 photos) compared with the control group may be due to the alcoholic extract of ginger, which may be attributed to the liberation of acid Alarkidunk located in phosphorescent fat that enters in the composition of the elk cells Friendly, leading to activation Almothinat Prostaglandins, which caused the expansion of blood vessels and the events of the expansion of the bile ducts³. As for the reduction of

the protein level of fat Lipoprotein lowland density of LDL-C, and raise the protein level of fat and high-density High-density Lipoproteins may inhibit ginger absorption of cholesterol from the intestine and increases raised as a result of increased Adrar yellow This is indicated by the researcher and his group¹³ thereby is reflected in the reduction of LDL-C and raise HDL-C, or perhaps because of the containment of ginger on the high content of vitamin C, which stimulates the secretion of insulin and works Kamadada antioxidants thus occurs on the reduction in LDL-C and raise the HDL-C and this is what he referred⁴ and the ability of Ginger rhizomes powder to cause swelling in the cells Liver compared to what is in the control treatment may be due to the possession of ginger extract compounds have a similar action to insulin hormone in its ability to alter the metabolism of carbohydrates and increase the formation of calcification by increasing the entry of glucose into the cells, causing swelling^(4,17)

Knowledge, Attitude and Practice of Mothers to Neonatal Jaundice

Aalan Hadi Al-Zamili¹, Zainab Allawi Saadoon²

¹M.B.Ch.B., C.A.B.P./ Professor/ Paediatrician/ College of Medicine/ University of Al-Qadissiyah/ Department of Paediatrics/ Al-Diwaniyah Province/ Iraq, ²M.B.Ch.B/ Al-Diwaniyah teaching hospital / Al-Diwaniyah Province/ Iraq

Abstract

Background: Neonatal severe hyperbilirubinemia represents a significant, yet preventable health problem, particularly in low- and middle-income countries (LMICs) ¹⁶. Adequate maternal knowledge, early perception, and care seeking behavior are fundamental components of effective management of NNJ ⁷. A number of studies revealed unexpected moderate knowledge and attitude scores of mothers in most knowledge domains, although the majority of them were illiterate or had low educational attainment.

Aim of the study: To assess the knowledge, attitude and practice responses of women during reproductive age toward neonatal jaundice and response correlation to demographic characteristics.

Patients and Method: In this hospital based study, in order to evaluate the knowledge background of ladies of reproductive age toward neonatal jaundice regarding causes, clinical manifestation, complications, mode of treatment and other aspects in addition to their attitude regarding conventional and traditional medical approaches and how to behave when facing the problem of neonatal jaundice, a sample of women was selected according to the duration of study.

Results: Most of women admit to know 2 symptoms of jaundice, where as small proportion of women knew only one symptom of jaundice, 80.2 % versus 15.8 %, respectively. Four women (4%) know none of symptoms of jaundice. Regarding dangerous symptoms of jaundice, most of women (88.1 %) knew a single symptom and a few of them (4 %) knew 3 symptoms. Positive attitude toward neonatal was seen in significantly high proportion of women enrolled in the study. Positive practice was correlated to older age, higher level of education and higher birth order

Conclusion: Knowledge, attitude and behavior of women about various aspects of neonatal jaundice were significantly better in older women in comparison with younger women, and highly significant better with increasing birth order, as well as it was significantly better in employee and with higher level of education.

Key words: Knowledge, Attitude and Practice, Mothers, Neonatal Jaundice.

Introduction

Neonatal jaundice is yellowish discoloration of the skin, conjunctiva and the sclera from elevated serum or plasma bilirubin in the newborn period ¹². The term jaundice is from the French word “jaune,” which means yellow ²⁴. Neonatal jaundice in most newborns is a mild and transient event. It is however imperative to identify newborns with jaundice that do not follow this pattern as failure to do so may lead to long-term sequelae ²¹. Almost all newborns will develop a total

bilirubin level above the upper limit of normal for adults and older children bilirubin of 1.5 mg/dl with less than 5% of the total bilirubin conjugated ³. Up to 60% of term infants and 80% of newborns with a gestational age of 35 weeks or more will develop jaundice, which occurs when serum bilirubin reaches and exceeds 5 mg/dl ¹⁰. Neonatal severe hyperbilirubinemia represents a significant, yet preventable health problem, particularly in low- and middle-income countries (LMICs) ¹⁶. Adequate maternal knowledge, early perception, and

care seeking behavior are fundamental components of effective management of NNJ⁷. A number of studies revealed unexpected moderate knowledge and attitude scores of mothers in most knowledge domains, although the majority of them were illiterate or had low educational attainment. This may be partly associated with successful implementation of extensive primary care network, as well as frequent broadcasting free health messages¹³. In terms of knowledge, some studies reported that participants had adequate knowledge about NNJ in the aspects of awareness, risk factors, management, and complications. Nonetheless, only little proportion of mothers had addressed breast feeding and preterm labor as risk factors for NNJ, respectively. This warrants adequate antenatal and postnatal dissemination of information on neonatal hyperbilirubinemia to the vast majority of mothers. Generally, frequency of correct responses of knowledge related to NNJ was inconsistent across studies conducted in developing world such as Ethiopia (63.5%)¹, Nigeria (57%)¹⁵, Iran (77%)², and Turkey (46%)²³. Utilization of different questionnaires, cultural diversity, and traditional beliefs could be factors that might have influenced such difference. Therefore the aim of the current study was to assess the knowledge, attitude and practice responses of women during reproductive age toward neonatal jaundice and response correlation to demographic characteristics.

Patients and Method

In this hospital based study, in order to evaluate the knowledge background of ladies of reproductive age toward neonatal jaundice regarding causes, clinical manifestation, complications, mode of treatment and other aspects in addition to their attitude regarding conventional and traditional medical approaches and how to behave when facing the problem of neonatal jaundice, a sample of women was selected according to the duration of study. The available conventional sample was collected as 2 to 3 cases per day, 3 days a week. At the end of the study we were able to collect information about 101 women. The study was carried out in the Al-Diwanyal Maternity and Child Teaching hospital during the period from October 2018 through January 2016. The following variables were included in the questionnaire form: Demographic characteristics including age, residency, education level and occupation, Mode of delivery and birth order of last child. Knowledge domain included Symptoms of jaundice, Dangerous symptoms of jaundice, Causes of neonatal jaundice, Effective treatment, Complication of severe jaundice, Best way

of diagnosis and Prevention during pregnancy. Attitude domain was evaluated through a number of questions regarding Neonatal jaundice development, traditional medicine harmful effect, worry of hospitalization, visiting physician when facing the problem of neonatal jaundice. Practice domain included direct questions with yes or no response. These questions were about Using medical herbs, Fluorescent use at home, Using sun light, Referring to physician and Referring to traditional healers. The study was approved by the institutional ethical approval committee and formal agreement was obtained from the directorate of Health in Al-Diwaniyah province, the formal representative of Iraqi Ministry of health.

Data were collected and transformed into a spread sheet of Microsoft Office Excel 2010 and then into an SPSS (statistical package for social sciences) version 23. Numeric quantitative data were expressed as mean, range and standard deviation (SD), whereas, qualitative data were expressed as number and percentage. Spearman correlation test was used to assess correlation among variables. The level of significance was considered at $P \leq 0.05$.

Results

Demographic characteristics of women enrolled in the present study were demonstrated in table 1. The frequency distribution of women according to knowledge domain is demonstrated in table 2. Most of women admit to know 2 symptoms of jaundice, where as small proportion of women knew only one symptom of jaundice, 80.2 % versus 15.8 %, respectively. Four women (4%) know none of symptoms of jaundice. Regarding dangerous symptoms of jaundice, most of women (88.1 %) knew a single symptom and a few of them (4 %) knew 3 symptoms. With respect to causes of jaundice, most women revealed knowledge of a single cause of jaundice and they accounted for 59.4 %, only 20.8 % of women knew 2 causes and 19.8 % of women were unable to recognize any cause of jaundice. Most of women (60.4 %) knew a single effective mode of therapy and 19.8 % of them knew two modes, whereas 19.8 % of them know none of effective treatment modes. The largest proportion of participating women knew nothing about complications of neonatal jaundice and they accounted for 44.6 %. Those who know 1, 2 or three complications accounted for 11.9 %, 23.8 and 19.8 %, respectively. Most of participating women had knowledge about 2 methods of diagnosis and they

accounted for 96.0 %, while 4% of them knew only a single diagnostic method. Unfortunately all participating women know nothing about how to prevent neonatal jaundice during pregnancy. Assessment of women Attitude domain toward neonatal jaundice and their frequency distribution according to response to attitude questions are shown in table 3. Regarding the first question “ I am worried about developing jaundice in my infant” 72.3 % of the response was strongly agree, 15.8 % of the response was “no idea” and 11.9 % of the response was disagree. Regarding the second question “I am worried about several blood testing of my infant because it can cause anemia” 100.0 % of the response was disagree. Regarding the third question “if jaundice develops in my infant, I shall use traditional medicine because this disease is not dangerous”, 92.1 %

of the response was disagree and 7.9 % was “no idea”. Regarding the fourth question “if jaundice develops in my infant, I won’t use traditional medicine because it may be harmful for him”, 96.0 % of the response was disagree and 4.0 % was “no idea”. Regarding the fifth question “if jaundice develops, since I am afraid of hospitalization, I won’t consult a physician”, 84.2 % of the response was disagree, 7.9% was strongly disagree, 4.0 % was “no idea” and 4.0 % was strongly agree. Regarding the sixth question “Neonatal jaundice is a serious condition”, 64.4 % of the response was strongly agree, 19.8 % was “no idea” and 15.8 % was disagree. Regarding the seventh question “early referring to the physician and getting proper treatment, neonatal jaundice is curable”, 84.2 % of the response was strongly agree, 11.9 % was “no idea” and 4.0 % was disagree.

Table 1: Frequency distribution of women according to response to knowledge domain questions

Referring to physician	97	96.0	4	4.0
Referring to traditional healers	0	0.0	101	100.0
Nothing	0	0.0	101	100.0

Discussion

In the present study, most of participating women had knowledge about 2 methods of diagnosis and they accounted for 96.0 %, while 4% of them knew only a single diagnostic method. This finding reflects fair knowledge of women in our community about method of diagnosing neonatal jaundice. However, unfortunately all participating women know nothing about how to

prevent neonatal jaundice during pregnancy. Therefore, healthcare provisional who are in touch with those women, namely governmental and private antenatal care clinics should spent more time and effort in order to explain to pregnant women the way how to avoid the problem of neonatal jaundice such as the establishment of community programs encouraging and supporting breastfeeding. In the current study, positive attitude toward neonatal was seen in significantly high

proportion of women enrolled in the study. For example worrying about development of neonatal jaundice was seen in 72.3 %, 92.1 % of the response disagree using traditional medicine, 100.0 % were unwary about multiple blood sampling to assess state of jaundice, 84.2 % of the response was disagree about avoidance of physician consultation and 64.4 % of the response was strongly agree with that neonatal jaundice should be considered seriously. This is consistent with previous studies from Nigeria ⁸ and Sri Lanka, ²⁰ and Egypt ¹³. For example, in Egypt 88.3% of participants strongly agreed to seek medical care if their babies developed NNJ. A study from Iran ¹⁹ reported similar results in perspective of the mean score; however, 63% of their study population had shown higher levels of attitudes. This difference might be attributable to the time lag between the onset of NNJ and seeking medical help, a finding corroborated by other studies ^(15, 8). This observation is an important reminder that providing education and knowledge is not sufficient itself to change maternal behavior ¹¹. The use of traditional medicine is common in underdeveloped countries and our findings are in agreement with the vast majority of literatures in this regard ^(1, 7, 5). We believe that in order to reduce such malpractices in the community, governmental effort should be directed to increase level of education of women in the community in addition to increasing the efforts offered by health workers in antenatal care clinics and institutes in addition to investing mass and social media in the correct direction of how to deal with prevention and management of neonatal jaundice. One of wrong approaches that were commonly practiced by women participating in the current study was the use of fluorescent use at home. However, one of good practices is the excellent proportion of positive response toward visiting physicians when facing problem of neonatal jaundice and avoiding traditional healers.

Conclusion

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Medicine/ University of Al-Qadissiyah/ Department of Paediatrics/ Al-Diwaniyah Province/ Iraq and all experiments were carried out in accordance with approved guidelines.

Measurements of Horizontal condylar inclination by using Cadiax compactII in patients with TMJ clicking before and after different treatments modalities

Hayder Mahdi Idan¹, Fawaz D. Al-Aswad²

¹B.D.S Msc. Oral Medicine, ²B.D.S Msc. PhD. Oral medicine, MFDS. RCPS Glasgow, College of Dentistry, University of Baghdad, Iraq

Abstract

Background: Temporomandibular joint can be defined as a small and complex joint in the body. The bony portions of the joint consist of glenoid fossa, mandibular condyle and articular eminence which is a part of the temporal bone. Between the two bony structures, the articular disc is found. Disc displacement characterized by alteration in the articular disc position (abnormal position) locating between the mandibular fossa and the head of the condyle. Clicking can be defined as a brief sounds that are created from the movements of mandible, associated with displacement of the disc with reduction. Remodeling of the joint or joint hypermobility can produce clicking like sounds. Horizontal condylar angle can be defined as an angle formed in the horizontal plane between the Frankfurt horizontal plane and a line connecting a point on the head of the condyle, in centric and protrusive position.

Aim of the Study: Measurement of horizontal condylar inclination in patients with clicking using Cadiax CompactII before and after the treatment.

Subjects, materials and Method: The study sample consisted of seventy eight patients with disk displacement and thirty one as control subjects. Patients with intra articular joint disorders were divided into four groups according to the Diagnostic Criteria for Temporomandibular Disorders (Group1-disk displacement with reduction. Group2-disk displacement with reduction with intermittent locking. Group3-disk displacement without reduction with limited opening. Group 4-disk displacement without reduction without limited opening).

Results: Horizontal condylar inclination, results concerning right and left sides shows highly significant differences between control and group 4, while no significant differences were seen in the studied disorder groups either for using splint or laser

Conclusions: The differences of Horizontal condylar inclination recorded by non-invasive Cadiax CompactII device may be used in the diagnosis of disc displacement without reduction without limited opening. The different modalities of treatment used do not influence the horizontal condylar inclination.

Keywords: horizontal condylar inclination, Cadiax compact II, clicking, splint, laser.

Introduction

Temporomandibular joint (TMJ) is arthroal ginglymus joint, which is formed from glenoid fossa, articular tubercle, articular disc, condyle, retro discal tissue, joints capsule and synovial membrane,^[1] consider the most commonly joint used in the human body with a bilateral concurrent capacity to move the lower jaw.

[2] Clicking is predominantly created as mandibular condyle travels above displaced disc with morphologic alterations. [3] Controversy quit remains as to whether or not anterior disc displacement in the lack of other signs and symptoms for example pain and/or mouth opening restriction should be treated.[4] Some investigators proposed that clicking may considered as usual variation, resultant from practical adaptation of TMJ

and/or aging. Other investigators involved degenerative TMJ disease as a part of relevant application process of TMJ. [5] Computed axiography allows non-invasive three-dimensional imaging of the condylar path on the basis of recorded hinge-axis movements. Axiographic recordings of the mandibular joint motion permit the diagnosis of muscular dyscoordination, hyper and hypomobility, dynamic asymmetries of movement and joint pathologies, [6] all are often assist in the identification of the causes. The present study consist of two modalities of treatment, occlusal splint and laser therapy, the most common purposes of intra oral appliance therapy are to provide joint stabilization, protect the teeth, redistribute forces, relax elevator muscles, and decrease or control the effects of bruxism. Stabilizing oral appliance that fully covers one arch and does not reposition the mandible or alter the occlusion is considered a standard part of therapy of temporomandibular joint disorders (TMDs). [7] Low level laser therapy (LLLT) is a type of therapy for musculoskeletal illness, with an anti-inflammatory, analgesic, regenerative actions, as well as limited time of treatment, easy applied with less contraindications. [8]

Subjects, materials and methods

The study sample consisted of seventy eight patients with intra articular joint disorders (Current TMJ noises, click(s) during jaw movement) and thirty one as control subjects with age range from 21-45 years old. Patients with intra articular joint disorders were divided into four groups according to the Diagnostic Criteria for Temporomandibular Disorders. [9]

1-Group1(thirty three patients with disk displacement with reduction).

2-Group2 (fifteen patients with disk displacement with reduction, with intermittent locking).

3-Group3 (fifteen patients with disk displacement without reduction, with limited opening), this group excluded from the measurements by Cadiax compact II due to limited mouth opening.

4-Group4 (fifteen patients with disk displacement without reduction, without limited opening).

The control group attending to the dental center for different diagnostic purposes which have not (TMDs) by clinical examination and patients were clinically diagnosed to have intra articular joint disorder.

Measurements of horizontal condylar inclination in control and patients with clicking using Cadiax compact II before and after the treatment; (Figure 1).

Hard occlusal splint of 2mm thickness was prepared to cover the maxillary teeth. The surface of splint was smooth and removing the posterior interferences to deliver centric relation occlusion, it was used for two months at night (eight hours) by patients and then repeated the measurements of horizontal condylar inclination by Cadiax Compact II to determine any change that occur.

Diode class IV laser of wave length 940 nm \pm 10 with the power of 4 watt using deep tissue handpiece (30mm diameter = 7.1cm² area), energy is 1200 J and energy density is 169 J/cm² for 300 second in each side.

Patients and dentist wear protective eye glasses during the session of treatment, patients were treated in four sessions (four weekly treatments). The deep tissue handpiece of laser probe was placed over the TMJ area which was identified throughout the clinical examination anterior to the ear, at the opening and closing of the mouth; (Figure 2).

Adequate level of beneficial energy in a short period of time was applied to the affected TMJs to provide active therapeutic effects. According to manufacturing recommendation, some patients may need more than one laser application or a series of treatments before significant improvement is stated.

Deep tissue handpiece is provided by disposable non-sterile protective shield used for only one patient, which was disinfected before and after any patient treatment.

Figure (2): Application of laser therapy to patient with temporomandibular joint clicking.

Results

Before treatment

The summary statistics regarding of the horizontal condylar inclination at 5 mm parameter in the studied groups before the treatment distributed in right and left sides, such that, mean values, standard deviation, standard

error, 95% confidence interval for the population mean; (Table 1).

Group 4 recorded the lowest mean value, followed by group 2, group 1. Control group recorded a higher mean value; (Table 1).

Table (1): The summary of statistics of horizontal condylar inclination at 5 mm parameter in the studied groups before treatment distributed in right and left sides.

Side	Groups	No.	Mean	Std. D.	Std. E.	95% C.I. for Mean	
						L.b.	U.b.
Right	Group1	33	49.27	7.76	1.35	46.52	52.02
	Group2	15	48.20	4.92	1.27	45.48	50.92
	Group4	15	42.67	9.55	2.47	37.38	47.96
	Control	31	51.16	7.39	1.33	48.45	53.87
Left	Group1	33	48.15	9.3	1.62	44.85	51.45
	Group2	15	47.27	5.57	1.44	44.18	50.35
	Group4	15	41.87	9.27	2.39	36.73	47
	Control	31	50.16	8.23	1.48	47.14	53.18

Results concerning right and left side, showed a highly significant difference ($P < 0.01$) between control and group 4. While no significant difference ($P > 0.05$) between control and other groups; (Table 2).

Table (2): Significant levels for testing all pairs of comparisons by (LSD).

Discussion

Horizontal condylar angle can be defined as an angle made in a horizontal plane between line joining

point on TMJ condyle in protrusive and centric location and Frankfurt-horizontal plane. [10]

Horizontal condylar inclination can be recorded by

several ways:

A-Interocclusal records. ^[11]

B-Pantographic tracings. ^[12]

C-Electronic jaw tracing devices. ^[13]

D-Radiographical methods. ^[14]

Many examiners evaluate the importance of electronic axiography in diagnosis of TMDs, due to precision and accuracy of their results. ^[15,16] Also, Obrez and Gallo, (2006) ^[17] identified the development of three-dimensional recorded systems provide more accurate data and information in the assessment of the movements of TMJ condylar head.

The findings of Cruzoe'-Rebello *et al.*, (2003) ^[18] through their clear expression of horizontal condylar inclination showed no existing difference statistically between average horizontal condylar inclination values of normal TMJs and TMJs with internal derangement. Similarly the results of this study showed no difference between average horizontal condylar inclination values of control group and patients with disc displacement with reduction (group 1 and group 2).

The present study demonstrated that mean value of horizontal condylar inclination at five mm in (both right and left) in control group, in the summary achievement of this researches this agrees with the study done by Alsawaf and Garlapo (1992), ^[19] they stated that the values of horizontal condylar inclination is between 44° and 55° which is near to the results done by Alfredo *et al.*, (2010), ^[20] they determine the mean horizontal condylar path inclination in occlusally healthy dentate subjects. Eccentric movements of five mm from reference positions were recorded using a Denar Cadiax Compact System.

In the study done by Čimić *et al.*, in 2015, ^[21] the mean value of sagittal condyle inclination 41.0° ±10.5 for right joint and 40.7° ±9.8 for the left joint. The different values in these studies may be explained by different samples in each study, considering the influence of the lower jaw function on eminence development, different patterns of chewing movements, variations in the condylar shape and condylar pathway, ^[22] condylar position in the glenoid fossa, ^[23] and chewing habits (chewing side preference). ^[24]

In a summary of all research accomplishments, current work have a specific issues that the pathway followed by condylar head in the glenoid fossa is curved, condyle moves along posterior incline of articular eminence from its superior-anterior location within glenoid fossa. The angle formed by the movement of condylar head away from horizontal reference plane mentioned as condyle guidance angle. As a result later slope of articular eminence and articular condyle surfaces effect horizontal condylar inclination. ^[25] Regarding horizontal condylar inclination right and left side, results were recorded lower mean value in group 4 than control group with a highly significant differences.

Conclusions

Horizontal condylar inclination is different in disordered groups compared to control. The differences of Horizontal condylar inclination recorded by non-invasive Cadiax CompactII device may be used in the diagnosis of disc displacement without reduction without limited opening. The different modalities of treatment used do not influence the horizontal condylar inclination.

DCGAN for Handling Imbalanced Malaria Dataset based on Over-Sampling Technique and using CNN

Liqaa M.Shoohi¹, Jamila H.Saud²

¹Mustansiriyah University, College of Science, dept. Computer Science, ²Mustansiriyah University, College of Science, dept. Computer Science

Abstract

Class imbalance problem as a significant research problem has been recognized in classification In recent years, where by using the number of approach to rebalancing distributions of class such as; under-sampling or over-sampling for learning datasets to improve accuracy of classification, that give good performance. Many algorithms have been developed for classification, such as Back Propagation (BP) neural networks, decision tree, Bayesian networks etc., and have been used repeatedly in many fields. In this paper, to rebalancing distributions of class for imbalanced Malaria dataset to detect infected and uninfected people by equal percentage we proposed approach Deep Convolutional Generative Adversarial Network (DCGAN) based on the O.S. technique, which are generate the synthetic samples for the minority class for imbalanced Malaria dataset and achieve a balance ratio between classes of majority and minority 100% for imbalanced Malaria dataset. As well as used Deep Learning, applied by using Convolutional Neural Network (CNN). The goal of CNN is to prove the validity of the proposed approach by firstly, will be train the imbalanced Malaria dataset and results are tested before using proposed approach. Secondly, will be training balanced Malaria dataset and results are tested after using proposed approach and comparison between them.

Keywords: DCGAN, Imbalanced Datasets, O.S., CNN.

Introduction

The data is imbalanced when the data distribution is not systematic across different classes ¹. In many applications learning occurs with the distribution of class imbalances regularly, and this situation occurs in the data when the number of examples in the minority class is much lower than number of examples in class of the majority. This means that the number of examples into the classes exceeds the number of examples in other classes ², the class which contains examples of a large number is called negative or majority class, either for the class which contains a few numbers of examples called positive or minority class. Minority class is a great impact when misclassified that will be considered as interest class ³. it is likely that the examples of minority class may be ignored or external values led to poor classification compared to the majority, the dominant class ⁴. Many problems of real-world contains several concepts with very few examples in a large group and are also described the cost of obtaining them or through their scarcity. Categories are either two classes or multi-

class. Required analyze methods to address the problem of multi-class data imbalance which focuses on many real-world problems such as medical diagnosis, fraud detection, defect detection software, network intrusion ^{5,6}. There are simple ways to overcome the problem of class imbalance in typical learning. It is usually to test the training data by taking examples of the minority too much. Another approach is cost-sensitive learning which in turn rewrites the algorithms by weighing the examples of the minority class ⁷. Techniques are used to process the imbalanced data classification such as ⁸: -

Approach of Data Level

Use unbalanced native dataset to obtain balanced dataset by using algorithms of machine learning to obtain desired results.

Approach of Algorithm Level

Use algorithms that can handle unbalanced of data.

Approach of Cost-Sensitive

Hybrid technology of the first and the second techniques are combined to achieve a decrease in the costs of poor classification and accuracy.

Data Level Approach is classified into different sets

Over-Sampling (O.S.) Technique

Over-Sampling (O.S.) technique, the data are balanced by adding examples of the minority class to the original data. Fig.1 shows how to generate synthetic samples and added them to the original data by using Synthetic Minority Over-Sampling Technique (SMOTE) algorithm⁹.

Fig.1: Synthetic Oversampling example by SMOTE algorithm [10]

Undersampling Technique

Undersampling technique, the data is balanced by removing examples from the majority class of the original data.

Hybrid Technique

Hybrid technique, the data is balanced by combining previous techniques, first O.S. technique is used and then undersampling technique is used³.

Convolutional Neural Networks (CNN)

In the computer vision problem CNN is the most widely used, which is DNNs Class that is based on Back Propagation technique and MLPs. It is different from traditional MLPs where they are used to extract the collection feature between the number of locally linked layers followed via the full number linked layer that are utilized in the classification. CNN has important characteristics, including the use of common weights and local communication, so the image of the input can learn the local features. Which consists of three layers, including the following sets:

- Convolutional layers.
- Subsampling (or Pooling) layers.

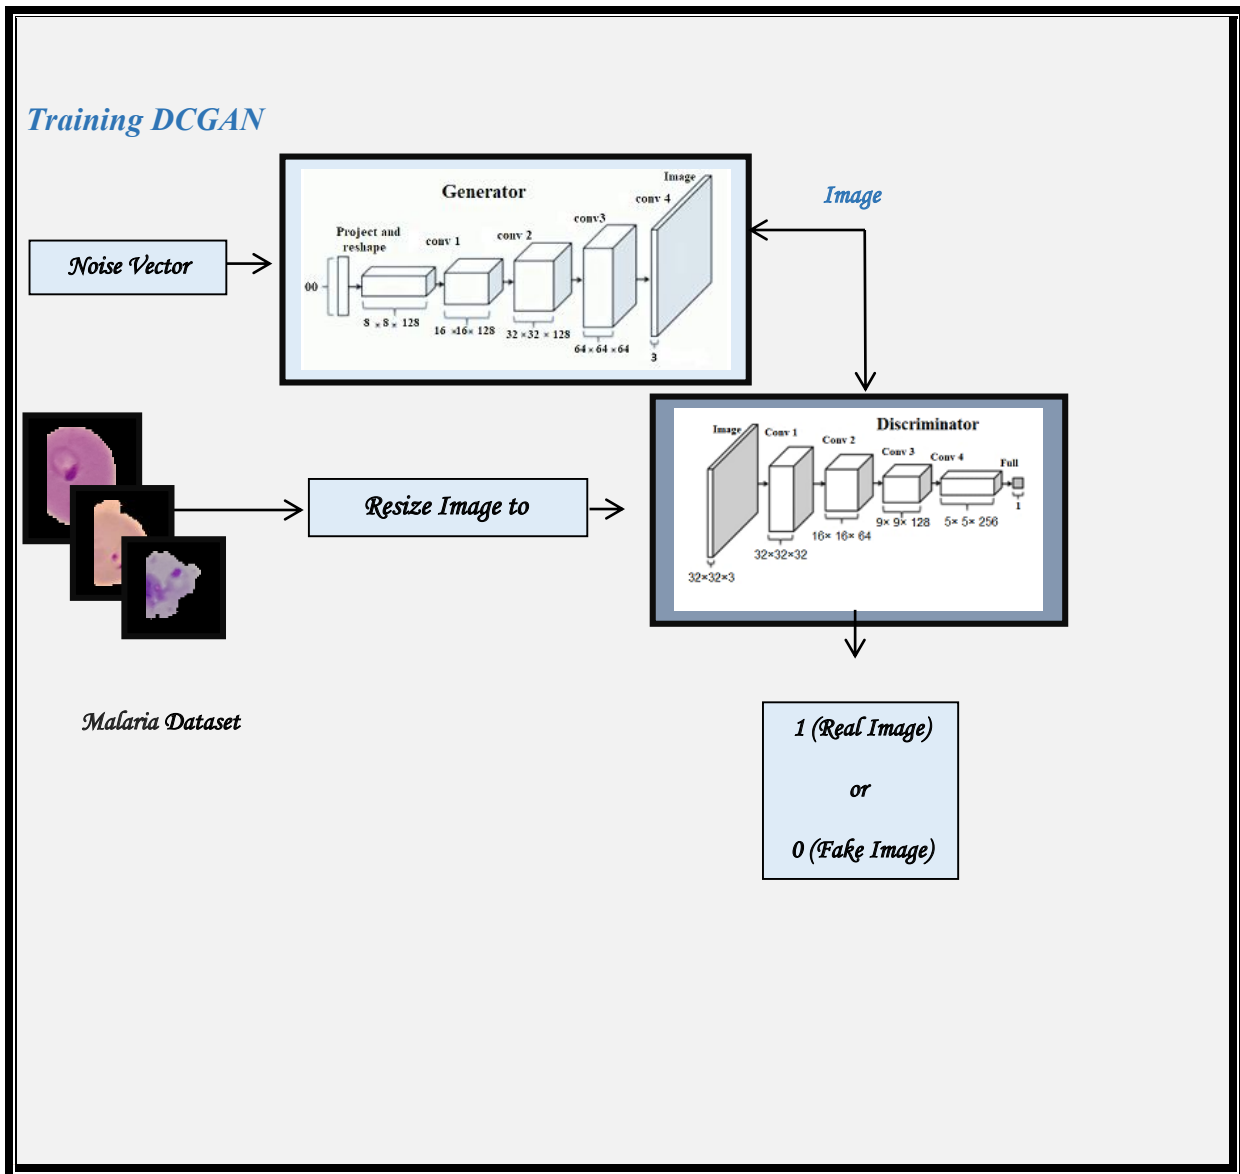

- Fully connected layers.

Related Works

Many research has been completed to solution the imbalance in O.S. datasets. Fannya and T. W. Cenggoro¹¹ are used the Class Expert Generative Adversarial Network (CE-GAN) was proposed in this research as a solution of imbalanced data classification. CE-GAN is the modification in the structure of a deep learning algorithm that does not assume that training data is imbalanced. To determine more details about a character for each class prior to the classification stage. The CE-GAN has been proven to give a good performance of imbalanced data classification. Ian J. Goodfellow et al.,¹² In order to estimate generative models through the adversarial process, a new framework has been proposed called Generative Adversarial Networks (GANs) which consist of two network models : 1.Generative model (G): which captures the data distribution where synthesis images are created. 2.Discriminative model (D): which discriminate between real images and images created from the generative model.

The Proposed Approach

Deep Convolutional Generative Adversarial Network (DCGAN)

(a)

DCGAN stands for a deep convolutional GAN. In general, most GANs rely on DCGAN architecture. Though the GAN was both deep and convolutional prior to the DCGANs. Where the DCGAN is useful of refer to this specific the style of architecture¹⁴. When a dataset consists of majority and minority classes, we will apply proposed approach of converting them from imbalanced dataset into a balanced dataset. Proposed approach is O.S. for minority class by DCGANs networks. The DCGAN network consists of the two networks:

The Discriminative Model (D): The discriminant form works like a normal binary classifier that is able to classify images into different categories. Specifies

whether the image is real or fake from a particular dataset.

The Generative Model (G): The generative model attempts to predict the features of given classes. The generator includes determining the probability of the feature given of the class. Input vector is entering into the layers used in the generating network, and the network generates fake images. Training and generating of DCGAN shows in Fig.2, where (a) is the training of DCGAN and (b) is generating of DCGAN.

Fig.2: Training and Generating of DCGAN. (a) Training (b) Generating

Experiment Setting

Dataset

Malaria dataset collection has been used from the Communications Engineering Branch is a warehouse to divide the cells from a thin image of a bloody scan of the malaria sort. In Bangladesh, falciparum-infected and 50 healthy patients are collected photographed at the Hospital of Chittagong Medical. The smartphone worked in camera obtained images of slides from each field of micro-vision. The images were illustrated manually by the expert slide reader at the Tropical Medicine Research Unit at Mahidol-Oxford in Thailand, Bangkok. Where applied the level-set based on algorithm to the detected and the segment a red blood cells. The dataset contains cell images instances of parasitized cell (Images containing malaria parasites in red blood cells) and uninfected cell (Images that do not contain malaria parasites in red blood cells).

Dataset Gathering

The Malaria dataset is dividing into two groups:

Imbalanced Malaria Dataset

The imbalance dataset consists of two-classes. And contains of (18,258) images. The dataset was divided

into two sets:

1. The training set: consists of (11,368). Where consisting of a number of parasitized cell is (1,034) images and a number of uninfected cell is (10,334) images.
2. The test set: consists of (6,890) images. Where consisting of a number of parasitized cell is (3,445) images and a number of uninfected cell is (3,445) images.

Balanced Malaria Dataset

The balance dataset consists of two-classes. And contains of (27,558) images. The dataset was divided into two sets:

1. The training set: consists of (20,668). Where consisting of same training set of imbalanced dataset that are describing in section (i), but we adding (9,300) images that are generating by proposed approach synthetic images are generated using O.S. for minority class by DCGAN.
2. The test set: using the same test set of imbalanced dataset that are describing in section (i).

A sample of Malaria dataset is show in Fig.3, where (a) is the original dataset for parasitized cell and (b) is the original dataset for uninfected cell.

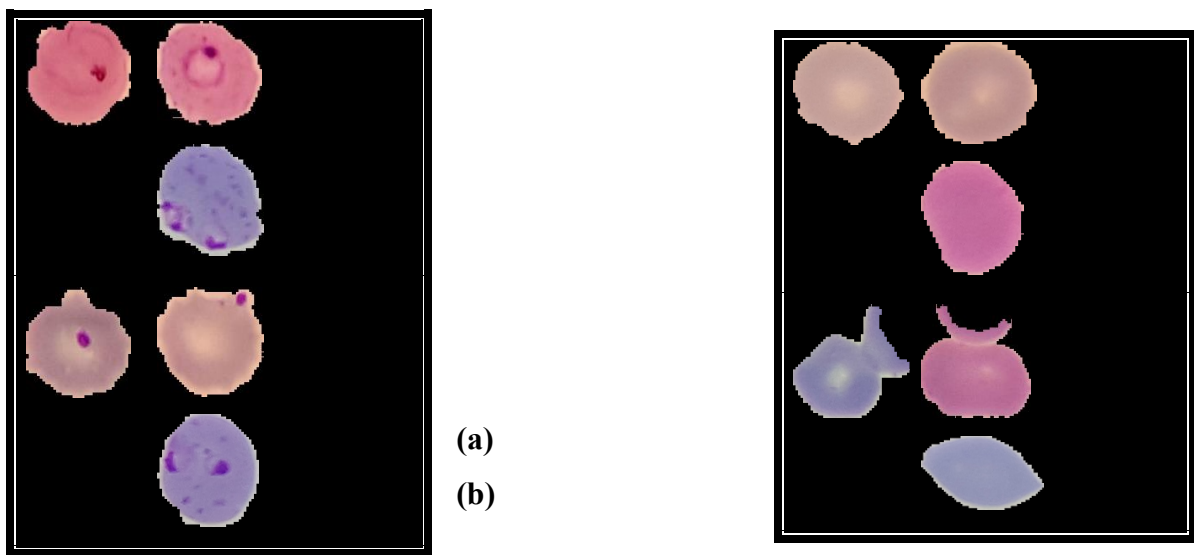

Fig.3: Sample of Malaria Dataset. (a) Parasitized cell (b) Uninfected cell

The Results of the Proposed Approach DCGAN

The result for these the proposed approach DCGAN is shown in Fig.4, where the synthetic images are generated by using O.S. for minority class by DCGAN.

Fig.4: Malaria Images Generate by DCGAN

The Proposed Convolutional Neural Networks (CNN)

CNN is an intelligent technique to implement the imbalance dataset classification problem. The goal of CNN is to prove the validity of the proposed approach O.S. for minority class by DCGAN. By firstly, will be train the CNN on imbalanced dataset and results are tested. Secondly, will be training the CNN on balanced dataset (The results which synthetic images are generated using O.S. for minority class by DCGAN) and results are tested. Following will be explaining CNN technique. For the CNN, extraction of the features will carried out within algorithm. Design and training classifier by using CNN technique: The image will be input directly to the CNN network after resizing to new size of 64×64 and perform operations through the four convolution layers to extract final features from the network. The result attributes input to the SoftMax activation function which assigns the probability of each the individual class of matching. Table 1 explains the proposed structure of CNN Layers.

Table1. The proposed structure of the CNN, the input and the output sizes are describing in (rows*cols*#kernels). The kernel is the specified as rows*cols; stride

No. Layers Input size Output size kernel

- 1 Convolution 1 + ReLU+ Dropout (0.25) $64 \times 64 \times 32 \times 32 \times 32$ 5×5 ; 2
- 2 Convolution 2 + ReLU+ Dropout (0.25) $32 \times 32 \times 32$ $16 \times 16 \times 64$ 3×3 ; 2
- 3 Convolution 3 + ReLU+ Dropout (0.5) $16 \times 16 \times 64$ $8 \times 8 \times 128$ 3×3 ; 2
- 4 Convolution 4 + ReLU+ Dropout (0.5) $8 \times 8 \times 128$ $4 \times 4 \times 256$ 3×3 ; 2
- 5 Fully connected + ReLU + Dropout (0.5) 4096 256
- 6 Fully connected + SoftMax 256 **number of classes**

Performance Measures

To evaluate the effectiveness of learning methods performance measures are used. In general, the measure most commonly used for classification functions is accuracy or (error rate). Accuracy is the proportion of the true results (both the true positives and the true negatives) in a population[4].

Where:

- True Positive (TP): Indicates a number of positive examples predicted by the classifier positively.
- True Negative (TN): Indicates a number of negative examples that have been negatively classified by the classifier as a number of negative examples.
- False Positive (FP): Often referred to as the false alarm clock, defined as a number of negative examples that have been incorrectly classified as positive by the classifier.
- False Negative (FN): It is specified as a number of positive examples that are incorrectly assigned as negatives by the classifier.

The Table 2 shows a confusion matrix which is used in the classification problem of two class, where through this matrix is evaluated the performance of the classification¹⁰.

Table 2. Confusion matrix for performance evaluation

Prediction Actual	Negative	Positive
Negative	TN (True Negative)	FP (False Positive)
Positive	FN (False Negative)	TP (True Positive)

However, by analyzing the four input in the confusion matrix, it is not sufficient to determine the performance of the classification. Therefore, many derivatives based on the confusion matrix are used to evaluate the classification. These performance measures of the confusion matrix are:

- Sensitivity or likewise Recall or the True Positive Rate (TPR)(REC) is the denoted as:

The sensitivity indicates to able of the classifier to correctly identify the positive category. The range from 0 to 1, where score 1 is perfect.

- Specificity or likewise the True Negative Rate (TNR) is the determined as:

- Specificity indicates that the classifier can correctly identify the negative category. The perfect result is 1 and the worst measure is 0.

- Precision

Precision is a measure how many the examples that have been correctly label as a positive.

- G-mean (geometric mean)

G-mean shows another measure, which is the G-mean in which the degree of inductive bias is evaluating in terms of positive accuracy and negative accuracy.

The Result of the Performance Measures

Table3 displays performance measures (Accuracy, Sensitivity, Specificity, Precision, G-mean) the comparison between using the imbalanced dataset with CNN technique and using the balanced dataset (imbalanced dataset with results of the proposed approach that synthetic images are generated using O.S. for minority class by DCGAN) with CNN techniques.

Table 3. Lists the Results of Classification (Accuracy, Sensitivity, Specificity, Precision, G-mean) for Malaria Dataset (Imbalanced and Balanced (using proposed approach DCGAN)) using the CNN technique

Type of Dataset	Accuracy	Sensitivity	Specificity	Precision	G-mean
Imbalanced Malaria Dataset	50%	0%	100%	0%	0%
Balanced Malaria Dataset(using proposed approach DCGAN)	94.5%	90%	99%	98.9%	94.4%

Conclusions

The proposed approach DCGAN gives better results. Which will convert the imbalanced dataset into balanced dataset because it gives the number of generated images that achieve balance between classes of majority and minority. In the traning stage of DCGAN, it is a possible to obtain the variable accuracy with the slight difference

between one implementation and the another because images used of the training change each for time because selection of the images used for the training is done a randomly for each time. In the classification stage, it is the possible to obtain the variable accuracy with the slight difference between one implementation and the another because images used of the training change

each for time because selection of the images used for the training is done a randomly for each time. Using the Convolutional Neural Network give a system more power and it give the good accuracy classifier.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under Mustansiriyah University, College of Science, dept. Computer Science, Iraq and all experiments were carried out in accordance with approved guidelines.

Seroprevalence of Toxoplasmosis Gondii Infection among Pregnant Women in Karbala Governorate 2014-2017

Radha. M. Lefta¹, Enaas K. AL-Khalide², Murtadha Kanim A.AL-Jebory³

¹Ph.D - Instructur / Community Health Nursing Department, College of Nursing, University of Al-Ameed, Ministry of Higher Education and Scientific Research, ²Assistant lecturer/ Microbiologist- College of Nursing, University of Al-Ameed, Ministry of Higher Education and Scientific Research, ³ Ph.D- Assist Prof, Community Health Nursing Department, College of Nursing, University of Kufa

Abstract

Objectives: To determine the prevalence for toxoplasmosis gondii infection among women pregnant and to find out between the relationships prevalence for toxoplasmosis gondii infection and risk factors among women pregnant and demographic data. A cross sectional study design was Carrie out of the study. A total of pregnant women are 500 attending antenatal clinic at Teaching of AL-Hussain Hospital in karbblla were selected by purposive sample for the study. The data collection process was initiated for the period of February 1st, 2018 through March 23th, 2018. The data collection are from medical recording in laboratory of hospital to identify about result of test and number of women's that attendant for laboratory and check among Testing for *Toxoplasma gondii* serology (IgM and IgG). The diagnostic test is according to stander IgG its positive have more than 0.9 and IgM is positive have more than 0.8. This is table that the show of the study results for demographic data for study sample that indicate age groups are (16-21) years are majority 33.3% within age groups. Regarded with (IgM) test are half of the study sample negative (51.8%) and (IgG) test is positive most of the study sample (95.8%).

Key Word: seroprevalence, *Toxoplasma gondii* infection, Risk factor of toxoplasma, (IgG) , (IgM)

Intruduction

Toxoplasmosis is prevalent parasitic disease that is common between humans and warm-blooded animals. This disease has a wide distribution globally and its prevalence in Iran varies in different locations ⁽¹⁾. Most patient with toxoplasma infection do not pleasure visit physicians, so their considered the risk of silent epidemics for this parasite arises. Although benign in healthy people, toxoplasmosis is a life-threatening disease in patients infected with AIDS/HIV+ as well as those taking immunosuppressant ⁽²⁾. Toxoplasmosis is one kind of this disease affecting the fetus and depending on the time at which pregnant women are infected, its clinical manifestation is different. Accordingly, infection of pregnant women is divided into three trimesters in which the risk of vertical transmission of the parasite increases over time but the disease severity decreases ⁽³⁾. Hydrocephaly, chorioretinitis, microcephaly and other CNS-related manifestations in newborns are of diagnostic importance in congenital toxoplasmosis.

The most common method for diagnosis of congenital toxoplasmosis is detection of IgG and IgM in pregnant women sera using various diagnostic tests, including enzyme-linked immunosorbent assay (ELISA) which enjoys higher validity. In addition to serodiagnostic tests such as ELISA, some types of polymerase chain reaction (PCR) methods, especially nested-PCR, are useful to find *T. gondii* parasite in the tissues of fetuses ⁽⁴⁾. Infections in humans happen after the eating of raw or uncooked meat containing tissue lumps (in the body) or by the eating of water, soil, or vegetables contaminated with oocytes released by infected cats. In most cases, the infected humans do not present medicine-based signs. However, when infection are happens in having a baby developing inside the body of women more than two, but not a lot of health problems can affect the unborn baby ⁽⁵⁾. The wide number range is due to the different (things that make it more likely that someone will get a disease), which might influence the chance of infection by *T. gondii* in a given population (e.g., eating of undercooked meat, unpasteurized milk, or educational

level. The transmitted to humans by eating of the tissue lumps (in the body) in raw or undercooked meat, as well as eating of food and water contaminated with oocysts from cat (brown, smelly waste from animals ⁽⁶⁾). Human infection with *T. gondii* is very frequent throughout the world the seroprevalence ranges from 15% in the United Kingdom to 80% in South America and certain (related to Europe) countries such as France. In developing countries, toxoplasmosis is also very frequent: in Turkey, IgG seroprevalence of *T. gondii* among (having a baby developing inside the body) women was 60% while in India it was 45%. Studies among Arab (groups of people/animals/things) have reported the seroprevalence of toxoplasmosis ranging from 22.9% in the United Arab Emirates to 47% in Jordan. Many studies focused to explore the seroprevalence of *T. gondii* among pregnant Iraqi women that reported (20%, 18.3%, and 16% respectively). A prevalence rate among patient that consumer for anti-Toxoplasma IgG (25%) and IgM (5%) was reported in the Eastern region from Iraq ⁽⁸⁾.

Material and Design of the study:

A cross sectional study design was carried out of the study. A total of pregnant women are 500 attending antenatal clinic at the Teaching AL-Hussain Hospital

karbla were selected by purposive sample for the study. **Ethical consideration:** clearance for the study was obtained from the ethical review Committee of the Faculty of nursing University of AL-Ameed Permission for data and sample collection was obtained from the AL-Hussain Teaching Hospital. **Data collection:** The data collection process was initiated for the period of February 1st, 2018 through March 23th, 2018. The data collection is from medical recording from laboratory of hospital to identify about result of test and number of women is that attendant for laboratory and check among Testing for *Toxoplasma gondii* serology (IgM and IgG). The diagnostic test is according to stander IgG its positive have more than 0.9 and IgM is positive have more than 0.8 this tests determine however pregnant have risk factor and incidence of toxoplasmosis.. **Instruments:** a questionnaire was fashioned for the purpose of the study. It is composed of three major parts included personal information sheet. Demographical data, social-demographic data and clinical data such as age, parity, period of gestation and laboratory test for women pregnant fulfillment from medical recording. **data Analysis:** In order to determine whether the objectives of the study were met or not, two statistical approaches were used for analyzing the data of the study.

Results of the Study

Table (1) Distribution of the study sample by their demographic data

Demographic data	Scale	Frequency	Percent	Cumulative Percent
Age/ years	<= 15	7	1.4	1.4
	16- 21	166	33.2	34.6
	22- 27	150	30	64.6
	28 - 33	100	20	84.6
	34 - 39	53	10.6	95.2
	40+	24	4.8	100
IgM	Negative	259	51.8	51.8
	positive	241	48.2	100
IgG	Positive	479	95.8	95.8
	Negative	21	4.2	100
Para	Non	380	76	76
	1	69	13.8	89.8
	2	33	6.6	96.4
	3	18	3.6	100

Cont... Table (1) Distribution of the study sample by their demographic data

Number of abortion	<= 2	378	75.6	75.6
	3 - 5	115	23	98.6
	6 - 8	3	0.6	99.2
	9+	4	0.8	100
Gravid	<= 2	407	81.4	81.4
	3 - 3	56	11.2	92.6
	4 - 4	25	5	97.6
	5+	12	2.4	100
Residence	Urban	77	15.4	15.4
	Suburban	316	63.2	78.6
	Rural	107	21.4	100
	Total	500	100	

This is table that the show of the study results for demographic data for study sample that indicate age groups are (16-21) years are majority 33.3% within age groups. Regarded with (IgM) test are half of the study

sample negative (51.8%) and (IgG) test is positive most of the study sample (95.8%). Concerned with para the study results indicate is Non-para (76%) and most of the study sample have number of abortion and gravid at least 2 (75.6% and 81.4%) respectively.

Table (2) Summery Statistics for the Relationship between (Igm) and Demographic Data

Demographic data	Value	df	Level of significant
Age/ years	1.949a	5	0.856
Number of Abortion	0.314a	3	0.957
Number of birth	2.828a	3	0.419
Residence	10.325a	2	0.006
Number of pregnant	2.092a	3	0.554

This table depict that the study results that there are Non-significance between some variables for demographic data such as (age, number of abortion, number of birth and number of pregnant data and (IgM). While there is high a significance between residence and (IgM) at p. value less that 0.01 is 0.006.

Table (3) Summery Statistics For The Relationship Between (IgG) and Demographic Data.

Demographic data	Chi.sq Value	df	Level of significant
Age/ years	13.554a	5	0.01 HS
Number of Abortion	1.835a	3	0.607 NS
Number of birth	6.633a	3	0.085 NS
Residence	.400a	2	0.819 NS
Number of pregnant	4.421a	3	0.219 NS

This table depict that the study results that there are Non-significance between most of variables for demographic data and (IgG) except age groups that there is high a significance with (IgG) at p. value less than 0.01.

Discussion

The study finding for study sample by their demographic data is indicate the majority for age groups are (16-21) years 33.3% within age groups. These finding is disagree with ⁽⁹⁾ that indicate their study to the prevalence increased with age from 31.0% for women aged 14 to 19 to 58.2% in cross-sectional study Toxoplasmosis among pregnant women in France: Risk factors and change of prevalence between 1995 and 2003. While other studies were supported with my study that authors are find an increase has been observed in the USA a 38.8% in *T. gondii* prevalence among 12- and 49-year-old ⁽¹⁰⁾.

Regarded with (IgM) test the study finding is half of the study sample is negative and (IgG) test is positive most of the study sample. These study finding com with study that the found the lowest *T. gondii* seronegative for (IgM) among persons residing in the western region of the United States and consistent with the high seropositivity (IgG) in previously found in western cities ⁽¹¹⁾.

Regarded with para the study results indicate is Non-para in most of the study sample and have number of abortion and gravid at least (2). Also most of the study sample is prevalence and suspected for *T. gondii* infection for women's are living in urban and suburban (table 1). These finding support with previous results are Toxoplasmosis prevalence increased with the number of pregnancies, regardless of age and have gravid. A study conducted in Brazil between 1997 and 1999 suggested that pregnant women were more vulnerable to *T. gondii* ⁽¹²⁾. Moreover another study in 1995 perinatal study showed a two-fold greater incidence of toxoplasmosis for primipara than for multipara ⁽¹³⁾. Other study performed with high risk pregnant women from central Mexico showed that 34.9% had anti-*T. gondii* IgG antibodies and living in urban setting ⁽¹⁶⁾.

Finding of study that there is Non-significance between some variables for demographic data such as (age, number of abortion, number of birth and number of pregnant data and (IgM). While there is high a significance between residence and (IgM) at p. value

less than 0.01 is 0.006 (table 2).

This finding deserves further investigation that is inconsistency with many studies by many researchers are test the association between sociodemographic, clinical, and behavioural characteristics of the studied women did not show any association with *T. gondii* infection for (IgM). Known factors associated with *T. gondii* infection in pregnant women such as drinking untreated water, contact with garden soil ⁽¹⁷⁾, age and increasing parity ⁽¹⁸⁾, consumption of cured meat and contact with cats.

We are study indicate that there is high significance between residence and (IgM) at p. value less than 0.01 is 0.006 (table 2), this finding that come with researcher ⁽¹⁹⁾ that found by his study associated with *T. gondii* infection through test for (IgM) and living in city (p = 0.004). Turkey meat consumption (p = 0.06), deer meat consumption (p = 0.08), squirrel meat consumption (p = 0.1), wild animals meat consumption (p = 0.06); and blood transfusion (p = 0.1).

These study finding that there is Non-significances between most of variables for demographic data and (IgG) test except age groups that there is high a significance with (IgG) test at p. value less than 0.01 (table 3). We are study consistent with a study that found seroprevalence of anti-Toxoplasma IgG antibodies for toxoplasmosis was 30.1%. ⁽¹³⁾. Also another researchers found Seroprevalence of IgG was positive association between IgG and age group in study Prevalence and Risk Factors of Toxoplasmosis among Pregnant Women in Fortaleza, Northeastern Brazil ⁽¹⁵⁾.

Another authors found Seroprevalence was increased with age (p=0.001) and with drinking water consumption other than bottled water (p=0.042). No significant relations were observed between anti-Toxoplasma IgG antibodies and education level, being native or migrant, abortion history, consumption of meat, vegetable and milk/milk products, personal or kitchen hygiene habits, cat owning at home of the pregnant women ⁽¹⁴⁾.

Conclusion

The conclusion most of the study participants are age between (16-22) years old within age groups. Most of the study subject haven't para. The study conclusion is depict the study subject have recurrent or multi abortion result to high prevalence of toxoplasma parasite

infection. Most of the participants are (IgG) seropositive and (IgM) seronegative, so they are high risk factors for incidence in *T. gondii* infection. There is association between some variable for demographic data such as residence and IgG.

²Department of Anatomy/Baghdad College of Medicine

Abstract

Coronary Heart Disease (CHD) is the world's leading cause of death and represents a serious global health problem. The general recommendations to operators in the prevention of CHD should include complete lipid profile testing, that is Total Cholesterol(TC), Total Triglycerides(TG), High Density Lipoprotein (HDL), Low Density Lipoprotein (LDL) and Very Low Density Lipoprotein (VLDL). Recent recommendations have supported non-fasting lipid assessment. On the other hand, classification of dyslipidemias was derived in fasting samples, and cohort studies and clinical trials have performed fasting assessments.

The aim of this study was to evaluate fasting versus non-fasting in measuring lipid profile & complete blood picture.

A total of 80 female were divided into four groups of 20 female each. The 1st three groups were fasting for 4, 6, 14 hours respectively and the 4th group was non-fasting. Blood samples were taken from these females for biochemical & hematological investigations.

The lipid profile parameters were measured using Synchron CX4 clinical system Beckman Coulter Inc., Brea, CA. Complete Blood Picture was measured by using automated hematological analyzers BC-3000 plus (Hamburg, Germany). Statistical analysis was carried out using SPSS(Statistical Package for Social Sciences) number 22.

Biochemically, for TC, TG & VLDL, it was found that fasting 6, 14 hours gave significant differences ($P < 0.05$) when compared with non-fasting group while there were non-significant results for the mean level of HDL & LDL between groups. Regarding hematological assessment, there were non-significant differences between groups in measuring Hemoglobin, Red blood cells, White blood cells, Platelet counts.

Since non-fasting may weaken the accuracy in diagnosing some forms of hyperlipidemia, we proposed that laboratories & organizations should also offer measurement of fasting triglycerides according to clinical situations, as in the case of very high non-fasting triglyceride concentration.

Keywords: Lipid profile, Complete blood picture, Fasting, Non-fasting.

Introduction

Coronary heart disease (CHD) is a leading cause of morbidity and mortality in many countries worldwide and is estimated that it will be the single largest cause of disease burden ⁽¹⁾. A number of factors are thought to increase the likelihood of developing CHD. It can be divided into two, which are controllable and uncontrollable risk factors and hypercholesterolemia is one of controllable risk factors⁽²⁾. Recent

recommendations have favored non-fasting lipid assessment ⁽³⁾. Practical advantages to using non-fasting measurements include increasing patient convenience avoiding separate return visits for laboratory draws and improving hospital and clinic efficiency. Moreover, non-fasting triglycerides may improve cardiovascular risk prediction ⁽⁴⁾. On the other hand, classification of dyslipidemias was historically derived in fasting samples, and cohort studies and clinical trials have traditionally performed fasting assessments ^(5,6).

Because of this controversy, the aim of our study was to evaluate fasting versus non-fasting in measuring lipid profile.

Material and Method

A total of 80 healthy volunteer females , ranging in age between 22-30 years, were divided into four groups of 20 female each . The first three groups are fasting groups that had not taken any diet for last 4, 6, 14 hours respectively while in the non-fating group, blood samples were collected after 2 hours of meal. The health status of our volunteer female was confirmed by clinical examination.

For biochemical & hematological investigations, venous blood samples were taken from these females from January 2018 to June 2018. The biochemical investigation includes Total Cholesterol(TC), Total Triglycerides(TG), High Density Lipoprotein (HDL), Low Density Lipoprotein (LDL) and Very Low Density Lipoprotein (VLDL) . They were measured using Synchron CX4 clinical system Beckman Coulter Inc., Brea, CA(standard clinical laboratory methods).The hematological investigation includes White Blood Cell (WBC), Red Blood Cell (RBC), Hemoglobin (HB) and Platelet Count (PLT), the whole blood was determined by using automated hematological analyzers BC-3000 plus (from Hamburg, Germany).

Statistical analysis was carried out using SPSS (Statistical Package for Social Sciences) number 22 with

regard to numerical features. It was described using the mean and standard deviation of the mean and was compared between the averages for the calculation of the samples under study at the level of 0.05. (7)

Results

Table 1 & Fig. 1 demonstrated that there were significant(p < 0.05) results for the mean level of TC , TG & VLDL when fasted for 6 & 14 hours while there were non-significant results between groups for the mean level of HDL & LDL.

The mean level of TC was 159.25 mg/dl, 142.25 mg/dl, 150.25 mg/dl, 172.50 mg/dl for fasting periods of 4 hours, 6 hours and 14 hours and the non-fasting respectively and mean level of TG was 72.75mg/dl, 59.0 mg/dl, 62.50mg/dl, 97.00 mg/dl for fasting hours of 4hours, 6 hours ,14 hours and the non- fasting respectively . Regarding VLDL, its mean level was 16mg/dl,14.25mg/dl,12.25mg/dl and 20.75 mg/dl for fasting periods of 4 hours, 6 hours and 14 hours and non-fasting respectively. From the above measurements, we concluded that fasting at least 6 hours gave significant differences (P< 0.05) in assessing TC,TG & VLDL.

There were non-significant differences between fasting & non-fasting in measuring HB , RBC, WBC and PCT as demonstrated in table 2 & Fig.2

Discussion

Venipuncture is implicated in testing the lipid profile in order to predict cardiovascular risk and/or monitor responses to lipid-lowering therapy. Some guidelines continue to promulgate the conventional practice of measuring the lipid profile in the fasting state ⁽⁸⁾ . Although other societies & laboratories adapted non-fasting lipid profiles. Since 2009, non-fasting lipid testing has become the clinical standard in Denmark, based on recommendations from the Danish

Society for Clinical Biochemistry that all laboratories in Denmark use random non-fasting lipid profiles as the standard, while offering clinicians the option of re-measuring triglyceride concentrations in the fasting state if non-fasting values are 4 mmol/L (350 mg/dL) ^(9,10) . Furthermore, the UK NICE guidelines have allowed non-fasting lipid testing in the primary prevention setting since 2014 ⁽¹¹⁾ .

For cardiovascular risk assessment, evidence is lacking that fasting is superior to non-fasting when evaluating the lipid profile. However, there are advantages to using non-fasting samples over fasting ones for measuring the lipid profile^(12,13).

Comparing our biochemical and hematological results, fasting is not needed for assessing complete blood picture as there were no significant differences between fasting & non-fasting in measuring Hb, RBC, WBC, PLT. For lipid profile assessment, fasting at least 6 hours was recommended for measuring TC, TG & VLDL while it was not necessary for assessing HDL & LDL. It was concluded by Cohn et al.⁽¹⁴⁾ & Mihos et al.⁽¹⁵⁾ the reason that preferred fasting lipid profiles is the increase in triglyceride concentration seen during a fat tolerance test. On the other hand, LDL cholesterol is often calculated by the Friedewald equation, which has been thought to be affected substantially by food intake. So if this equation is employed, there may be some underestimation of LDL cholesterol when chylomicrons are present⁽¹⁶⁾. In addition to that non-fasting condition may marginally lower plasma LDL cholesterol concentrations due to liberal intake of fluids, and therefore lead to minor misclassification of cardiovascular risk, as well as to error in initiating or altering lipid-lowering medication especially to diabetic subjects^(17,18,19).

Since non-fasting may weaken the accuracy in diagnosing some forms of hyperlipidaemia, we suggested that laboratories & organizations should also offer measurement of fasting triglycerides according to clinical situations, as in the case of very high non-fasting triglyceride concentration.

Zinc Deficiency is Associated with Meprin α in Iraqi Patients with Crohn's Disease

Fatima A.Mohammad¹, Fatin Fadhel Alkazazz², Sura A.Abdlusattar³

¹ Department of Chemistry, College of Science, Mosul University, Iraq, ²Department of Chemistry, College of Science, AL Mustasyriah University, Iraq, ³Chemistry and Biochemistry, College of Medicine, AL Mustasyriah University, Iraq

Abstract

Zinc deficiency in Crohn's disease (CD) is considered a frequent finding and may exacerbate CD activity. We aimed to assess the prevalence of zinc deficiency in CD patients in clinical remission, its association with meprin and to analyze a potential impact on future disease course. Proper history with blood samples were collected from (30) healthy control group, (30) Crohn's disease patients have been respond to biological therapy (infliximab IFX) (response group) and (30) CD patients with (non-response group) to biological therapy undergoing surgical intervention for the estimation of zinc concentration and meprin activity. This study demonstrate a significant decrease in both zinc and meprin levels between (non- response group) and control group ($p < 0.01$). Similarly, zinc and meprin levels were decreased significantly ($p < 0.01$) in (non- response) group as compared with re sponse group. While there were no differences between control and CD patients that have been treated with infliximab only. Meprin α is a zinc metalloproteinase, and therefore a deficiency of zinc may result in a decrease of meprin level or activity. Thus, we should maintain the balance between the meprin α that is affected by the zinc concentration then may affect the Crohn disease.

Keyword: Zinc, Crohn's disease, Infliximab, meprin α

Introduction

Crohn's disease CD is a chronic inflammatory disorder that could¹ involve any part of alimentary tract from mouth to anus. These disorders were first described by Dr. Burril Crohn's and his team in²1932. Although its aetiopathogenesis is still not clear, it has been well recognized that CD is one of the complicated disorders which result from³interaction of environmental, microbial, and genetic factors. Zinc is an essential trace element, which is absorbed in the small intestine and serves as a cofactor for numerous enzymes involved in growth, immune⁴ function, and tissue repair. Zinc is a micronutrient, which has been linked to inflammatory diseases such as IBD, zinc levels are often low in patients with chronic diarrhea or malabsorptive disorders. Similarly,

zinc deficiency (ZD) appears to compromise gastrointestinal barrier function, which can perpetuate different diseases such as celiac disease, chronic diarrhea or IBD, is common during disease and in remission, with a prevalence ranging from 15% to⁵40%. Pre-clinical data as well as human studies support that zinc deficiency may contribute to mucosal inflammation in patients with IBD. In animal models, zinc deficiency exacerbates colitis and potentiates production of pro-inflammatory cytokines, including tumor necrosis (6, 7) factor α (TNF α). Furthermore, previous work indicates that a low zinc diet in healthy volunteers results in a decrease in the Th1, cytokines, IFN- γ and IL-2, as well as diminished lytic activity of natural killer cells⁸. In addition to the impact of zinc on immune function, studies involving both animal models of colitis and Crohn's disease (CD) patients have demonstrated improvement in mucosal permeability with (8,9) zinc supplementation. zinc plays a crucial role in the development¹⁰ and function of cells mediating innate immunity has direct

Corresponding author:

Fatima A.Mohammad

email: fstmmaatrosi76@gmail.com

anti-inflammatory effects via zinc-finger protein, and has a positive effect on intestinal tight junctions and intestinal repair. Furthermore, zinc can act via metallothioneins (MTs). MTs are a family of small proteins with a high cysteine content at conserved positions that are rapidly up regulated in response to an inflammatory stimulus such as tumor necrosis factor (TNF).¹¹ MT function seems to be dependent upon the presence of zinc. Effects of MTs include reduction of apoptosis and antimicrobial^(13,14) activity. Zinc also is important for early and late autophagy. Autophagy is thought to suppress inflammation via degradation of¹⁵ inflammasomes and inflammasome-agonists. Zinc deficiency is common in CD, with up to one third of all patients presenting with^(16,17) low serum zinc levels, even in patients in clinical remission. ZD may exacerbate CD by increasing mucosal permeability, leading to¹⁸ neutrophil transmigration and luminal antigen permeation, such increased mucosal permeability has been shown to correlate with^(19,20)

both, CD activity and relapse probability. Despite high prevalence of ZD in IBD and its links to inflammation, so far no study investigated the role of serum zinc as a potential predictive serum marker for future disease course and its potential causative role in patients with a low or absent inflammatory disease activity. Low-normal zinc values were defined as below the 30th percentile of the normal range. Meprin expression in the intestinal tract is highest in the ileum and large intestine where host and microorganisms are in contact, and where intestinal inflammatory diseases develop. Meprins are zinc metalloproteinases that are highly expressed in the epithelial cells of the human and mouse intestine, and are found membrane bound and/or secreted into the²¹ lumen of the intestine. In addition to the abundant expression in the epithelium, meprin alpha is expressed in human intestinal lamina propria leukocytes and in mouse mesenteric lymph nodes²² both in the presence and absence of intestinal inflammation

Inflammatory bowel diseases (IBDs) are a collection of clinically heterogeneous intestinal diseases that result in damage to intestinal²⁷ epithelium and affect million people in the USA

Material and Method

Study subject:

This research has been approved by the Ethics committee, department of chemistry, college of

science, Mustansiriyah University, Bagdad, Iraq, and the Iraqi Ministry of Health approved this work as well. The blood samples were taken after informed consent of participant were recruited from Gastroenterology and Hepatology teaching hospital at Bagdad Medical city, while the healthy group were volunteers. All the patients were diagnosed by senior doctors specialist in gastroenterology field, (60) sixty unrelated Iraqi Crohn's disease patient's divided in to two groups according to response to biological therapy (infiximab) the first group (30) patients was respond to infiximab according to classical regimen (loading dose 5mg/kg at week 0,2,and 6 followed by repeated infusion of 5mg/kg every 8 weeks) and (30) patients not respond to infiximab undergoing surgical intervention as well as (30) unrelated healthy person termed as control group without any systemic disease. All the patients and control aged between 18 and 64 years. Five milliliters of venous blood was obtained from patients and control group by 5 ml disposable syringe (without tourniquet) drained into get plain tubes and left in room temperature (25C°) for 15 minutes, Then it was centrifuged at 2000 xg for 10 minutes in order to collect sera. Sera aliquots were placed in eppendorf tubes and stored at -40C° until used.

Biochemical analysis

The human Serum MEP1A(Meprin A subunit alpha) were using ELISA Kit obtained from Mybiosource using the sandwich enzyme linked immune sorbent (ELISA) assay technology method according to manufactures instruction (Cat No. MBS 765586, My bio source / USA). While Zinc Serum concentration determined by Atomic Absorption/ flame spectrophotometer(AA 680G) (SHIMADZU, Japan).

Statistical analysis²⁸

The statistical analysis system SAS program has been utilized to compare between control and two CD patients groups (response and non-response to biological therapy) in study parameters. (Analysis of variation- ANOVA) was used to compare between means (P value of 0.05 and 0.01 has been considered to be statistically significant).

Result and Discussion

Mean \pm SD value of zinc and meprin α were recorded from all subscribers as shown in table 1. Results of this study shown a significant decrease in both zinc and meprin levels between (non-response

group) and control group ($p < 0.01$). Similarly, zinc and meprin levels were decreased significantly ($p < 0.01$) in (non-response) group as compared with response group as shown in table (2). While there were no differences between control and CD patients that have been treated with infiximab only. According to the currently accepted hypothesis, both UC and CD result from a dysregulated response of the intestinal immune system to antigens of microbial origin or pathogenic bacteria in genetically predisposed individuals. MEP1A has been identified as a genetic^(23,25) susceptibility factor for IBD. It encodes meprin α , a metalloprotease highly expressed in the intestine. Meprin α is secreted into the intestinal lumen or accumulates at the apical brush border membrane of polarized epithelial cells retained by meprin β . Thus any decrease in meprin α or β expression can lead to similar defects in the host. In this study we determine the levels of serum meprin α in Iraqi patients with Crohn Disease which include two main groups (respond and non respond to biological therapy), as well as the correlation between zinc with serum meprin α in these groups. The results showed strongly significant association between meprin α and zinc.

A total of 60 patients with Crohn's disease (CD), (30) patients treated with infiximab and (30) with surgical treatment were included in the analysis. zinc deficiency was associated with an increased risk of surgeries in patients with CD. Normalization of zinc was associated with improvement in these outcomes in patients with both CD. Meprin is involved in inflammation by the release and maturation of cytokines^(26,29) and proteoglycans, it induce extracellular matrix assembly and fibrosis, and enhance cancer progression through trans-activation of²⁵ EGF receptors, which is reflected by defined cleavage specificity³⁰ and structural features unique among all proteases. Meprin α is shed by furin during the secretory pathway and secreted into extracellular space. Interestingly, this show that meprin α tends to oligomerize to huge complexes up to the mega Dalton range, which²⁶ makes it the largest extracellular protease (See Fig. 1). These fascinating ring and chain like structures can easily be visualized by transmission electron microscopy (TEM), but structure-function relationships are still ambiguous, meprin α was found to be differentially expressed in the small and large intestine, leucocytes,³¹ and several tumors. In normal dermal

skin, meprin α is higher expressed than meprin β , and are highly up-regulated in keloid tissue ³²

Our results and those of others have led to the hypothesis that meprin α play a role in the pathogenesis of IBDs. Data indicate that meprin α influence CD by affecting intestinal leukocyte dissemination to inflammatory sites in the gut, by interacting with bacteria at the epithelial surface, by degradation of compounds such as defenses that kill bacteria, or by exacerbating host tissue damage in the inflamed gut. Previous studies had demonstrated

high expression of meprin subunits in leukocytes of ²² the lamina propria of human inflammatory sites. This observation, plus the known ability of Meprin α to hydrolyze extracellular matrix proteins, led to the speculation that Meprin α play a role in the movement of macrophages to inflammatory sites. Our study has several strengths and some limitations. We provide the first study evaluating an association of serum zinc levels and meprin in CD patients.

Abstracts

Objective of the study: To evaluate the attitude and knowledge and barriers of a sample of Iraqi medical undergraduate students(in Babylon college of medicine and college of dentistry) toward research. Across sectional study was done using self-administered pretested questionnaire to measure the knowledge ,barriers and attitudes of students toward research. Two hundred eight students were responded to this study from Hammurabi medical college, and college of dentistry in the University of Babylon. Females constituted 67%. The female to male ratio was 2:1. Regarding barriers to conducting research activities the study revealed that (55.3%)of the students had efficient internet connection and 1.5% had no internet connection at home This study explained that the skill of English language writing is very low, only 5.3% of them mentioned that they had very good skill of writing in 66.5 % mentioned that they had intermediate level of writing English. Regarding speaking English language (which is the language of training for the medical students) only one in fifth of them had good skill in speaking fluent English language. Regarding the attitude 73.3% of the participants had positive attitudes and they mentioned that they are interested in conducting research during undergraduate training.

Keywords: *medical students , undergraduate, knowledge, attitude, barriers , Babylon, Iraq*

Introduction

Research is a systematic process to achieve new knowledge by the use standard methods, simply research can be defined as “a systematic collection of data that uses disciplined methods to answer questions or solve problems ^{1,2}. Health research is an integral component in developing health systems, understanding the roots and consequences of poor health, as well as anticipating and mitigating the effects of various factors on health. Promoting and fostering an environment conducive for health research is mandatory for planning, designing and implementing research and for sharing, using and translating its findings into evidence-informed health policies and cost-effective interventions ³ Health research has an impact on the prevention, diagnosis and treatment of diseases and especially on health care programs policy ^{4,5} Research is essential in all areas of health development. However, medical students frequently lack the time and training on performing research. This is especially prevalent in resource-limited settings ⁶. It is now evident that engaging students in research may lead

to increased participation in research after completion of training ⁷. However, due to the burdens of patient care, students are frequently too busy to find sufficient time for research activities ^{8,9}. Scholarly research activity programs are essential components of the modern undergraduate medical curriculum ¹⁰. Undertaking research can help develop transferable skills such as communication skills, time management, medical statistics, academic writing, systematic thinking, critical appraisal skills, information technology (IT) skills and how to practice evidence-based medicine ^{4,10}. Medical student involvement in research has been declining over the years ¹¹. Medical students’ engagement in research has been associated with the acquisition of teamwork, time management and critical thinking, gaining experience and motivation for a research career, improving critical thinking abilities and fostering positive attitudes toward science and scientific methodology ^{12,16}. Unfortunately, the future of academic medicine has come into question as recent reports point to declining numbers of clinician–scientists in both developed and developing countries ^{17–20}. In conducting research inadequate knowledge is one

of the most common reasons behind suboptimal study design or interpretation²¹⁻²³. The curriculum should be revised to address the gaps in research training. A small group learning model should be adopted to train students in research and provide supervision to group research projects. This model would improve academic learning, skills acquisition, encourage student interest in research, reduce barriers to student research and make better use of limited resources²⁴. The three main factors seen to impact on research success in the literature are: attitude to, knowledge of and barriers toward research²⁵⁻²⁸. This study was done to evaluate the knowledge, attitude to and the barriers toward research among undergraduate medical and dentistry students in Babylon university. To our best knowledge There is no published study to date that assessed the context of research training provided to undergraduate medical students in Iraq.

Methodology

This survey was conducted according to with the Helsinki declaration and national research ethical guidelines. The approval of the proposal for ethical clearance by the Research Technical and Ethical Committee at the Hammurabi College of Medicine. The purpose of the study was explained to the respondents and verbal informed consent was obtained from each one of them after explaining the objectives of the study. The questionnaire was anonymous and took about 10 minutes to complete. This was a cross-sectional study which was conducted at the University of Babylon – Hammurabi college of medicine (the first and second grade undergraduate students) and the college of dentistry (4th and 5th grade students) during the academic year 2019-2020. The research instrument was a self-administered coded questionnaire constructed from variables obtained from literature on the topic. We collected data using the self-administered, structured questionnaire within a span of 6 months. The questionnaire was adapted from the previous studies.^{29,30} The questionnaire consisted of sociodemographic, previous experience of scientific research, knowledge and attitudes toward research, and perceived barrier conducting research. The purpose of the questionnaire was to assess the knowledge and attitude of undergraduate medical student to research; motives for conducting research in the college; and barriers to student research at the university. Data was analyzed using SPSS version 21. Descriptive frequency analysis was performed for all variables in the questionnaire.

Chi-squared tests were conducted to investigate the association between variables and The statistical level of significance was a *p* value less than 0.05

Results

Table 1: shows the distribution of 206 students according to the availability of internet connection, 55.3% of the students have efficient internet connection. 1.5% have no internet what so ever. Figure (1) reveals that females number is higher with male to female ratio 2:1 Table 2: shows the distribution of 206 participates according to their skills in English language (writing, reading, and speaking), less than one third of the students mentioned that they are good in writing English language, the result is similar regarding speaking English. Table 3: explains the Distribution of students according to their attitude towards conducting research during undergraduate study, the table depicts positive attitudes toward research. Table 4 depicts the distribution of students according to exposure to encouragement to conduct research by their tutors only 70 respondents (34.5%) mentioned that the received encouragement from their tutors to participate in research activity while one fifth of them agree that tutors are easily available to supervise research. Only 8.7% of the participants believe that there are many chances are available in the college to involve in research. Regarding the obstacles table 5 shows the distribution of students according to their access to scientific journals and capacity building in research methodologies during their undergraduate study one in sixth 32 (15.8%) said that they have Easy access to scientific journals through university and 72.3% of them said that there was no enough training activities in research methodology and only 7.5% of the respondents had participated in some sort of research activities during their training courses. Table 6 shows that 85% of students believe that research is important for their future medical practice and academic study. Table 7 reveals that only 11% don't know the importance of studying the research methodology the curriculum as a goal for their future career and self-learning. More than half of the study group (57%) believe research will be a career goal for you in the future. The proportion of students who know that studying research methodology will help in engagement in self-learning about research.

Figure (2) shows that 88% of the respondents either disagree or they don't know that there are awards to encourage engage in research.

Figure (3) shows that 3% of participant know that the government support research activities in Iraq.

Table 1: distribution of 206 students according to the availability of internet connection

Internet Connection (total N=206)	N (%)
No internet	3 (1.5)
Slow connection (not always available)	89 (43.2)
High speed connection	114 (55.3)

Table 2: distribution of 206 participates according to their skills in English language (writing, reading, and speaking)

English language skills – Writing (total N=206)	N (%)
Very poor	7 (3.4)
Poor	4 (1.9)
Intermediate	137 (66.5)
Good	47 (22.8)
Very good	11 (5.3)
English language skills – Speaking (total N=206)	N (%)
Very poor	6 (2.9)
Poor	32 (15.5)
Intermediate	122 (59.2)
Good	37 (18)
Very good	9 (4.4)
English language skills – Reading (total N=206)	N (%)
Very poor	5 (2.4)
Poor	11 (5.3)
Intermediate	110 (53.4)
Good	63 (30.6)
Very good	17 (8.3)

Table 3: Distribution of students according to their attitude towards conducting research during undergraduate study.

Research involvement status (total N=206)	N (%)
Not interested in research	55 (26.7)
Interested but don't know how to involve in research	108 (52.4)
Actively looking to involve in research	43 (20.9)

Table 4: Distribution of students according to exposure to encouragement to conduct research by their tutors

Encouragement by academic staff to participate in academic research (total N=203)	N (%)
Encouraged	70 (34.5)
Not encouraged	133 (65.5)
Tutors are easily available to supervise research (Total N=204)	N (%)
Don't know	71 (34.8)
Disagree	42 (20.6)
Average	50 (24.5)
Agree	41 (20.1)
Many chances are available to involve in research (Total N=206)	N (%)
Don't know	70 (34)
Disagree	78 (37.9)
Average	40 (19.4)
Agree	18 (8.7)

Table 5: distribution of students according to the access to scientific journals and capacity building in research methodologies during their undergraduate study.

Easy access to scientific journals through university library (Total N=202)	N (%)
Don't know	40 (19.8)
Disagree	84 (41.6)
Average	46 (22.8)
Agree	32 (15.8)
There are enough training in research methods (Total N=198)	N (%)
Strongly disagree	38 (19.2)
Disagree	97 (49)
Neutral	47 (23.7)
Agree	15 (7.6)
Strongly agree	1 (0.5)
Participated in training course about medical research (Total N=200)	N (%)
Strongly disagree	
Disagree	58 (29)
Neutral	107 (53.5)
Agree	20 (10)
Strongly agree	10 (5)
	5 (2.5)

Table 6: distribution of students according to their believe that research is important for medical practice and academic study.

Research is important in medical practice (total N=201)	N (%)
Strongly disagree	7 (3.5)
Disagree	2 (1)
Neutral	21 (10.4)
Agree	69 (34.3)
Strongly agree	102 (50.7)
Research is important during academic study (Total N=202)	N (%)
Strongly disagree	9 (4.5)
Disagree	7 (3.5)
Neutral	29 (14.4)
Agree	82 (40.6)
Strongly agree	75 37.1)

Discussion

The engagement of undergraduate medical students in scientific health research had been widely advocated in the last decades in order to provide the new generations of physician with knowledge and skills of applying evidence based medicine in their career. In developing countries including Iraq, medical students are less involved in research activities owing to limited resources and other barriers. Attitude of undergraduate medical students and other students in health science, their knowledge about research and the barriers toward this educational activity are three key components that have an impact on research success. In this study there is a positive attitude toward research conducting among the study group (67.7%) of them cited that research is an important tool for undergraduate medical education , this finding goes in line with the finding of other studies ¹⁸ Positive attitude among the study group indicates very good sign to encourage them in this crucial field because negative attitudes toward research serve as an obstacle to learning associated with poor performance in research. There are many barriers mentioned by the participants which are , weak English language skills (writing, reading and speaking) , lack of resources that facilitate the process of conducting research such as high speed internet, award and encouragement in the teaching environment to enhance research work as a learning tool that stimulating critical thinking and help them to gain critical appraisal skills that help in understanding the evidence medicine practice in their future career, these findings are similar to the findings reported by other

researchers ²⁴

Conclusion

The undergraduate medical and dental students had the moderate level of knowledge and positive attitudes toward the conduct of medical research. Lack of competent English language skills (reading, writing and speaking) funding, awarding , poor internet connection and limited access to relevant medical journals and databases were the major barriers.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Hammurabi College of Medicine and all experiments were carried out in accordance with approved guidelines.

Macrophage Migration Inhibitory Factor (MIF) Gene Polymorphism of Urothelial Carcinoma Patients in Iraq

Ishraq Abdul Ameer Salih

Assistant prof., Department of Biology, Science For Women, University of Babylon

Abstract

Bladder cancer is the 2nd most frequent malignancy of the genitourinary tract and the fourth most common cancer in men. This study was designed to shed light on the association between polymorphism of macrophage migration inhibitory factor (MIF) gene at -173 locus as risk factor of bladder cancer in Iraqi population by PCR-RFLP. In a hospital-based case-control study of 70 patients with bladder cancer and 30 cancer-free controls frequency-matched by age, sex, smoking status, and alcohol use, we genotyped the MIF polymorphism and analyzed immunohistochemical stained operational bladder cancer tissue sections for MIF. We found that individuals with GC/GG genotype had a significantly decreased risk of bladder cancer (OR = 1.55, 95% CI, 0.498 to 8.85) than those with CC genotype. The frequencies of the C allele on the MIF gene were significantly increased in Urinary bladder carcinoma patients. MIF -173G>C polymorphism may play a role in the etiology of bladder cancer in Iraqi.

Keywords : MIF gene, RFLP, Urinary bladder carcinoma.

Introduction

Urothelial cell carcinoma occurs in the cells that line the inside of bladder. Bladder cancer is the ninth most frequent cancer, and it is estimated that there were 340,000 newly diagnosed bladder cancer cases and 130,000 related deaths world wide in ¹. MIF enhancement of macrophage transcription, activation and viability, coupled with its inhibitory effects on anti-tumor cell cytotoxic lymphocytes, suggests that MIF overexpression in developing malignancies may act in concert to facilitate increased tumor growth which present an important link between inflammation and cancer due to its pro-inflammatory role. Its molecular mechanisms involve, among others, the inhibition of p53 which promote tumor cell proliferation, cell survival and tumor-associated neoangiogenesis ^(2, 3). Macrophage migration inhibitory factor (MIF) functions as a pleiotropic protein, participating in inflammatory and immune responses. MIF was originally discovered as a lymphokine involved in delayed hypersensitivity and various macrophage functions, including production of proinflammatory cytokines, glucocorticoid-induced immunomodulator, and natural killer cell inhibitory factor (NKIF), regulation of toll-like receptor expression, adherence and phagocytosis of macrophages, as well as

induction of metalloproteinase. ⁴. The imbalance in the regulation of inflammation that occurs in many cancers can induce cellular damage. This stimulates interaction between immune cells and the damaged cells, which then proliferate, invade, and subsequently develop into tumors ⁵. As a functional promoter, the MIF-173 situate in the 50 flanking region of MIF gene, which is strongly associated with protein production. In 2007, Meyer-Siegler et al. ⁶ reported that the MIF allele defined by -173C SNP was associated independently with prostate cancer and independently with elevate levels of circulating MIF. The human MIF gene situated on 22q11.2 having a single nucleotide polymorphism (SNP; G to C transition) in the 50-flanking region at position -173, which has been associated with susceptibility to adult inflammation ⁷. In 2005, Ziino et al. ⁸ revealed that the MIF-173 G[C polymorphism did not contribute to prednisone poor response in vivo in childhood acute lymphoblastic leukemia. Approximately 20% of all cancers arise in association with infection and chronic inflammation and even those cancers that do not develop as a consequence of chronic inflammation, exhibit extensive inflammatory infiltrates with high levels of cytokine expression in the tumor microenvironment.

Materials and Method

Sampling and data collection

This a case-control study consisted of 70 patients with RA and 30 healthy persons (before surgery for UBC group). All subjects signed an informed consent, and clinical data of patients were collected from patient files and questionnaires. Our study was approved by the Research Ethics of the Iraqi Ministry of Health. About 2 ml of whole blood was collected from all subjects

DNA extraction and purification

Genomic DNA was extracted from whole blood collected in EDTA-tubes from all subjects (patients and control individuals) using Genomic DNA Extraction Blood DNA Mini Kit (FAVORGENE). The concentration (ng/ml) and purity (260/280 nm) of the DNA extracts were measured at 260 nm and 280 nm with a NanoDrop spectrophotometer (OPTIZEN POP – Korea).

Genotyping

The candidate SNP *MIF*₋₁₇₃ was investigated using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique. The amplification reaction was done with 3 µl of 200ng/µl of genomic DNA, 12.5 µl of 1X Master Mix (Promega), 1.5 µl of 10 pmol of each specific primer pair (forward and reverse primer), and completed the volume of 20 µl PCR mixture with DNase free water. The source of the primer was Bioneer (South Korea). Primer sequences of *MIF*₋₁₇₃ were forward (5'- 5-ACTAAGAAAGACCCGAGGC-/3) and reverse (5'-GGGGCACGTTGGTGTTTA ')⁸.

The technique for PCR included a pre-denaturing temperature at 95°C for 10min, followed by 30 cycles at 95°C for 45 s; 62°C for 45 s; and 72°C for 30 min with a final extension at 72°C for 10 min. Ten µl of PCR products (366 bp in length) was digested according to Promega company protocol, which the digestion reaction mixture (36 µl) composed of 0.5 µl *Alu I*, 2 µl of buffer B, 0.2 µl BSA buffer, 7 µl of 1X Muti core buffer and 16.3 µl of DH₂O; the reaction was incubated at 37°C for 16h. Subsequently, The product was separated on a 1.5% agarose gel for 45min and power 70 volt and 20mA. Finally, The gel was viewed by RedSafe™ Nucleic Acid Staining (iNtRON) under ultraviolet light . DNA Marker;G/G:Homozygous for absence of *AluI* restriction site (268bp 98bp); C/C: Homozygous for *AluI* restriction site (206bp, 98bp,62Heterozygous for *AluI* restriction site (268bp,206bp,98bp,62bp).

Statistical analysis

Two-sided x2 test was used to evaluate the frequency distributions of select demographic variables, smoking status, alcohol use, and alleles and genotypes of MIF polymorphism between the test subjects and controls. The associations between MIF genotypes and the risk of bladder cancer were estimated by computing the crude and adjusted odds ratios (ORs) and their 95% confidence intervals (95% CIs) from logistic regression analyses.

Results and Discussion

The frequency of genotypes distribution and alleles of the groups are presented in table (3-18). The GG, GC, and CC genotype frequencies were 41.4%, 10% and 44.2%, respectively among the UBC cases and 67.5, 15, and 17.5%, respectively, respectively among healthy cases , as shown in table (3)

Table (1) Distribution of allele frequency and genotype of *MIF* in case-control study.

Genotype	Patients N(% 70(100%))	ControlN% 40(100%)		TEST X2	Odd ratio	CI 95%
GG	29(41.4%)	27(67.5%)		0		
GC	10(14.4%)	6(15%)		0.001*	1,55	0.498 to 8.85
CC	31(44.2 %)	7 (17.5%)			4,12	1.55 to 10.91
Allele Frequency						
G	68(49%)	54(67%)	1.8		2.411	1.3530 to 4.299
C	72(51%)	26(33%)				

OR: Odd Ratio.

CI: Confidence Interval.

Figure (1) Electrophoresis pattern of (MIF) Amplification using PCR technique 2% agarose, 75V, 20mA, for 60 min, line 1 (50 bp) DNA marker, line 1-8 MIF genotype for patients, lane 9-12 MIF genotype for control.

Figure (2) Gel electrophoresis of *MIF*₋₁₇₃ polymorphism (RFLP by *AluI*); M: DNA Marker (100); 4, G/G: Homozygous for absence of *AluI* restriction site (268bp, 98bp); 5 C/C: Homozygous for *AluI* restriction site (206bp, 98bp, 62bp); 6, 7, 8 G/C: Heterozygous for *AluI* restriction site (268bp, 206bp, 98bp, 62bp).

The results nearly agreed with the results reported by ¹¹ who found that individuals with GC/CC genotype had a significantly decreased risk of bladder cancer than those with GG genotype and the CC genotype frequency of *MIF* was lower among the cases. The GG, GC, and CC genotype frequencies were 63.4, 30.5, and 6.1%, respectively, among the cases and 50.7, 43.2, and 6.1%, respectively, among the controls.

The human *MIF* gene is located on chromosome 22q11.2 which contains 3 exons and 2 introns. Gene mapping has shown that the *MIF* gene displays polymorphism, including microsatellite polymorphism and single nucleotide polymorphism, at 4 sites (11,12). G/C polymorphism is located at -173, T/G polymorphism is located at +254, C/G polymorphism.

Although, how the *MIF*-173 G/C polymorphisms affect the inflammatory factor activity remains to be investigated, some studies suggested that the polymorphisms may affect the protein functions. Arikan

et al. ¹⁴ revealed that *MIF*-173C allele frequency was significantly higher in biliary atresia patients than both the chronic liver disease patients and healthy control groups. Makhija et al. ¹⁵ reported that the *MIF*-173C alleles was over expressed in acute pancreatitis patients. Their data all suggested that the polymorphisms might affect on *MIF* protein expression and activity.

Conclusion

We found that individuals with GC/GG genotype had a significantly decreased risk of bladder cancer (OR = 1.55, 95% CI, 0.498 to 8.85) than those with CC genotype. The frequencies of the C allele on the *MIF* gene were significantly increased in Urinary bladder carcinoma patients. *MIF* -173G>C polymorphism may play a role in the etiology of bladder cancer in Iraqi.

Financial Disclosure: There is no financial disclosure.

Study Impact of Hyperuricemia on the Occurrence of Atrial Fibrillation in Patients Admitted to CCU in Al-Diwaniyah Teaching Hospital

Mazin Zamel Al-Shibani¹, Hend Saddam Asmaeel²

¹M.B.Ch.B., F.I.C.M.S./ Professor/Consultant Physician / department of Medicine/ College of Medicine/ University of Al-Qadisiyah / Al-Diwaniyah province/ Iraq, ² M.B.Ch.B/ Al-Diwaniyah Teaching Hospital// Al-Diwaniyah Province/ Iraq

Abstract

Background: A possible direct link between SUA and AF has barely been addressed. Several studies have reported an association between SUA and AF. An increasing body of evidence suggests that SUA may represent a marker of AF risk. The association between SUA level and AF has been demonstrated. Moreover, Nyrenes A et al. found that serum uric acid levels in men are higher than in women throughout life, although SUA levels increase after menopause, and that baseline SUA was associated with an increased risk for future AF in both sexes. In addition, the occurrence of AF increases with age, and the fact that SUA levels in women, in contrast to men, increase with age may account for the higher risk estimates seen in women.

Aim of the study: To evaluate the possible association between serum uric acid and atrial fibrillation in patients admitted to coronary care unit.

Patients and Method: In this hospital based study, in order to explore the prevalence rate of hyperuricemia in patients with atrial fibrillation, the coronary care unit in Al-Diwaniyah teaching hospital was prospectively reviewed for newly admitted patients with atrial fibrillation during the period extending from April the 15th 2019 through July the 15 the 2019.

Results: A cross sectional study enrolled 191 patients with cardiac problems. The study result revealed 53.4% of cases were males and 46.5% were females; the male to female ratio was 1: 1.14. The mean age of all patients was 51.9±4.6 years. The patients were examined and investigated for the presence of atrial fibrillation and then were divided into two groups, atrial fibrillation positive (20.5 %) and atrial fibrillation negative (77.5 %). Hyperuricemia was significantly associated with atrial fibrillation ($P < 0.001$) and the risk subjected by hyperuricemia was 3.5 in terms of odds ratio.

Conclusion: There was significant association between hyperuricemia and presence of atrial fibrillation in patients admitted to CCU indicating that hyperuricemia is a risk factor for AF development.

Key words: Atrial fibrillation, hyperuricemia, Iraq

Introduction

Atrial fibrillation is the most common type of heart arrhythmia. It is due to abnormal electrical activity within the atria of the heart causing them to fibrillate. Is characterized as a tachyarrhythmia, which means that the heart rate is often fast. This arrhythmia may be paroxysmal (less than 7 days) or persistent (more than 7 days). Due to its rhythm irregularity, blood flow

through the heart becomes turbulent and has a high chance of forming a thrombus (blood clot) which can ultimately dislodge and cause a stroke. Atrial fibrillation is the leading cardiac cause of stroke. Risk factors for atrial fibrillation include advanced age, high blood pressure, underlying heart and lung disease, congenital heart disease, and increased alcohol consumption. Symptoms vary from asymptomatic to symptoms such

as chest pain, palpitations, fast heart rate, shortness of breath, nausea, dizziness, diaphoresis (severe sweating), and generalized fatigue. Although atrial fibrillation may be a permanent disease, various treatments have been developed, and risk modifying strategies to help reduce the risk of stroke in patients that remain in atrial fibrillation exist. Treatments include anticoagulation, rate control medication, rhythm control medication, cardioversion, ablation, and other interventional cardiac procedures (1,2).

A possible direct link between SUA and AF has barely been addressed. Several studies have reported an association between SUA and AF³. An increasing body of evidence suggests that SUA may represent a marker of AF risk. The association between SUA level and AF has been demonstrated. Moreover, Nyrnes *et al*³ found that serum uric acid levels in men are higher than in women throughout life, although SUA levels increase after menopause, and that baseline SUA was associated with an increased risk for future AF in both sexes. In addition, the occurrence of AF increases with age, and the fact that SUA levels in women, in contrast to men, increase with age may account for the higher risk estimates seen in women³.

Furthermore, in a small observational study, Letsas *et al.* showed a stepwise increase of SUA levels in patients with paroxysmal AF and permanent AF compared to control subjects, while after multivariate analysis, SUA was an independent predictor of permanent⁴ (Letsas *et al.*, 2010). Also, in a retrospective observational study of hospitalized patients over 40 years an independent association between high SUA levels and AF (paroxysmal or persistent) was evident⁵. In the ARIC study, a large prospective cohort study, elevated SUA was associated with a greater risk of AF development during the follow-up⁶. In the same line, a Japanese hospital-based cohort study demonstrated an independent association between SUA and AF⁷. Another very recent study showed that SUA levels ≥ 8 mg/dl was an independent predictor of AF while SUA increased significantly between the last year and the year of the first AF detection suggesting a possible involvement in AF development. Besides, Tze-Fan Chao *et al.* showed that hyperuricemia was associated with a larger left atrial size and may be a novel risk factor for the development of AF. K. Letsas *et al.* also found an independent association between increased levels of SUA and permanent AF⁴.

The poverty of national reports and limited numbers of Iraqi studies dealing with the association of atrial fibrillation and hyperuricemia in Iraqi patients and based on the clinical daily observation in coronary care center in Al-Diwaniyah province, Mid-Euphrates region of Iraq, we planned and conducted the current study to disclose the possible association between hyperuricemia and atrial fibrillation in Iraq.

The aim of the present study was to evaluate the possible association between hyperuricemia and atrial fibrillation.

Patients and Methods

In this hospital based study, in order to explore the prevalence rate of hyperuricemia in patients with atrial fibrillation, the coronary care unit in Al-Diwaniyah teaching hospital was prospectively reviewed for newly admitted patients with atrial fibrillation during the period extending from April the 15th 2019 through July the 15th 2019. Any patient admitted to CCU during the period of the study was enrolled in the current study. Any patient who refused to participate in the current study and patients who were unfortunately unable to complete interview questionnaire were excluded from study. Following application of these exclusion criteria, the sample of included patients became 191.

The following variables were included in the questionnaire form: Age, gender, occupation, education level, residency, socioeconomic status, marital status history of smoking, history of alcoholism, history of chronic illness, the main presenting clinical features. Investigations included ECG findings, serum uric acid and thyroid function test in addition to CBC, LFT, RFT, Lipid profile, cardiac biomarkers. Echocardiographic findings were also included. The study was approved by the institutional ethical approval committee and formal agreement was obtained from the directorate of Health in Al-Diwaniyah province, the formal representative of Iraqi Ministry of health. Data were collected and transformed into a spread sheet of Microsoft Office Excel 2010 and then into an SPSS (statistical package for social sciences) version 23. Numeric quantitative data were expressed as mean, range and standard deviation (SD), whereas, qualitative data were expressed as number and percentage. Comparison of mean between any two groups was done according to independent sample t-test, while chi-square test was used to evaluate association between any two categorical variables. The

level of significance was considered at $P \leq 0.05$.

Results

A cross sectional study enrolled 191 patients with cardiac problems. The study result reveals 53.4% of sample were male and 46.5% were female, in ratio 1:1.14, with mean age for all sample 51.9 ± 4.6 years. After patients' examination by physician and ECG finding, classified patients into groups according to presence of

atrial fibrillation. Twenty point five percent of patients were had atrial fibrillation and 77.5% percent of patients had other cardiac problems rather than AF. Sixty seven out of 191 patients had hyperuricemia and 124 had no hyperuricemia. There was highly significant association between hyperuricemia and AF ($P < 0.001$) with an odds ratio of 3.15 (95 % confidence interval of 1.73 to 7.08) and an etiologic fraction of 0.42, as shown in table 1. However, there was no significant association between AF and any of other patients' characteristics, table 2.

Table 1: Association between hyperuricemia and atrial fibrillation

AF	Hyperuricemia				P †	OR	95 % CI	EF
	Positive n = 67		Negative n = 124					
	n	%	n	%				
Positive	25	37.3	18	14.5	< 0.001 HS	3.51	1.73 - 7.08	0.42
Negative	42	62.7	106	85.5				

†: Chi-square test; HS: highly significant at $P \leq 0.01$; OR: odds ratio; CI: confidence interval; EF: etiologic fraction

Table 2: Association between atrial fibrillation and other possible risk factors

Factor	P
Gender	> 0.05 NS
Age	> 0.05 NS
Hypertension	> 0.05 NS
IHD & Heart failure	> 0.05 NS
Valvular heart disease	> 0.05 NS
Mixed group	> 0.05 NS
IHD & Thyroid disease	> 0.05 NS
IHD & Kidney disease	> 0.05 NS
IHD & Diabetes mellitus	> 0.05 NS
IHD & Smoking	> 0.05 NS
IHD & CVA	> 0.05 NS

NS: Not significant at $P > 0.05$

Discussion

Atrial fibrillation newly becomes highly health problems worldwide due to largely relation to elevate diseases burden and increase death rate in general. In previous study reported AF prevalence 2.4%-3.5% in general population. Which was estimated more than 30 million of population survive with AF⁸. Patients with AF had been rise incidence of other diseases such as stroke, dementia and heart failure etc⁹. Many theories appear to explain pathophysiology and predisposing factors to AF. That had been reported a reaction of oxidative factors that cause inflammation in cell level¹⁰.

Numerous new studies expected the inflammation and oxidative processes behind the development of AF, in same way with presence of other predisposing factors like increase age of patient⁸.

The serum uric acid had been implicated to proceeding the inflammation pathways and oxidation processes in many pathological states of different diseases one of them AF. Also related to AF in accompany of others diseases such as hypertension, heart failure, hemodialysis and diabetes. Serum uric acid is the end product of purine catabolism. In our cross sectional study was revealed 43 out of 191 had AF (22.5%), which was more than reported in china studies, one of them did in Yunnan hospital reported AF prevalence in patients of age 80 years equal to 0.9% of patients treated in that hospital. Another study recorded prevalence AF 6% of 350 patients in suburban area similar risk factors. In addition a large number study in wide geographical region include more than 1000 patients reported AF prevalence in older patients equal 9%¹¹. In north of Iraq a study by reveal AF prevalence among stroke patients in ward of three hospital 17.5% of middle and older patients¹². For same study design in south of Iraq 9.8% of stroke patients that admitted to hospital associated with AF¹³.

In conclusion, there was significant association between hyperuricemia and presence of atrial fibrillation in patients admitted to CCU indicating that hyperuricemia is a risk factor for AF development.

Quality of Life of Parents Having Cancer and Non-cancer Children: A Comparative Study

Awayi Ghazy Abdulkareem¹, Zhian Salah Ramzi², Jamal Ahmad Rashid³

¹Assistant prof., Pediatric Nursing Department, College of Nursing, ² Assistant prof., Community Health Department, College of Nursing, ³ Assistant prof., Pediatric Department, College of Medicine, University of Sulaimani, Kurdistan Region, Republic of Iraq

Abstract

Purpose: Cancer is the second leading cause among children and the child and parents suffering from cancer also exhibit side effects of chemotherapy. The present study aimed to examine the issues with the quality of life of the parents having children with cancer as compared to those having children without cancer.

Methods: This is an investigative and descriptive study that included a sample of 300 parents along with their children with cancer; registered to the Hiwa Oncology Hospital in Sulaymaniyah City, Iraq and 300 other parents with their non-cancerous children; visited Pediatric Teaching Hospital in Sulaymaniyah City, Iraq. A questionnaire elaborated by the authors and the quality of life scale (WHOQOL-BREF) questionnaire was applied.

Results : The biggest difference between the overall quality of life of a parent with child with cancer and the parent without a child with cancer, the majority of the mothers and fathers in the control group, their quality of life fall between high to very high than the case group.

Conclusion : Thus, this study indicated the need for parental support while providing intervention to the child with cancer.

Keywords: *quality of life, parents, children, cancer*

Introduction

Cancer is one of the major issues worldwide. The number of cancer cases among children is gradually increasing.¹ Childhood cancer is the second leading cause of death among children aged 1-18 years.² In recent decades, improved technology and discovery of novel treatment increased the survival rate dramatically.³ According to the World Health Organization (WHO), the definition of quality of life is an individual's perception of his/her lives with respect to his/her goals, expectations, standards, and concerns. In addition, the

individual's physical health, psychological state, level of independence, social relationships, and the social relation to salient features of the environment are also considered.⁴ The impact of the disease and side effects of the treatments of the child affected the quality of life of the parents because the parents take care of the ill child during his/her condition.⁵ This long-term childhood disease may negatively affect the parenting and the quality of life of the parents of the child with the disease than that of both parents with a child without cancer.⁶ In the current study, we aimed to investigate the quality of life of parents with a child with cancer in Sulaymaniyah City, Iraq physically, socially, environmentally, spiritually, and level of independence as compared to parents with a child without cancer. Moreover, we also investigated how the respondents rate their quality of life and whether they were satisfied with their health. The key component of the empirical part of the study was the survey using a standardized questionnaire.⁷

Methodology

This case-control study was carried out from September 21, 2017 to April 22, 2018 at the Hiwa Oncology and Pediatric Teaching Hospitals in Sulaymaniyah City/Iraq.

Data collection

Part one

This part included the sociodemographic data of the parents of children with cancer undergoing chemotherapy. The education, occupation, marital status, and economic status were recorded for both mothers and fathers.

Part two

In order to evaluate the quality of life of the parent, a standardized questionnaire was designed by the WHO^{7,8}. The Slovak version was used for examining the quality of life based on five domains as follows:

1. General domain: This is the last domain that examined the general health of the individual by asking them to rate their quality of life and whether they were satisfied with their health.

2. Physical domain: It mapped the extent to which the pain affects the individual's life with respect to the energy, sleep, and rest. Also, the level of independence for mobility, dependence on the medication, the activities of daily life, and work capacity were assessed.

3. Psychological domain: It investigated the degree of satisfaction of the individuals with their life. It also focused on the frequency of the occurrence of negative emotional states as despair, depression, and anxiety.

4. Social domain: It reflected the satisfaction with personal relationships, sex life, as well as the support that people receive from friends and the local community.

5. Environmental domain: This part investigated the level of quality of life with respect to environmental factors, such as the feeling of safety and quality of the environment of the individuals and accessibility of financial and information resources or health services.

Thus, these facets of the quality of life domains were used for both parents of the study sample as well as the control group.

Study design

The present study was conducted in the Hiwa Oncology Hospital, the only hospital for hematology and oncology providing care for cancer patients both adults as well as children.

The second set of the study was carried out at the Pediatric Teaching Hospital that was established in 1988 in Sulaymaniyah City/Kurdistan region of Iraq. This hospital includes emergency and medical units and provides health care for ill children, aged <15-years-old.

Sampling of the study

The sample consisted of 300 parents of children with several types of cancers in comparison with 300 control parents of children without cancer. The present cohort was selected among children with cancer in the Hiwa Oncology Hospital. Taking into account certain inclusion criteria including children undergoing chemotherapy, children diagnosed with different types of cancer and children registered in Hiwa Oncology Hospital are considered. Verbal consent was obtained from the parents of both cases and controls to confirm the voluntary participation in the study.

Data collection

The data were collected through a direct interview of the participants, including both samples parents of case and control groups, using a standardized questionnaire.

Statistical Analysis

All data were analyzed using SPSS version 23, and the level of significance was set at $P \leq 0.05$.

Results and Discussion

sociodemographic characteristics of mothers of both case and control groups. The age of the sample group in the cohort was between 31 and 42 years (69.3%), while in the control group, about 54.7% were aged between 19 and 30 years. Moreover, the age group 43-54 years constituted 12.3% of the sample group and 6.7% of the control group. Next, the education level of the mothers ranged from illiterate to college graduate, the majority was primary school graduates (45.0%), the lowest percentage of the study sample constituted of institute graduates (2%), 26% graduated from secondary school, and only 8.3% graduated from college among the control group.

In both the case and control groups, 82.3% and 67% of the mothers were housewives, respectively, and all the participants were married. Based on the consanguinity between parents, about 62.7% of the cases were relatives, whereas 75% of the control group was not related. Approximately, 67% in the case group scored the socioeconomic status as insufficient, while 83% in the control group scored the same as sufficient.

The father's sociodemographic characteristics in both groups. The majority of the participants in the case and control groups were aged between 33 and 45 years (65.7% and 58.3%, respectively). The educational qualification in case and control groups was secondary school for most of the fathers, and the majority of the participants were non-governmental employees in both groups.

Table 1 demonstrates a comparison between the mother's quality of life in case and control groups. The comparison between the mean score of general and four domains of the quality of life among the mothers in the case and control groups revealed that the mean score of the general, physical, psychological, social, and environmental domain was significantly higher among the control group ($P < 0.001$) than among the case group; however, the difference was statistically non-significant ($P = 0.047$). However, the mean score of the overall quality of life was significantly higher among the case group (87.2 ± 12.4) as compared to the control group (102.4 ± 11.3) ($P < 0.001$).

Lastly, Table 2 presents a comparison between the father's quality of life in case and control groups. The comparison between the mean score of general and four domains of the quality of life among fathers in the case and control groups revealed that the mean score of the general domain, physical, psychological, social, and environmental was significantly higher among control groups ($P < 0.001$). Hence, although the mean score was higher among controls as compared to the cases, albeit non-significantly ($P = 0.766$). However, the overall quality of life among cases (92.5 ± 15.0) was significantly higher as compared to the controls (102.4 ± 12.2) ($P < 0.001$).

To the best of our knowledge, this is the first study to investigate how cancer affects the quality of life of parents. The results showed that the children's condition affects the quality of life of the parents. All the parents had specific rules and ways of coexistence. Day-by-day,

the number of parents who have a child with cancer have in increasing, and thus, improving the health care for such children is essential. Interestingly, parents do not realize the influence of the child's condition on the whole family. The lives of the families of such children are altered dramatically. These families need to adapt to a new situation, realize the challenging condition and the imposing burden on all the family members. This research aimed to find out about the quality of parents of children with cancers with parents without cancers, namely from general, physical, psychological, social and environmental domains. Moreover, we were investigating how the respondents themselves. The result shows that most parents of children with cancers there was a minimal difference between how parents from parents of a child without cancer are satisfied with their health. The study shows that the sense that living in with child having cancer or without cancer has satisfied of mother and fathers with their health. In this study determine that the quality of life of parents of children with cancers from the physical domain will be significantly poorer than those parents had a child with cancer.

Therefore, we can state that parents with a child with cancer are less satisfied with their mobility, sleep, the sufficiency of energy and perceive a higher level of discomfort in physical area than parents of children without cancer.

The obtained result shows that there is a significant difference between the level of quality of life of parents of a child with cancer and parents of a child without cancer. Hence, we can state that the participants from parents of children with cancers perceive life as meaning full and joy-full to a smaller extent compared to parents of a child without cancer.

The results demonstrated that the quality of life of parents of children with cancers and without cancers from social domain approximately the same result found among two groups of parents and this no sign of the result. Therefore, we can state that parents of children with cancer are equally satisfied with personal relationships and supports that they receive from friends and the local community as parents of a child without cancers.

The result obtained that from the environmental domain of quality of life of parents of children without cancers scored higher than parents with parents of a

child with cancer. The difference emerging from the results is markedly significant, actually the biggest from all domains. Therefore, we can state that the level of feeling of safety and quality of the environment of parents of a child with cancer hence the accessibility of financial and information resources and health services, is much lower than of parents of children without cancer. The domain involves mainly the economic side, so its, understandable that parents of a child with cancer perceive a higher level of discomfort in this area as it needs more financial resources to satisfy all its needs and proper functioning than parents of children without cancer. According to (Lisa,2014), coping with burdensome situations appears as a significant indicator of the quality of life. She distinguishes between two terms – adaptation and coping. According to her, adaptation means coming to terms with the ordinary and increased burden (within limits of our tolerance of burden, we apply methods of solving burdensome situations to which we have predispositions and experience).

Coping represents a higher level of adaptation that is necessary for dealing with limit and extreme burden (we find ourselves at the limit of our tolerance of burden, it's a matter of solving sudden, unusual burdensome situations which often overreach our resources; we need to find, examine, test and adopt necessary coping methods first). Nakane (2006) understands coping with life burdens as a dynamic process in which it comes to transactions (mutual interactions between a person and a given situation). On one hand, there is a given person (or a family) with certain resources, possibilities, values, beliefs. On the other hand, there is a disability imposing certain requirements on a person (or a family) and influences them variously.

The results of this study are agreed with a study done by (Andrea,2015), she showed that there was the only big difference of quality of life of a family with a child with a disability and without disability in the environmental domain.

Table 1. Comparison between mother's quality of life domains in case and control groups

Mother's quality of life domains	Case	Control	P-Value of Independent t-test
	M ± SD	M ± SD	
General domain	6.17 ± 2.09	8.10 ± 1.54	< 0.001
Domain 1/Physical	23.5 ± 3.97	27.0 ± 3.51	< 0.001
Domain 2/Psychological	20.8 ± 3.84	23.3 ± 2.81	< 0.001
Domain 3/Social	9.18 ± 2.65	10.6 ± 2.75	0.047
Domain 4/Environment	26.4 ± 3.92	32.8 ± 4.88	< 0.001
Overall quality of life	87.2 ± 12.4	102.4 ± 11.3	< 0.001

Table 2. Comparison between father's quality of life domains in case and control groups

Father's quality of life domains	Case	Control	P-Value of Independent t-test
	M ± SD	M ± SD	
General domain	6.81 ± 2.09	7.78 ± 1.50	< 0.001
Domain1/Physical	25.3 ± 3.96	27.1 ± 3.58	< 0.001
Domain 2/Psychological	22.2 ± 4.08	23.9 ± 4.56	< 0.001
Domain3/Social	10.1 ± 2.86	10.1 ± 2.32	0.766
Domain4/Environment	28.0 ± 5.03	33.3 ± 4.28	< 0.001
Overall quality of life	92.5 ± 15.0	102.4 ± 12.2	< 0.001

Conclusion

There is a biggest difference between the quality of the life of parents who have a child with cancer and parents who have a child without cancer. Strikingly, in the case of parents with a child with cancer have their life more decorticated than others and need additional support. Importantly, all the social and health services in the governorate in every country need to focus on providing support to the families and designing a specific educational program for parents who have a child with cancer.

Sleep habits and Physiological Pineal Gland Calcification (A Magnified Topographical Evolution Study)

Sattar R. AL-Esawi¹, Ashwan Abdulzahra Hashim², Zhraa Ayad Jabber³, Riyadh W. AL-Esawi⁴

¹Radiologist Consultant, Department of Radiology, AL-Sadder Medical City, ²Psychiatrist, Department of Medicine, Medical College, University of Kufa, ³Radiologist, Al-Sadder Medical City-Middle Euphrates Neuroscience Center, ⁴Assistant prof. Department of Radiology, Medical college, University of Kufa

Abstract

Physiological pineal gland calcification is a frequent finding in computed tomography brain (CT) and its volume, shape and density is variable. Melatonin is the main product of pineal gland, and its role in sleep is well documented. Two-hundred ten patients were enrolled in this cross-sectional study done at Al-Sadder Medical City-Middle Euphrates Neuroscience Center (MENC)-Najaf; between February 2016 and December 2016. Several PGC parameters include PGC density, PGC volume and PGC cross sectional area were measured. We took their demographic information and their BMI and then questions about their sleep habits was applied to patients. the study group was ($n=210$) was referred for Brain CT for different reasons, mean age (43.9 years), of them male was (118), and female was (92) they represent (56.2% and 43.8%) respectively, that had insomnia was (85, 40.5%), the mean of pineal gland calcification volume (mm³), density (Hu) and cross sectional area (mm²) was (57.5, 131 and 12.5) respectively. In this study there were a strong correlation between PGC density and age, male gender and use of diazepam and Sleep with light on at night & decreased hours of night sleep showed statistically significant correlation with PGC volume and thus on PG function.

Keyword: pineal gland, calcification, sleep habit, topographical evaluation.

Introduction

The pineal body is shaped like a pinecone, from which the name pineal is derived ¹. It has a role in controlling the/onset of puberty. The pineal body also influence the sleep-wake cycle ¹. The pineal gland (PG) measurements about 7.0 x 3.0 x 6.0 mm and is located in between the thalamic bodies ². Normal sizes is 14 mm ³.

PG action in humans are still not well understood, its neuroendocrine transducer that forms an integral part of brain. The PG mainly synthesis of melatonin (MEL) is made and secreted in/rhythmic fashion, in the darkest time of the day-night cycle. MEL synthesis and release is supervised by an endogenous/circadian system and is also inhibited by light. Recent studies show a relationship between endogenous MEL levels and the puberty onset. Finally, there was abnormal daily MEL profiles in many of psychiatric disorders and neurological diseases but the important of these was unclear ⁴.

Melatonin plays roles in various physiological functions including, inducer of spontaneous sleep, protecting cell death so it has anticancer effect⁽⁵⁻⁸⁾.

MRI was the best method for imaging of pineal gland and it is superior to CT and radiograph, although it has poor sensitivity to evaluate calcification ⁹.

Calcification of PG is a physiological intracranial calcifications that can be said that as all age-related physiologic and neurodegenerative calcifications that are unaccompanied by any evidence of disease and no pathological cause. The calcification increased with increase ¹⁰. With PGC its function will be hampered to an extent, affecting the synthesis of melatonin. If this happens we expect sleep problems. It can also effect on human sexual development and function. Some of PGC is due to increase amount of fluoride in water, other causes of PGC can include: Halides, Calcium supplements and Pesticides⁽¹⁰⁻¹²⁾. PGC lead to sleep related disturbances and daytime tiredness ¹³.

Patients and Method

Two-hundred ten patients were enrolled in this cross-sectional study which is conducted at Al-Sadder Medical City-Middle Euphrates Neuroscience Center (MENC)-Najaf, from February 2016 through December 2016. All patients were referred for non contrast brain CT scan study (spiral computed tomography scan Brilliance 64, Philips 2010) for various neurological conditions.

Inclusion criteria: any patient aged 10 years or older who already had brain CT scan and agreed to be enrolled in this study, the patient should be fully conscious and oriented to time, place and person.

Exclusion criteria: patients aged less than 10 years (as this study concerned with physiological PGC), patients with pineal gland lesions, those who are disoriented to time, place and person, those who had emergency condition, and those with hearing impairment (as this study include list of questions).

Two-hundred ten patients were participated after obtaining their or their family verbal consents and approval from local ethical committee of Medicine a middle Euphrates neuro-center.

The data about patients age ,gender, BMI, Hx of smoking, their occupations and any history of chronic physical illness was obtained.

PGC appears either as oval, round or irregular, we measure its density, volume and cross sectional area (CSA). The PGC density were measured by two methods 1st one manually by taken the density of 1.5mm area in the central of the calcification area and the 2nd method automatically by the machine, the two method show no significant difference statistically so that we depend on the manual method.

To assess the sleep pattern of each patient we applied a list of questions that were used in different sleep researches^(14,15) as the following.

1. time of going to bed

2. time of awake
3. hours of sleeping
4. night awake
5. sleep with light on
6. use of media for more than one hour before sleep
7. insomnia
8. wake with alarm
9. drink coffee or tea at night
10. working during day or night
11. Use of sleep medication

These questions were applied to all patients with details about their sleeping adequate hours and their night habits include sleeping with light on during night, uses of media before sleep more than one hour and consumption of tea or coffee.

Data were entered and analyzed using the statistical package for social sciences (SPSS) version 24, 2015, IBM, USA. Descriptive statistics were presented as mean, standard deviation, frequencies and percentages. Student's t test (independent model) was used to compare mean Pineal gland volume, density and cross sectional area across the (Yes vs. No) subgroups. Analysis of variances (ANOVA) test was used to compare the mean across the age, BMI categories and physical activity subgroups.

Results

Two-hundred ten patients were enrolled in this study. Those patients were referred for brain CT scan noncontract study for various neurological conditions and we correlated the present of PGC with different parameter and the result were as the following:

Table 1. Demographic characteristics of the studied group (N=210)

Variable		No.	%
Age (year)	10-20	18	8.6
	21 - 30	39	18.6
	31 – 40	48	22.9
	41 – 50	31	14.8
	51 – 60	35	16.7
	> 60	39	18.6
	Mean ± SD	43.9 ± 17.6	-
	Range	10 – 86	-
Gender	Male	118	56.2
	Female	92	43.8
Occupational Physical activity	Light	83	39.5
	Moderate	92	43.8
	High	35	16.7
Smoking	Yes	47	22.4
	No	163	77.6
BMI category	Underweight	8	3.8
	Normal	68	32.4
	Overweight	74	35.2
	Obese	60	28.6
	Mean ± SD	27.9 ± 7.1	-
	Range	15.6 – 46.2	-

In this table show that this study include one hundred eighteen male and ninety two female and only forty seven was smokers and only sixty eight patient within normal BMI. The patients enrolled in this study were (60) patient with hypertension and (25) patient with diabetes mellitus and (12) patient with history of different tumors and (12) with chronic physical pain the other remaining (101) had no medical history of illness.

Table 2. Distribution of sleep related parameters

Variable	No.	%	
Sleep with light on	Yes	70	33.3
	No	140	66.7
Media use before sleep	Yes	59	28.1
	No	151	71.9
Sleep Medication use	Yes	23	11.0
	No	187	89.0
Insomnia	Yes	85	40.5
	No	125	59.5
Awake with alarm	Yes	43	20.5
	No	167	79.5
Tea or coffee intake at night	Yes	48	22.9
	No	162	77.1
Day or night work	Day	197	93.8
	Night	13	6.2

This table shows that patients that sleep with light on were seventy and those use sleep medication were twenty three while those with insomnia were eighty five and those who drink tea or coffee were forty eight and only thirteen were work at night.

Table 3. Mean values of Pineal gland calcification parameters of the patients and Correlation with sleep hour (N=210)

Parameter	Mean	SD	Minimum	Maximum	Correlation coefficient (R)	P. value
PGC volume (mm3)	57.5	62.8	0.2	375.6	-0.223	0.001*
PGC density (HU)	131.0	67.1	6.3	350.0	-0.038	0.585
Cross sectional area of PGC (mm2)	12.5	10.3	0.2	48.6	-0.060	0.389
*Correlation is significant at the 0.05 level						

There was a significant inverse correlation between PGC volume and the hours of sleep (P= 0.001). While there was no significant correlation between time spend in the bed neither with PGC density nor with cross sectional area (P= 0.585 and 0.389) respectively.

Table 4. Correlation between sleep related variable and PGC volume, density and cross sectional area, of the studied group (N=210)

Variable	Mean	Pineal gland volume		P. value Mean	Pineal gland density		P. value Mean	Cross sectional area of PGC		P. value
		SD			SD			SD		
Sleep with light on	Yes	74.1	9.0	0.03*	132.5	7.3	0.89	12.2	1.2	0.55
	No	53.6	4.9		131.2	5.9		13.1	0.9	
Media use	Yes	57.3	6.9	0.67	128.1	8.1	0.63	13.1	1.2	0.80
	No	61.6	5.6		133.0	5.6		12.7	0.9	
Sleep medication use	Yes	57.4	12.7	0.82	164.1	18.4	0.013*	16.1	2.7	0.098
	No	60.7	4.8		127.6	4.6		12.4	0.7	
Insomnia	Yes	62.7	6.8	0.66	129.3	7.7	0.68	11.7	1.0	0.19
	No	58.7	5.9		133.2	5.7		13.6	1.0	
Awake with alarm	Yes	66.5	10.5	0.48	140.6	10.0	0.32	14.2	1.8	0.35
	No	58.7	4.9		129.3	5.2		12.5	0.8	
Tea or coffee intake	Yes	71.4	9.7	0.17	134.6	11.0	0.72	16.2	1.8	0.012*
	No	56.9	5.0		130.7	5.0		11.9	0.7	
day or night work	Night	61.6	4.7	0.27	131.0	4.8	0.61	12.8	0.7	0.73
	Day	40.9	13.5		141.0	18.6		13.8	2.9	

There was a significant correlation between PGC volume and sleep with light on during night ($P = 0.03$). While there was no significant correlation with other parameters, ($P > 0.05$). There was a significant correlation between PGC density and use of sleep

medication (diazepam) before night and ($P = 0.013$), while no correlation found with other parameter. There was a significant correlation between PGC cross sectional area and night intake of tea or coffee, ($P = 0.012$) while no correlation with other parameter ($P = 0.35$ and more).

Table 5. Correlation between demographic characteristics and Pineal gland calcification volume, density and cross sectional area of PGC, of the studied group (N=210)

Variable Mean		Pineal gland calc. volume		P. value Mean	Pineal gland calc. density		P. value Mean	Pineal gland calc. Cross sectional area		P. value
		SD			SD			SD		
Age (year)	≤ 20	73.0	16.7	0.65	97.4	10.9	0.038*	11.7	1.8	0.63
	21 - 30	65.6	9.0		120.9	9.1		11.5	1.5	
	31 - 40	47.8	8.7		123.9	10.0		12.8	1.5	
	41 - 50	57.0	9.9		137.5	9.6		13.5	1.9	
	51 - 60	67.3	9.7		153.7	12.8		15.4	2.2	
	> 60	61.0	14.3		143.1	12.2		11.8	1.4	
Gender	Male	62.0	5.9	0.68	139.9	6.5	0.041*	12.9	0.9	0.85
	Female	58.3	6.9		120.9	6.3		12.7	1.1	
BMI categories	Underweight	39.5	15.7	0.79	124.5	30.7	0.68	7.5	1.6	0.36
	Normal	63.9	7.4		128.5	8.3		12.6	1.3	
	Overweight	58.5	7.0		139.3	7.6		14.0	1.3	
	Obese	61.1	9.7		126.7	8.4		12.4	1.3	
Physical activity	Light	64.5	7.8	0.69	137.5	8.0	0.60	13.5	1.1	0.70
	Moderate	59.0	6.3		128.1	6.4		12.2	1.0	
	Heavy	53.9	9.7		127.3	11.2		13.0	2.1	
Smoking	Yes	66.9	8.7	0.43	141.8	10.8	0.23	12.7	1.6	0.95
	No	58.5	5.2		128.7	5.1		12.8	0.8	

This table shows that there is no significant correlation between PGC volume and cross sectional area with different selected demographic characteristics ($P = 0.43$ and $P > 0.3$) respectively. There was a significant correlation between PGC density and the age as well as male gender ($P = 0.038$ and $P = 0.041$) respectively.

Discussion

Since its first description autopsy specimens skull radiographs by Schüller in 1918¹⁵, the exact mechanisms behind the development of calcification in pineal gland are difficult to found, although there is an evidence (experimental), that calcification may be an indicator of the past secretory activity of the gland and/or of degeneration. The increased incidence of calcification in pineal gland with person's age it may suggests cerebral degenerative changes¹⁷.

This current study shows correlation between PGC (density, volume and CSA) primarily with patient's sleep pattern and secondarily with several other selected parameters. in regard to sleeping pattern this study found that there was a significant correlation between PGC density and sleep with light on ($P=0.013$), this finding was comparable with a study done by [Bogdan Lewczuk](#) (2014)¹⁸ They discuss relationship between light exposure and MEL with breast cancer risk, they found there was a significant correlation between use of light on and production of MEL which result in increased PGC density. Another study was done by Nathan PJ¹⁹ showed that plasma MEL concentration which is inhibited by light have indicated this may be related with PGC; although no direct study correlate the PGC and sleep with light on during night as they depend indirectly on the level of MEL.

Conclusion

Age showed statistically significant correlation with increase PGC density and in turn on PG function, male gender showed statistically significant correlation with increase PGC density and in turn on PG function. Use of diazepam showed statistically significant correlation with increase PGC density and in turn on PG function, sleep with light on at night and decreased hours of night sleep showed statistically significant correlation with increase PGC volume, and tea or coffee consumption at night showed statistically significant correlation with increase cross-section area of PGC. And physical activity, BMI, smoking and past medical history showed no significant correlation with other PGC parameters.

Investigation of Microbial and Mineral Contamination of Imported Meat

Haider Mashkooor Hussein

College of science. University of Alqadisiyah

Abstract

The study was carried out for the purpose of investigating the microbial and mineral pollutants in the imported red meat. This research included field work and random sampling of the markets of Diwaniya Governorate. In addition, laboratory tests were carried out on samples from the following countries: (Saudi Arabia, Turkey, Jordan, Lebanon) in the laboratories of the Department of Life Sciences. Some bacterial species were investigated in the studied meat samples. Microbial contamination The results of the study showed a high level of bacterial content and the results were the emergence of Staph bacteria. aureus in the nutritious dish. The other dishes showed no growth due to the good storage of meat. The dish in which the bacteria appeared was due to poor storage or preservatives used in the storage process. As for the chemical analysis of heavy metals using the Atomic Absorption Spectrometer technique, the concentrations were as follows: Concentration of the copper component (0.013-0.310) $\mu\text{g} / \text{g}$, while the concentration of the lead element (0.001-0.111) $\mu\text{g} / \text{G}$; for cadmium, its concentration was 0.001-0.004 $\mu\text{g} / \text{g}$ and the concentration of chromium was 0.003-0.020 $\mu\text{g} / \text{g}$. The results showed that levels of copper, lead, chromium and cadmium were higher than those allowed by the World Health Organization (WHO) and FAO in some imported meat samples.

Keywords: *Microbial, Mineral contamination, Meat*

Introduction

Meat:

Meat is one of the most important and important products in human life since ancient times. The source of animal protein is of high value for its vital amino acids necessary for the survival of life. Due to the important role that meat plays in our daily lives, meat has been preserved in different ways 1. In general, this has greatly contributed to the slaughtering of the animal in a given country and its consumption in another country 2. Therefore, it was important to control these meat for the large use of people, especially the Iraqi street, Including bacteriophages, fungi and viruses to humans, causing many diseases. Meat generally contains protein, amino acids, important minerals and vitamins, including B-Complex. The nutritional value of meat depends on the content of these important ingredients, depending on the age of the animal, the type of herd, the fat content of the meat 12 . The meat is rich in important components of the human being and is also considered to be perishable

and therefore undergoes natural changes (chemical and biological), which have a major effect on the suitability of these meat for human consumption. Meat can be preserved from these natural effects by freezing (freezing meat 8 . The method of freezing does not eliminate the microbes found in meat in general, since microbial growth generally stops at -10°C for bacteria, and for fungus it can grow on meat products clearly, leaving different spots on meat products and increasing the image Especially if the tempera-ture is higher than -11°C . This results in a noticeable change in the color and texture of the meat, since the optimal temperature for meat preservation (-18°C) 5 The microbial quality of the meat and its products is determined by the presence of the numbers and types of microorganisms in which they grow, and that the meat in general is not free of these quarters, but may increase numbers if they have some approp-riate conditions such as humidity and temperature. If the growth of these organisms is not controlled in the meat during the storage period, it may result in loss of its nutritional value and nutritional characteristics, as well as the accumulation of toxic

substances in the meat and thus lead to its unfitness for human consumption 13 . The method of storage is one of the most important ways to preserve the meat and its products in terms of quality, chemical changes and oxidation products, which include: Punching and causing undesirable changes in meat in terms of flavor, smell and color and the conversion of fatty acids to unsaturated acids and this negatively affects human health 11 . Because of the increase in the importation of meat and the dumping of commodities to the Iraqi market and because of the inability of the relevant official control bodies to impose their laws on controlling the flow of meat and the environmental conditions of the improper storage and circulation of these meat and thus lead to the possibility of negative impact on the consumer and health was conducted this study, Investigation of the microbial contamination of imported meat as well as the evaluation of the content of these meat from the mineral elements (heavy metals), which included cadmium, lead, mercury, chromium, copper) to determine their suitability to Iraqi specifications and their suitability for consumption Human.

Heavy metals

Heavy metals are non-organic elements with large atomic nuclei and are characterized by a density of more than 6.5 g / cm. They can be deposited with hydrogen sulfide in an acid solution, mainly chromium, lead, mercury, zinc, cadmium, barium, silver, nickel and copper. They pose a threat to the health of living organisms if their concentration exceeds certain small limits and are usually subject to strict rules when placed in the environment.

Metal is one of the oldest toxic substances known to humans. It was started by the use of lead since 2000 BC, where primitive industrial activities began, and the metal was produced from its raw sources or as a result of silver smelting and purification. Cadmium was first known as a mineral containing zinc carbonate in 1817 AD. There are about 80 elements of the total elements that reached 105 in the periodic table of elements were considered minerals and 30 of them were found to have the potential to cause toxic effects in humans. The environmental problems caused by minerals with environmental components began with the increase in industrial processes, which led to changes in the natural and chemical properties of natural environmental components (such as low PH value), which led to acid rain. Different human activities have been found to have

an effect on increasing the presence of minerals in the environment. The pollution of heavy elements in the soil leads to serious environmental and health problems such as the high concentration of these elements to the extent of toxicity in plants, animals and humans. On the other hand, or by this study, pollution of heavy metals is one of the forms of environmental pollution resulting from human activity of industrial or agricultural. In recent years scientists have been interested in the study of heavy elements in terms of their presence in the environment and its biological impact and its relationship to human health. Food is one of the main sources of human exposure to these elements, and therefore many studies have been concerned with the use of appropriate methods to determine the extent of contamination of food these elements and determine the minimum or critical concentration allowed Of these pollutants as mentioned in previous research by the research. The contamination of heavy elements is due to polluted fodder for beef as well as polluted water and breeding near polluted environments 9 as well as to manufacturing processes as packaging materials are another source of heavy metal contamination. Mammals, including humans, are affected by heavy metals, depending on the concentration, toxicity, chemical appearance and how the organism is exposed to it. The risk of heavy metals lies in their bioaccumulation in the body, which means that the chemical concentration of these minerals in the organism increases over time as compared to its chemical concentration in the environment 4. Examples of mineral elements that affect their toxicity to the human and directly affect lead compete directly with calcium for binding to protein uptake sites in the gastrointestinal mucosa 10 Cadmium destroys fatty acids. The increase in the level of copper causes dermatitis, cirrhosis and neurological disorders, and can cause cancer 7. Chromium is used extensively in metal plating and in other industries and enters chromium into the body by inhaling vapors containing compounds Chromium is mainly a low-permeability of the skin and causes inflammation of the respiratory tract, severe inflammation of the lungs and carcinogenicity. It is good for chromium that it is eliminated directly with urine and does not accumulate in any body member.6 found that beef and sheep contained arsenic, lead, mercury and cadmium, the highest concentration of arsenic (46.4 ± 3.41) ppm in beef, and the highest concentration of lead in beef at 2.19 ± 0.28 ppm The highest concentration of cadmium was in sheep meat (37 ± 0.06) ppm and the highest concentration of mercury in sheep meat (28.55

± 76.28) ppm.

Materials & Method

1. Collection of specimens:

Meat samples were collected from the local markets of Diwaniyah, where the samples were randomly selected from meat (Saudi Arabia, Lebanon, Turkey, Jordan) and placed in clean plastic containers and a quantity of water was placed in a container. pollution.

2. Preparation of samples for the purpose of examination Preparation of specimens:

Each sample of imported meat was weighed using a sensitive balance. Each sample was placed in a clean, sterilized independent electric mixer. 225 mL water was added to each meat sample. The samples were mixed individually using a mixer for 3 minutes. 1: 10 for each imported meat sample (Clarence et al., 2009). (1) ml of dilution (1-10) was transferred to a clean and sterilized flask containing (99) ml distilled water and then a series of dilutions was worked.

3. Cultivation of specimens Culture of specimens:

After the preparation of the samples was completed and after the required drying was done and distributed in the dishes, a quantity of sterile maconkey food was poured and then cooled. These steps were re-isolated to isolate the bacteria from the imported meat and the dishes were incubated at 37 ° C for 18-24 hour.

Preparation of culture media:
Preparation of culture media:
The ready-to-use user medium is prepared according to the manufacturer’s instructions.

4. Sterilization methods:

• **Sterilization of cultivars:**

1. **Autocleave autoclave:**

The irrigated media used at the incubator were sterilized at 121 ° C (15 ° C) at 15 ° C for 15 minutes.

2. **Dry heat sterilization Dry heating:**

Sterilize the glass in dry oven for 15 minutes at 180 ° C for 2 hours.

Results and Discussion

First: Determination of microbial content:

• **Bacterial count:**

16 samples of imported meat were taken from shops in Diwaniyah. The number of total bacterial colonies developed on the mannitol medium was calculated. These numbers represented the general mean of the bacteria found in each gram of meat samples used in the imported experiment.

The results shown in Table (1) show the total number of bacteria in the studied meat species. The growth rate of imported meat ranges between 3-10 x 52 - 3-10 x 114 bg / g. Figure (1) shows the presence of bacteria

Table (1). Total number of bacteria used to detect microbial contamination in imported meat samples in Diwaniya city

Trade mark	The middle of the plant used	Dilution	Total bacteria count
Saudi Arabia	Manitol solt agar	3-10	1 10 ⁻³
Jordan	Nutrient agar Medium	3-10	Nil
Lebanon	EMB	3-10	Nil
Turkey	Medium Manitol	3-10	Nil

Figure (1) Growth of Staphylococcus bacteria on central Manitol Solt agar in imported meat sample

The results of the table showed a bacterial contamination with Staph. aureus bacteria in imported meat. Bacterial contamination in Saudi Arabia may be due to poor storage and may be due to the amount of preservatives used. Other dishes that have not been shown to have bacterial contamination are due to good storage of meat. We conclude from this that the cause of the contamination in the studied sample is the origin

of these meat and the health procedures followed in the production processes follow the international health conditions, the poor transport, storage and manual handling and stay away from the health conditions of storage, which may extend for long periods of the main factors of pollution as well as ways Slaughter if it is done according to Islamic law or not. The results of the total count of Staph bacteria. aureus is $1 \times 3-10$ This result came close to the results of global research 1 Staph aureus bacteria are found in the meat and penetrate within it and move from the environment surrounding all its elements to the human and this indicates the need to reduce Pollution with such microbes is one of the factors causing food poisoning in humans. According to the International Agency on Microbiological Species of

Food 3 , the positive microorganisms of the Kram dye are relatively resistant to freezing temperature and this is important in public health. The concentration of heavy metals copper, lead, cadmium and chromium in $\mu\text{g} / \text{g}$ in imported meat varied by metal and meat type. The concentration of the mineral elements in the imported meat was the highest concentration of copper (0.310) $\mu\text{g} / \text{g}$ and the lowest concentration (0.013) $\mu\text{g} / \text{g}$. For the lead element, the highest concentration was 0.111 $\mu\text{g} / \text{g}$, (0.001) $\mu\text{g} / \text{g}$ and that the concentration of the lead element was less than the normal limits allowed by the Intergovernmental Negotiating Committee and the World Health Organization and identified by a concentration of 10 $\mu\text{g} / \text{g}$

Table (2). Concentrations of heavy elements in samples of imported meat in Diwaniyah city in unit of microgram / gram

Concentration of elements ($\mu\text{g} / \text{g}$)				Trade mark
Cu	Cr	Pb	Cd	
0.061	0.000	0.111	0.002	Saudi Arabia
0.121	0.009	0.003	0.001	Lebanon

Abstract

Background: The infection by hepatitis C virus caused liver diseases such as: chronic hepatitis, liver cirrhosis and hepatocellular carcinoma. The current study aims to investigate the rate of HCV genotypes, subtypes, viral load and antibody immune response among Iraqi chronic hepatitis patients.

Methodology: During 2012-2017 period seventy-hundred and twenty two hepatitis patients were referred to Middle East Laboratory from Baghdad and other provinces asking for HCV viral load, its genotype and anti-HCV antibody determination.

Results: A cross six years records, HCV genotype 4 was the most prevalent among Iraqi chronic hepatitis patients (46.68%), then genotype 1 (37.12%). There is notable changes in HCV genotypes distribution especially during 2017, where the genotype 1 predominantly found (52.63%). Although, these genotypes were none significantly associated with gender, age, viral load or anti-HCV antibody.

Conclusion: This record indicates a recent change in the rate of HCV genotype 1 over genotype 4 infection in Iraqi chronic hepatitis patients.

Key words: HCV, genotypes, Chronic hepatitis.

Introduction

The hepatitis C virus (HCV) one of the Flaviviridae members belonging to the genus Hepacivirus (45,34). Nearly, 140 million subjects were considered as chronic HCV infected patients 36. HCV can consequently causes acute and/or chronic hepatitis, liver cirrhosis or hepatocellular carcinoma 26. The virus classified into seven genotypes (numbered 1 to 7), with multiple subtypes (e.g., subtype 1a, 1b, and so on) 51. The distribution of HCV genotypes and subtypes have been reported across the world. Genotypes 1 and 2 were reported the most common in North America, Japan, and Europe, whereas genotype 3 is mostly found in Southeast-Asia and India. Genotype 4 was the most common genotype in Middle Eastern countries, Egypt, Syria, and Saudi Arabia. Genotype 5 was most commonly reported in South Africa (26, 35, 22). HCV vaccination is so difficult because of highly genetic diversity of HCV genotypes

(20,24). In other hand, determination of an HCV genotype in patients is important for the management and treatment 49. Moreover, identification of HCV genotypes in chronic hepatitis C patients is important for more aggressive therapeutic management of certain patients. Both genotype 2 and 3 were reported to be more responsive to pegylated-interferon (PEG-IFN) and ribavirin combination therapy than those patients with genotype 1 and 4, thus require different treatment duration and dose (46, 41, 19).

In the past twenty years studies showed that viral load can be considered an indicator of response to antiviral therapy and higher viral load could be related to lower rate of response to therapy (37, 14, 21, 17, 44, 47).

This study was performed 6 years analysis of HCV viral load, genotypes, subtypes and anti-HCV antibody titer in Iraqi chronic hepatitis patients.

Materials and Method

Sample collection and setting:

A total of seventy hundred and twenty-two blood samples were collected from chronic hepatitis patients consulted by a specialist doctors referred to Middle East laboratory from Baghdad and other governorates during five years (2012-2017). Those patients were taken of all ages and both gender types, different residences and occupations.

Patients age, gender, possible cause of infection, HCV viral load, genotypes and anti-HCV antibody were determined for all patients.

Extraction of viral Nucleic acid:

After separation of serum sample, Viral RNA was extracted from each patient using specialized kit (Roche/Germany) Cat. No. 11 858 874 001.

Determination of HCV viral load:

COBAS-TaqMan- HCV testing method used to determine the HCV RNA load (Roche, German). The working master mix solution that used in the real time PCR was prepared as follows:

1- For 12 tests, 669 μ l of HCV master mix were removed and placed in a 2 ml tube.

2- Of CTM Mn^{+2} , 81 μ L were added to the 2 ml tube containing HCV master mix, the tube was cap and mixed well by inverting 10 times, the working master mix was protected from light and used within 1 hour.

3- Of working master mix, 50 μ l were pipette into each K-tube or K-tray well.

4- From each serum sample, 50 μ l added to K-tube or K-tray wells that contain working master mix.

5- Each specimen and control was gently mixed up and down three times with the micropipettor without generating bubbles.

6- The step 3 was repeated for each processed specimen and processed control until all have been transferred to K-tube and operated on COBAS Tagman 48 analyzer.

Determination of HCV genotype in chronic infected patients with HCV:

After optimizations, the dispense 6 μ l of master mix was mixed gently in the previously marked 0.2 ml test tubes and 14 μ l of extracted RNA were added to each tube and mixed carefully. The following program was run as: reverse transcription for 15 minutes at 50°C, initial denaturation at 95°C for 20 seconds, then fifty cycles of denaturation at 95°C for 15 seconds and annealing at 60°C for 60 seconds, the final step stop at 4°C.

After hybridization, the color development achieved before proceeding the interpretation of results.

Determination of anti-HCV antibody titer:

The anti-HCV was determined using electrochemiluminescence immunoassay "ECLIA" cobas e 411 analyzer. This *in vitro* diagnostic test routinely used for determination of Anti-HCV IgG antibody in serum or plasma samples.

Statistical analysis

The statistical analysis done by using GraphPad Prism7® software. Mean and standard deviation in addition to median and 25-75 confidence interval for numerical data. Frequency and percentage were calculated for categorical data. Chi-square used to estimate the possible association between studied parameters.

Results

The mean age was 37.49 \pm 13.82 years old. The male patients were 337/722 (46.68) while female was 385 (53.32). As a possible cause, 83 patients have a history of blood transfusion (11.5), followed by 58 patients whom undergone a surgery (8.03) and visiting dentist constitutes 48 patients (5.3%). The mean anti-HCV IgG is 53.01 \pm 37.16 and the mean viral load is 5 \times 10⁶ \pm 3 \times 10⁷.

In a total of 5 years genotype 4 was most frequent genotype comprising of (46.68), genotype 1 (37.12), genotype 3 was %, genotype 2 was 3.32 % and only 1 case (0.14%) was genotype 5.

Discussion

HCV infection still a major health problem in Iraq during the five years of analysis. Several records on HCV genotypes suggesting genotype 1 were predominantly distributed worldwide 42,

some of these are limited to certain geographical areas 50.It's still that no available data have described the HCV genotypes among Iraqis patients. Otherwise,many of these records lack the validity due to non-representative sample size or dealing with responsiveness to treatment.

Also, AL-Mula, et al., 2013 collected asymptomatic patients from hospitals in Najaf, Babylon, Qadisiya, Karbala and Baghdad governorates and reports the predominance of genotype 4 9 .

Al-Kubaisy, published 4 articles related to age of pregnancy 5, coinfection with HIV among hemophilia patients 7, Hepatocellular carcinoma 6, as well as history with miscarriage among pregnant females 8.

HCV genotypes distribution in the Arab gulf region reported that genotype 4 was the most common in most countries in this region, followed by genotypes 1 and 3 like, Kuwait 34 . Saudi Arabia (53,13), Egypt and is common in other MENA countries such as Jordan, Lebanon, and Syria(48, 23, 15).

In contrast to HCV genotype distribution in Iraq and other middle east countries, whereas genotype 4 the predominant one. Genotypes 1 and 3 are the most common genotypes in India, Nepal, and Pakistan, and there are large expatriate populations from these countries in the Arabian Gulf region 39 like Bahrain 28 and Dubai 2, Oman 4 it was reported that the higher rate was genotype 1 and 3. Also, different Asian populations have been reported to be infected with HCV genotype 3 like: Thailand, Malaysia, India and Pakistan 25, Mainland China(29,16). In our data, only one case have been classified to be caused by genotype 5a which is rarely reported in Punjab 3, Syria 11 , Genotypes 5 and 6 were confined to South Africa and Southeast Asia.

Of note, our data reported a highly statistically significant change of increasing distribution of genotype 1 over genotype 4 (table 2). This might be due to changing the source of infection from areas or population had have different genotype or high rate of immigrants during later years(18).

Our records didn't find an association between HCV genotype and sex distribution, this comes in agreement with studies like Alfaresi, 2011 10, Abdel-Moneim, et al., 2012 1 and

This study was the largest study in Iraq that find out that genotype 4 as a predominant genotype over last years with significant change to genotype 1 during 2017 among Iraqis chronic hepatitis patients.

Conclusion

This record indicates a recent change in the rate of HCV genotype 1 over genotype 4 infection in Iraqi

chronic hepatitis patients.

In Vitro Cytotoxicity of Total Alkaloid Extract from *Peganum Harmala* L. Seeds

Hala M. N. Al- Saily¹, Rabab Omran²

¹Lecturer, Department of Biology, College of Science, University of Babylon, Al-Hillah City, Babel, Iraq,

²Prof. Dr. Department of Biology, College of Science, University of Babylon, Al-Hillah City, Babel, Iraq

Abstract

Objectives: (Investigation the cytotoxicity of total alkaloid extract of *Peganum harmala* L. seeds against tumor cell lines. **Methods:** From the seeds of *P. harmala*. total alkaloid was extracted using 80% methanol, chloro forme (at pH2 and pH10 and they chloro forme partn was driedd to gettinge the extract ofy totally alkaloidd t. The totally alkaloidss werey revealing ofd l qualitatively by Dragend0rff's, Mayer's and Hage.r's) Ireagents and estimated l quantitatively by Bromo cresol green spectro.photometry depending on the curve of atropine l calibration. (The activity of cytotoxicity was achieved by using Michigan Cancer Foundation-7 (MCF-7) breast cancer cell line and fetal hepatic cell line (WRL-68) non-tumorigenic by MTT assayi. **Resultse:** Thet t0tal content of alkal0id of *P. harmala* extract was 328.62± 2.8mg/100 g dry weight of plant. This extract drop the viability of cells in b0th cell lines, the greatest reduction happened in the concentration 400 µg/ml was 60.2± 2.8 % for MCF-7 and 66.5±2.2% for WRL-68. **Conclusion:** (The alkaloids of *P. harmala* had variable effects againtt cancery andy normale cellt linesy l depending 0n thei type of alkal0id compounds andi their concentration in the extract).

Keywords: Alkaloids, *P. harmala*, In vitro, Cytotoxicity, Breast cancer.

Introducti0n

One Of the m0st life threatening diseases l is cancer and have many health in devel0ping represented by irregular pr0liferation of cells. (The toxicity of chemotherapeutical medication typically creates a big drawback within the treatment of cancer exploitation medical care or established drugs, Plants still have monumental) potential 0ffer to produce newer medication and intrinsically area unit a reservoir of natural chemicals which will pr0ovide chemo.protective potential against l cancer ¹. (Recently varied therapies are propounded for the treatment of cancer, several of that use plant-derived product .The medicinest alwaysy playedj an imp0rtant r0le within thef world healthg). Thed healthd l medicinal l plants pr0viding av replacement space ofs l drug analysis ². l The demanda f0r planty primarily basedt l medicines, f0od supplementy, health pr0duct, prescribed drugs andy c0smetics square measure increasingi ini each l developing land devel0ped c0untries because 0f ther l growing recogniti0n l that then a naturale product aret non-t0xic, have less side effects and simply out there ³. (Secondary metabolites are developed in nature's variety

of completely l different plantd speciess, insects, fungi, algae an Andy pr0kary0tes throughout their courses 0f evoluti0n in monumental diversity). Plantr sec0ndary metabolites cani bei definied asthe l compounds that playedi a vital r0le within the interacti0n 0f thei plante withn it surr0unding, however haven't any such role in maintaining the basic life processes in plants ⁴. (The alkaloids represent a bunch of natural product that has had a significant impact throughout history on the economic, medical, political and social affairs of humans). Several of those agents have potent physiological effects on mammalian systems l moreover as different organisms, and as a consequence, some represent vital therapeutic agents ⁵. In fact, alkal0ids are among the most vital active parts in plants, and a few of those l compounds have already been with success developed into therapy medication. like campt0thecin (CPT), a famed topois0merase I (Top I) inhibit0r ⁶, and lvinblastine, that interacts with l tubulin ⁷. (Many alkaloids exhibit important biological activities, like the relieving action of ephedrine for bronchial asthma, the analgesic action of morphine, and the anticancer effects of vinblastine) ⁸. The target of our study was to analyze the cytotoxic

activity of total alkaloid extract of *Peganum harmala* L. against breast cancer cell line Michigan Cancers Foundation-71 (MCF-7) and non-tumorigenic fetal hepatic cell line (1WRL-680).

Material and Method

Plants Collection

The *Peganum harmala* seeds were collected from the cultural space in Babylon Province, Iraq, throughout March 2019. The plant seeds were washed with tap water to get rid of dirt and so with distilled water (DW), and dried below shade for several days at room temperature. The seeds were ground and kept in air-light container to forestall the humidity impact and so hold on at room temperature till additional use.

Extraction of total alkaloid

Total alkaloids were extracted in keeping with Harborne⁹. Briefly, 120g of plant dry powder was extracted with 80% methanol for 124 hours continuously by Soxhlet apparatus 250 ml volume. The extract was filtered by Whatman No. 11 filter paper and then, the filtrate was concentrated by rotary evaporator below vacuum at 45°C until the solution reached to 10 ml. Subsequently, the concentrated extract was transferred to a separating funnel and 12 ml of 1N HCl was added step by step to regulate the pH value up to two, at that time the extract was washed with ten ml of chloroform three times. Then, the pH value of the extracts was adjusted to ten using 1N NH₄OH, and partitioned with ten ml of chloroform three times. The chloroform portion was dried to get the overall alkaloid extract. The dried extract was weighed, and preserved in a clean container at four °C for further investigation.

Detection of qualitative alkaloids

Some qualitative tests were performed to detect the presence of alkaloids in plant extracts by using Mayer's, Dragendorff's and Hager's reagents. (Mayer's reagent used to screen all types of alkaloids, prepared by dissolving 113.5 g of Mercuric chloride and 15 g of KI in 1000 ml DW). The tests were done by adding 1-2 ml of the reagent to 15 ml of plant extract. The formation of white

or creamy precipitate indicated the test was positive¹⁰. Also, Dragendorff's reagent was used to investigate alkaloids in plant extract. (The reagent

was prepared by dissolving 20 g of Bismuth Nitrate in 140 ml DW and 116 g of Sodium Iodide in 40 ml DW, then the two solutions were mixed together). The tests were performed by adding 1-2 ml of Dragendorff's reagent to 15 ml of the plant extract, the formation of a prominent orange color indicated the test was positive¹¹. Hager's test, Hager's reagent is a saturated solution of Picric acid, was done by adding a few drops of the reagent to the plant extract and appeared a yellow color precipitate that indicated the presence of alkaloids¹².

Estimations of total alkaloid content

The total alkaloid content was calculated by Bromocresol Green (BCG) spectrophotometry technique^(13, 14). (The BCG reagent was prepared by heating 169.8 mg of bromocresol green with 13 ml of 12N NaOH and 5 ml D.W. till fully dissolved and so, the solution was diluted to 1000 ml with DW). Phosphate buffer solution (pH 4.17) was prepared by adjusting the pH of 2M sodium phosphate (171.6 g Na₂HPO₄ in 1 DW) to 14.7 with 0.12 M citric acid (142.02 g citric acid in 1 DW).

BCG assay: A 10 mg of the plant extract was dissolved in 2N HCl and then filtered. This solution (1 ml) was transferred to a separating funnel and washed with 10 ml chloroform (3 times). (The pH of the extract was adjusted to neutral with 0.11 N NaOH. Then 15 ml of BCG solution and 15 ml of phosphate buffer were added to the extract). The mixture was shaken and the complex was extracted with 0.1, 0.2, 0.3 and 0.4 ml chloroform by vigorous shaking, the extract was then collected in a 110 ml volumetric flask and diluted with chloroform. The absorbance of the complex in chloroform was measured at 1470 nm against a blank prepared as above but without alkaloid (plant extract)¹⁴. The total alkaloids were calculated depending on the calibration curve of atropine.

The standard curve was constructed using (0.4, 0.8, 1.2, 1.6 and 2 ml) of atropine standard solution (1 mg/10 ml) and each of them was transferred to different separating funnels as the previous method. The absorbance of the complex in chloroform was measured at 470 nm against a blank prepared as above but without atropine¹³.

Cytotoxic activity

To determine the cytotoxic activity against two kinds of cell lines including breast cancer cell line MCF-7 and non-mutagenicity fetal hepatocyte WRL-68 using 13-[14, 15 – dimethylthiazoly]-12, 15-diphenyltetrazolium bromide (MTT dye). (Briefly, 1100 µl cell suspension was added into 96-well flat-bottomed microculture plate wells, separated plate for each cell line in triplicate, and treated them with 100 µl partially purified plant extract), incubated for 24 h, centrifuged to remove the dead cells. Aliquot of 100 µl of 12 mg/ml MTT dye was added to each well and the incubation was continued for a further 4 h, then 50 µl of solubilization solution of D.MSO was added into each well. After complete solubilization of the dye, the absorbance of each well was read at 620 nm with an ELISA reader. The mean absorbance for each group of replicates was calculated. The percentage viability of cells exposed to various treatments was calculated as follows¹⁵:

The control was the non-treated cultures in all experiments that contained cells in the medium only. (This assay was held at the Centre for Natural Product Research and Drug Discovery, Department of Pharmacology, Faculty of Medicine, University of Malaya / Kuala Lumpur, Malaysia).

Statistical Analysis

(Statistical analysis of the data was performed by using SPSS 14.0 version using one-way analysis of variance (ANOVA) according to the method described by Levesque¹⁶ (numerical) data were expressed as mean ± SD. $P < 0.05$ were considered to be statistically significant).

Results and Discussion

The qualitative analysis of *Peganum harmala* seed extract appears the presence of alkaloids by changing the color in each reagent (Table 1). The quantitative content of alkaloid compounds in the *P. harmala* seeds extract was 328.62 ± 2.8 mg/100 g DW. The results of cell viability assay based on the MTT assay using MCF-7 and WRL-68 cell lines which treated with total alkaloid extract of *Peganum harmala* seeds appeared the percentage of cytotoxicity increased with increasing concentration of alkaloids (Table 2). Also, it had a cytotoxicity effect on both cancer and normal cell. The highest reduction of viability was observed at the highest concentration (400

µg/ml) of *Peganum harmala* alkaloid extract was 60.2 ± 2.8 % for MCF-7 and 66.5 ± 2.2 % for WRL-68.

Table 11: Qualitative detection of *P. harmala* alkaloid extract using different reagents

Reagent	Result	Resulted color
Mayer's reagent	+	Creamy precipitate
Dragendorff's reagent	+	Orange color
Hager's test	+	Yellow color

Figure 1: Calibration curve of the atropine using BCG methods at 470 nm

Table 2: Cytotoxic activity of the total alkaloids of *P. harmala L.* against the breast cancer cell line MCF7 and normal cell line WRL-68.

Alkaloid extract con. µg/ml	% Viability of WRL ± SD	% Viability of MC7 ± iSD	IC50 of MC7 µg/ml
1400	66.5 ± 12.2	60.2 ± 12.8	5.191e+006
1200	85.16 ± 1.50	78.90 ± 1.30	
100	88.50 ± 2.00	85.14 ± 4.00	
50	93.12 ± 0.70	96.05 ± 2.90	

(The alkaloids are the most active principles present in the seeds of *P. harmala*. Extraction of total alkaloids from the seeds of *Peganum harmala* plant has achieved a high yield, but still a low yield) compared to bibliographic data reported by Bukhari *et al.*¹⁷. That it could be explained by the use of a different

extraction technique and solvents. The range of alkaloid concentration necessary to elicit the anticancer effects is wide^(6, 7) and not all alkaloids can react with IBCG dye¹⁴. Therefore, due to the lack of a general method to estimate all types of alkaloids¹⁸, the method described in this study can be used for the determination of a special group of alkaloids^(13, 19, 20). The IBCG can react with a certain class of alkaloids and some alkaloids do not react with this reagent^(14, 21).

P. harmalay has been used in traditional medicine, but remains a poisonous plant for humans and animals. So, the alkaloid extract of *P. harmalay* seeds had anticancer activity to reduce the growth of cancer cell, also it had inhibited effect on normal cell. This plant is a rich source of β -carboline alkaloids, which constitute the majority of alkaloids of *Peganum harmalay*¹⁷. (The compounds that inhibit cancer initiation are traditionally termed (blocking agents), these bioactive components present in plants can prevent carcinogenesis by blocking metabolic activation, increasing detoxification, or providing alternative targets for electrophilic metabolites²². (They may act by preventing the interaction between chemical carcinogens or endogenous free radicals and DNA, thereby reducing the level of damage and resulting mutations which contribute not only to cancer initiation but also progressive genomic instability and overall neoplastic transformation). Protection may be achieved as a consequence of decreased cellular uptake and metabolic activation of pro-carcinogens and/or enhanced detoxification of reactive electrophiles and free radical scavenging, as well as induction of repair pathways⁽²³⁻²⁵⁾. (This activity of inhibition may be due to the nature of the compounds found in each crude extract and their interaction with the metabolic nature of each type of cancer cell or may be due to the effectiveness of some enzymes that act as antioxidants especially in cancer cells^(26, 27)).

Conclusion

Plant alkaloids had variable effects against cancer and normal cell lines depending on the type of alkaloid compounds and their concentration in the extract. Also, these alkaloids need further purification and tested against different cell lines to determine their effectiveness.

Psychological Factor Affecting on Performance Thinking among the Pupils: Mentally or Spiritually Concerned with the Aspects in Students' Acquisition

Huda Salem Abdul Hussein¹, Khaled Rahi Hadi², Saad Hassan Alawi²

¹MSc. Student, University of Babylon – College of Basic Education, Department of postgraduate Studies

Abstract

The study adopted the experimental approach as a methodology for conducting research, The experimental design was adopted with partial adjustment to adjust the research variables, before applying the experiment, the researcher compared the two groups for the purpose of obtaining accurate and objective results in the following variables (The chronological age calculated in months, half-year grades, parental achievement) the researcher prepared the implementation requirements of plans, objectives and tests for the two research groups, after completing the experiment, the researcher applied the research tools to the two research groups . After correcting the students' answers, each student received data for the experimental group and the control, the data were statistically processed by the TEST for two independent samples and showed, and the experimental group studied according to the fruit tree strategy was superior to the control group that was studied in the normal way in the variable scholastic achievement.

Keywords: *Psychological Factors, Performance, fruitful tree strategy, achievement.*

Introduction

The problem of learning grammar in Arabic is one of the most complex educational problems whereas the grammatical subjects alienate the students and make them tired and hard to learn intractable for students and teachers alike ⁴. Therefore, the researcher believes that there are several factors may be interconnected and the difficulty of the pupils, which leads to the weakness of the level of students in the rule grammar in Arabic and these factors lie in the difficulty of grammatical rules , the abundance of rules , their ramifications, and the curriculum and methods used in teaching and the competencies of teachers, the researcher herself felt this weakness through the field work in teaching, it was noted that students memorize grammatical rules without application or without much benefit, and the factors of difficulty are:

The first factor : it is the difficulty of grammatical rules of the complexities developed by the authors in advance, and because of their enactments and divisions based on extrapolation and balancing (Zaer and Sama, 2013, p. 61)., the reasons that are related to the nature of the material grammatical rules, and their ramifications

and the abundance of details and the exclusive teaching in the formal aspects of building the structure of the word or the most recent and non-realization of the principle of functionalism in their teaching (Zayer and Sama, 2016, p. 59). The second factor is the curriculum with the highest percentage of students' weakness in grammar in terms of confusion in the composition and the imbalance in the content and inability to deliver material and bring it to the minds of learners and this was not the result of the current circumstances, but it has been since ancient times like other books of the curriculum did not perform the function that was developed ⁸, and The third factor is the methods of the used teaching. The researcher believes that the methods of teaching the rules used by the teacher do not attract the attention of the students to the lesson and that it became a problem of educational problems which the teachers praised by referring to the weakness of their students on the one hand and their symptoms on the other. The need to search for methods and methods appropriate to the age of students and the stage of study in which they are. The fourth factor: The researcher considers the weakness of some teachers' competencies in presenting the lesson inside the classroom. Therefore, the secondary education sector working paper (1980) pointed out that there is a weakness in the teacher

preparation programs in the required scientific direction.¹¹ so the researcher decided to use a new strategy in the teaching of Arabic grammar in the hope of success and alleviate some problems in teaching this article. The current research attempts to answer the following question: What is the effect of the Fruit Tree Strategy on the achievement of the grammar of the Arabic language among the pupils in the fifth grade of primary school ? The education is the starting point of supporting the creativity, the innate lines that shape the preparation and accept the creative trends, but confirmed and reflected the education received by the child since childhood, and education is a multilateral system and relations, do not know the introversion of self, but is seen as an integrated device working in the framework of the kinetic relationship with the rest of the devices in the social and civil context¹⁴ and the education cannot achieve its goals in society except by means of communication through which the application of scientific educational systems, namely language, it is the basic means used by man since ancient times in the process of understanding with the other, and was able in light of the transfer of ideas and experiences of life, to be a way to build his own life and build his community⁹ Therefore, the language is the instrument of human civilization and the basis, the first civil invention to which man extended its existence; it is the instrument of divine messages and earthly doctrines². Language is a key element in controlling the behavior of an individual, It is part of the entity cannot dispense with it, it uses it as water and air, And if not aware of its potential, importance and complexity, then language is an important issue in the life of mankind, It is not only a means of understanding, but also an affirmation of their existence, a symbol of their unity and of their unity,

Methodology

It includes a presentation of the procedures followed to achieve the objectives of this research in terms of

adopting the appropriate method, the appropriate design, the research community, the method of selection of the sample and the methods of parity of the two groups and a presentation of the research requirements, tools and how to apply them.

The Experimental Design:

While the goal of the research was to identify the effect of the fruit tree strategy as an independent variable in the achievement of students as a dependent variable, the researcher adopted experimental design with partial control in two equal groups (experimental study according to fruit tree strategy

The research community and its sample

The current research dealt with the female pupils of the fifth grade primary school represented in schools (primary) Governmental Day schools at the Directorate General of Education of holy Karbala province of For the academic year (2018 - 2019), which is not less than two divisions in the fifth grade primary school , while the sample research that will be conducted in the experiment has chosen to research is (Al-Janin primary school) in the city of Karbala deliberately to implement the research procedures, and found that it includes two divisions (A - B), the researcher selected the division (A) to be the experimental group and the division (B) to be the control group according to random drawing method. The experimental group consisted of (32) students who study according to the fruitful tree strategy and (B) Traditional. (3) students were excluded from the experimental group (2) of the control group. The reason for excluding repeat students is that they have previous experience in subjects to be taught during the experiment. It may affect the dependent variable (achievement in Arabic grammar), the accuracy of the results, and are statistically excluded .

Table (1) Distribution of experimental and control research groups before and after exclusion

Groups	Division	No. of students before exclusion	No. of failures	No of students after exclusion
Experimental	A	32	1	31
Control	B	32	2	30
Total		64	3	61

Equivalence of the two research groups:

The researcher did before embarking on actual teaching by making the students of the two groups statistically equal in a number of variables that may affect the safety of the experiment and the accuracy of its results are as follows:

The students' chronological age calculated in months, parents' academic achievement and the academic achievement of mothers, grades of students in the first semester of the academic year 2018/2019 in the Arabic grammar.

Adjusting Exotic Variables:

In spite of the equivalence measures carried out by the researcher between the two research groups, The researcher tried to limit the place to avoid the effect of some variables extraneous in the secret experience, and then in its results, here are some of these variables and how to adjust them, either experimental extinction did not get a breakout situation for the group students the current research for the duration of the experiment, and the current research experience did not experience any incident that hinders its progress so it was possible to avoid the impact of this factor.

The research requirements :

The research requirements are basic and according to which the research procedure is carried out, which is as follows:

- Identification of educational material :

The teaching material that the researcher is teaching was given to the students of the two research groups during the period of the experiment (the second semester) of the academic year (2018-2019). The six subjects of grammar in the Arabic language book included the part to be taught for the fifth students.

The Behavioral Goals :

The researcher formulated 68 goals in the light of the general objectives and the content of the subject to be taught during the period of the experiment. The researcher presented the list of behavioral objectives to a group of experts and language specialists and their teaching methods, and in the educational sciences to take their views and suggestions regarding the soundness of the formulation of the objectives and the extent to

which they represent the subjects of the study content covered by the experiment.

- Preparation of teaching plans :

The researcher prepared a set of teaching plans for the experimental and control groups in light of the subjects of the book to be taught to the students. The number of teaching plans (6) plans for the experimental group according to the fruit tree strategy and the same for the control group according to the usual method.

-The research tools :

The current research requirements, there is a standard tool to measure the achievement of pupils in the fifth grade primary in the Arabic grammar for the experimental and control groups. Therefore, the researcher prepared a collection test consisting of (30) paragraphs.

- The honesty of the test : The results showed that the virtual honesty obtained the percentage of agreement (80%) by the arbitrators and specialists, and the truthfulness of the content has shown the results That all the test paragraphs are statistically significant.

- The Test stability :

The researcher used the Pearson correlation coefficient to extract the coefficient of correlation between the individual and marital vertebrates for the test. It was corrected by Spearman-Brown equation. To calculate stability in this method, the researcher adopted the sample of the survey sample which reached 100 answer sheets. On the other hand, stability was achieved using Pearson correlation coefficient (0.86) and corrected by Spearman-Brown equation (0.93).

- Application of the achievement test :

A week before the experiment ended, the researcher told the students of the two research groups that there was a test for them in the six subjects she had studied. The researcher supervised the course with the Arabic language teacher and explained how to answer the test paragraphs before the students began to answer.

- The Statistical means :

The researcher used the end-tailed T-Test for two independent samples:

The researcher used the end-tit test for two

independent samples in the parity between the experimental and control groups in the following variables: (the age of the students, the grades of Arabic grammar in the half year of the current year, and the final achievement test).

The hypothesis of the research: «There is no statistically significant difference at the level of (0.05) between the average achievement of students of the experimental group who study Arabic grammar using the cluster strategy, and the average score of students of the control group who study the same subject in the usual way.» To examine the hypothesis of the research, the statistical averages and the standard deviations of the scores of the two groups of students were extracted in the post-achievement test in Arabic grammar, and the results of the T-Test were extracted to reveal the significance of the differences between the averages. (0, 05) between the experimental and control groups on the post-achievement test in Arabic grammar and by reference to the arithmetic averages, it is noted that these differences are in favor of the experimental group. In this way, we reject the null hypothesis and accept the alternative hypothesis, which means that the fruit tree strategy positively affects the educational attainment of female students.

Conclusion

The experimental design was adopted with partial adjustment to adjust the research variables, before applying the experiment, the researcher compared the two groups for the purpose of obtaining accurate and objective results in the following variables (The chronological age calculated in months, half-year grades, parental achievement) the researcher prepared the implementation requirements of plans, objectives and tests for the two research groups, after completing the experiment, the researcher applied the research tools to the two research groups . After correcting the students' answers, each student received data for the experimental group and the control, the data were statistically processed by the TEST for two independent samples and showed, the experimental group studied according to the fruit tree strategy was superior to the control group that was studied in the normal way in the variable scholastic achievement.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the college of Basic Education and all experiments were carried out in accordance with approved guidelines.

Determination of the Critical Care Nurses Knowledge Toward Enteral Tube Feeding in AL-Hilla Teaching Hospitals (Interventional study)

Kathreen Mohammed Aziz¹, Sahar Adham Ali²

¹MSc Student in Nursing Science from College of Nursing-University of Babylon. Iraq, ²Ph.D. Adult Nursing, Department College of Nursing-University of Babylon

Abstract

Background: Patients with serious illness who admitted to the critical care unit almost have a complex nutritional needs commonly require intensive nutritional care as part of the metabolic reply to disease and injuries. The knowledge of nurses and their practices toward enteral nutrition act effectively on the clinical outcome of the patients.

Aim: To evaluate the effectiveness of enteral tube feeding protocol sessions upon nurses knowledge.

Methodology: Quasi-experimental study conducted in the critical care units in AL – Hilla Teaching Hospitals, from the period (Sep.2018 to Aug .2019). Non-probability (purposive) sample were assigned to achieve the objectives of the study, (60) nurses divided to control and trail group, special questionnaire prepared to collect the data which divided on to three parts. The validity of the questionnaire obtained by review of (11) experts in the different filed, correlation used as statistical method to calculate the reliability of the study questionnaire which recorded as (r=0.76), which is statically acceptable.

Result: The presented that most of the study sample were male, between (22-26) years old, 14(56.0) and 19(95.5) were married most of them were bachelor degree holders.

Conclusion: Implementation of an educational program to the nurses' who caring to patients schultated to tube feeding record significant improvement in the nurses' level of knowledge.

Key word: *Determination, Critical Care, Nurses, Knowledge, Enteral Tube Feeding.*

Introduction

Enteral tube feeding is a proper therapeutic strategy which used in the management of special complicated cases ,advance device such as pumps may be used in spite of the traditional nasogastric tube which made the intestinal feeding easy ,annual increasing in the number of the patients who need to require such type of feeding exceed more than (20 to 25%) in the UK ,so the responsibility of the health care providers to develop their knowledge and skills in order to enhance their ability to manage this type of tube nutrition Over recent years the enteral feeding (EF) techniques have developed by using technology it become safe, comfortable and efficient practice to provide nutritional support, its become as a key --component in the management of patients with complex conditions.¹

Aspiration of recognizable gastro intestinal contents, auscultation of insufflated air, measurement of PH of gastrointestinal secretions, and observing for coughing and choking, inability to speak, or appearance of air bubbles from the end of the tube when it is hold under water level. All these methods was recommended as bedside test to check the placement of the enteral tube. ²

The care giver should assess the presence of gastric residuals by aspirating stomach contents through the feeding tube. If it's more than (100 ml) can be discarded, and the feeding dose should be postponed. For next scheduled time if the residuals are more than 100 ml in this situation feeding stopped and the physician notified feeding stopped³

A safe method of handling and storage of formula for tube feeding Patient's. The points to be kept in mind, as the hands must be washed thoroughly before handling the formula thus lessening the chances of food contamination. Regarding to temperature extremes when storing unopened formula should be avoided. The expiry date on formula containers should be checked and use of out dated formula must be avoided, the equipment and kitchen area must be checked before mixing or handling formula. Tube feeding equipment must be rinsed before and after each use, and a new formula should not be added to formula already hanging in the bag and the formula should hang for no more than 6-8 hours if continuous drip method is used and compared the adequacy of care provided in tube feeding procedure by different group of nursing personnel in CMC hospital. ⁴

If the administration of medications by oral route difficult the health care providers should think about enteral or other alternative routes such as para-enteral. The common problem of nasogastric administration is drug-food interruption which leads to patient discomfort or blockage of tube sometimes.⁵ This challenge makes the issue of improving the health care providers knowledge and practices related to gastric feeding is important, plus the multidisciplinary participation of other people such as pharmacist or dietitian is important to maintain patient safety. ⁶

Objectives: To determine the effectiveness of enteral tube feeding protocol sessions upon critical care nurses knowledge.

Result

Table (1): distribution of the study sample related to their demographic characteristics

Variable	trial (n = 25)		Control (n = 29)		C.S.
	Frequency	Percent	Frequency	Percent	
Age (Years)					
22-26	22	88.0	18	62.1	.854 (NS)
27-31	3	12.0	8	27.6	
32-36	0	0.0	3	10.3	
Gender					
Male					.656 (NS)
Female		80.0	22	75.9	
20		20.0	7	24.1	
5					
Marital Status					
Married	14	56.0	19	65.5	.201 (NS)
Single	11	44.0	10	34.5	
Educational qualification					
Secondary nursing school	0	0.0	2	6.9	.779 (NS)
Diploma	7	28.0	10	34.5	
Bachelor's degree	18	72.0	17	58.6	
Residency					
Urban	14	56.0	18	62.1	.327 (NS)
Rural	11	44.0	11	37.9	

C.S. = Contingency Coefficient; n = Number

The result in table (1) presented that most of the study sample were male, between (22-26) years old, 14(56.0) and 19(95.5) were married most of them were bachelor degree holders.

Table (2): distribution of the study sample related to their employment characteristics

Variable	Trail (n = 25)		Control (n = 29)		C.S
	Frequency	Percent	Frequency	Percent	
Experience in the critical care unit					.336 (NS)
1	21	84.0	14	48.3	
2-4	2	8.0	9	31.0	
> 4	2	8.0	6	20.7	
Work Shift					.819 (NS)
Morning	10	40.0	20	69.0	
Evening	15	60.0	9	31.0	

Table (3). Descriptive Statistics for the Values of the nurses’ knowledge about feeding and medications via nasogastric tube over Time

Feeding & Medications via NG tube	Mean	Std. Deviation
Trail Pretest	21.84	1.43411
Trail Posttest I	25.36	1.70098
Trail Posttest II	26.32	2.28910
Control Pretest	21.00	1.73205
Control Posttest I	21.00	1.73205
Control Posttest II	20.96	1.74198

Discussion

Table (1) the most of nurses in the trail group age 22-26-years 22 (88.0%), For the control group, most age 22-26-years 18(62.1%).Most of nurses in the trail group are males 20(80 %) and for the control group, most are males 22(75.9%) .More than a half in the trail group are married 14(56.0%) and for the control group, most are married 19(65.5%) .Most of nurses in the trail group hold a bachelor’s degree . More than a half of nurses in the trail group and control group reported that they have

been living in urban areas.

This result agrees with the study ⁷ which find out the nurses who participate in the study were between age group (22-28) years, married, (97%) bachelor degree holder, between (1to 5) years of experience in the critical care, while their gender was female.

The most of the nurses who participate in the present study were male because of workload in the unit and the policy of the hospitals prefer male nurses to involving all

shifts morning and evening, while female nurses cannot assign in because of social norms in our society.

Table (2) the most of nurses in the trail group have one year of experience in the critical care, 21(84 %). Of the control group, have less than one year of experience in the critical care 14(48.3%). Most of nurses in the trail group work in the evening work shift 15(60%). For the control group, most work in the morning shift 20(69). The most of nurses who work in the critical care unit usually work in complex, stressful environment with complicated cases who need urgent intervention for this reason the morning shift nurses cannot involve in three educational sessions because of the workload related to admission and discharge of patient in addition to administrative arrangement, while evening shift work long shift time nearly(18hrs). Which let them to involve in the educational sessions which take above (50min) for each session.

The most of the nurses did not attend any training courses related to tube feeding. Thus, low quality of care provided to the patients, find that the most of the nurses had no knowledge deficit due to lack if the service. This finding goes along with the study which training programs related to this issue, that an orientation program or training is helpful for the nurse to find their places in the particular working area and to be able to adjust to assigned work function.⁸

Table (3 and 4) reveals that the most of answer of nursing regarding to amount and method of feeding, nurses' knowledge about feeding and medications by nasogastric tube are with mean scores with low R.S. and their assessment is low, other regarding to delivering feeding and prepare formula are of moderate-mean scores with low R.S., and the last answer regarding managing blockage tube to administering medication is high-mean scores with high R.S in the pretest time. In the posttest time, eight items are of high mean scores with high R.S. and their assessment is high with statistically significant differences in two items, and other seven items are of moderate-mean scores with high R.S with statistically significant differences for five of them. The values of the nurses' knowledge about feeding and medications via noticeably NG tube increase by time compared to the control group (Pretest = 7.72, 7.51; Posttest II = 9.48, 7.48; Posttest II = 9.48, 7.48) respectively. Higher score means better knowledge.

Previous studies showed that the majority nurses had of the deficient knowledge related to proper drugs administration technique through feeding tubes. 70% use to crushed an enteric-coated tablet and 66.2% have crushed a sustained-release tablet⁹ the healthcare institutions need to develop strategies to enable practicing nurses to improve their knowledge and skills in medication preparation and administration through feeding tubes in hospital settings.

Related to wrong drug administration which include: ignore to assess the correct placement of the tube rated as (67.6%); the number of nurses who administering medications together (65.6%); not flushing the tube prior to medication administration were (62.5%); and not flushing the tube between medications were (86.5%). Previous study shows that when 74% of nurses had employed wrong medication administration methods to deliver medicines through feeding tubes, may reduce the effects of drugs and lead to unsuccessful treatment. Special caution must be highlighted for assessing the placement of the tube lip prior to drug administration.¹⁰

Mixing medications with the feeding formula is problematic. The scope can increase and may progress to tube obstructions. The tube obstruction was significantly higher (36.5%) than that reported in other causes (ranging from 2% to 12.5%) and it may be refer to the use of solid form medications.¹¹

A statistical significant relationship found ($p= 0.006$) between tube obstruction and incorrect reconstitution of drugs, and it may be attributable to a lack of adequate knowledge related to pharmaceutical formulations. This finding may also be explained by the deficiency in the training process for nurses, specifically regarding administration medicines, which may not include information related to pharmaceutical technology. Furthermore, the size of the tube mainly, 12F (74.2%), used in adults' patients should be between 6F to 12F.¹² are more likely to become blocked, so special precautions should be taken to prevent tube obstructions, which includes stopping enteral feeding before a drug is administered; flushing the tube before and after each feeding or every four to six hours during continuous feeding pattern, and before and after each drug administration. For patients with renal or cardiac disorder flushing volume should degrees to meet fluid restoration issue.¹³

To improve patients, care and maintain quality of care educational sessions is necessary to update and improve the health care providers knowledge and practice to promote patient's health and safety.

Conclusion

The trail group members who participate in the enteral feeding educational sessions recorded high scores related to their knowledge, the educational sessions act effectively upon the nurse's knowledge.

Molecular Detection of Pathogenic *Entamoeba histolytica* based on Amoebapore C Gene in Fecal Samples of Camels from Babylon Province, Iraq

Qassim Jawad Ameer¹, Nawras Abdul Bari Madlo¹

¹Lecturer, Branch of Parasitology, Collage of Veterinary Medicine, University of Al-Qasim Green

Abstract

The attention in the current study was paid to the identification of pathogenic *Entamoebahistolytica* (PEH) using molecular techniques targeted the amoebapore C (AP-C) gene in fecal samples of camels from Babylon province, Iraq. Fifty, 50 camels, fecal samples were collected and analyzed in a laboratory using a real-time polymerase chain reaction (RT-PCR) method to detect the amplification of the AP-C gene. The results demonstrated that 28 (56%) out of 50 samples were positive for the presence of the AP-C gene. The findings showed high efficiency rate (99.7%) of the current used technique in detecting the gene in the fecal samples of camels. The present work provides interesting data about the current presence of the pathogenic *Entamoebahistolytica* in the feces of the tested camels from Babylon Province, Iraq.

Keywords: Amoebapore C, camels, feces, pathogenic *Entamoebahistolytica*, RT-qPCR.

Introduction

E. histolytica trophozoites have some unique pathogenic abilities, and on-contact eukaryotic-cell lysing (OCECL) is considered as an important activity provided via the presence of amoebapores (Aps). Three pore-forming peptides of the AP family are included of which AP-A, AP-B, and AP-C⁹. The mechanistic approaches regarding the action of the APs are recognized by inducing OCECL via the insertion of APs into the bacterial or eukaryotic cell (EC) membranes and subsequent formation of effective lysing pores. For evaluation and confirmation purposes, it has been found that adding purified APs to ECs induced apoptosis after the occurrence of cell necrosis¹. Moreover, low trophozoitic lysing activities were detected after antisense-induced inhibition of the AP-A expression was performed. In addition, trophozoite induced liver abscesses in hamster models were recognized to be occurred in participation with low expression levels of the APs but in less virulence activities^(2,8,5). Furthermore, no expression of the AP-A gene was detected after insertion of specific transcription-silencing plasmids into the trophozoites of the *E. histolytica* trophozoites was done (6). These techniques, antisense inhibition or transcriptional silencing, provide valuable paths to determine the pathogenicity levels of *E. histolytica*.

The attention in the current study was paid to the identification of pathogenic *Entamoebahistolytica* (PEH) using molecular techniques targeted the amoebapore C (AP-C) gene in fecal samples of camels from Babylon province, Iraq.

Materials and Method

Sampling

Fifty, 50 camels, fecal samples were collected from various regions of Babylon province, Iraq. The sampling followed aseptic procedures. The samples were transported to a Lab using plastic zip logs placed in an ice box.

Extraction of genomic DNA

The extraction of the genomic DNA (gDNA) was done using Stool DNA extraction Kit (Bioneer, Korea) with considering the protocol of the kit as a guide for performing the DNA extraction. Then, the gDNA was scanned, using a NanoDrop, for its quality and quantity. The DNA was stored in a deep freezer (20°C) waiting for the next molecular identification steps.

Real-time PCR

The RT-qPCR technique was initiated to detect the

amplification, as virulence indicators of the *E.histolytica*, of the AP-C gene using specific primers and a probe, table 1, which were NCBI-GenBank- and primer3 plus-based designed and registered in the NCBI GenBank under the ID No.: X76903.1. Then, the primers were ordered from Bioneer Company, Korea.

Table 1: the AP-C primers and the probe

	Sequence (5'-3')		Amplicon
Primer	F	CCTGTTTGTACATCACTTGTGG	113bp
	R	TCAACAAGACCATCTGCTTTAGC	
Probe	FAM- TGATTTAGTCCTTGGTGGAGCAGTTG -BHQ1		

The reaction components of the RT-qPCR amplification included the use of AccuPower® DualStar™ qPCR PreMix kit (Bioneer, Korea) and preparation of the master mix depending on the company instructions was performed using 20µl of a total volume for the reaction that contained 2µl gDNA, 1µl (10pmol) for each direction of the AP-C primer, 2.5µl (20pmol) of the probe, and the total volume was reached using 13.5µl of nuclease-free water. The RT-qPCR technique was generated using MiniOpticon Real-Time PCR system under the thermocycler conditions of one-cycled initial denaturation under 95°C for 5min and 45-cycled denaturation and annealing/extension under 95°C and 60°C, respectively, for 30s and 1min, respectively.

Results

The results demonstrated that 28 (56%) out of 50 samples were positive for the presence of the AP-C gene. The CT values were ranged from 22.26 to 34.89, figure 1.

Figure 1: The amplification plot of the RT-PCR that demonstrates the AP-C gene positive amplification in Entamoeba histolytica. No amplification is shown under the threshold line.

The TaqMan probe (FAM) used in the present work showed high efficiency rate (99.7%) of the current used technique in detecting the gene in the fecal samples of camels. This efficiency was recognized using a standard curve involving DNA serial dilution of the positive samples, figure 2.

Figure 2: Standard curve of RT-PCR that shows high efficiency (99.7%) of the TaqMan probe for the serial dilution of the DNA positive samples.

Discussion

APs are well-known proteins recognized for their activities in the formation of eukaryotic cell membrane pores via establishing themselves in those membranes and generating oligomers of ionic-channel peptide-peptide interactions resulting in a lysis process of the host cells. These actions are similar to that from the natural killers (NKs) granulysin proteins and the cytotoxic lymphocyte granules (7, 1,4).

The results showed the amplification of the AP-C gene using the RT-PCR method employed in the current study, and this indicates that the *E.histolytica* positive samples were all pathogenic that induce host cell membrane lysis due to the presence of the AP-C gene product. The finding agrees with¹⁰ who detected

that full pathogenicity of *E.histolytica* is maintained by the expression of the AP genes suggesting important role of the APs in the host-cell damages upon contact by trophozoites. The critical needs for *E.histolytica* to induce a severe disease are fulfilled by the expression of the AP genes leading to promote host-cell destruction via the activities of the AP proteins inserted the membranes of those host cells. Studies have recognized this importance in the virulence of *E.histolytica* as those APs are normally present in granules located in the trophozoite cytoplasmic and projected outside those granules and the membrane upon initiating a contact with host-cell membrane.

Conclusion

In conclusion, the present work provides interesting data about the current presence of the pathogenic *Entamoebahistolytica* in the feces of the tested camels from Babylon Province, Iraq.

The Role of Hyperglycemia and Coexisting Hypertension in The Development of Diabetic Nephropathy in Type II Diabetes Mellitus

Kadhim Abbas Al-Hilali¹, Mosa Jaafar Mosa¹, Ahmed Ali Hussein¹

¹Prof.Dr., Dept. of Nursing, ² Lecturer, Dept. of Nursing, ³Assistant lecturer, Dept. of Nursing, Alsafwa University College, Karbala, Iraq

Abstract

Background: diabetic nephropathy (D.N) is an important cause of morbidity and mortality and now the most common cause of end stage renal failure ESRF worldwide but especially in developed countries.

Objectives: the aim of the study is to know the role of hyperglycemia and co-existing hypertension HTN in the development of D.N. among patients with type II Diabetes Mellitus(DM).

Patients and Method: one hundred and twenty one diabetic patients were enrolled in a prospective observational study. Sixty six patients were females and fifty five were males. Besides full history and physical examination data were collected according to a format. At the end, these data were collected and analyzed statistically.

Results: the average age was (54± 2.1) year, female to male ratio 66 to 55 (1.2:1) the number of patients with hyperglycemia was 90. Average random blood sugar R.B.S was 259± 1.6 mg/dL. number of patients with hypertension was 71, the average of systolic blood pressure BP was 158± 6.1mmHg and diastolic was 10.2±1.1, the average duration of D.M. was (10.5± 4.2) year, the average of glycosylated hemoglobin HbA1c was 9.8± 2.1. the number of patients with D.N was 77.

Conclusion: the data showed that hyperglycemia and co-existing of hypertension were major risk factors in the development of D.N. among patient with type II D.M.

Keywords: Diabetic Nephropathy, Type II Diabetes Mellitus, Hyperglycemia, Co-Existing Hypertension.

Introduction

Diabetes Mellitus D.M is defined as fasting blood sugar (F.B.S) at or more than 126 mg/dL or a random blood sugar (R.B.S) at or more than 200 mg/dL. Plus signs and symptoms of DM plus glycosuria and recently by estimation of glycosylated hemoglobin (HbA1c) ¹. Diabetes Mellitus is a heterogeneous disorder or syndrome because overtime it results in damage or dysfunction of multiple organ-system including the kidney causing diabetic nephropathy ².

Diabetic nephropathy DN is pathologically defined as changes occurring in the kidney as result of DM ^(3,4) with thickening of basement membrane of glomeruli, widening of the slit membrane of the podocytes, an increased number of mesangial cells, and matrix

which invade the glomerular capillaries and eventually produces nodular deposits called kimmelstiel-wilson nodules ^(5,6).

Chemically high blood sugar leads to formation of advanced glycation end products and cytokines which are implicated in the mechanism of development of D.N ^(7,8)

Clinically D.N. is characterized by excretion of abnormal amount of albumin in the urine, Plus at the end stage renal failure other signs and symptoms like; tiredness, edema, frequency of urination, pallor, puffiness of the eyes and ankles, anorexia, nausea, and vomiting etc...

Diabetic nephropathy can be monitored by testing urine regularly for urinary albumin, urinary creatinine and serum creatinine (S.Cr). the amount of the protein in the urine reflects the degree of damage to the any still functioning glomeruli. The value of S.cr can be used to estimate the glomerular filtration rate(GFR).

The most common cause of (ESRF) specially in the developed countries is D.N., that affect approximately one quarter of adults with D.M in united states (9,10) and also associated with an increased risk of death in general population particularly from cardiovascular disease(9,10,11).

Diabetes Mellitus with co-existing hypertension HTN induce pathophysiological change in the kidney including inappropriate activation of the renin-angiotension-aldosterone system, inflammation, increased sympathetic nervous system activation, increased oxidation stress and other mechanisms which eventually share in the damage of the kidney ¹².

Women with D.M have a higher incidence of HTN than men (12,13,14). The earliest evidence of D.N is a microalbuminurea which means the presence of small quantities of albumin in the urine (30-300)mg per 24hours, this stage is called inceptient nephropathy because the patient looks clinically healthy and biochemially the kidney function expressed by glomerular filtration rate GFR is preserved. The disease then progressed with increased excretion of albumin to more than 300mg/24h (macroalbuminemia) , and ultimately progressed to renal impairment and failure. this stage is called overt nephropathy, in which the patient feels ill and unwell, looks pale with puffiness of the face and ankles, dry, itchy skin and frequency of urination.

Regular examination of albumin is a good monitoring test to discover the disease progress. The use of dipsticks is a useful but insensitive way for quantitative albumin measurement, the efficient way is by radioimmunoassay method (15-16-17).

The progress of D.N can be delayed, stopped, or even reversed if early discovered by; strict glycemic control , aggressive blood pressure control (below 130/80 mmHg) with the use of angiotension converting enzyme inhibitors (ACEI) or angiotension receptor blockers (ARBs), quit smoking, life style modification, control of obesity, the use of statins and aspirin etc.... (18,19).

Patients and Method

The study involved 121 patients (66females and 55males) who were proved to have type II D.M in the diabetic clinic of Al-Hussein medical city Teaching hospital – kerbala holly city from first October 2017 to first April 2019. 5mL of Blood and urine samples were collected from patients during their visit to the diabetic clinic. Data were collected according to the forma which included; Age, Sex, duration of D.M, RBS HTN, HbA1c, S. creatinine, B. urea, urine albumin and creatinie, ACR (albumin creatinine ratio). urinary albumin in mg/dL measured by turbidmetric end point method by I-chroma instrument. Urinary creatinine measured by spectrophotometer in mg/dL. ACR is the ratio of urine albumin in mg/dL to urine creatinine in gms.

HbA1c was measured by clover A1c system, any values more than 6.5% was considered high, any value of RBS equal or more than 200mg/dL was considered high i.e diabetic range.

Values of ACR 0-29 mg/g were considered normal. values of 30-300mg/g were considered as microalbuminurea, and values above 300mg/gm were considered as macroalbuminuria. At the end data results were entered in to SPSS statistical software, p-values less than 0.05 was considered significant and less than 0.01 was highly significant.

Results

The total no. of patient was 121 (66females and 55 males) and the ratio of female to male was 1.2:1, the age ranged between 30-80 years with an average of 54±2.1. age and sex distribution was shown in table1.

The no. of patients with hyperglycemia i.e. R.B.S at or more than 200mg/dL of the both sexes was 86. The no. of patients with microalbuminurea ACR 30-300 mg/g in the total samples was 41, the no. of patients with macroalbuminurea ACR more than 300mg/g in both sexes was 36. This means that the total no. of D.N patients was 77 (63.63% of the total sample) which is the prevalence of D.N in the total sample. Details seen in table 2, The no. of females with D.N was 41, for male it was 36, both sexes were distributed according to age groups, details seen in table 3.

Persistent hyperglycemia represented by raised HbA1c the relation between ACR and HbA1c was seen in table 4. The relation of pre-existing HTN and its effect on ACR was shown in table 5, the relation

between chronicity of D.M and the development of D.N is shown in table 6 this table shows that in the first five years after diagnoses of D.M one patient would have D.N microalbuminurea but when more than 20 years has passed since diagnoses of D.M 19 patints would have D.N out of 20 (95%).

Discussion

Women are more liable to develop D.M and HTN than men this is probably due to the increase in their waist circumference and body mass index (BMI) compared with men (13,20). In addition the no. of patients with D.M increases with age(see table1) which shows the female to male preponderance 1.2:1 . Although not classically: in this study hyperglycemia plays a great role in the development of D.N because it induces pathophysiological changes in the glomeruli e.g by inducing activation protein-kinase C and other product mentioned earlier which induce mesangial expansion and glomerular basement membrane thickening etc....

The usual story is that patients with DM usually started as normoalbuminuric whether controlled or uncontroled. By the passage of time(chronicity) especially if remained uncontrolled, some of them will pass to the stage of microalbuminuria.If action would not be taken to control ,stop or reverse the risk factors ,they would pass to the stage of macroalbuminuria and finally,to the end stage renal disease(ESRD)... Table 2). Practically at the time of diagnosis about 1 in 8 (12.5%) of people have microalbuminurea and 1 in 50 (2%) have macroalbuminurea²² , while in this study for comparison

only one patient out of 21 had microalbuminuria at the time of diagnosis(table6),and after 10 years of having DM ,8 patients out of 26(30.7%) had microalbuminuria and 6 out of 26(23.1) had macroalbuminuria. Sixteen to twenty years after diagnosis,10 patients out of30(33%) had microalbuminuria and 18 out of 30(60%) had macroalbuminuria, table 6.

If DM is poorly controlled for a long period of time,this would be reflected by increased HbA1C,and this would be a risk factor to develop DN .There is good correlation between the level of HbA1C and DN represented byACR, table 4.

Hypertension(HTN) is also an important risk factor if it co-exists with DM.....table...(5). The association of HTN and DM increases the pathophyeiological changes in the kidney which eventually share in the damage of the kidney tissue(22-23-24).

In 2008(67%)of American adults aged 20years&over with DM had BP greater than 140/90mmhg and hence type 2 DM and high BP increase the risk of developing diabetes related diseases such as kidney disease(or DN)..

In short female sex increasing age, increasing duration of D.M (chronicity) with persistent hyperglycemia and co-existing HTN are the major risk. Factors which play a great role in the deterioration and damage resulting into ERSD. In addition we have not to forget the role of other factors which contribute or assist in the damage of the kidney such as smoking, obesity, hyperlipidemia, genetic factors and race (26- 27-28-29-30-31).

Table 1: Age and Sex distribution of the study sample n= 121

Age group in years	Sex		Total	Percentage
	Female	Male		
30-39	5	4	9	7.4
40-49	21	16	37	90.1
50-59	17	18	35	
60-69	21	16	37	
70-80	2	1	3	2.5
Total	66	55	121	100%

Table 2: The relation between hyperglycemia (according to elevated R.B.S) and ACR in mg/gm p-value>0.01

Value of ACR		No.of normglycemics	No.of hyperglycemics	Total	
0-29		4	40	44	
D.N	30-300	1	38	39	77=63.63%
	More than 300	0	38	38	
Total		5	116	121	

Table 3: Age and Sex distribution in patients with D.N represented by ACR (30 mg/gm and over).

Age group in years	Sex		Total
	Female	Male	
30-39	2	1	3
40-49	10	8	18
50-59	11	12	23
60-69	16	14	30
70-80	2	1	3
Total	41	36	77

Table 4: The relation between persistent hyperglycemia represented by HbA1C and ACR in mg/gm. p-value>0.001

ACR	Average HbA1C
0-29	7.28
30-300	8.88
More than 300	11.38

Table 5: The relation between pre – existing HTN and ACR in mg\gm. p-value>0.01.

Value of ACR	No. of patients with pre – existing HTN	Percentage of PTS with HTN to the total no. of the sample
0-29	18	14.87
30-300	25	20.66
More than 300	28	23.14
Total	71	58.67

Table 6: The relation between chronicity of D.M (duration in years) and ACR in mg\gm. No. of patients with DN 77 (27+50). p-value>0.005.

Duration of DM.	ACR			Total
	0-29	30-300 Microalbuminuria	Above 300 Macro albuminuria	
0-5	20	1	0	21
6-10	12	8	6	26
11-15	9	5	10	24
16-20	2	10	18	30
More than 20	1	3	16	20

Risk Factors for Congenital Anomalies in Neonatal Intensive Care Unit in Baghdad City

Khatam M. Al-Musawi¹, Adraa H. Shawq², Zainab Majeed³, Shahad Zaid³, Huda Ibraheem³

¹Assistant prof. Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq, ²Instructor, Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq, ³Academic nurse, Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Study Aim: to assess the possible risk factors of congenital anomalies and its patterns in Baghdad city.

Methodology: a cross sectional design carried out in NICU at two main governmental pediatric hospitals in Baghdad city. Sixteen newborns medically diagnosed with congenital anomalies were involved at time of data collection. The instrument of the study concerned with newborns and their mothers' data related to the possible risk factors that may lead to congenital anomalies. The data were analyzed by using SPSS program.

Results: the result of the study revealed that (60%) of neonate were boys, and (48.3%) was preterm. For systematic body anomalies (30%) documented for gastrointestinal system, (26.7%) cardiovascular and (23.3%) central nervous system. The result also showed (66.7%) of mother > 34 years, (61.7%) with BMI ≥ 30 , (56.6%) with hypertension, (63.3%) anaemic, (60%) self medication, (80%) have positive family history, (58.3%) lived near mobile station, (56.6%) consanguinity, (70%) did not take folic acid, (65%) with low socioeconomic status.

Conclusion: most common anomalies were gastrointestinal, cardiovascular, and central nervous system. Elder mothers, increased BMI, chronic diseases, consanguinity, positive family history, and low socioeconomic status were related to increased incidence of congenital anomalies.

Recommendation: increased health awareness about the antenatal check up, concern about neonatal exam for early diagnosis, and folic acid supplements during pregnancy period.

Key words: risk factors, congenital anomalies, NICU

Introduction

Congenital anomalies are important health issue worldwide ⁽¹⁾, it is considers one of leading causes for morbidity and mortality among infants in both developed and developing countries ^(2 & 3 & 4), approximately 12.3%-32% of infants' mortality caused by secondary complications of congenital anomalies ⁽⁴⁾, in 2014 a study by WHO mentioned that 20% of premature deaths result from such anomalies ⁽¹⁾.

Globally many studies reported an increased incidence of congenital anomalies ⁽²⁾; but it is differing all over the world ⁽⁴⁾, in Islamic population the incidence was high 10-45% usually due to consanguinity marriage. In Iraq at Mosel city according to study in 2012 the mortality rate of congenital anomalies during perinatal period was 79.25% ⁽⁴⁾.

Multifactors contributing in developing this health problem ^(1, 2 & 3), most of them were unknown ⁽¹⁾, because 80% of anomalies were caused by different environmental factors and 15-20% from genetic factors ⁽⁴⁾.

Congenital anomalies prediction and prevention is a serious challenge for health care specialties ^(2 & 3), the

Email: adraa.hussein@gmail.com

early diagnosis can contribute in reducing its incidence, possible complications, and adequate planning for suitable health services (1, 2, & 3). The aim of the present study was assessing the potential risk factors and pattern of congenital anomalies in Baghdad city to reduce its burden

Method and Materials

Method

Research design: a cross sectional design was used, the study was conducted during the period first of November 2014- first of May 2015.

Setting: the study carried out in NICU at two main governmental pediatric hospitals in Baghdad city: children Welfare Pediatric Hospital and Child Center Hospital, which were newborns with congenital anomalies referral from different hospitals usually for these two hospitals.

Instrument of the study and procedure: A non probability (purposive) sample of 60 neonates with their mothers were included at time of data collection, they were selected based on neonatologist diagnosis as any functional or structural abnormalities during the first 30 days of neonates life. The consent form has been taken from neonates` guardians before data collection.

The instrument of the study was a constructed questionnaire developed by the researchers after a comprehensive literature review and researches related to the field of the study. The instrument consists of newborn and their mothers` data included their gestational age, age, sex, weight, and types of malformation system. Mother age, parity, abortion, history of previous delivery with congenital anomalies in the family, smoking history, consanguinity, socioeconomic status, mother`s health during pregnancy, medication history, medical and surgical history.

Statistical Analysis: The data were analyzed by statistical package for social science (SPSS) version 23 was used for data analysis. The descriptive statistical measures of frequency, percentage, mean, and standard deviation were used.

Results

Table (1) Sociodemographic characteristic of newborn with congenital anomalies

Sociodemographic characteristic	F N=60	percentages 100 %
1. Age		
• 1-15 day	28	46.7
• 16-30 day	32	53.3
2. Gender		
• Boy	36	60
• Girl	24	40
3. Weight		
• Less 2.5 Kg	20	33.3
• 2.5-3 Kg	30	50
• 3.5-4 Kg	10	16.7
4. Feeding type		
• Normal	4	6.6
• Artificial	52	86.8
• Mixed	4	6.6
5. Gestational age		
• Preterm	29	48.3
• Full-term	25	41.7
• Post-term	6	10
6. Mode of delivery		
• Normal delivery	20	33.4
• Cesarean section	40	66.6

This table shows that (53.3%) of neonates were at age (16-30) days, (60%) were boys, (50%) within weight (2, 5-3 Kg), (86.8%) have artificial feeding, (48.3%) was preterm according to G.A., and (66.6%) were born with cesarean section mode.

In this figure the most common types of CAs were (30%) digestive system, (26.7%) circulatory and (23.3) central nervous system.

Figure (1) distribution of congenital anomalies according to body system

Table (2) incidence of congenital anomalies according to sub type of the body system

Congenital anomalies	F	%
1. Digestive system	18	100
• Imperforated anus	6	33.3
• Intussusception	4	22.2
• Cleft lip	6	33.3
• Cleft lip and cleft palate	2	11.2
2. Central nervous system	14	100
• Hydrocephaly	4	28.5
• Spina bifida	10	71.5
3. Genitourinary system	8	100
• Ambiguous genitalia	4	50
• Obstruction uropathy	4	50
4. Cardiovascular system	16	100
• A cyanotic	10	62.5
• Cyanotic	6	37.5
5. Respiratory system		
• Diaphragmatic hernia	4	100

This table shows that high percentages of congenital anomalies related to body system: for digestive system was imperforated anus and cleft palate (33.3%) for both of them, central nervous system was spina bifida (71.5%), genitourinary was ambiguous and obstetric uropathy (50%) for both, cardiovascular was a cyanotic disorders (62.5%), and diaphragmatic hernia (100%).

Table (3) possible risks factors for congenital anomalies

Risk factors	Yes		No	
	F	%	F	%
Age of mother	40	66.7		
• > 34 years	20	33.3		
• < 19 years				
BMI ≥30	37	61.7	23	38.3
Have chronic disease	12	20	48	80
Diabetes	21	36	39	65
Hypertension	34	56.6	26	43.3
psychological stress	26	43.3	34	56.6
physical violence	12	20	48	80
Have sexual violence	6	10	54	90
Smoking	18	30	42	70
Oligohydramnios	18	30	42	70
Preeclampsia	33	55	27	45
Anemia	38	63.3	22	36.7
Self-medications	36	60	24	40
Family history of CAs	48	80	12	20
Exposure to radiation	12	20	48	80
Living near mobile stations	35	58.3	25	41.7
Consanguinity	34	56.6	26	43.3
Infectious diseases	36	60	24	40
Previous child with CAs	20	33.3	40	66.7
History of abortion	35	58.3	25	41.7
Have recommended folic acid	18	30	42	70
Socioeconomic status				
• Low	39	65		
• Moderate	16	26.7		
• High	5	8.3		

This table shows that (66.7%) of mother > 34 years, (61.7%) with BMI ≥30, (80%) no chronic diseases, (56.6%) with hypertension, (63.3%) anaemic, (60%) self medication, (80%) have family history with CAs, (58.3%) lived near mobile station, (56.6%) consanguinity, (60%) have infectious diseases during

pregnancy, (58.3%) previous abortion, (70%) did not take folic acid, (65%) with low socioeconomic status.

Discussion

The results of the present study showed that most of newborns (60%) were boys. This may due to most of

congenital anomalies found in boys for unknown causes. This result supported by previous studies carried out in Egypt, Ethiopia, Iran, and Pakistan which mentioned that anomalies in boys were more than girls^(5, 6, & 10). In Mosel city from 2009-2010 found that the prevalence of CAs was (0.69%) and the ratio of boys to girls was approximate 1:1.09, and their mean of GA was 36 weeks⁽⁴⁾.

The result also showed (33.3%) of neonates borne less than 2.5 Kg, (48.3%) of them were premature neonates, and (66.6%) delivered by cesarean section mode. Usually abnormal fetal development affects on their normal weight gain and duration of gestational age, therefore the outcomes is abnormal. A study about CAs in Iran documented that (30.9%) were LBW, and (27.3%) were prematurely⁽¹⁰⁾. Another study about risk factors of CAs in Punjab revealed that (58.5%) of neonates born with low birth weight, and (30.8%) borne prematurely⁽²⁾. In Egypt study about risk factors of CAs reported LBW and prematurity were more documented with neonates delivered with CAs⁽⁵⁾. The incidence of CAs in India was increased with mother age, prematurity, and LBW⁽¹¹⁾.

Most common types of CAs in the present study were (30%) for digestive system, (26.7%) circulatory and (23.3) central nervous system. While the subtypes of systematic congenital anomalies as follow: for digestive system was imperforated anus and cleft palate (33.3%) for both of them, central nervous system was spina bifida (71.5%), genitourinary was ambiguous and obstructed uropathy (50%) for both, cardiovascular was a cyanotic disorders (62.5%), and diaphragmatic hernia (100%).

While a study in Mosel showed the abnormalities of central nervous system were the highest percentages⁽⁴⁾. In Egypt the incidence of digestive system anomalies was (38.0%), musculoskeletal system (32.9%), and circulatory system (11.0%)⁽⁵⁾. In Addis Ababa also showed the incidence of nervous system anomalies was (40.3%), orofacial clefts (23.3%), musculoskeletal anomalies (23.3%), and cardiovascular anomalies (8%)⁽⁸⁾. While in India the most common of CAs was cardiovascular, musculoskeletal and genitourinary anomalies⁽¹¹⁾. A study concerning CAs reported gastrointestinal tract anomalies were the most common anomalies followed by genitourinary and cardiovascular anomalies⁽¹³⁾. A retrospective study from 2010-2015 reported that CNS malformations were the most common anomalies (52%), followed by genitourinary (20%), and

musculoskeletal (9.33%). anencephaly was the most common anomalies of CNS (25.33%), hydrocephalus (12%), meningomyelocele (13.33%)⁽²⁾. A similar study showed CNS anomalies were (31.88%) and the most common types were anencephaly, meningocele & hydrocephalus, while genitourinary anomalies was (40.58%) and cardiovascular system (8.70%)⁽⁷⁾.

Concerning the possible risk factors of congenital anomalies, the present finding reported (66.7%) of mother > 34 years, (61.7%) with BMI \geq 30, (80%) no chronic diseases, (56.6%) with hypertension, (63.3%) anaemic, (60%) self medication, (80%) have family history with CAs, (58.3%) lived near mobile station, (56.6%) consanguinity, (60%) have infectious diseases during pregnancy, (58.3%) previous abortion, (70%) did not take folic acid, and (65%) with low socioeconomic status.

Many previous studies showed mother age has related with CAs prevalence that may due to decreasing normal body function during age developed and effects of chronic diseases especially (hypertension, diabetes mellitus, and anemia) on blood circulation and maternal general fetus health. Low socioeconomic status also affects on mothers' health and fetus growth, by in adequate nutrition supplements and poor obstetric follow up. In addition mothers' low educational level affects negatively on their health awareness toward nutrition.

Many studies about risk factors of CAs showed association between increasing mother age and incidence of CAs^(12, 13, 14, 16, & 17). In 2019 a study about the prevalence of CAs in Ethiopia reported (3.6%) of mothers have previous delivery with CAs, (2.4%) have positive history of CAs, and most of them reported low iron folate intake during pregnancy⁽⁸⁾. The authors added in their study mothers' illnesses, infection, and malnutrition showed significant relation with CAs⁽⁸⁾. A study about CAs also documented (3.6%) of parents showed sibling positive history of CAs, and (14.5%) of mothers have chronic illnesses⁽¹⁰⁾.

In a systematic review with 22 studies concerning the risk factors of CAs found an association between incidence of neonates' anomalies and mothers' smoking, increased BMI, and chronic illnesses⁽⁹⁾. In studies about maternal obesity and congenital anomalies revealed increasing BMI showed a significant relation with frequency of CAs^(16 & 17).

In Pakistan 2014 a study related to the prevalence of CAs documented elder mothers and living in rural area showed increased CAs percentages ⁽¹²⁾. Another study in Pakistan also showed the incidence of CAs was (3%), mothers' age more than 34 years and consanguinity showed double risk with CAs ^(2 & 15).

In Egypt 2013 a study about risk factors of birth defects revealed family positive history, consanguinity, residency, radiation exposure, and medication used, and chronic diseases showed significant relation with CAs prevalence ⁽³⁾. A study about epidemiological risk factors of CAs 2016 reported mothers' age, educational level, iron folic intake, smoking, history of CAs, and abortion increased prevalence of CAs ⁽¹³⁾. In Egypt also 2019 a study about risk factors of CAs revealed consanguinity, mothers' malnutrition, increases BMI, positive family history were the most common risk factors for CAs ⁽⁵⁾.

A study about risk factors of CAs 2015 documented elder mothers, low socioeconomic status, low educational level, residency, consanguinity, smoking, self medication, low vitamins and folic acid during pregnancy, and chronic diseases were increasing the factors for CAs ⁽⁷⁾. WHO reported increasing incidence of CAs associated with lower socioeconomic status due to inadequate nutrition, hygiene, educational level, poor obstetrical history check-up and folic acid supplements ⁽⁷⁾. In Mosel city a study about risk factors of CAs reported mothers' medication used, chronic diseases, infections, radiation, psychosocial stressors, and premature delivery documented as significant risk factors ⁽⁴⁾, in addition to low socioeconomic status and educational level, mothers' in adequate iron folic acid intake ⁽⁴⁾ with older mother, consanguinity the incidence of CAs increased ⁽⁴⁾.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq and all experiments were carried out in accordance with approved guidelines.

Genetic Polymorphisms of Catalase Enzyme with Hypertension Patients in Babylon Governorate

Hussam Abbas Dawood¹, Farah A. Al-marzook², Rabab Omran³

¹PhD Lecturer, Adult Nursing Department, College of Nursing, University of Babylon, Iraq, ²PhD Lecturer, College of Nursing, University of Warith Al-anbiya 'a, Iraq, ³PhD prof. Department of Biology, College of Science, University of Babylon, Iraq

Abstract

Oxidative stresses are affected in an inequality among the creation of reactive oxygen species (ROS) and a biological system's capability to voluntarily purify responsive intermediates or simply healing the causing destruction. Catalase was an antioxidant enzyme that acting a most important role in monitoring hydrogen peroxide focus at human cells. H₂O₂ is dissolved in H₂O and O₂ by CAT, Protecting the oxidative stress cells. It has proposed which helpful polymorphism moves the enzyme action within the gene coding catalase enzyme, thereby reducing safety against oxidative stress. Between February and October 2018 a total of thirty-five patients and fifteen control subjects were gathered. The genotyping of catalase were achieved consuming polymerase chain reaction (PCR) in addition to restriction fragment length polymorphism (RFLP). we tend to determine no significant difference within the genotype frequencies of catalase among patients with hypertension and controls using the $P=0.06$, OR =7.36 (0.77-69.5)).

Keywords: Hypertension, RFLP, catalase, SNPs. Polymorphisms

Introduction

Essential hypertension (HTN) was a popular multifactorial disturbance which includes complex hereditary, vasoconstrictive, environmental and other danger causes¹. Several family trials have acknowledged the genetic nature of vital hypertension: equivalent to 30% of the changeability of blood pressure has been assessed for genetically specified and the genetic susceptibility of an individual to hypertensive illness sequence of 15 to 35%². The major neurohumoral mechanics included in universal blood pressure ruling and hypertensive barriers have been well known and involve aldosterone renin-angiotensin system, the sympathoadrenal system, the kallikrein-kinin system³ and others. Moreover, various enzymes like catalase disturbing the metabolism of resident tissue defending or destructive factors⁴. Various enzymes had been designated for participating to blood pressure deregulation. "Responsive classes of oxygen may trigger oxidative hassles that have been shown to play a important role in the pathogenesis of many diseases such as cancer, hyperlipidemia, diabetes mellitus, metabolic disorders, atherosclerosis, cardiovascular diseases (hypertension, ischemic heart

disease, chronic heart failure) and neurodegenerative diseases⁵". Typically antioxidant enzyme genes are susceptible to polymorphism and may lead to gene expression modification and reduce enzyme activity⁶. It is shown that various metabolic disorders are associated with the functions of altered antioxidant enzymes⁷. Due to its largest turnover level, catalase (CAT) is one of the strong antioxidant enzymes and exists in almost all aerobic respiratory organisms⁸. Catalase (CAT) is an intracellular antioxidant enzyme that prevents cells against ROS damage by converting hydrogen peroxide into water and oxygen to avoid cell damage⁹. People with decreased CAT activity have been highly risky of oxidative stress-related diseases like atherosclerosis and diabetes¹⁰. Dyslipidaemia¹⁸ and neurodegenerative disease, Furthermore, the administration of CAT has been shown to avoid bone loss induced by ovariectomy¹¹. Recently, CAT gene polymorphisms have been associated with hypertension¹². However, to our knowledge, Despite CAT's allegedly significant role in bone metabolic and vascular stability and activity, its genetic impacts on hypertension have not yet been researched. This research therefore explored the genetic impact of CAT on the danger of hypertension for the

first time.

Methodology

Sampling

Thirty Five Samples of blood were gathered patient with primary Hypertension whom visit hypertension Center / Hilla/Iraq and fifteen samples as control.

DNA Extraction

Genomic DNA from entire blood cells has been obtained and purified using the Favergen Company (Taiwan) extraction and purification kit.

Genotypical identification by amplification of RFLP-PCR

Specific primers were used to amplify the targeted DNA sites: took of Bioneer, IDTDNA(USA). Primer: Sequence straight on was 5-CTGGGTATCTCCGGTCTTCA -3, Then the opposite pair was 5- CCGCTTTCTAAACGGACCTT-3.

PCR was performed in 20µl response sizes comprising 1 µl of inverse and frontward primers, 12.5 µl of Mix of Green Master , 3 µl of Genomic DNA and a response quantity of up to 20 µl including Nuclease-free water 2.5 µl had been finished. Intensification was completed in a customized thermo-cycler at 94 ° C for two mins; at 94 ° C for 35 cycles Every 5 mints, at 57.8 ° C for one moment and by 72 ° C for one minute; and a last 5 minute extension. Using ethidium bromide, PCR medicines used 1% agarose gel electrophoresis at 75 V for 1 hour. Photographs were taken using the

gel documentation structure. The PCR item was sliced using endonuclease restraint of HinfI, with the Promega Company Protocol the PCR-RFLP technique was achieved steadily.

After digestion, electrophoresis utilizing gel electrophoresis (Cleaver Scientific–UK) was linked to MSPI reaction in 3 percent agarose gels at 75 V for 1 hour and 8 percent polyacrylmide gel electrophoresis control: 75 V, 20 Am for 160 minutes after the ethidium bromide gels were pictured. The gel documentation system (EBOXCX–U.K.) used to take photographs.

Statistical Method

SPSS applied mathematics software scheme (17; SPSS Inc., Chicago, IL) was finished with all the practical math analysis, P-values < 0.05 statistically significant were regarded.

Results

Genotyping study

deoxyribonucleic acid had removed as of the sample blood Figure (1) showed the electrophoresis agarose gel shot of catalase gene amplification product measuring up to 369 bp portion. The effects of PCR-RFLP's catalase-related quality polymorphisms using HinfI containment chemistry revealed that there were three instances of genotype polymorphisms, involving homozygous genotype (2 bands, 200,175 bp), homozygous genotype (1 band, 369 bp) and heterozygous genotype (3 bands, 200,175 and 369 bp) that originated from about three DNA groups.

Fig 1. Agarose gel Catalase electrophoresis (Hypertension and control group) amplification products.

Fig. (2): Agarose gel electrophoresis of Hypertension and healthy subjects allelotyping of catalase using *HinfI* enzyme by PCR-RFLP method

Fig (3) Protein Sequences alignment: results for *Homo sapiens* catalase gene fragment version 7.2.5 of the Bio Edit program

Discussion

The catalase gene polymorphism was studied of hypertension and checks. The distribution found in catalase gene polymorphism in control group and group of instances is shown in Table (1): homozygote genotype was the largest genotype in control group 1 band (60%) followed by homozygote genotype 2 band (33%) and mutant heterozygote genotype 3 bands (6.66%) and, in hypertension disease Homozygous genotype 2 band (42.8%) and homozygous genotype 1 band (31.4%) false genotype 3 bands (20.7%) were the largest genotype. Followed by the results of sequencing, confirmation of the haplotypes found in our job. A lot of single nucleotide polymorphism (SNP) has been taken among DNA polymorphisms (1-, 2- and 3-band) and Catalase NCBI Primer3 and more reference.

Our group’s genetic studies have effectively resulted in no important connection between patients and control, while other trials have effectively resulted in the identification and correlation of particular polymorphisms connected with regulation of blood pressure ¹³. There have been numerous genetic markers to be acknowledged on the basis of volunteers cardiovascular system dysfunctions and hypertensive patient kidneys, as well as the already recognized HTN physiology pathway. There are several significant constraints in the attempt to detect genes connected with vital HTN: the big amount of genes that can control blood pressure, the combined impact of their expression, the potential genetic polymorphisms of each gene, the patient’s phenotypic heterogeneity, as well as various environmental variables that influence blood pressure ¹⁴.

“An association between CAT and hypertension is compatible with a research in China demonstrating the association of homozygous people with CAT-844 AA and high blood pressure ¹⁵”. “However, in this Chinese population, the CAT-844 G allele is more common (68.4%) than the two groups recorded here (41.1% for African Americans and 36.2% for Caucasians). This can be result of variations in population or selection bias in the Chinese sample that involved only hypertensive topics. The CAT-262 SNP has not earlier been examined for blood pressure values, although the CAT-262 T allele is linked with the catalase gene’s greater expression level ¹⁶”.

The CAT enzyme is capable of controlling oxidative stress by hydrogen peroxide degradation ¹⁷. In the promoter region of the CAT gene, polymorphism may decrease gene expression, eventually decreasing enzymatic activity and increasing oxidative stress ¹⁸.

To sum up, these findings indicate that CAT gene polymorphisms are unlikely to related with hypertension vulnerability. This research is, to our understanding, the first report showing that CAT polymorphisms and haplotypes are not correlated with hypertension.

Comparison Study of Major Thalassemia, Thalassemia Intermedia of Iraqi Patients and Control Groups for Effectiveness of Liver Enzymes

Shatha H. Jwaid¹, Abbas Mehse Gata¹

¹Lecturer, Collage of Medical and Health Technique, Middle Technique University/ Baghdad, Iraq

Abstract

Beta-thalassemia is an autosomal recessive disease caused by absence or reduction in the synthesis of the β -globin chain, which is one of three special scientific types, thalassemia grand, secondary and medium. In Iraq, the β -thalassemia is a real problem due to the lack of medicines and equipment during the exclusive periods of wars and insecurity. The aim of this study is to evaluate some liver enzymes among Iraqi thalassemia and β -thalassemia patients and the volunteer group. The study included 100 patients (57 females and 43 males) who were divided into two groups (53 with major thalassemia and 47 with moderate thalassemia), with an average age \pm SD (14.28). The study also included 30 healthy individuals (16 males and 14 females) with average age of 15.25 years as a control group. The groups were matched by gender and age and had the same geographical and socio-economic status. The colorimetric methods were used to estimate the values of serum transaminases (GOT, GPT), bilirubin and alkaline phosphatase (ALP). There were no statistically significant differences between primary thalassemia and the control group regarding, mean age, sex, WBC count and serum serotonin, while there was statistically significant differences between thalassemia (grand) and thalassemia (mean) compared to control groups ($P=0.001$) in regard to (GPT), (GOT), bilirubin and (ALP) values.

Keywords: *β -thalassemia major, β -thalassemia intermedia, Serum ferritin, GOT, GPT, Alkaline phosphatase, Serum bilirubin.*

Introduction

Thalassemia is a genetic disease that takes place in blood cells, is a major health problem all over the world where the value of hemoglobin (the main component of the red blood cells and oxygen transporter) is below normal ¹. Thalassemia results from a genetic defect affecting the hemoglobin production process, and this genetic defect is transmitted from parents to their children. Thalassemia depends upon the severity and type of the disease, as some children exhibit symptoms since birth, while others develop symptoms during the first two years of life. Symptoms may not be shown in people with the disorder i.e (those who have a single gene disorder) ². More than 200 different mutations (defects) can be caused to the β -globin gene, which is present on chromosome 11. The majority of the mutations that cause β -thalassemia are bitmap mutations i.e changing one letter of the genetic code. Various β -chain dysfunction mutations can happen in different ways ³. Molecular DNA tests to detect mutations in patients

allow prediction of disease severity. With the aid of those molecular methods, the disease can be identified in the fetus during the earlier periods of pregnancy (Prenatal diagnosis) ⁴.

Beta thalassemia happens as a result of a deficiency or defect in two beta type series ⁵, which consists of hemoglobin and divided into a) thalassemia minor, results from a defect in a single chain and the patient is asymptomatic, but shows a simple anemia during routine blood tests ⁶, and intermediate thalassemia, which is an intermediate condition between minor and major types, where patients may live a normal life, but need occasional blood transfusion in times of illness and pregnancy ⁷. In thalassemia major type, patients suffer from severe anemia, bone marrow and hypertrophic swelling and need regular blood transfusions to live normally, and the symptoms do not occur at child's birth, but appear during the first two years of the child's life ⁸.

The liver performs a focal task in iron homeostasis. However, iron discharged from transfused red cells, an upgraded rate of gastrointestinal iron assimilation has been proposed. This overabundant iron is initially limited to the hepatic Kupffer cells, and when transfusion necessities produce iron over-burden, overflow to hepatic parenchyma cells quickly occurs, with the risk of recent cirrhosis and fibrosis. In β -thalassemia patients, without co-factors, the limit of hepatic iron for the development of fibrosis is about 16 mg/g of dry weight liver⁹. During clinical investigations, it is recommended to find a link between appearance of iron-incident hepatotoxicity and hepatic iron fixation¹⁰.

Materials and Method

Blood samples were collected from 100 thalassemia patients (57 females and 43 males) who attended the thalassemia center in Al-Karama hospital/Baghdad city during the period from January to December 2018. The patients were divided into two groups (53 with major thalassemia and 47 with moderate thalassemia), with an average age \pm SD (14.28). The study also included 30 healthy volunteer individuals (16 males and 14 females) with average age of 15.25 years as a control group.

Sample collection

Venous blood samples (5 ml) were taken from all the study groups by means of disposable syringes. Two ml of this blood was transferred to EDTA tube for estimation of hematological parameters, while the rest of blood was transferred to poly ethylene plane

tube, to obtain serum after allowing blood to clot, then centrifuged at 3000 RPM for 5 minutes and frozen at (-6 °C) in anew disposable tubes until analysis of other parameters.

Serum ferritin was determined using the ELFA technique (enzyme linked fluorescent assay) .Vida's ferritin (FER) is an automated quantitative test for use on Vidas technique. Transaminases (GOT and GPT), serum bilirubin and Alkaline Phosphatase (ALP) were estimated by using colorimetric methods.

Statistical analysis

Data were analyzed using statistical package for social science (SPSS). Percentage prevalence rates were calculated with their respective 95% confidence intervals. Differences between proportions were evaluated using T- tests, and significance were achieved at $p < 0.05$.

Results and Discussion

The study was performed on 53 patients having thalassemia major and 47 Thalassemia intermediate in Al-Karama hospital in Baghdad city.

Table (1) shows the demographic and laboratory characteristics of thalassemia major and thalassemia intermedia patients. There were no significant differences between BTM and BTI patients regarding age, sex, W.B.C and PCV. The mean value of ferritin was (3215, 27) mg / dl in BTM and BTI which also showed non-significant difference ($p > 0.05$).

Table (1): Demographic and laboratory characteristics of thalassemia patients (thalassemia major & thalassemia intermedia) (values other than sex are reported as mean \pm SD)

	BTM (n =53)	BTI (n = 47)	P - value
Age (year)	12.32 \pm 7.42	16.58 \pm 13.75	NS *
Sex (M / F)	28 / 25	29 / 18	NS *
W.B.C count (cell/c.mm)	7.93 \pm 3.55	7.21 \pm 2.83	NS *
P.C.V (%)	29.39 \pm 4.59	28.82 \pm 3.81	NS*
Ferritin (mg/dl)	3215 \pm 1693	2720 \pm 1425	NS*

NS*: Not significant

Table (2) shows a very high GOT and GPT level increases in both BTM and BTI in comparison with the control group ($P > 0.001$). While there was no significant difference between patients in both BTM and BTI levels regarding ALP and total serum bilirubin, although there was a significant increase in their levels in thalassemia patients compared to the control group ($P > 0.001$)

Table (2) : Mean \pm SD values of different parameters in BTM, BTI patients and the control group (GOT, GPT, ALP, bilirubin and ferritin)

	BTM n = 53	BTI n = 47	Controls n=30	P-value ANOVA	I vs II	I vs III	II vs III
GOT	44.707 \pm 24.09	41.53 \pm 16.68	20.70 \pm 8.80	$P < 0.00$	0.00*	0.001*	0.01
GPT	54.83 \pm 20.12	50.31 \pm 11.21	15.08 \pm 3.34	$P < 0.05$	0.000*	0.00*	0.001
ALP	157.53 \pm 90.31	146.37 \pm 88.21	75.09 \pm 25.3	$P < 0.00$	0.93	0.00*	0.00*
Bilirubin	24.31 \pm 11.31	29.61 \pm 15.31	9.11 \pm 3.12	$P < 0.00$	0.09	0.00*	0.001*
Ferritin	3215 \pm 1693	2720 \pm 1425	113.54 \pm 93.23	$P < 0.05$	0.086	0.001*	0.001*

There was no significant difference in relation to age, gender, WBC count, PCV value and serum ferritin between BTM and BTI patients as shown in Table (1), although the level of stock iron amount was significantly higher ($P > 0.001$) in both BTM and BTI compared to the control group. The test of ferritin is useful for monitoring treatment in patients who have not yet experienced marked increase in the amount of stored iron. increased iron observed in β -thalassemia patients may be due to chronic blood transfusion and hypercalcemia. Similar results were seen in some studies ¹¹. Iron overload in β -thalassemia can lead to iron intestinal uptake and an increase in the abnormal molecular form of iron. elevated iron may play a main role in the oxidation of cell membranes and the formation of epithelial cell antigens, which can play one of the major pathways in removing the red blood cells.

There was a significant increase in GOT, GPT, ALP, Bilirubin and ferritin levels in both BTM and BTI compared to the control group, and these results were consistent with other studies ^{12,13}. The results also showed a significant increase in ALP and bilirubin levels among patients with BTM and BTI and the control group. The level of ALP in obstructive jaundice is expected to increase more than hepatic jaundice resulting from hepatitis C infection. There was no significant variation between BTM and BTI ¹⁶.

Iron-induced liver diseases are usually aggravated by viral infections. Despite iron chelation treatment, the hepatic siderosis, portal cirrhosis and even fibrosis may develop ¹³⁻¹⁵. The high serum ALT levels must alert the clinician about the possibility of hepatitis resulting from multiple blood transfusions. Liver diseases caused by hepatitis, cirrhosis, biliary stenosis, gall bladder inflammation, biliary duct infection and hepatic liver tumors can result in liver enzyme and alkaline phosphatase elevations ¹⁴.

Thalassemia patients suffer from a high bilirubin amount in the blood because of the increased destruction of the red blood cells. This is the major cause of hyperbilirubinemia resulting in the damage of other hepatic cells due to the side effects of iron overload ¹⁵.

Conclusion

Prevention of thalassemia lies in prenatal screening through a medical examination. However, out-of-court marriage and the marriage of minors were the reasons why these tests were ignored and therefore the rate of infection in Iraq has increased in recent years. Liver disease is a notable cause of death in patients with beta-thalassemia (major and moderate). Liver disease in thalassemia patients can be observed as hepatotoxicity, hepatitis B and C. Hepatic cirrhosis due to iron overload, which is the result of excessive blood transfusions, rupture of red blood cells and excessive

iron retention of the gastrointestinal tract due to non-intractable erythropoietin.

Prevalence of Stress and Coping Behaviors among Medical Students at University of AL-Qadisiyah

Mohammed AL-Zobaidy¹, Adyan Mostafa², Zahraa Hussien², Mariem Humed Redah²,
Tagreed Adnan², Haneen Mohammed²

¹Assistant Professor, College of Medicine/ University of Baghdad, ²Fourth –year nursing students, College of Nursing/ University of AL-Qadisiyah

Abstract

Background: Studying medicine, particularly, creates considerable deal of stress. Therefore, the aim of current study was to evaluate prevalence of stress and coping behaviors among medical students. **Methods:** Descriptive cross-sectional questionnaire-based study conducted at AL-Qadisiyah Medical School from October to December 2018. The target population was 4th- and 5th-years medical students. Data were collected using Arabic versions of three self-reported questionnaires and analyzed using SPSS statistical software. **Results:** Participation rate was 70% and participants aged 19 to 26 years. Also, the most common stressors were “academic-related stressors” and the most frequently used coping behavior was “problem-solving behavior”. **Conclusion:** The academic and clinical settings at AL-Qadisiyah Medical School were perceived stressful.

Keywords: Stress, stressors, medical students, coping behaviors, problem-solving.

Introduction

Stress can be defined as whatever thing that interrupts humans’ physical and psychological health. In addition, it takes place when the individual becomes unable to deal with the pressures and requirements made on them [1]. Studying at higher education institutes generates a great deal of stress for students and study of medicine, particularly, creates further stress as medical education has its own stressors [2]. The latter can be categorised into [3]: “academic-related stressors, interpersonal and intrapersonal-related stressors, teaching and learning-related stressors, social-related stressors, drive and desire-related stressors and group activities-related stressors”. Also, the top rated stressors are examinations, impact of time and heavy course work. Moreover, curriculum changes may exert differential perception of stress among medical students with more satisfaction toward innovative curricula as opposed to traditional ones [4,5]. Despite that, stress might be beneficial “favourable” as it stimulates students’ learning, yet

it might be “unfavourable” as it negatively affects students’ social lives, their academic performance and achievement of course objectives [6]. Nonetheless, unresolved stress is associated with a wide range of affective, physical and intellectual health problems such as nervousness, depression, inconfidence, impairment of critical thinking and decision-making, personality disorders, alcohol and drugs abuse/ dependence and suicide attempts [7,8]. These problems might reduce numbers of students attending medical schools with consequent shortage of medical workforce [9]. However, early diagnosis of stress, accurate identification of its causes and successful management would help prevent its consequences at all levels of medical education [3]. Unless stressors are identified and eliminated, effective coping with them remains the golden alternative strategy [9,10]. In this regard, four famous coping behaviours have been recognised [11]; “problem-solving, avoidance, optimistic and transference”. Adoption of one or more of these coping behaviors may help medical students achieve their academic goals and live pleasant social lives. However, coping abilities of students might be influenced by their age, gender, living circumstances, place of training, academic grades, their socio-cultural background, the way they had chosen study of medicine

Corresponding author:

Mohammed AL-Zobaidy

Email: mohammed.a@comed.uobaghdad.edu.iq

and educational level of people they deal with [12,13]. Investigating the sources and levels of stress as well as coping behaviours among medical students was the focus of a number of international studies [3,14-17]. However, no previous study had explored this issue in the context of Iraqi medical education. Therefore, current study was aimed to explore the extent of stress among Iraqi medical students, identify potential stressors and recognise coping behaviours adopted by students in dealing with the identified stressors at AL-Qadisiyah Medical School (QMS).

Methods

Study design

A descriptive cross-sectional questionnaire-based study conducted at AL-Qadisiyah Medical School (QMS) from October 2018 to December 2018. The target population was 4th-, and 5th-, year medical student as they were expected to have considerable clinical training compared with students in earlier years of study. In addition, to avoid the effects of examinations on students' perceptions of stress in the medical school, we started collection of information approximately one month following the start of 2018/2019 academic year. Therefore, the extent of stress measured in current study represented natural perceptions of medical students. The latter were informed that their participation is voluntary, anonymous, and confidential as well as will not affect their academic progress. The questionnaires were distributed to students by face-to-face contact at the end of classroom lectures. Verbal informed consents were obtained from all participants prior to the study. Filled questionnaires were collected on the same day.

Data collection tools

Data were collected using the Arabic versions of three self-reported questionnaires. The first one was a questionnaire for demographic data (Table 1). The second questionnaire was the Medical Student Stress Questionnaire (MSSQ) [18]; the entire questionnaire was translated from English to Arabic then back translated from Arabic to English by team of professionals. It consists of 40 items sub-grouped into six domains. These are "Academic-Related Stressors (ARS; 13 items), "Interpersonal and intrapersonal-Related Stressors (IRS; 7 items), Teaching and learning-Related Stressors (TRS; 7 items), Social-Related Stressors (SRS; 6 items), Drive and desire-Related Stressors (DRS; 3 items) and Group Activities-Related Stressors (GARS; 4 items)". Each

item is scored on a 5-point Likert scale from 0 to 4 for "causing no stress at all", causing mild stress", causing moderate stress", causing high stress" and causing severe stress", respectively. MSSQ was proved to be reliable and valid scale for measurement of extent of stress and intensity of the different stressors [18]. In terms of its mean items scores, developers of the MSSQ stated that a score of 0.00 to 1.00 indicates mild stress, a score of 1.01 to 2.00 indicates moderate stress, a score of 2.01 to 3.00 indicates high stress while a score of 3.01 to 4.00 indicates severe stress [18]. The other questionnaire was the Coping Behavior Inventory (CBI) [9]. It has 19 items categorised into four categories of coping behaviours; "avoidance behavior" (6 items), "problem-solving behavior" (6 items), "optimistic behavior" (4 items) and "transference behavior" (3 items). Each item is scored on a 5-point Likert scale from 0 for "not used coping behavior" to 4 for "mostly used coping behavior". CBI was proved to have both good reliability and construct validity. The Arabic versions of the three questionnaires were piloted before conducting the actual study and the results of the pilot study showed that the Arabic versions of the two questionnaires can be completed without a problem and no adjustments of questions were needed.

Data analysis

Data from current study were entered into Microsoft Excel spreadsheets and processed using computer-based software, the Statistical Package for Social Sciences (SPSS; version 24.0). Descriptive statistics were applied to present percentages and socio demographic data. Data from entire inventories and scores for categorized domains and each item were expressed as Mean \pm Standard Deviation (SD).

Results and Discussion

Results of current study also showed that 76.85% of participants had an intrinsic motivation to study medical sciences, whereas 17.73% decided to study medicine for vocational reasons (extrinsic motivation) (Table 1). In addition, 56.15% of our participants had relatives working in medicine. However, only 43.84% of them had previous experience of looking after sick people. Furthermore, participants' fathers seemed to have higher educational levels than mothers and the vast majority of our participants (86.69%) were living with their families, despite that, 13.79% of them were facing financial difficulties.

A previous study [14] reported participation rate of 72% with 62% of participants were females. Also, [15] reported a response rate of 89.7% with mean(SD) age of participants of 21.4(2.34) years. However, another study [16] reported that 59% of respondents were males and 41% were females with mean(SD) age of 20.31(1.74) years.

One possible explanation for the high participation rate reported in current study was that the researchers informed students that their participation is voluntary, confidential and anonymous. Also, data collection well before final exams would help avoid any potential exam-generated stress that could affect students' natural perceptions. Moreover, the high number of female participants reflected gender distribution within the target population.

Data showed that our participants were young adults; therefore, their immature performance, unreliability, emotional liability and being inexperienced would create a great deal of stress for them during academic as well as clinical studies [19].

Medical students who participated in current study had some demographic criteria that would protect them from stress and its potential complications (Table 1). Despite that, previous studies revealed that the only predictor of stress among medical students was year of study [14].

Level of stress

Medical students at QMS expressed an overall moderate level of stress as the global mean(SD) items score for MSSQ was 1.80(0.54). In addition, this level of stress was similarly expressed by participants in the two years of study with no gender-wise differences (Table 2).

Previous studies reported moderate to high levels of stress among medical students which was higher than among the public as well as higher than among students doing other courses [14,15,20].

Reasons behind this stressful atmosphere at QMS may include curriculum overload, exam anxiety and authoritarian inexperienced [21].

Types of stressors

In terms of stressors, the most common stressors perceived by medical students at QMS were "Academic-

related stressors", "Teaching and learning-related stressors", "Social-related stressors", "Group activities-related stressors", "Interpersonal and intrapersonal-related stressors" and "Drive and desire-related stressors", respectively. In addition, these findings were mostly not affected by year of study (Table 2).

Our findings were in agreement with those reported by [14,15] who showed that the most common stressors for medical students were related to academic issues such as heavy course work, inadequate time for revision and inability to meet the needs of a challenging and demanding clinical environment.

One reason behind our findings could be the traditional curriculum implemented at QMS and the unprogrammed clinical training [22]. However, stressors related to student-student relationships created lower levels of stress as majority of students at QMS were local students and living with their families (Table 2).

Coping behaviors

Results of current study revealed that there was an overall average, without gender-related differences, use of coping behaviors among participants at QMS (Table 3).

On the other hand, coping behaviors employed by participants were "problem-solving behaviors", "optimistic coping behaviors", "transference behaviors", "avoidance behaviors", respectively; this finding was not affected by year of study or student's gender (Table 3).

A previous study [14] showed that medical students used active coping behaviors rather than avoidance behavior. Another study also reported frequent use of "problem-solving" behavior among undergraduate medical students [15].

Adoption of coping behaviors by medical students is greatly influenced by cultural norms and values [13].

Problem-solving behavior is the most effective coping strategy and it is usually adopted by senior medical students [23] who are experienced and skillful in contrast to "avoidance behavior" that is frequently adopted by junior medical students who are unconfident and have inadequate knowledge and skills [24].

"Transference behavior" is adopted when stress results from looking after patients as students depend on

their teachers when conflicts happen [25].

Furthermore, “optimistic behavior” is usually adopted by students who choose medicine for job security, therefore, they need to be self-assured, realistic and having constructive attitudes when dealing with stressful circumstances [26].

Conclusions

The academic and clinical settings at QMS were perceived stressful and remedial interventions are highly indicated to lessen this stress. In addition, implementation of novel medical curriculum, establishment of students’ support system and educating students about time-, self- and stress-management are highly recommended.

Assessment of Self-Esteem among Patients with Major Depressive Disorder in Sulaimani City

Taha Ahmad Faraj¹, Salwa Shakir Muhsin²

¹Lecturer, College of Nursing/University of Sulaimani, ²College of Nursing/University of Sulaimani

Abstract

Background: Major depressive disorder has been associated with greater morbidity and mortality. Many researchers have been sought complex association between depressions with self-esteem. The levels of severity of such factors can play role in the causes, recovery and predictor of depression.

Objectives: The main objective of this study is to assess the levels of self-esteem.

Methods: A quantitative descriptive design, conducted at psychiatric clinic in Ali Kamal medical consultation center in Sulaimani City. A non-probability, convenient sampling was recruited of 150 patients with major depressive disorder attending the psychiatric clinic. The data were collected from December, 21st, 2017 to April 1st, 2018 by the researcher of current study through the utilization of structured Face-to-Face interview guided by the questionnaire.

Result: The result shows that the patients with major depressive disorder experience low self-esteem.

Conclusions: The study conclude that high self-esteem value on its own the strongest significant factor may represents emotional source and possibly used to handle or cope with depressed mood by the patients.

Keywords: *Self-esteem, Depression*

Introduction

Research findings indicated an association between self-esteem with major depressive disorder⁵. It can be the contributory factors to depression²⁹. Depression has become one of the most common mental disorders with high prevalence throughout a lifetime⁴. It affects approximately 3.6% of the global population in 2013². In the view of¹⁴ self-esteem can both lead to and result from clinical depression. Self-esteem has been regarded as an essential component of mental health. It is the personal judgment of worthiness that expressed in attitude the person hold toward himself³⁰. Higher self-esteem tends to report more positive affective states, grater wellness and more life satisfaction²⁷. Low self-esteem has been frequent finding in depression and suicide behavior¹. Recent empirical studies using longitudinal data and cross-lagged regression models have consistently supported the idea that self-esteem negatively predicts depression¹⁹.

When low self-esteem is formed it affects all aspects of an individual's life³. It contributes to the development of a poor or negative self-image²⁹ and its partial mediator of the relationship between hopelessness and depression²⁷. Understanding self-esteem is important for interventions and prevention of depression¹.

The contemporary models of depression emphasized the role of low self-esteem in the etiology of depressive disorder^(9, 17).²⁴ devised two models, the vulnerability and scar models in their metal-analysis longitudinal study, found a total of 53 studies published in the year, 1984, 2000, 2010. The study indicated that low self-esteem had role in causes of depression. In addition, other studies suggested that self-esteem fluctuation is a factor in the etiology and maintenance of depression. Low self-esteem is more prevalent among depressed people and can predict a depression onset¹⁴. However, a major problem exists in examining the relationship between self-esteem and depression, self-esteem may be part of definition of an illness and in no way a causal²⁷. The findings by¹², revealed that low self-esteem on

its own dose not predict future episodes. Nonetheless it may do so interaction with other factors such as stress, hopelessness.

Greif is the painful psychological and physiological response to loss. Although it is most commonly associated with death of loved one, grief occurs when there is any significant loss, including loss of self-esteem; identity, dignity or sense of worth ⁶. Greif an accompanied by guilt about sustained loss of self-esteem and ambivalence about living is an indication that suicide risk increased and help is needed for such people. Low self-esteem primarily is common among major depression disorder ².

The current study designed to identify self-esteem among patients with major depressive disorder, identifying the level of severity of this factor is expected to have particular important for nursing interventions and prevention of major depressive disorder.

Method

A quantitative-descriptive design was used to assess self-esteem levels among patients with major depressive

disorder. The study was carried out from December, 10th, 2017 to October, 1st, 2018. This study carried out at Psychiatric clinic in Ali Kamal medical Consultation Center which is affiliated to the Teaching Hospital in Sulaimani City. A non-probability, convenient sampling of 150 patients previously diagnosed with major depressive disorder were recruited from consecutively attended the psychiatric department during the period of data collection.

A questionnaire was developed to measure the variables underlying the present study, using the Rosenberg self-esteem scale. Validity of the questionnaire was determined through a panel of 20 experts and reliability was determined through the computation of Cronbach's Alpha. The result of reliability was (0.843) for the self-esteem scale. The data were collected from December 21st, 2017 to April 1st 2018. Statistical package for social science (SPSS) version 22 is used for data analysis.

Results

Table 1: Distribution the socio-demographic characteristics of the sample

Sociodemographic	Characteristics	Frequency	Percentage
Age	18-27 year	31	%20.7
	28-37 year	51	%34.0
	38-47 year	40	%26.7
	48-57 year	21	%14.0
	58 Year or more	7	%4.6
	Mean ± 37.5 11.03		
Gender	Male	99	%66
	Female	51	%34
Marital status	Single	33	%22
	Married	87	%58
	Divorced	24	%16
	Widowed	6	%4
Educational level	Illiterate	36	%24
	Primary school	39	%26
	Intermediate school	24	%16
	Secondary school	21	%14
	Institute or university	30	%20
Occupation	Employed	51	%34
	Unemployed	99	%66
Total	150	%100	

Table (1) shows that the mean of age is (37.5 ± 11.3). Most of them male (66%) and married (58%). According to their educational level, the high percentage of the sample (26%) has primary school, and 24% of them illiterate, while 20% of them graduated from college or institute. Approximately two third (66%) of the study sample are not employed.

Table 2 Distribution of the sample according to their psychiatric history characteristics

Psychiatric history	Clinical characteristics	Frequency	Percentage
Duration of illness	1-5 years	87	%58
	6-10 years	36	%24
	11-15 years	12	%8
	16-20 years	6	%4
	21-25 years	9	%6
Number of hospitalization	Non	111	%74
	1 time	15	%10
	2 times	12	%8
	3 times	6	%4
	4 times and more	6	%4
Suicidal attempt	No	102	%68
	Yes	48	%32
Number of Suicidal attempt	No attempt	102	%68
	1 attempt	9	%6
	2 attempt	9	%6
	3 attempt	12	%8
	4 attempt and more	18	%12
Total		150	%100

Table (2) shows that the mean of duration of illness is (6.14) years, ± 6.3. The majority of the study sample (74%) has no admission to mental hospital. The table shows that two third of the sample (68%) have no suicidal attempt while (32%) of them have suicidal attempt and (12%) of them attempted more than four attempts, then (8%) of them attempted three attempts, also the same percentage (6%) of them attempted one or two attempts.

Table 3 the significant difference between calculated mean and theoretical mean in self-esteem measure, using -test

Variable	Sample	Calculative mean	standard deviation	theoretical mean	value	Level of significance
Self-esteem	150	14.380	4.097	15	1.853	Nonsignificant

Table (3) appears that statistically non-significant difference was found between calculated mean (14.380) and theoretical mean (x=15), (-test = 1.853, ± 4.097) at >0.05 level in self-esteem scale.

Table 4 Distribution of the sample according to the self-esteem levels

Statistical Indicator	Level of self-esteem			Total
	Low level (0-14)	Medium level (15-24)	High level (25-30)	
Frequency	78	69	3	150
Percentage	%52	%46	%2	%100

Table (4) shows the distribution of the patients according to self-esteem scale index. The table indicates that the highest percentage (52%) of the total patients were low level of self-esteem and the mean score ranged from (0-14), and the lowest percentage (2%) of the total patients were high level of self-esteem and the mean score ranged from (25-30).

Table 5 the significant difference of self-esteem in regard to patient's gender factor among sample

Variable	Group	Number	Mean score	Standard Deviation	value	Level of significant
Self-esteem	Males	99	14.45	3.81	0.310	Nonsignificant
	Females	51	14.23	4.62		

The table (5) appears that there was statistically non-significant difference mean score of self-esteem, in compare to patients gender because p- value was greater than common alpha 0.05 for the study variable (- test = 0.310). The table reveals that gender factor is not impact factor affecting the self-esteem in major depressive disorder among study patients.

Table 6 the significance differences of mean score of self-esteem in regard to suicide attempt factor among patients

Variables	Suicide attempt	Number	Mean score	Standard Deviation	value	Level of significant
Self-esteem	No	102	15.47	3.90	5.142	0.001
	Yes	48	12.06	3.52		

Table (6) shows that there were statistically highly significant differences mean score of self-esteem (-test =5.142 at <0.001) in regard to patients attempted suicide. Table 7 reveals that the suicidal attempt is highly an impact factor affecting self-esteem in major depressive disorder.

Discussion

The result shows that the mean and standard deviation of age were 37.511.3. This result is slightly

consistent with the result of ³⁰ who found that one third of 150 depressive outpatients of convenient sampling their age ranged from 24-34 years old, in Pakistan. Also ⁸ found that more than one third of depressive outpatients age 28-37 years old in Sulaimani city. ¹¹ confirmed the results of this study and mentioned that the average of age of onset for major depression has been consider the middle thirties. Although the most frequent age of onset for depression may range 25 to 44 years old age group, people in younger age group have an ever increasing risk

of developing depression²⁹. Some data indicate that the onset of depression at an early adolescents age²⁷ or at age 55years or more¹.

In this study the results revealed that the predominance gender were males (66%). This results are almost similar with the findings of¹ who found that males (57%) more than females (43%) of depressive outpatients in Kashmir/ India, also³⁰ found that the predominance males gender more than females among outpatients in Pakistan. On the other hand this results are inconsistent with²⁷ in Malaysia, ¹⁸ in Brazil, who found that the predominance gender were females among depressed patients. Literatures noted that gender roles continue to linger and contribute to high rates of depression among women^(7, 10). The findings of this study is that male-female ratio could be explained as females psychiatric patients were less frequently brought to psychiatric governmental clinics due to the feeling of shame and public stigma and self-stigma²⁸. More than half (58%) of the sample, their marital status married, and (22%) single. This result goes with the results of¹⁵ and ¹⁶ found that approximately more than half of study depressed patients were married. The finding of the present study may be explained by the late onset or recovery from acute onset among the sample of this study and fortunately such patients tend to have fewer difficulties in maintaining their daily life and exhibiting social roles and social integration²⁸.

About half of the studied depressed patients were low educational level, and two thirds of them were unemployed. This result similar to the findings of²² who founds that more than one third of depressed patient with low educational level, while they found that more than half of their sample were employed which are inconsistent to the results of this study.

The main characteristics of depressed patients show that their duration of illness was 1-5 years (58%). This results is consistent with findings of¹, ²¹ and ¹⁶. The finding of the present study predicts that the study patient's condition may have reached a chronic limit or in remission.²⁵ confirm the result of this study and stated that acute episodes of major depression last a limited amount of time.

Most of the study sample is not admitted to psychiatric hospital (74%) they treated in outpatient's psychiatric clinics. These results are in agreement of the findings of¹ in India, found that most study depressed

subjects were treated in homes. Today the emphasis in psychiatric care treatment is on outpatients or community-based interventions that address the treatment needs of psychiatric clients striving to maintain a position within the community.

The current study showed that one third of the depressed participants were attempted suicide and 18% of them have more than four attempts. The findings of²⁰, ¹⁵ and ¹³ confirmed the results of this study and mentioned that depression is one of the factors confirm risk for suicide ideation, attempts and death.

The results showed that the depressed participants observed (calculated) mean score of self-esteem (14.580 4.676) were non-significantly difference with theoretical mean score (15 4.676) of Rosenberg self-esteem scale ($p>0.05$). The distribution of studied sample revealed 52% low self-esteem level, 46% moderate self-esteem only 2% with high self-esteem. This finding is similar to the finding by³⁰ study in Pakistan. Who found that the main logistic regression results indicate that depressed patients had lower self-esteem than non-depressed population Also,²⁹ study in Malaysia found that depressed mood and low self-esteem occur with disproportionately high prevalence among adults, And also in adolescents²⁷.

Recently emerging studies suggest that low self-esteem contributes to the development of depression²⁶. In contrary,¹⁴ reported that there is a reciprocal relationship between self-esteem and depression, yet the causal direction of this association is not establish and noted that self-esteem can both lead to and result from clinical depression and suggested that the self-esteem fluctuation is a factor in a etiology and maintenance of depression.²⁹ determined that self-esteem emerged as the strongest predictor of depression, in contrast²³ revealed that low self-esteem and its own does not predict future depressive episodes, nonetheless, it may do so interaction with other factors.

This finding of the current study point out that low self-esteem is a state dependent on depressed mood and acts as a vulnerability factor for the development of major depression among study patients.

In this study, the findings showed that the gender is not significant factors effecting self-esteem levels ($p>0.05$). These findings are inconsistent with²⁹ found that self-esteem score significantly affected by gender. Suicidal attempts is highly significant factors effecting

patients self-esteem levels ($p < 0.001$). This findings are consistent with the findings of previous studies¹⁵ noted that lowest self-esteem increase the risk of suicide attempts in depressed patients.

Conclusion

Most of patients were male, unemployed, living in urban areas, practicing religious activities and their mean of age 37.5 years and most of them were less admitting to hospital although the long duration of illness ranged from 1-25 years. The patients experience low self-esteem level. The self-esteem levels are affected by suicide attempts. Patient gender is not significant factor.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing/University of Sulaimani, Iraq and all experiments were carried out in accordance with approved guidelines.

Evaluation of an Education Program for Elementary School Teachers Regarding Post-Traumatic Stress Disorder among Pupils in Mosul City

Nawaf Mohammed Dhahir¹, Saja Hashem Mohammed²

¹Ph.D /Instructor, Faculty of Nursing, University of Babylon, Iraq, ²Professor, Faculty of Nursing, University of Babylon, Iraq

Abstract

Background: The ability of teachers to recognize and respond appropriately to the emotional and social needs of their pupils plays a key role in promoting pupils' mental health. In the absence of teachers' supportive roles, some susceptible pupils may experience unrecognized sadness, despair, and/or anger. As a result pupils can get low academic performance, and loss of control over their lives. Therefore, teachers must be involved in specific education programs and training sessions about common childhood mental health disorders, especially post-traumatic stress disorder. In addition, ensuring that the majority of teachers have benefited from such programs is an important aspect.

Objectives: The study objective is to construct and evaluate an education program for elementary school teachers about post-traumatic stress disorder among pupils.

Materials and Method: A Quasi-experimental design was carried out through the present study with application of pre and post-tests approach. The study sample consisted of (60) teachers participated voluntarily in the study. Teachers were randomly selected from (60) elementary schools inside Mosul (Mosul is the second largest city in Iraq). The study subjects were divided into two equal groups of (30) teachers, study group which was exposed to the education program, while the control group was not exposed to the education program. Data were analyzed by using SPSS version-25.

Results: The results reveal that there are statistically significant differences in teachers' knowledge regarding all (PTSD) related knowledge domains in comparison between pre and post tests for study group compared with control group.

Conclusion: The study concludes that there is a considerable acquisition in teachers' knowledge regarding post-traumatic stress disorder following program implementation.

Recommendations: The study recommends to construct and apply such mental health education programs in most Iraqi governorates elementary schools.

Keywords: *Evaluation, Education Program, Post-traumatic Stress Disorder.*

Introduction

Mental health education programs can provide instructions and advices for teachers to support the pupils

with mental health disorder at schools. The risk of mental health disorders can be reduced significantly by routine attention, psychological awareness, support, as well as referral for pupils with psychological distress symptoms to mental health professionals. Pupils, especially those at schools located in regions which were exposed armed conflict and wars events, are more vulnerable to get emotional disturbing symptoms¹. To motivate teachers' supportive roles, they should be given proper

and adequate training, and opportunities for continuing mental health education. To achieve that, constructing an education program about post-traumatic stress disorder is necessary to help teachers improving and developing their knowledge and practices to insure mental well-being for pupils ^(1, 2). Post-traumatic stress disorder (PTSD) is a severe mental disorder which develop in response to an unexpected emotional or physical trauma that could not be controlled ³. With PTSD, a person feels distress long after the event is over ⁴. Since classroom teachers spend several continuous hours a day with their pupils, they are often in an excellent position to detect early physical, psychological and behavioral changes in pupils at school. Teachers may observe differences in the usual pattern for a particular pupil ^(4, 5). Education of teachers about the impacts of such traumatic events provides an opportunity for direct treatment of issues affecting the children and his or her environment. Education can help teachers acquire specific knowledge and practices for effective and appropriate interaction with pupils, and for successful management of challenging situations ⁶. Experts believe that the course of mental illness may be less severe if early detection and effective intervention are implemented. In addition, teachers education is particularly effective in relieving children from the burden of traumatic events and their related emotions, as well as in mitigating the consequences and symptoms of the trauma ⁷.

Objectives

The study aimed to construct and evaluate an education program for elementary school teachers about post-traumatic disorder among pupils in Mosul city.

Methodology

A quasi-experimental design was applied to attain the objectives of this study for the period from (1st December 2018 to 30th August 2019). After reviewing reports of mental health disorders in Nineveh directorate of health and consulting many mental health professionals there, it was obvious that post-traumatic stress disorder had high prevalence rates among elementary school pupils

in Mosul city, so, the researchers selected this disorder to construct an education program regarding it and apply it on the elementary school teachers. Therefore, the researchers constructed PTSD related lectures and a special questionnaire after reviewing many PTSD related literatures. The questionnaire was composed of two main parts: **Part-I:** Teachers' socio-demographical data such as (age, gender, marital status, years of employment, and educational level)., **Part-II:** This part is concerned with multiple choice questions (MCQs) to evaluate the teachers' post-traumatic stress related knowledge which included six domains as follow: **Domain-1:** Eight (MCQs) about concepts of childhood mental health., **Domain-2:** Eight (MCQs) about the psychological trauma., **Domain-3:** Eight (MCQs) about the impacts of psychological trauma., **Domain-4:** Eight (MCQs) about Post-traumatic Stress Disorder and its symptoms., **Domain-5:** Eight (MCQs) about DSM-5 Criteria for PTSD., **Domain-6:** Eight (MCQs) about protection factors and prevention. The program lectures and questionnaire were exposed to (15) experts for validation. The questionnaire reliability was measured through a technique of test-retest after application that on ten teachers out of the study sample, the reliability was ($r= 0.83$). The study sample consisted of (60) teachers who participated voluntarily in the study. Teachers were randomly selected from (60) elementary schools inside Mosul city after dividing the city into two sides (Right side and left side of Tigris River), then selected (30) schools from each side and one teacher was selected from each school in a probable manner. The sample was divided randomly into two equal groups of (30) teachers, one group was exposed to the education program; **study group**, while the second was not exposed to the education program; **control group**. The education program was consisted of five major sessions, it has been implemented on (30) teachers of study group only through six classroom sessions. All sessions were conducted in a special hall in Nineveh directorate of education- department of preparation and training which located in left side of Mosul city. The educational program was started in 13th April till 30th April, 2019.

Results

Table(1): Distribution of Socio-demographical Characteristics of the Study Subjects and Homogeneity between Study and Control Groups:

Characteristics	Groups	Study (n = 30)		Control (n=30)		Total (n=60)		Homo-geneity
		F	%	F	%	F	%	t
Age	30-40 years	17	56.7	15	50.0	32	53.4	-.167

	Mean (SD)	42.23 (7.66)		42.57 (7.79)		42.40 (7.66)		
Gender	Group	F	%	F	%	F	%	χ^2
	Male	14	46.7	17	56.7	31	51.7	.601
	Female	16	53.3	13	43.3	29	48.3	
Marital Status	Single	5	16.7	4	13.3	9	15.0	.137
	Married	19	63.3	20	66.7	39	65.0	
	Widowed	4	13.3	4	13.3	8	13.3	
	Divorced	2	6.7	2	6.7	4	6.7	
Years of Employment	1-5 years	4	13.3	3	10.0	7	11.7	1.190
	6-10 years	6	20.0	6	20.0	12	20.0	
	11-15 years	11	36.7	10	33.3	21	35.0	
	16-20 years	1	3.3	3	10.0	4	6.7	
	≤ 21 years	8	26.7	8	26.7	16	26.7	
Educational levels	Preparative	8	26.7	10	33.3	18	30.0	Z = -.482
	Institute	12	40.1	11	36.6	23	38.3	
	University	10	33.3	9	30.0	19	31.7	

N: Number, F: Frequency, %: Percent, t: t-test, χ^2 : Chi-square, z: Mann-Whitney U Statistics.

This table illustrates that the total number of teachers who participated in the study were (60) teachers. Their age ranged between (30-60) years old. The overall mean age for the participants is 42.40 (SD=7.66). The table also shows that the highest percentage of the sample (53.4%) was at the age group of (30-40) years old, while the lowest percentage of them (18.3%) was at the age group

of (51-60) years old. Concerning other demographical variables; the table shows that about (51.7%) of the sample were male. On the other hand, the majority of teachers (65%) were married. Regarding teacher's work experience, the table indicates that (35%; n=21) of the sample were having years of employment ranged between (11-15) years. Finally, the table demonstrates

that the highest percentage (38.3%) of sample were possess a diploma degree and approximately (31.7%) were having bachelor’s degree.

Table(2): Distribution of Baseline(pre-test) Among Post-Traumatic Stress Disorder Related Knowledge domains and Homogeneity Between Study and Control groups:

	Groups	Study (n =30)		Control (n=30)		Total (n=60)		t
	Domains	M	SD	M	SD	M	SD	
PTSD Related Knowledge	Domain One	3.53	1.43	3.47	1.33	3.57	1.267	.187
	Domain Two	2.97	1.32	3.30	1.05	2.97	1.221	-1.077
	Domain Three	3.00	1.20	3.30	1.14	3.03	1.057	-.987
	Domain Four	2.87	1.45	2.80	1.42	2.93	1.233	.179
	Domain Five	3.17	1.39	3.17	1.41	3.12	1.223	.000
	Domain Six	3.37	1.15	2.90	.923	3.38	1.027	1.725
	Total Knowledge	18.90	4.83	19.10	3.18	19.00	4.058	-.189

M: Mean, SD: Standard deviation, t: t-test, Maximum PTSD domains knowledge Score= 8; Minimum PTSD domains knowledge Score= 0; Maximum PTSD total knowledge Score=48; Minimum PTSD total knowledge Score= 0, All group differences $p > 0.05$.

This table indicates that there were no statistically significant differences in baseline (pre-test) among post-traumatic stress disorder related knowledge domains between study and control groups.

Table(3): Descriptive Statistics and Results of Mixed ANOVA Measuring Change in Post-Traumatic Stress Disorder Related Knowledge over Time across Study Groups:

PTSD Related Knowledge	Groups	M (SD)			Multivariate F
		Time-1	Time-2	Time-3	
Domain One	Study	3.53 (1.43)	4.67 (1.64)	4.40 (1.40)	F (2, 57) = 9.682, $p < .001$, $\eta^2 = .254$
	Control	3.47 (1.33)	3.93 (1.11)	3.83 (1.08)	
Domain Two	Study	2.97 (1.32)	4.27 (1.43)	3.90 (1.42)	F (2, 57) = 6.375, $p = .003$, $\eta^2 = .183$
	Control	3.30 (1.05)	3.20 (1.34)	2.90 (1.29)	
Domain Three	Study	3.00 (1.20)	5.80 (1.56)	5.50 (0.93)	F (2, 57) = 9.698, $p < 0.001$, $\eta^2 = .554$
	Control	3.30 (1.14)	3.50 (1.30)	3.40 (1.10)	

Cont... Table(3): Descriptive Statistics and Results of Mixed ANOVA Measuring Change in Post-Traumatic Stress Disorder Related Knowledge over Time across Study Groups:

Domain Four	Study	2.87 (1.45)	5.17 (1.55)	5.37 (1.15)	F (2, 57) = 17.433, p < 0.001, η ² = .380
	Control	2.80 (1.42)	3.00 (1.01)	2.80 (0.96)	
Domain Five	Study	3.17 (1.39)	5.23 (1.87)	5.27 (1.72)	F (2, 57) = 13.736, p < 0.001, η ² = .325
	Control	3.17 (1.41)	3.13 (0.81)	3.27 (1.17)	
Domain Six	Study	3.37 (1.15)	4.97 (1.75)	4.63 (1.67)	F (2, 57) = 11.006, p < 0.001, η ² = .279
	Control	2.90 (.923)	3.27 (1.17)	3.23 (1.30)	
Total Knowledge	Study	18.9 (4.83)	30.1 (3.60)	29.0 (3.95)	F (2, 57) = 67.654, p < 0.001, η ² = .704
	Control	19.1 (3.18)	20.0 (3.03)	19.4 (3.15)	

Study group (n = 30); Control group (n = 30); M: mean, SD: standard deviation, minimum domain score = 0, maximum domain score =8, minimum total PTSD knowledge score = 0, maximum total PTSD knowledge score = 48, p < 0.000 indicated in bold, η²: Eta Squared.

This table shows the results for Mixed design analysis of variance (ANOVA). For this analysis, there was one between subjects’ factor (group with two levels; [study (intervention) and control (non-intervention)]) and one within subject factor (time of testing with three levels: Time-1, Time-2, Time-3). All effects reported as significant at P < 0.05. This test showed that the changes among knowledge mean scores were a result of time, not of condition (group) or interaction between time of test and types of groups.

Table (4): Post-hoc Test Using Bonferroni Corrections Procedure:

PTSD Related Knowledge	Groups	Post hoc Using Bonferroni		
		T1 vs. T2	T1 vs. T3	T2 vs. T3
Domain One	Study	.000	.000	.037
	Control	.485	.796	1.000
Domain Two	Study	.000	.003	.446
	Control	1.000	1.000	.708
Domain Three	Study	.000	.000	.791
	Control	.437	.705	1.000
Domain Four	Study	.000	.000	1.000
	Control	1.000	1.000	1.000
Domain Five	Study	.000	.000	1.000
	Control	1.000	1.000	1.000
Domain Six	Study	.000	.000	.544
	Control	1.000	1.000	1.000
Total Knowledge	Study	.000	.000	.105
	Control	.630	1.000	.644

Study group (n = 30), Control group (n = 30), p < 0.05 indicated in bold.

On the basis of these results, the post-hoc procedure by using Bonferroni corrections test was conducted to

determine where the differences among the changed knowledge exactly lies. The test revealed that the scores of knowledge were significantly different among study group over times ($p < 0.05$). Concerning control group, the post-hoc test revealed fluctuation of the knowledge mean score over times. However, no exact improvement or stable continuous significant change in score over time was observed.

Discussion

The most challenges that the researchers faced, were that there were no any related literature and previous studies about such health education program regarding post-traumatic stress disorder among pupils. The study findings revealed that the participants' age is ranged between (30-60) years old. **Table-1** showed that the [mean (\pm SD)] of teachers' age for study (experimental) group was [42.23 (\pm 7.66)] and for control group was [42.57 (\pm 7.79)]. This table also demonstrated that the highest percentage of the study group gender was females(53.3%), while the highest percentage of the control group gender was males (56.7%). **Table-1** also illustrated that the majority of the study and control group subjects were married, they accounted (63.3%, 66.7%) respectively. **Table-1** identified that (35%; n=21) of the study subjects(study and control groups) were having years of employment ranged between (11-15) years.

Table-1 also illustrated that about (38.3% ; n=23) of sample were possess an institute degree certificate and approximately (31.7%; n=19) were having university degree certificate. Finally, **Table-1** revealed that there were no statistically significant differences between study and control groups' demographical characteristics; [$p > 0.05$ for t , χ^2 , and Z]. This means that all teachers were homogenous and they relatively had the same socio-demographical characteristics.

A pretest was carried out for both study and control groups prior to implementation the education program and after that all sessions had been given for the study group only. The results of pretest indicated that there were no statistically significant differences between study and control groups ($p > 0.05$) in the scores of the teachers' knowledge towards all (PTSD) domains at baseline. This means that teachers had the same knowledge about (PTSD) at pretest (**Table-2**). This table also revealed that the mean of total knowledge scores of the participants in study and control groups was

(18.90, 19.00) respectively. That means that teachers' knowledge level was low at pretest.

One week after completion of the education program, a posttest-1 was administrated for both groups. The results of posttest-1 indicated that there were significant differences among all (PTSD) related knowledge domains (**Table-3; 4**). This means that teachers had got a significant improvement in their knowledge regarding post-traumatic stress disorder (PTSD). And then after (3) months of program finishing, a posttest-2 was performed for both groups to investigate the effectiveness of the education program. A comparison of all test scores was carried out (**Table-3; 4**).

The post-hoc results revealed that the score of knowledge were significantly different among study group over times ($p < 0.05$). This indicates that there was a good acquisition in teachers' knowledge regarding post-traumatic stress disorder, while for control group, the post-hoc result revealed there is no exact improvement in teachers' scores over time was observed (**Table-4**).

The findings of this study were relatively compatible with the results of a previous study done by ⁸. He was studied the effectiveness of an education program on primary school teachers' knowledge towards Attention deficit-hyperactivity disorder among pupils at primary schools in AL- Najaf city. In his mentioned study, Al-kraawi proved that there is a considerable lack in teachers' knowledge towards such common childhood mental health disorder among pupils. His study also illustrated that the education program was effective.

Conclusions

The study concluded that there is a significant lack of teachers' knowledge towards post-traumatic stress disorder before implementation of the educational program at pre-program test. The study also concluded that there was a large and obvious effect for the education program on teachers throughout a good acquisition of knowledge after conducting the education program.

Financial Disclosure: There is no financial disclosure.

Histological Changes in Liver Tissue Resulting from Hydatid Cyst Infection: Comparison between Sheep and Cattle in Iraq

Intidhar Mohammed Mnati¹, Baydaa Hussain Mutlak¹, Noora Dhyaaldain Abed²

¹College of Education for Pure Sciences (Ibn Al-Haithum), Baghdad University,

²College of Education for Pure Sciences, Diyala University

Abstract

Hydatidosis is one of the most common parasitic zoonosis diseases not only in Iraq but throughout the world. Liver infected with hydatid cysts were randomly collected from 15 sheep and 18 cows of different ages and sexes during the period extended from September 2018 to December 2018. This study was aimed to provide insight on the histological changes of liver associated with *E. granulosus* and to compare the changes of liver tissue between sheep and cattle. Samples were collected from private (individual) butchers' places at Diyala province in Iraq. Livers had been transferred to Zoology Laboratory in Department of Biology in College of Education for Pure Sciences in Diyala University. Specimens from infected livers were immediately taken and fixed in 10 % formalin. Then the routine histological sections were done. The results showed that there were many histological changes resulting from infection with hydatid cysts infection including infiltration of inflammatory cells, necrosis, degeneration of liver tissue, fibrosis, fibrosis around portal veins, congestion of portal vein, increase in bile duct numbers, maladjustment of hepatic cords. A comparison between the histological changes of sheep and cattle showed the same histological changes, with a difference in the severity of these changes as they were more severe and developed in the livers of cattle than in sheep.

Key words: hydatid cyst, histological changes, cattle, sheep

Introduction

Hydatidosis is one of the most common parasitic zoonosis diseases not only in Iraq but throughout the world. The disease considers as a major threat to public health in many regions of the world, especially in developing countries, as well as large economic losses resulting from the infection of livestock ⁵. Despite the variety rates of infection in different countries, the incidence of this disease in both human beings and economic animals constitute a significant importance and may be a potential factor for new infection ¹⁰.

The disease caused by the larval stage of the small tapeworm *Echinococcus granulosus* (family *Taeniidae*). This parasite lives as a small intestinal cestode of dogs and occasionally other carnivores while their larval form lives in domestic animals and accidentally in man ¹¹. As the symptoms of this disease has been slowly developing, the disease is only detected after the infection has been exacerbated. The primary location of this cyst is the liver and lung but it could have located in other organs like

kidneys, bone marrow, spleen, heart and brain etc. ¹³.

Most of domestic animals represents as the main source of food for human in Iraqi populations and they have been used as a source both milk and meat. Liver is a vital organ as it characterized by multiple functions categorized broadly as synthetic, catabolic, detoxifying, secretory and excretory ⁴. Most of domestic animals represents as the main source of food for human in Iraqi populations and they have been used as a source both milk and meat. Liver is a vital organ as it characterized by its multiple functions including synthetic, catabolic, detoxifying, secretory and excretory in addition to use it as food ⁹. As other organs, the liver may have affected by a variety of pathogens causes resulting in huge economic losses either directly through throw it ¹⁴ or indirectly by effect on animal production ^(9, 14). The examination of histology changes provides highlights into interactions between pathogens and their host that it ¹⁶. This study was aimed to provide insight on the histological changes of liver associated with *E. granulosus* and to compare

the changes of liver tissue between sheep and cattle.

Materials and Method

Liver infected with hydatid cysts were randomly collected from 15 sheep and 18 cattle of different ages and sexes during the period extended from September 2018 to December 2018. Samples were collected from private (individual) butchers' places at Diyala province in Iraq. Livers had been transferred to Zoology Laboratory in Department of Biology in College of

Education for Pure Sciences in Diyala University and careful visual examination and identification of hydatid cysts was carried out. Specimens from infected livers were immediately taken and fixed in 10 % formalin. After fixation, the specimens were cut into about 1cm pieces, trimmed, washed, dehydrated in graduated concentrations of ethyl alcohol, then cleared in xylol and embedded in paraffin. Then the samples were sectioned at 4-6 microns and stained with hematoxylin and eosin stain for general histological examination.

Results

Th

The histological examination in the present study obtained that there are many hydatid cysts embedded in liver tissue in 7 of examined livers of sheep and 5 of examined livers of cows resulting in histological changes in infected livers of both cattle and sheep. Both these animals have the same changes with deference in severity. The changes included as shows in Figures, the germinal layer of the cyst surrounded with fibrosis and infiltration of lymphocyte cells and other inflammation cells and there is a necrosis in the tissue (Figure1), in addition of necrosis and infiltration of inflammatory cells around the bile ducts and blood sinusoids, there is propagation in bile duct numbers and expansion of blood sinusoids(Figure2)

Fig.1: Sheep liver: a. germinal layer of the hydatid cyst, b. fibrosis, c. infiltration of lymphocytes , d. necrosis (4x)

Fig.2 sheep liver: a. and b. necrosis, c. propagation in bile duct numbers, d. expansion of blood sinusoids, e and f, infiltration of lymphocytes(10x)

In Figure 3 and 4 there is clearly occurrence of fibrosis and maladjustment of hepatic cords as well as heavy infiltration of inflammation cells, in addition to necrosis in both figures.

Fig3:sheep liver: a. maladjustment of hepatic cords, b. fibrosis of the connective fibers (10x)

Fig4:sheep liver a. fibrosis, b. spot of hemorrhage , c. maladjustment of hepatic cords(10x)

Congestion and expansion of portal vein and infiltration of lymphocyte around portal vein in addition to expansion of blood sinusoids as shows in Figure 5. The central veins expended and there is a congestion in these veins with increase of connective tissue around the portal and central veins (Figure 6).

Fig5: cow liver a Congestion and expansion of portal vein, b. infiltration of lymphocyte around portal vein, c. expansion of blood sinusoids.(10x)

Fig. 6: cow liver: The expansion and congestion in central veins, b. increase of connective tissue around the portal and central veins.(4x)

Figure 7: liver: a. expansion and congestion of portal vein, b. infiltration of lymphocyte cells(10x)

Figure 8: liver: a. expansion of portal vein and increase of thickness wall of portal vein, b. lymphocytes, c. fibrosis around portal vein (10x)

Histological changes included also, Necrosis, fibrosis, infiltration of inflammatory cell, cirrhosis in Figure(9). Necrosis, fibrosis, inflammatory cell in portal area, maladjustment of hepatic cords

Both Figures(11) and (12) obtained fibrosis around portal veins and infiltration of inflammatory cells and congestion of portal vein and necrosis, it can be seen the increase in bile duct numbers and the layer of hydatid cyst surrounded with fibrosis in Figure(12). A comparison between the histological changes of sheep and cattle showed the same histological changes, with a difference in the severity of these changes as they were more severe and developed in the livers of cattle than in sheep.

Figure 9: cow liver: a. fibrosis, b. expansion in portal vein, c. infiltration of inflammatory cell (10x) **Figure10:cow liver: a. fibrosis, b. inflammatory cell around portal area, c. maladjustment of hepatic cords (10x)**

Figure11:cow liver: a. necrosis, b infiltration of inflammatory cells, c. congestion , d fibrosis(10x) **Figure12:cow liver: a. hydatid cyst wall, b. fibrosis, c. congestion ,d. fibrosis around portal vein, e. bile ducts (4x)**

Discussion

Hydatid cysts may arise anywhere in the intermediate host body (animals and human) but it mostly arise in

liver as hepatic capillary network forms the first capillary filter for circulating hexacanth embryos¹, they slowly develop to the hydatid cyst in this organ¹⁸. So, the disease remains asymptomatic in intermediate animal hosts until they reach to suitable volume to initiate the symptoms⁸. Although, there are many histological changes resulting from hydatid cysts infection. The present results of this study obtained that they are many changes in liver tissue and these changes including: infiltration of inflammatory cells, necrosis, degeneration of liver tissue, fibrosis, fibrosis around portal veins, congestion of portal vein, increase in bile duct numbers, maladjustment of hepatic cords, These results agree with many previous studies (2,4,12) as they reported that the hydatid cysts infection resulting in many histological changes in any infected organ.

The enlarged cysts pressed on the hepatocytes and congested the portal veins in addition to maladjustment of hepatic cords caused as a result of the pressure resulting from these cysts and this agree with⁶ who recorded that the experimentally infected mice have histopathological changes including hepatocytes and congested the portal veins in addition to maladjustment of hepatic cords resulting from the pressure of enlarged cysts. The same authors obtained that the reactions, such as lymphocytes infiltration and fibrosis capsules were occurred for the final cleanup of the residual debris of cysts⁶. These results as well as to the results that recorded by³ concur with the present study that revealed that fibrosis was occurred heavily in cattle liver tissue compare with sheep liver tissue as the age of slaughtered animals (the mean cattle age was one year while the mean sheep age was five months). The difference in age between cattle and sheep gives the time for the development and growing of the cysts in the cows according to the fact that this process is slowly. The fibrous tissue developed as a host's reaction to the parasite inflammatory effect, initiated in the early development stages of the cyst and the intensity of this reaction effect on the cystic development, if there is a heavily reaction it will lead to degeneration or death of the parasite while a moderate reaction allows the development of a viable cyst¹⁵. The present study compared between the liver's histological changes in both of sheep and cattle infected with hydatid cyst. In both, the reaction of the host to the presence of hydatid cyst referred to very clear chronic inflammatory reaction characterized by fibrosis associated with lymphocytic reaction and congestion, centrally with areas of necrosis and this agree with³

There was infiltration of lymphocytes recorded in the present study in both of sheep and cattle liver this due to inflammatory reaction of host –parasite interaction as¹⁷ study suggest the impact of the host's susceptibility on the composition of T lymphocytes which are locally activated in response to hydatid infection of the liver.

Increase in the number of bile ducts and thicken in their wall and expand their cavity occur in the liver in present study. This agree with⁷ who obtained that a large hydatid cyst caused compression on the bile duct bifurcation with proximal bile duct dilatation. In the hepatic parenchyma a slight hemorrhage and mild hepatocellular degeneration occurred in the present study and were in accordance with the findings of an earlier worker,¹⁸. These changes may due to the pressure of hydatid cyst that that cause in destruction of hepatocells.

This study concludes that the hydatid cyst infection result in many histopathological changes in both of cattle and sheep with difference in severity tend to cattle.

The Effect of Special Exercises by Using Training Methods to Assist in the Development of Some Motor Abilities and Handstand Skill of Still Rings for Young People

Anmar Atshan Khargan¹, Sadeq Yyousif Muhammad¹, Hekmat Abdul Sattar Alwan¹

¹Student, University of Thi-Qar- College of Physical Education and Sport Sciences

Abstract

Artistic gymnastics is considered as one of the plays that developed, in which the performance reaches to the top, we exactly dedicate to the still rings device that its exercises characterized by strength, stability, pronation and tucks flyaway of handstand, so an athlete needs to strength, speed, endurance, fitness, balance and flexibility. This study aims at preparing some special exercises using assistance tools to improve some motor and skills abilities on the Still Rings device. This study hypothesized that there is no significant differences between pre and post-tests of the experimental and control groups in the motor abilities and handstand skills of still rings device for the good of experimental group. The researchers used descriptive method with two groups. After homogenizing and equaling the sample of the research, the researchers applied special exercises on the experimental group that made up of (24) training modules. The researchers concluded that the special exercises with assistance tools have a great role in improving the motor and skillful abilities of the experimental group. The use of these assistance tools in improving the performance of some skills which assist in saving time and effort of the trainer and the player.

Keywords: *Handstand Skill, Still Rings and Motor Abilities.*

Introduction

The role of sports training lies in applying its principles, rules and scientific bases in building the essential training curriculum in each game and sports effectiveness, including the gymnastics game, which has the specificity of special physical requirements and high performance art in addition to that of its practitioners must be young people comparing with players in some other sports. Gymnastics works to form and build body and gain good strength and enjoy high fitness, although, it is a single game but it offers an infinite opportunity in creating the ability to invent and success through performing motors which leads to the development of the ability of consistency, continuity and compatibility

among players. The still rings device is considered as a lovely device, because it has lots of features as well as the extent of invention in the skills used, hence the movements on this device is characterized by strength, stability and the diversity of movements and their interconnection in a form that combines tuck flyaway, strength, stability and motor pronation to perform a series of motions ended with weakening. The significance of the study lies in preparing exercises for the special strength using training tools to assist in developing the physical, motor and skill abilities of players, because these exercises have a great role in building muscle strength and developing performance art, which requires performance exercises that related with the skill to be performed, exercises will be selected to correspond to the motor performance of the skill to be performed on a device that contributes to improving the performance art of this skill to achieve the best in gymnastics game.

Statement of the Problem

The gymnastics art is a game that was improved, in which the performance rising to a greater extent,

we indicate specifically the still rings device that characterized by strength, stability, pronation and tucks flyaway of handstand, so an athlete needs to strength, speed, endurance, fitness, balance and flexibility in order to perform the skills in this device. Through the researchers' experience as trainer, former player and by follow up of all gymnastics tournaments that take place at the country level for young people as well as their the training courses, the researchers illustrated that there was a problem lies in weak performance of handstand skills of still rings for young people, which represented in big litigations by the execution (E) committee, as a result of tuck flyaway and non-stability that leads to litigate the score. The researchers believed that the lowly artistic performance according to trainers' views is due to the lack of physical preparation that associated with the skillful part because most of the gymnastics training skills depends on experience and self-assessment as well as the lack of use of devices and assistive training devices due to the lack of most of them, which encouraged the researcher to use the training devices as well as prepare exercises for skillful performance that work to improve physical and motor abilities and artistic performance by using the still rings device.

Aims of the Study

1- Preparing special exercises by using some tools to improve some motor and skillful abilities by using the still rings device.

2- Identify the effect of special strength exercises by using some tools to improve some motor abilities and the skill of handstand by using the still rings device.

3- Identify the significant differences between the experimental and control groups in pre and post-tests of the motor abilities and handstand skill on the still rings device.

Hypothesis

1. There are significant differences between the results of the pre and post-tests of the experimental and

control groups in motor abilities and the handstand skill by using the still rings device for the good of post-tests.

2. There are significant differences between the results of the post-tests of the experimental and control groups in motor abilities and the handstand skill by using the still rings device for the good of experimental group.

Limitations

Human limit: Gymnastics players (young people) who their ages ranged (10-12) years, Training Center in Thi-Qar.

Time limit: the period from 1/1/2019 to 1/9/2019.

Place limit: The hall of Nasiriyah Specialized Gymnastics Training Center

Practical Framework

Methodology

The researchers used a descriptive method with two equaling groups (experimental and control groups) of the pre and post-tests in order to appropriate the problem of the study.

The Sample and Community of the Study

The study community represented by the young gymnasts who have trained at the specialized training center in Nasiriyah, who numbered (8) players, their ages ranged between (10-12) years, the sample selected in the intentional way represented (100%), the random method was adopted in dividing the sample of the study, so the researcher adopted the method of the lottery by dividing the sample into two groups (experimental and control), each group included (4) players, the researcher homogenizing the study sample by using Coefficient of Skewness as in table (1), through the variables of coefficient of skewness value, less than ± 3 that means the sample normally divided.

Table (1). Shows the Homogeneity of the Study Sample Members in the Sample Specifications

No.	Variables	Measurement Unit	Mean X	SD	Coefficient of Skewness (SK.)
1	Length	Cm.	139,37	10,43	0,32
2	Mass	Kg.	33,75	7,36	0,02
3	Age	Month	132,00	9,07	0,00
4	Training age	Month	52,50	10,99	0,99

The researcher made equalization between the experimental and control groups, which illustrated by table (2)

Table (2) shows the equalization of the two groups

No.	Variables	Measurement Unit	Experimental group		Control group		Sig.	Significance Level
			Mean X	SD.	Mean X	SD.		
1	Length	cm.	137,50	8,081	141,25	12,91	0,64	Non-sig.
2	Mass	Kg.	35,25	8,73	32,25	6,65	0,60	Non-sig.
3	Age	Month	132,00	9,79	132,00	9,79	1,00	Non-sig.
4	Training age	Month	51,00	11,48	54,00	12,00	0,73	Non-sig.
9	Imbalance	Second	16,25	0,95	15,75	1,70	0,62	Non-sig.
10	Fitness	number	5,75	0,50	5,50	0,87	0,53	Non-sig.
13	Handstand	degree	3,50	0,57	3,25	0,50	0,53	Non-sig.

The Procedures of the Study

Fitness Test

Test name: Burpee (Squat Thrust) of stand:

Aim of the Test: to measure the fitness.

Age and gender level: from 9 to 17, both male and female.

Tools used: Stopwatch

Performance specifications: The experimenter takes stand mode, with the starting signal moves to squat, then to the Burpee Squat Thrust, then back to squat, and finally to stand mode, the body must be straight when passing standing mode, and in squat mode the ground must touch the hands repeatedly as much as possible for 10 seconds.

Scoring Points: each standing has one score, for example if the experimenter completed four exercises then turn in the fifth time to squat, would got only (4.25) degree, if he/ she reaches to Burpee (Squat Thrust), which provide him/her (4.5) degree and if he/she returns to the squat mode after Burpee (Squat Thrust) he will get (4.75) degree, every experimenter has the right to try

three times, then the best performance will be scored.

Hard balance test

The aim of the test: this test aims to measure the dynamic balance.

Tools used: Pommel horse - stopwatch, foam mats.

Performance specifications: The experimenter takes a parallel standing mode - capture the two rings of the Pommel horse, with the start signal, the player jumps to center open, and strength in the longest mode as long as possible.

Scoring Points: Calculating the time of stability per second.

Description of skill tests:

The researcher conducted pre-skill tests for the members of the study sample, the tests included the performance of the members of the study sample for the skill of handstand and was photographed and presented to the referees to be evaluated by a jury made up of four referees, it has done by agreed with the jury members to evaluate the artistic performance of the study sample by

watching TV show of the pre and post skills test. The questionnaire contained referees' scores, which each one were (10), and write off the highest and the lowest scores as well as adding the two mean scores then divided by 2, in order to extract the final score of the player.

Pre-Tests:

The researcher conducted pre-tests of the special motor abilities of the experimental and control groups as well as the artistic performance on the still rings device on Saturday (2/3/2019).

Special Exercises:

The researcher prepared special exercises aimed at improving motor abilities and skill handstand among the players, these exercises characterized as contributing to the achievement of the aims of the special preparation level (physical and skill) for young players (specialist center - Nasiriyah) as well as homogenizing the exercises insides with their motor and skill characteristics, that exercises were applied by extracting medium tension for all exercises used.

1. The first training unit was conducted on Monday (4 March 2019) after pre-tests.

2. The researchers prepared training exercises after taking the opinion of the experts to prepare a set of exercises for ability, fitness and balance.

3. Through these exercises the researchers aim to improve fitness and balance by using skill training using body weight.

4. Applying the exercises took eight weeks at the rate of three training units per week which are (Monday, Wednesday and Friday), the total time of the training unit was (25-40 minutes) taking into account the gender, age, training age and physical capabilities of the study sample.

Table (3) shows SDs. and means X of pre and post-tests for some skillful tests, motor abilities, calculated T value and the significant level of the experimental group.

No.	Abilities and Skills	Measurement Unit	Pre-test		Post-test		Sig.	Significance Level
			Mean X	SD.	Mean X	SD.		
1	Handstand	degree	3,25	0,50	6,75	0,95	6,48	sig.
2	Fitness	number	5,50	0,57	8,75	0,95	5,81	sig.
3	Imbalance	Sec.	15,75	1,70	23,50	1,29	7,24	sig.

View and analyze the results of pre and post-tests of motor and skill abilities in the experimental group:

4. The number of training units was (24).

6. Identify the aim to be reached through each training module.

7. The ratio ripple factor was 2-1.

8. The researcher supervised the special exercises and the training units were applied to the experimental group by the trainer.

9. The researcher used exercises in the main section.

10. The researcher used the method of training and repetition.

11. The researcher started applying training units in the special preparation period.

Post-Tests:

The researcher conducted tests for the sample of the study on Saturday (7/5/2019) to test the motor and skill abilities, after the expiry of the period of the exercises and in the same method of pre-test, the researcher was keen to prepare the post-tests similar to pre-tests in terms of spatial and temporal conditions as much as possible.

Statistical Methods:

The data was processed by a computer using the Statistical Package for the Social Sciences (SPSS 24), whereas the researcher used the following statistical methods:

Show, Analyze and Discuss the Results of the Study:

Presentation and analysis of the results of pre and post-tests of motor abilities and handstand skills in the control group:

Table (4) shows SDs. and means X of pre and post-tests for some skillful tests, motor abilities, calculated sig. value and the significant level of the experimental group.

No.	Motor Abilities and Skillful	Measurement Unit	Pre-test		Post-test		Sig.	Significance Level
			Mean X	SD.	Mean X	SD.		
1	Handstand	degree	3,50	0,57	8,25	0,50	12,43	sig.
2	Fitness	number	5,75	0,50	12,25	0,95	12,03	sig.
3	Imbalance	Sec.	16,25	0,95	28,75	0,95	18,46	sig.

Showing, analyze and discuss the results of the post-tests of the motor abilities and handstand skill for in the control and experimental groups:

Table (5). Shows SDs. and means X of post-tests for motor abilities and handstand skill of the experimental and control groups

No.	Motor Abilities and Skillful	Measurement Unit	Pre-test of the control group		Post-test of the experimental group		T	Sig.	Significance Level
			Mean X	SD.	Mean X	SD.			
1	Handstand	degree	6,75	0,95	8,25	0,50	2,77	0,03	sig.
2	Fitness	number	8,75	0,95	12,25	0,95	5,17	0,00	sig.
3	Imbalance	Sec.	23,50	1,29	28,75	0,95	6,53	0,00	sig.

Discuss the results of the Test of the Two Control and Experimental Study Groups:

Through the tables (3,4 and 5), the researchers believe that the training program used by the trainer has affected the members of the sample of the control group, and that the development that occurred in (motor abilities, skillful) of the members of the control group as a result of continuing training, feedback and commitment on weekdays All helped to develop and apply the training program prepared accurately, according to his style, in addition to his choice of exercises that play a role in the development, it is clear that the physical tests in the control group got evolved through the observation of the arithmetic means (X) but did not reach the significant similar to what happened in the experimental group, the researcher believes through these exercises that motor

abilities have been developed clearly although the development that occurred to the control group due to the continuation of training and exercises used by the trainer. The use of special exercises from the experimental group only in the main section of the training unit had a clear impact in the development of motor abilities as the main section contained special exercises prepared by the researcher which served as a new way to remove the boredom that dominated the players as a result, the use of exercises using assisting tools, as well as the use of the method of training with the weight of the body, which has had a great impact in the development of motor abilities as it led to the rush of players to perform their exercises seriously and with great interaction as a result of pleasure in the performance of their own exercises, that the association of abilities Skills are a necessary and important factor in creating a fully-

fledged player. We also note a great improvement in the development of fitness and the researcher also attributes this to the diversity in exercises that have given great benefit to most of the muscles of the player's body and to the process of linking movements together by consensus and agility and its use for it whether in the general or private direction, which led to stability and adjustment on the performance of exercise and the constant renewal of the motor path and compatibility between muscles involved in performance, concentration, motor binding, motor control. We also note an improvement in balance and the researcher may attribute this to the use of the experimental group and its application of exercises that worked on the development of this characteristic and the ability of these exercises to absorb the weight of motor weight with the organization of muscle tension, body weight, reaction of concentration and acquisition of the art of motor performance taking into account the lifting.

Conclusions

The researcher found out the following conclusions:

- 1- The special exercises that used assisting tools have an active role in the development of motor and skill abilities in the experimental group.
- 2- Using the tools to assist in the process of improving the performance of some skills which contributes to saving time and effort for the trainer and the player.
- 4- The experimental group has surpassed the control group, which applied special exercises in all the study variables that is significantly and clearly.

Abstract

Jenang Kutai judges or judges of custom law are judges that are selected from traditional leaders, community leaders or religious leaders. They are highly respected as they are considered as a role model and are prestigious in the society. Well-mannered characteristics owned by custom law judges is underpinned by their maturity balanced with applicable norms in the society. As a judge, *Jenang Kutai* judge should be calm, assertive, fair, and bold in making decision or delivering a verdict. This is done in order to enforce the law. Even though sometimes such judges psychologically have sympathy for the defendant, they have to pass sentence because people they believe that God's punishment through hazard disaster will come for those who commit the crime and do not enforce the law.

Keywords: Psychology, Jenang Kutei, Tempung Mata Bilai Verdict, Cuci Kampong, Rejang Lebong Society

Introduction

The acknowledgement of custom law is officially ruled by and stated in the second amendment of The 1945 constitution of the republic of Indonesia article 18B paragraph (2) that states "*The state shall acknowledge and respect traditional societies along with their customary rights as long as these remain in existence and are in accordance with the societal development and the principles of the Unitary State of the Republic of Indonesia, and shall be regulated by law.*"⁽¹⁾

According to Soerojo Wignjodipoero, the existence of custom law is underpinned by the decisions in the society, particularly decisions made by society leaders concerning law enforcement activities.⁽²⁾ The aforementioned decisions are made for any kind of disputes and should be based on the result of deliberation. Such decisions are made by considering the values exist in the society and applicable within the society itself.⁽³⁾

Katrina Cuskelly defines custom law as "the custom and usage with law enforcement power". However, there is a possibility that custom law refers to custom acceptance and appropriateness since certain society members have already obliged to certain custom or after being regulated by state court. These two interpretations may result different meaning. In this case, the most comprehensive understanding on the definition of custom law is given by the constitution of Papua New Guinea.⁽⁴⁾

The definition states that an ethnic custom law is indigeneous law that is specifically applicable for certain society or ethnicity. On the other hand, Islamic law is certain law that is applicable along with the custom law and is applied based on the religion of its citizens. Oji continue states that the application of these laws dualism is influenced by British colonial law.⁽⁵⁾

Law of the Republic of Indonesia about village regulates the formation of institute of indigeneous village (Article 95) and village people (Article 96) under certain conditions. Therefore, there are efforts in discussion how to apply custom law along with common law, even though such efforts are not significant yet.

The existence of *Jenang Kutei* as an indigeneous institution and *Kelpeak Ukum Adat Ngen Riyan Ca'o Kutei Jang* as the guidance for the people of *Rejang* tribe is in line with the statement of Von Savigny in which this called as *Volkgeist* or the core of the state. In this case, law is a reflection of *Volkgeist*, or the battle of human and space and time. *Volkgeist* is a concept of faith, context and locality⁽⁶⁾.

As a law enforcer in a court, a judge should have high integrity and be professional. Moreover, a judge also needs to gain trust from the society and justice seekers in order to perform his duty fairly. One of the characteristics that the society considers in trusting a judge is from his behavior, both in workplace and in daily life. In this case, integrity and dignity are closely related to personal trait and well-mannered character.⁽⁷⁾ Concerning the selection of *Jenang Kutei* judges, only selected people or the society leaders having comprehensive understanding about its custom and healthy psychology that may be selected for this position⁽⁸⁾.

Therefore, this present article aims to analyze how the psychological condition of *Jenang Kutei* judges in making decision of *Tempung Matai Bilai* and *Cuci Kampung* (a form of purification ritual) in *Rejang Lebong* regency, *Bengkulu* province.

Method

This study was a legal research in health. It employs qualitative, non-doctrinal approach.⁽⁹⁾ Data were collected using study of documentations or secondary data, then analyzed descriptively.

Findings and Discussion

The abundance of problems or conflicts happen in the society requires indigeneous judges or *Jenang Jutei* as the decision maker to fairly participate and decide the case according to the applicable custom law. They have to consider their decisions according to the *Kelpeak Ukum Adat Ngen Riyan Cao Kutei Jang*. For example, if there is a man who commits sexual assault, he will be charged with certain punishment in custom law as follow:

(1) *Conducting certain purification rituals. Those activities are not allowed to be conducted at night (however, in the case of Tempung matai bilal, the activities are no longer conducted as they were considered extreme under the new BMA leader)*⁽¹⁰⁾.

The other sanctions are fined as much as murder case (2) fine charged to female criminals is based on the demands approved by the male side. (3) The criminals are whipped 10 times by using a hundred pieces of small sticks⁽⁷⁾.

Another example of punishment is given to someone committed premarital sex. For such criminal, she is obliged to slaughter a goat. The slaughter is conducted after the baby is delivered. For the family who does not obey the law, a simple punishment is available. According to *Kadirman*, the punishment is limiting their social interaction⁽¹¹⁾.

Jenang Kutei judges should be selected from traditional leaders, community leaders or religious leaders. They are considered as selected person that this selection is officially authorized and stated in the decree of reagent. Currently, there are only three *Jenang Kutei* judges. Formerly, there were 20 judges, and then it remained five judges, and now there are only three judges. As judges, *Jenang Kutei* are highly respected as they are considered as a role model and are prestigious in the society.⁽⁷⁾

This make they are considered have stable state of psychological condition. As the results, they are trusted to make wise decisions. Their wisdom proves that such judges are able to survive in the middle of new culture diversity. Such judges have the ability to accommodate the elements of other culture and integrate their own culture with the development of other aspects in life⁽¹²⁾.

Well-mannered characteristics owned by custom law judges is underpinned by their maturity balanced with applicable norms in the society. Well-mannered person always use his/her sense, thought and careful consideration in everything he/she does. In other words, each action that is performed is logical. Noble attitude of judges indicates that being a judge is a noble job or *officium Nobile*. A profession particularly that is based on professional ethics and has been recognized by public is considered as a noble job or *officium nobile* if it consists of following aspects: solid professional association, professional standard, professional ethics, public recognition and formal educational background.⁽¹³⁾ The main duty of a judge is to fairly adjudicate every case filed to the court according to the applicable law without distinguishing people based on their ethnic, religion, race, profession or social status.

Judges' duty in adjudicating cases actually has two

interpretations; enforce justice and enforce the law. In term of enforcing justice, the main duty of a judge is to enforce justice without having extension to the law. As a law enforcer, a judge not only has to enforce justice but also have to reinforce the broken law⁽¹⁴⁾. One of the examples is concerning sanction for adulterer or rapist that is decided by the Village Consultative Body. The decided sanction is to conduct *Cuci Kampung*, a form of purification ritual and *Tempung Matai Bilai*

In delivering sentence or making decision toward the violation of custom law, the decisions made depend on the minority or majority of the violation itself. For minor violation, some sanctions given include reprimand, warning letter, apology or obligation to conduct alms giving ceremony or purification rituals. For more severe, major violation, the decided sanction usually include being excommunicated or outcasted from the society.⁽¹⁵⁾

Aharon Barak states that the duty of judges is not only to resolve disputes, but judges also have responsibility to bridge the gap between citizen and the law⁽¹⁶⁾.

According to Glendon Schubert, judges are ordinary people. Thus, it is assumed that judges and people involved in a case are human biological substance in term of personality. In this case, there are three main psychological function of personality substance, namely perception, cognition, and decision-making. Glendon Schubert employs behavioral jurisprudence analysis in analyzing judges' behavior.⁽¹⁷⁾ The result shows that there is a process of interaction and communication, interest articulation and aggregation. It also explains that personality variable is correlated with social and cultural spaces. Cultural spaces refer to widely-accepted pattern of faith and social values such as myth, custom and law. The contents of social spaces itself tend to be ideological values instead of direct, observable activities.

In regard to legal culture, Lawrence M. Friedman defines it as legally oriented values, ideas, attitudes and behavior.⁽¹⁸⁾ The overlapping socio-psychological segment between personality and social system is closely related to individual socialization and recruitment. Such segment is also correlated to one's attributes and behavior

Psycho-cultural segments in which personality and cultural system are overlapping is one's individual conception of his roles and ideology. Therefore, its three subsystems namely personality, social and culture share the same meeting point with segments of socio-

psychological, psycho-cultural and sociocultural. Due to the complexity of the problem judges and court may encounter, it is no longer comprehensive if the theory frameworks that are used to analyze the case are legal sociology and anthropology approach. Instead, it also needs legal psychological approach.⁽¹⁸⁾

Legal psychology or psychology of law perceives law as an embodiment of one's developmental psychology. This discipline analyzes one's legal behavior that may become the representative of certain psychological symptoms as well as the psychological basis underpinned that certain behavior. The study of legal psychology emphasis on psychological factors that influence one or people's behavior in every legal action they do. For example is judge's behavior or attitude in investigating, adjudicating and making decision. Judge's psychological condition may affect his ability in making decision or delivering the verdict. This situation is also applicable for the other law enforcement officers. As for the last segment, sociocultural segment is closely related to social and cultural system that represents the organizational pattern and accommodation and regulation output function from one's behavior.⁽¹⁹⁾

The use of custom law as the legal basis to solve cases occurred in society is considered due to the characteristic that custom law is not contradictory with society's interests. That is why there is a correlation between legal existence and its effectiveness. Legal effectiveness refers to a condition that certain law has achieved its goals. It means that the certain law has been completely, legally applicable.⁽²⁰⁾ In this case, custom law is applicable because it is a part of law originated from customs, social principles that are made and protected by authoritative leaders and functioned to control legal relations within the society.

Village people always identify themselves as an integrated part of the universe in a related, dependent and influential relation. The most important thing is how they can create harmonic, balanced atmosphere between society and the surrounding area. In other words, it can be said that the reputation of Indonesian people is formed and built from the reputation of village people.⁽²¹⁾

Conceptually, the core and the meaning of law enforcement is in the actions of balancing the correlation between values described in consistent, manifest principles and people's behavior as the elaboration of the last value. This is aimed to create and maintain peace

As a judge, *Jenang Kutai* judge should be calm, assertive, fair, and bold in making decision or delivering a verdict. This is done in order to enforce the law. Even though sometimes such judges psychologically have sympathy for the defendant, they have to pass sentence because people they believe that God's punishment through hazard disaster will come for those who commit the crime and do not enforce the law.

It is in line with what is stated by the law "... after a decision has been determined, Tepung Tawar ritual or purification ritual is conducted as a form of purification or the village people called as a way to make the situation in harmony as former/ original situation. According to the traditional leader, in Tepung tawar ritual, a bowl of rice water added by sergayau (an endemic plant), turmeric and pumpkin leaves are used. The traditional leader, then, splashes the mixed water into the palms of the people in dispute. It is done to symbolize that the dispute is settled without acrimony."⁽²²⁾

Conclusion

Jenang Kutei judges should be selected from traditional leaders, community leaders or religious leaders. They are considered as selected person that this selection is officially authorized and stated in the decree of reagent. As judges, *Jenang Kutei* is highly respected people as they are considered as a role model and are prestigious in the society.

As a judge, *Jenang Kutai* judge should be calm, assertive, fair, and bold in making decision or delivering a verdict. This is done in order to enforce the law. As a judge, *Jenang Kutei* should be psychologically assertive in making decision and giving sentence. That is why only selected people (traditional or religious leaders) that have good condition of psychology ad socio-culture that is eligible to be a judge in custom law.

Mechanism of Family-coping in Treating Patient with Schizophrenia Viewed from Factors that Affected it at Public Health Center of Balowerti, Kediri

Byba Melda Suhita¹, Prima Dewi Kusumawati¹, Heri Saputro¹, Ahmad Yusuf²

¹Lecturer, Nursing Science Program, Institute of Health Science "Surya Mitra Husada", Kediri,

²Associate Professor, Nursing Faculty, Universitas Airlangga, Indonesia

Abstract

Coping is a cognitive process and behavior that aims at reducing depression while facing stress situation. Treating patient with schizophrenia is a stressor for family and the family will tend to undergo pressure situation from either the environment or the inside part until it can influence family-coping in treating family who suffers mental disorder, such as schizophrenia. Moreover, this research aimed at knowing factors that influenced mechanism of family-coping in treating patient with schizophrenia. Data analysis utilized logistic-regression-test. The result showed that the factors that influenced against family-coping were self-esteem and social-support, meanwhile, the factors that did not influence it were knowledge, stress, and patient's behavior in social-isolation.

Keywords: *schizophrenia, family, coping*

Introduction

The problem of mental health actually does not become one of problems of the mortality cause directly, but this problem can cause someone's inability to do many things and to behave well. Hence, it can cause a problem for a group, including society.⁽¹⁾ There are three types of hard mental disorder, which are schizophrenia, bipolar disorder, and acute psychosis. Schizophrenia is the most dominant disease that is suffered by the population in the world, which is in 1% until 3% in the world⁽²⁾.

Schizophrenia is a multifactorial disorder of neural development that is influenced by either genetic factor or environment factor and it is characterized by either positive, negative, or cognitive symptoms. Psychotic symptom is indicated by abnormality in form and content of mind, perception, emotion, and behavior. The symptoms that can be observed in the patient with schizophrenia are the appearance and general behavior,

speech disruption, behavior disorder, affective disorder, perception disorder, and mind disorder. Cognitive symptoms often precedes the occurrence of psychosis. The positive symptom includes suspicion, hallucination, being rowdy restless, strange behavior, hostility attitude, and formal thinking disorder. The negative symptom includes difficulty in starting conversation, flat effect, less motivation, less attention, being passive, being apatis, self-withdrawal socially, and discomfort. However, patient with schizophrenia tends to self-withdrawal socially⁽³⁾.

According to report result from WHO⁽⁴⁾, sufferer of mental disorder with schizophrenia diagnosis had reached 24 millions of people around the world. Meanwhile, according to data of Basic-Health-Research⁽⁵⁾, in Indonesia, mental disorder rate had undergone significant increase from 0.5 per mil in 2007 to be 1,7 per-mil in 2013, from the total population in 251 millions of people. West Java Province was one of provinces with the highest rate of mental disorder in Indonesia that reached 20% from 45 millions of people or around 9 millions of people. Among mental disorders which were often found, one of them was schizophrenia. Meanwhile, in East-Java showed rate of 2,2 of people

Corresponding author:

Byba Melda Suhita

Address: Jl. Manila-37, Sumberece, Tosaren, Pesantren, Kediri-Indonesia

based on population data in East-Java, which was 38.005.413 peoples, hence, it could be concluded that 83.612 peoples underwent mental disorder in East Java-Indonesia.

Patient with schizophrenia who could not function normally caused she/he needed a caregiver. Caregiver was an individual who generally treated and supported another individual in her/his life⁽⁶⁾. Family was the closest unit and was a “main caregiver” for the sufferer. Support from family and routine treatment could minimize the symptoms of schizophrenia. In line with the treatment process for the patient with schizophrenia, family would undergo physical and emotional fatigue. In order to overcome this condition, the family needed to conduct coping strategy during treating patient with schizophrenia. Lazarus & Folkman⁽⁷⁾ defined coping strategy was as a change from a condition to another

condition as a way to face unexpected situation which empirically, it was known as a process and divided it into problem focused coping (PFC) and emotion focused coping (EFC).

Method

Data collection in this research was conducted by using questionnaire that was distributed to 70 respondents of family with schizophrenia patient in area of Public Health Center of Balowerti, Kediri, East Java, Indonesia. The dependent variable was mechanism of family variable in treating patient with schizophrenia and the independent variables were knowledge, self-esteem, stress, social-support, patient’s behavior in self-withdrawal socially. The data were analyzed by utilizing logistic-regression-test.

Findings

Table 1. Distribution of knowledge, self-esteem, stress, social-support, coping-effort of care-giver and aggressive-behavior and social-isolation of patient

Care-giver’s knowledge	Percentage	Frequency
• Less	17.1	12
• Adequate	52.9	37
• Good	30	21
Care-Giver’s Self-esteem		
• Negative	50	35
• Positive	50	35
Care-giver’s stres		
• High	21.4	15
• Medium	54.3	38
• Low	24.3	17
Care-Giver’s Social-support		
• Less	21.4	15
• Adequate	45.7	32
• Good	32.9	23
Care-Giver’s coping-effort		
• Emotional based coping	45.7	32
• Problem based coping	54.3	38
Patient’s aggressive-behavior and social-isolation		
• Social-isolation	78.6	55
• Aggressive-behavior	21.4	15

It showed that the care-giver’s knowledge mostly had adequate, the most of care-giver’s self-esteem was negative, the most of care-giver’s stress was in medium, the most of care-giver had adequate social-support, the most of care-giver’s coping-effort had problem based coping, the most of patient with schizophrenia had behavior of social-isolation.

It showed that the value of Hosmer and Lemeshow Goodness of Fit was 4.689; p-value was 0.790, hence, the model was fit.

Table 2. Overall Model Fit

Interation	-2 Log likelihood
Step 0	96.526
Step 1	67.246

It was occurred the decrease value between the value of -2 Log Likelihood in block 0 and the value of -2 Log Likelihood in block 1, which was in $96.526 - 67.246 = 29.280$. This condition showed that the model was hypothesized in fit with the data, which meant that overall, logistic regression model that was used was a good model.

Based on logistic-regression-test:

1. Knowledge

Regression coefficient was 1.105; Wald-value was 3.302; p-value was 0.069: there was no significant influence of knowledge on family-coping.

2. Self-esteem

Regression coefficient was 2.062; Wald-value was 7.123; p-value was 0.008: there was a significant influence of self-esteem on family-coping.

3. Stress

Regression coefficient was -1.308; Wald-value was 3.417; p-value was 0.065: there was no significant influence of stress level on family-coping.

4. Social-support

Regression coefficient was 1.402; Wald-value was 7.506; p-value was 0.006: there was a significant influence of social-support on family-coping.

5. Social-isolation

Regression coefficient was -1.368; Wald-value was 2.641; p-value was 0.104: there was no significant influence of behavior of social-isolation on family-coping.

Discussion

Coping-mechanism

The result showed that the most number of coping-mechanism category was problem based coping. It was supported by a conducted research by Bakhtiar & Ariani⁽⁸⁾. Coping was defined as all cognitive and behavior efforts to solve, prevent, and endure the demands⁽⁹⁾. Family’s burden in treating the schizophrenia was a psychological distress for family situation which was indicated by the increase of physical activities, there was emotional and social pressure in treating the schizophrenia patient⁽¹⁰⁾. The family could have high pressure if they did not have good adaptive coping-mechanism⁽¹¹⁾. High pressure would be faced as a result of financial problem, lack of time to socialize, poor family health, the dependence from the family members to the schizophrenia, and there was family conflict. Moreover, that condition impacted to the family’s ability in treating schizophrenia patient and the decrease of family’s life quality⁽⁶⁾.

When the family knew that there was a family member suffered schizophrenia, this family would be in emotional focused coping stage. In this phase, the family would respond this as a hurtful situation and could make them feel stressful. In this phase, the family also could be through escape-avoidance coping strategy, which meant that they tended to avoid this problem, to escape from reality, and how to make important decision. Along the time, the experience and belief that they had and perception that was gradually positive to the family member who suffered schizophrenia could make the family in planful problem solving condition, that was a condition when the family showed their real effort to solve the problem. The way they solved the problem could be from asking for more information about this disease, how to treat the patient, and how to prevent the relapse of this disease.⁽¹²⁾

Knowledge

The result showed that knowledge did not affect coping-mechanism toward schizophrenia patient. This result was not in line with Bakhtiar & Ariani⁽⁸⁾. Treating

patient with chronic disease like schizophrenia was not easy. They needed knowledge, high willing, loyalty, and patience. The family would do some treatments continuously to make the patient got better, normal, and got back to the family again⁽¹³⁾ and this was not in line with conducted research by Wardaningsih et al.⁽¹⁴⁾, who showed that factors that affected coping-mechanism were faith, financial, knowledge, communication, and social-support. Coping-strategy that was often used could be seen from the family-coping strategies, such as internal family-coping that relied on family, problem control, holding and solving problem, and revealing the problem together.

Self-esteem

The result showed that self-esteem had a significant influence on family-coping. Coping-mechanism was influenced by several factors, such as physical health, faith or positive mindset, problem solving skill, social skill, social-support, occupation, age, sex, and education. Respondent's anxiety level was also influenced by several factors, such as family-coping material, intimidation against self-esteem that was coming from external factors like the fear of losing the loved one, divorce, the change of occupation status, group pressure, and social culture⁽¹⁵⁾.

Schizophrenia patient had limited ability in doing activities. Many psychological problems such as the loss of independency, social-role, health and mental condition, and other problems made them need continuous treatment. This treatment would cost much. Besides, this condition also could cause a pressure for the family⁽¹⁶⁾. One of psychological responses that was in subjective pressure was the feeling of shame⁽¹⁷⁾. The family who had another family member who suffered schizophrenia would feel embarrassed and this feeling tended to cause low self-esteem on the family. The pressure that was felt by the family and low self-esteem on the family would cause disorder against family's role and function, including for how mechanism of family-coping in treating family who suffered health problem.

Stress

The result showed that stress level did not affect coping-mechanism. Stress was part of human life. It was caused by transaction among individual with the environment that created gap among demands which were coming from many situations biologically, psychologically, and socially.

Family was an internal strength so that they had control against life and torture. Significant situation, such as having a family member who suffered this disease made them stressful so that it became demand to cope and adapt with the problem for surviving and developing. Stress emerged when the family felt that they could not cope the problem because of the condition of the family who suffered the disease, thus, they would feel stressful. Nevertheless, stress was not one of the factors that influenced coping-mechanism because the stress level from each person would be different. This difference could alter the stress level. Person with low stress level would be able to manage himself/ herself and would try to give strength to the other family members to manage their stress level and support each others for the effort of increasing family welfare with the schizophrenia patient.

Social-support

The result showed that social-support gave significant influence against coping-mechanism. According to Taylor et al.⁽¹⁸⁾, people with high social-support would feel that the other people noticed more and needed the individual and could direct the individual to the healthy life style, thus, for the family who had health problem on the family members could increase their caring to the environment, particularly against the family member's health.

Support from family, working colleagues, society in social space had negative correlation with the emergence of positive symptom from schizophrenia patient. It explicitly meant that social-support could minimize the patient's relapse, hence, the family could treat the patient easily and they could also manage self the coping. Sarafino⁽¹⁹⁾ stated that interaction with other people could modify even change people's perception toward particular situation.

Support from family showed positive impact to the patient in which they would have better health and it was different with the patient who did not have support anymore. People with high relation with others also had higher chance to live with better health and it was different with those who had low relation with other people⁽²⁰⁾. Gerungan⁽²¹⁾ stated that social relation could support people's health and welfare. Moreover, health and happiness were not only influenced by social welfare but also close relation that supported each others would cause low risk from a disease. Support would decrease a

chance to suffer from disease. It meant that people with good relation would have intimate relationship with other people, could rely on, could support each other so that they could prevent the disease.

Social-isolation Behavior

The results showed that exclusion behavior from the schizophrenia patient did not give any significant aspect against coping-mechanism. Keliat et al.(22) stated that schizophrenia was a chronic disease that was indicated by inability or communication difficulties, reality problem, abnormal behavior, cognitive disturbance, and the difficulty to do daily activities. There were positive and negative symptoms of this disease. The positive symptoms included missed perception, hallucination, sense problem (hearing, sighting, tasting, smelling, and touching) without any external stimulation, the change of thinking and behavior. Negative symptoms included apathy or ignorance, blocking, social-isolation from the society and decrease daily social activities. Besides, the negative symptoms on schizophrenia patient caused the client underwent function disorder in social-isolation..

Coping-ability for schizophrenia patient would need external input, such as social-support. It could be from family, working colleagues, or communities. Sarason⁽²³⁾ stated that social-support would really help individual to adapt well, along with positive coping and self-building. It could prevent someone to get disturbance from psychological effect especially for schizophrenia patient who tended to exclude themselves from society. According to Friedman et al.⁽²⁴⁾, there were four aspects of supports which could be given by the family. They were emotional support, informational support, instrumental support, and assessment support and they were correlated each others. If the individual got the support maximally, they would learn to use positive coping to defense themselves from either internal or external pressure.

Social-isolation on schizophrenia patient did not have any significant influence against family-coping-mechanism, but family-coping-mechanism and teamwork would give positive impact for the patient. It was because the tendency to isolate from society was influenced by how good the relation between the patient with other people around. Moreover, schizophrenia patient had limited ability to do activities. Some psychosocial problems such as the loss of independency, social roles, health and mental problem became a

stimulus of stressor, hence, they had difficulty to adapt in society. In this case, family support and routine treatment would be very important for schizophrenia patient, hence, the patient could adapt well with the social function and this could prevent the patient to isolate from the society. In conclusion, good social-support would give positive influence for coping-mechanism and good family-coping would give positive influence against schizophrenia patient's behavior. Nevertheless, skill that was obtained by the individual regarding good coping strategy from family could make the individual to behave independently. Thus, the individual could do his/ her role in social function as usual without having any social-isolation.

Conclusion

The result showed that the factors that influenced against family-coping were self-esteem and social-support.

Effectiveness of Stress-Adaptation and Cognitive Behavior (SACB) Model for Independent Health Recovery for Clients with Coronary Heart Disease in the Community

Heni Nurhaeni¹, Ratna Aryani², Suryati B.¹, Ani Nuraeni¹

¹Associate Professor, ²Assistant Professor, Health Polytechnic of Jakarta I, Indonesia

Abstract

The main risk factors of coronary heart disease are: hypertension, hypercholesterolemia, and smoking, as factors that can be controlled and are reversible. Other risk factors are age, race, gender, heredity, geography, diet, obesity, diabetes, exercise, behavior and other life habits, stress, social changes and reversible mass changes. Lifestyle management, stopping smoking and effective changes in hypertension can reduce risk and death. Through this research, it is expected that the effectiveness of the Stress-Adaptation and Cognitive Behavior (SACB) Model on the ability to independently recover health care for clients with coronary heart disease. The design of this study was pretest-posttest with control group. Samples were 29 patients with coronary heart disease in RW 03 and RW 08, Pondok Labu, South Jakarta, which were selected by cluster random sampling technique, which were further divided into intervention and control groups. The intervention given was the Stress-Adaptation and Cognitive Behavior (SACB) model. The research instrument was the ENRICHD Social Support Instrument (ESSI) and modified the SF-36 Mental Health Index and Social Functioning subscale. Measurements included rehabilitation behavior, self recovery, blood pressure and pulse. Data were collected through observation and questionnaires, then analyzed using logistic regression tests and Mancova. Based on the results of the study it can be concluded that the Stress-Adaptation and Cognitive Behavior (SACB) Model is effective for building the ability of people with coronary heart disease to recover health independently.

Keywords: *coronary heart disease; stress-adaptation and cognitive behavior (SACB) model; independent health recovery*

Introduction

In Indonesia there has been a shift in the incidence of heart and blood vessel disease, from the 10th in 1980 to the 8th in 1986. While the cause of death remains third. Many factors affect the occurrence of coronary heart disease (CHD) so prevention efforts must be multifactorial. Prevention must be tried as much as possible by controlling the risk factors for CHD. Primary prevention is aimed more at those who are healthy, but has a high risk, while secondary prevention is an effort to prevent worsening of the disease condition. Various studies have been conducted for more than 50 years, where there are variations in the incidence of CHD that differ in geographical conditions and certain social conditions that have been increasing since 1930, and starting in 1960 this disease became the main cause of death in industrialized countries.⁽¹⁾

The main risk factors of CHD are: hypertension, hypercholesterolemia, and smoking, as factors that can be controlled and are reversible. Other risk factors are age, race, gender, heredity, geography, diet, obesity, diabetes, exercise, behavior and other life habits, stress, social changes and reversible mass changes. Lifestyle management, stopping smoking and effective changes in hypertension can reduce risk and death.

Based on the 2013 Basic Health Research, the highest rate of hypertension was 30.9% and the lowest was 16.8%. CHD with hypertension as the cause becomes very alarming. In a sick condition, the client experiences continuous stress, and can aggravate his physical and psychological condition, thereby threatening productivity in daily activities, also decreasing the client's contribution in the family and community.⁽²⁾ Hypertension cases cause around 9.4 deaths worldwide

each year. Hypertension causes at least 45% of deaths due to heart disease and 51% of deaths due to stroke. Deaths caused by cardiovascular disease, especially CHD and stroke are expected to continue to increase to reach 23.3 million in 2030. Every year World Heart Day is celebrated every September 29.⁽³⁾

Likewise, A Randomized Controlled Trial of Stress Reduction in African American Treated for Hypertension for Over One Year through a 20-minute intervention in the form of Progressive Muscle Relaxation (ROP), results in a decrease in blood pressure.⁽⁴⁾ Clients with CHD have risk factors that can be avoided, namely smoking, obesity, lack of physical activity, and stress, including eating patterns. Overall risk factors are generally known by the client, but he often underestimates and violates them. Other healthy behaviors are avoiding fatty foods, consuming fibrous foods (vegetables and fruits), avoiding salt or flavoring, consuming vitamins, consuming water, avoiding soft drinks, and getting enough sleep.

Clients with CHD at home who have been left out of care need family support and health workers to be able to carry out their health recovery independently (ENFICHD) from the beginning of stress and must adapt to the conditions of illness, both ways of regulating lifestyle healthy to independent abilities, both cognitive abilities and monitoring their health conditions. Stress-Adaptation and Cognitive Behavior (SACB) models can strengthen the client’s ability to adapt through mindset and immune system, each other has a connection that can be explained through communication of cells that are experiencing stress and neurotransmitter factors⁽⁵⁾, in order to carry out recovery health independently through adjustments to coping mechanisms and health

status. Strengthened with the Cognitive Behavior model, it is expected that the client is able to recognize the structure, content and function in dealing with his pathophysiological conditions, especially the ability of assimilation until the client is able to independently monitor his health condition.⁽⁶⁾

Through this research, it is expected that the effectiveness of the Stress-Adaptation and Cognitive Behavior (SACB) Model on the ability to independently recover health care for clients with CHD.

Method

The design of this study was pretest-posttest with control group. Samples were 29 patients with CHD in RW 03 and RW 08, Pondok Labu, South Jakarta, which were selected by cluster random sampling technique, which were further divided into intervention and control groups. The intervention given was the Stress-Adaptation and Cognitive Behavior (SACB) model. The research instrument was the ENRICHD Social Support Instrument (ESSI) and modified the SF-36 Mental Health Index and Social Functioning subscale.⁽⁷⁾ Measurements included rehabilitation behavior, self recovery, blood pressure and pulse. Data were collected through observation and questionnaires, then analyzed using logistic regression tests and Mancova.

Findings

The analysis showed that there were differences in sex, education and history of DM between the intervention group and the control group. But there was no difference in history of hypertension and history of CHD.

Table 1. The equality test

Variable	Intervention group		Control group		P-value
	f	%	f	%	
Gender					0.004
• Male	11	44	2	8	
• Female	14	56	23	92

Self recovery	Intervention Group Before After Difference	45.520 46.520 -1.000	2.380	-1.982 - -0.017	-2.100	0.046
	Control Group Before After Difference	48.400 46.360 2.040	7.976	-1.252 – 5.332	1.279	0.213
Systolic	Intervention Group Before After Difference	133.76 132.68 1.080	10.711	-3.341 – 5.501	0.504	0.619
	Control Group Before After Difference	141.20 142.29 -1.040	2.835	-2.210 – 0.130	-1.834	0.079
Diastolic	Intervention Group Before After Difference	85.040 80.720 4.320	10.823	-0.147 – 8.787	1.996	0.057
	Control Group Before After Difference	86.20 86.96 -0.76	5,117	-2.872 – 1.352	-0.743	0.465
Pulse	Intervention Group Before After Difference	94.400 92.560 1.840	6.749	-0.946 – 4.626	1.363	0.186
	Control Group Before After Difference	94.36 93.12 1.24	6.200	-1.319 – 3.799	1.000	0.327

The results of the analysis showed that there were differences in rehabilitation behavior in the intervention group before and after the intervention ($p = 0,000$), with the difference in attitude score = 2,640; there was a difference in self-recovery in the intervention group before and after the intervention ($p = 0.046$), with a difference in mean score = 1,000; and there was a diastolic blood pressure difference between before and after the administration of the intervention ($p = 0.057$), with the mean score difference = 0.4320.

Table 4. Comparison of knowledge, self-recovery and diastolic blood pressure, after intervention between the two groups

Variable	Group	n	Mean	SD	95% CI	F	P-value
Self adaptation	Intervention	25	-2.64	2.157	-3.684 – (-1.835)	32.260	0.000
	Control	25	0.12	0.665			
Self recovery	Intervention	25	-9.200	2.379	-2.960 – 1.664	1.556	0.056
	Control	25	2.040	7.976			
Diastolic blood pressure	Intervention	25	4.320	10.823	0.215 – 9.944	12.189	0.041
	Control	25	-0.760	-0.766			

The analysis showed that there were differences in self adaptation and diastolic blood pressure between the intervention group and the control group after the intervention ($p = 0,000$; $p = 0.041$).

Table 5. Effect of respondent characteristics on self adaptation, self recovery and diastolic blood pressure

Independent variable	Dependent variable	Mean Square	df	F	P-value
The duration of CHD	- Knowledge	21.174	1	10.341	0.003
	- Self recovery	3.949	1	0.103	0.750
	- Diastolic blood pressure	5.179	1	0.066	0.799
Gender	- Knowledge	9.401	1	4.591	0.038
	- Self recovery	40.248	1	1.049	0.312
	- Diastolic blood pressure	2.071	1	0.026	0.872
Education	- Knowledge	5.470	2	2.672	0.081
	- Self recovery	0.826	2	0.022	0.979
	- Diastolic blood pressure	65.661	2	0.834	0.442
Cognitive: history of DM and family support	- Knowledge	0.324	1	0.158	0.693
	- Self recovery	2.868	1	0.075	0.786
	- Diastolic blood pressure	57.082	1	0.725	0.399

Based on the results of the MANCOVA test, it was found that the length of suffering from CHD, gender and education affected the variable of respondents' knowledge about the treatment of CHD, including family support

Discussion

Differences in levels of knowledge, self adaptation, self recovery, blood pressure and pulse between before and after the intervention in the intervention group and

the control group

Based on the results of data analysis it is known that there are differences in knowledge in the intervention group between before and after the intervention; there were differences in self-recovery in the intervention group between before and after the intervention; there were also differences in diastolic blood pressure in the intervention group between before and after the administration of the intervention. Experience forms

the behavior of an individual, the ability of individuals to act and the appearance of desirable behavior is a very simple process of action (stimulus) and reaction (response). Hosland, et al (1953) in Notoatmodjo (1997) ⁽⁸⁾ said that the process of behavior change is essentially the same as the learning process. Three variables that influence it are attention, understanding, and acceptance. Understanding (cognitive) is the acquisition, structuring, and use of knowledge. In the learning process, a person who has long suffered from CHD will try to involve his relationship with the environment as a stimulus and response relationship, more than that, learning involves a very complex thought process, especially the desire to recover. Through Jean Piaget’s cognitivism, the client will carry out the processes of assimilation, accommodation, and equilibration both internally and externally with the everyday environment.

Thus, through exposure to information about CHD and how to recognize the signs of symptoms and the dangers instinctively to the respondent, from the beginning of the pre-test to post-test, the respondent came to understand the importance of maintaining his health condition (assimilation). Respondents apply knowledge about CHD (accommodation), until the respondent is able to treat himself with his own initiative, in order to monitor his health independently.

Clients with CHD who have implemented and internalized their abilities, will also automatically adapt to themselves, especially when clients initially experience stress which then adapts to stressors of CHD. The respondent’s ability to adapt to stress is that the client is able to adjust constructively to CHD, feel relatively free from tension and anxiety about the dangers of CHD, obtain satisfaction and independent efforts to monitor his health or life struggle against CHD, feel more satisfied to provide information about CHD to friends in the community, especially when carrying out control with the group.

The healthy people are people who can prevent interference caused by stressors, and are influenced by the size of the stressor, intensity, meaning, culture, and so on. Thus, the more individuals have varying coping capacities, which are influenced by the environment, stress conditions, and the sources and support available, the individual becomes healthy with adaptation, and has adaptive coping, including assessments of stressors, coping sources and coping mechanisms that are well.⁽⁹⁾

Differences in levels of knowledge, self-recovery and diastolic blood pressure after intervention between the two groups

After the intervention, it was found that there were differences in respondents’ knowledge and diastolic blood pressure between the intervention group and the control group. Diastolic blood pressure is an illustration of a heart pump disorder that can be categorized as follows.

Table 6. The Classification of blood pressure

Classification of blood pressure	Systolic (mmHg)	Diastolic (mmHg)
Normal	< 120	<80
Prehypertension	120-139	80-89
Stage 1 hypertension	140-159	90-99
Stage 2 hypertension	160 atau >160	100 atau >100

Clients with CHD who already have good knowledge, cognitively will continue to maintain themselves, always have an alarm to maintain healthy behavior. Many factors affect the occurrence of CHD, both can be avoided or can not be avoided. After the client is able to adapt to the stress of his CHD, of course with SOR (Cognitive Behavior theory), the respondent will keep himself healthy. Respondents from several questions and answers through the independent monitoring booklet can answer more than 85% correctly about how to recognize and prevent the increasingly severe CHD they are experiencing. Therefore, changes in blood pressure towards improvement are the result of good self-monitoring of respondents.

The effect of respondent characteristics on the level of knowledge, self-recovery and diastolic pressure of patients with CHD.

Based on the results of data analysis, duration of CHD, knowledge, self-recovery, diastolic blood pressure are influenced by the characteristics of the respondents. Based on the results of the MANCOVA test, it was found that the duration of CHD, gender and education had an influence on knowledge about the treatment of CHD.

Wahyuni & Rezkiki⁽⁹⁾ reported a significant difference if clients with CHD were given interventions for self-efficacy and empowerment, especially providing structured health education.

The elements of knowledge about CHD can be internalized by providing knowledge continuously through an independent health monitoring booklet, namely; Heart disease is a condition when the heart's blood vessels are damaged due to accumulation of fat or cholesterol in the heart's blood vessels. As a result, the heart blood vessels harden and narrow so that blood flow is blocked, so that the heart does not get the oxygen and food needed to function normally.

Clients with CHD at home who have been left out of care need family support and health workers to be able to carry out their health recovery independently (ENFICHHD) from the beginning of stress and must adapt to the conditions of illness, both ways of regulating lifestyle healthy to independent abilities, both cognitive abilities and monitoring their health conditions. Stress-Adaptation and Cognitive Behavior (SACB) models can strengthen the client's ability to adapt through mindset and immune system, each other has a connection that can be explained through communication of cells that are experiencing stress and neurotransmitter factors⁽⁵⁾, in order to carry out recovery health independently through adjustments to coping mechanisms and health status. Strengthened with the Cognitive Behavior model, it is expected that the client is able to recognize the structure, content and function in dealing with his pathophysiological conditions, especially the ability of assimilation until the client is able to independently monitor his health condition.⁽⁶⁾

Conflict of Interest-No

Source of Funding- Authors

Ethical Clearance- Yes

Conclusion

Based on the results of the study it can be concluded that the Stress-Adaptation and Cognitive Behavior (SACB) Model is effective for building the ability of people with CHD to recover health independently

The Influence of Massage Therapy on Children Body Temperature which Fever

Lia Herliana¹, Ai Cahyati¹

¹Lecturer, School of Nursing, Poltekkes Kemenkes Tasikmalaya, Indonesia

Abstract

Massage is the oldest touch therapy known to man. With massage is expected to improve the evaporation process by widening blood vessels and opening pores in the child's body so that fever is expected to quickly go down. This study aims to identify whether there is an effect of massage therapy on the body temperature of children who have a fever. This research used pre and posttest control group design. Research location in Hospital Dr. Soekardjo Tasikmalaya. The sample size were 41 people. The result was a significant difference in the average body temperature before and after the compress (p-value=0.000) and massage therapy (p-value=0.000) in both the first and second measurements. Comparison of temperature reduction before and after the compress and massage therapy results were significant at first measurement (p-value=0.002) but not significant in the second measurement (p-value=0.0388). It is expected that nurses on duty in the children's room can increase the participation of families in handling health in children, especially children with fever. And for researchers, further research should be done regarding massage therapy with the use of topical alternative medicine to further enrich family knowledge in the management of sick children.

Keywords: *child fever; warm compresses; body temperature; massage therapy*

Introduction

Fever is a clinical sign of a disease in children. These health problems are often faced by health workers. Traditionally fever is defined as an increase in body temperature above normal. Many parents consider fever dangerous for children's health because it can cause seizures and brain damage⁽¹⁾. Body temperature in the condition of fever can be used as one important measure that can give clues about the deterioration or improvement of the patient's condition⁽²⁾.

Fever refers to an increase in body temperature as a result of infection or inflammation in response to microbial invasion, certain white blood cells secrete a chemical known as endogenous pyrogen which has many effects to fight infection⁽³⁾. Fever is a condition where an increase in temperature up to 38⁰ C or more. There also are taking limits of more than 37.8⁰ °C. Meanwhile, when a temperature greater than 40⁰ °C is called a high

fever/hyperpyrexia⁽²⁾. Broadly speaking there are two categories of fever namely infectious fever and non-infectious fever. Fever infection is the fever that occurs as the body's response to an increase in *set-point* such as flu, sore throat, mumps, measles, scarlet fever, fever, *typhoid* and so on. Non-infectious fever is an increase in body temperature due to excessive heat formation but not accompanied by an increase in *s-points* such as in patients with mumps/aspirin poisoning⁽⁴⁾. WHO stated the number of fever cases around the world reached 18-34 million. Children are the most susceptible to fever, although symptoms experienced by children are lighter than adults. In almost all endemic areas, the incidence of fever mostly occurs in children aged 5-19 years⁽⁵⁾.

Many ways are done to treat fever. The most commonly used method is, of course, taking fever-lowering drugs such as paracetamol or ibuprofen. Also, of course, treat the cause of fever, if due to infection by bacteria then given antibiotics to kill bacteria. But medicine alone is not enough, so compresses are needed to help reduce fever⁽⁶⁾. The factors that can be used in decreasing debris body temperature include traditional medicines, antipyretic drugs, and hot and cold compresses⁽⁷⁾. Wet warm compresses, dry warm compresses (bladder), wet cold compresses (water

ordinary), dry cold compresses (ice crates), electric pillows and blankets, irradiation lamps, hot arcs⁽⁸⁾. Warm compresses are a method for lowering body temperature⁽⁹⁾. By the receptor temperature in the body, then a decrease in body temperature by cooling can be done on the hypothalamus, spinal cord, abdominal organs and around large veins⁽¹⁾. In addition to warm compresses, another traditional therapy for handling fever is by massage or massage. Massage is the oldest touch therapy known to man. Touch and massage in infants known as a *baby massage* after birth can assure ongoing body contact that can maintain a feeling of security in the baby⁽⁴⁾.

Massage has been practiced almost all over the world since a long time ago including in Indonesia. The art of massage is taught from generation to generation, although it is not known how massage and touch can have such a positive effect on the human body. The positive influence of touch on the process of growth and development of children has long been known to humans. But scientific research on this matter is still not much done. Although it still needs further research, the findings that have been produced have become the basis for routine baby massage to maintain a baby's health. Especially because this baby massage is cheap, easy, and is commonly done in Indonesia so it is not a new thing for our culture⁽¹⁰⁾. The results of Mardianti and Komalasari's research⁽¹⁰⁾ on the effect of massage therapy on the frequency of breastfeeding were carried out in 60 infants aged 1-3 months using a quasi-experimental design. there was no effect of massage therapy on the duration of breastfeeding (p-value=0.563).

Research on the effects of massage with coconut oil versus mineral oil and placebo (powder) on growth speed and behavior in premature babies⁽²⁾. Premature babies are randomized to receive a good massage with palm oil, minerals or powder. Massage oil is given by a trained person four times a day until discharge and subsequently by the mother until the baby is 31 days old. The result is that coconut oil massage produces a significantly greater

speed of weight gain compared to increases in mineral oil and powder in the premature baby group.

In the literature review written by Field⁽³⁾ about massage methods with kinesthetic and tactile touches, there is evidence that massage therapy influences weight gain, especially for premature babies, this has been applied in various countries including⁽¹⁾ in the Philippines, a group of experts Neonatologists reported a 47% increase in weight gain after the Field massage procedure.

Method

This research used pre-test and post-test with control design, where this design compares the difference between before and after being given compresses and antipyretics in the control group and the difference between before and after being given antipyretics and massage therapy in the experimental group. The experimental group performed massage therapy twice a day for 5 minutes after the antipyretic administration⁽¹¹⁾. Body temperature measurements were carried out before and after the experiment using a calibrated digital thermometer. The difference between before and after the experiment is assumed to be the effect of the experiment Group 1 was referred to as the control group that only received antipyretic and compress administration, while group 2 was called the experimental group that received antipyretic and massage therapy⁽¹²⁾. The sample was toddler-aged children who had a fever and were treated at Dr. Soekardjo Tasikmalaya in August to October 2019. The research instrument used was the SOP for the implementation of massage therapy and observation guidelines for the measurement of body temperature. Data were analyzed using paired t-test and independent t-test.

Findings

Table 1 shows the average body temperature before the intervention.

Table 1. Body temperature before the intervention

Group	Mean	SD	Min-Max	95%-CI
First measurement				
Control	38.5	0.8498	37.3-40.2	38.102-38.898
Experimental	38.586	0.6077	37.4-39.5	38.309-38.862
Second measurement				
Control	38.175	0.5288	37.5-39.6	37.840-38.322
Experimental	38.081	0.6750	37.2-39.5	37.859-38.491

After the intervention, body temperature in each group experienced changes, as shown in the following table 2.

Table 2. Body temperature after the intervention

Group	Mean	SD	Min-Max	95%-CI
First measurement				
Control	38.150	0.6194	37.5-39.6	37.860-38.440
Experimental	37.457	0.7096	36.0-38.5	37.134-37.780
Second measurement				
Control	37.2	0.8985	36.0-38.5	36.779-37.621
Experimental	36.995	0.5491	36.2-38.0	36.745-37.245

The results of the normality test is described in Table 3.

Table 3. The result of normality test

Body temperature	Shapiro-Wilk	Skewness
Before intervention	0.116	1.37
After intervention	0.09	1.10

The normality test based on Shapiro-Wilk on body temperature before intervention was 0.016, so the data was normally distributed, as well as the results of the division between skewness and standard error, the result was 1.37, which means that the data was normally distributed (Table 3).

Discussion

Compress and its effect on body temperature

The rationale for compressing is the conduction method, which is the heat transfer of another object by direct contact. When warm skin touches the warm, there will be heat transfer through evaporation, so that the transfer of heat energy becomes gas⁽¹⁴⁾. The body temperature of the first measurement in the control group before compressing was 38.500°C, while after a compress was 38,150°C. From T-test obtained p-value=0.000 (there is a significant difference in body temperature before intervention in the control group). At the second measurement, body temperature before compressing 38.175°C, while after the pack was 37.200°C. The mean difference in the first measurement was 0.350, meaning that the respondent experienced a change in temperature of 0.350 points as a result of the action taken. Likewise in the second measurement, the mean difference was 0.975, which means that there was

a change in temperature of 0.975 points after the fever was compressed. The T-test obtained p-value=0.000 (there is significant differences in body temperature before intervention in the control group). This is in line with research conducted by^{(8),(9)} who have all proven the effectiveness of giving compresses to children with fever through the tepid sponge or compress method plus alternative medicine.

Massage therapy and its effect on body temperature

Touch therapy or massage has been used since ancient times, at least since 1800 BC massage was the main form of treatment before the advent of the pharmaceutical era in around 1940. Touches in particular that contain elements of emphasis are known to have a variety of positive effects such as reducing oxygen demand and giving a feeling of being comfortable and being loved. A Cochrane meta-analysis found evidence suggestive that infant massage can increase the interaction and affinity

of the baby with the mother, improve sleep quality, reduce the baby's crying, and have a beneficial effect on stress hormones. But unfortunately, there is not enough evidence to support the positive impact of massage on changes in body temperature in children with fever. The mother is the parent closest to the child, where the mother's message to her child is gentle stroking of the fabric of affection. The mother's skin is the earliest skin recognized by a child. Touch and massage given by the mother is a form of communication that can build closeness between mother and child by combining eye contact, smile, facial expression. If the stimulation is often given, the mutual love relationship between mother and child will be stronger⁽¹⁵⁾. The purpose of massaging the body is to expedite the flow of blood so that we can feel the sensation of the body that gets better afterward.

In the research that has been done, the body temperature in children with fever has experienced the following changes in the first measurement of the average body temperature before doing massage therapy was 38.585 °C, while body temperature after massage therapy was 37.457 °C. The T-test obtained p-value=0.000 (there is significant differences in body temperature before and after massage on the first measurement. In the second measurement, the body temperature was 38.081 °C, while after massage was 36.995 °C. The mean difference in the first measurement is smaller than in the second measurement. This is possible because in the second measurement the respondent's initial temperature is the result of the previous intervention and the respondent has done massage intervention twice. The T-test obtained p-value of 0.000 (there is a significant difference in body temperature before and after massage therapy in the second measurement).

The results obtained in the first measurement of the control group before compressing was 38.50 and the intervention group was 38.586. The mean difference was -0.0857 (the mean of the experimental group was higher by 0.0857 points compared to the control group), so that the significance obtained by 0.714 meant that there was no significant difference in the respondent's initial temperature in the two groups prior to the intervention. Significant results were obtained in statistical testing after the intervention both in the control group and the experimental group (p-value =0.002). The mean difference was 0.6929 (massage therapy can make changes to a body temperature of 0.6929 points compared to the group of respondents who get compresses).

As in the first measurement, in the second measurement, the mean difference between the control and intervention groups before the intervention was 0.0940 (there was no differences in the initial temperatures of the two groups (p-value=0.624). This is possible because in both the control group and the experimental group the initial temperature is obtained a few hours after each respondent gets the intervention on the first measurement.

The difference in mean after administration of the action was 0.2048 while the significance of p-value=0.388 (there was no difference in the administration of massage therapy compared with the provision of compresses in reducing the temperature of children during fever). This result is not in line with the theory put forward by⁽⁵⁾ which states that massage in children is not permitted when children have a fever because it can cause hypermetabolism and excessive vasodilation in blood vessels. Massage in children can also cause a decrease in temperature so that it can be used as a non-pharmacological alternative in handling child fever.

Conclusion

The conclusion are:

1. There is significant differences in body temperature in the first and second measurements before and after the intervention was carried out in both the compressed group and the massage therapy group.
2. There is significant difference in the mean body temperature after the intervention in the compressed group compared with the massage therapy group at the first measurement.
3. There was no significant difference in mean body temperature after the intervention in the compressed group compared with the massage therapy group on the second measurement.

The suggestions are:

1. The hospital as a means of providing health services should be able to implement a policy that massage therapy can be an alternative antipyretic companion in handling fever in children.
2. Nurses on duty in the children's room are expected to increase the role of families in handling health in children, especially children with fever.

3. For researchers, further research should be done regarding massage therapy with the use of topical alternative medicine to further enrich family knowledge in the management of sick children.

Celiac Disease in Children with Short Stature (Incidence and Morphometric Study)

Mohammed Abdul-Aziz. Hayawi

Nursing college, University of Mosul, Mosul, Iraq

Abstract

A study was aimed to determine the incidence of celiac disease (CD) and to make morphometric analysis of duodenal biopsy in children already diagnosed as a short stature in Mosul city. One hundred and seventy seven children aged between 3-17 years with short stature were examined. Their age, gender, serum antitransglutaminase antibody; and small intestinal biopsy were taken. The changes in the biopsy were evaluated and graded by Corazza and Villanacci grading system. Short stature children serologically positive for celiac disease were only subjected to small intestinal biopsy. Results revealed that most predominate age group were those between 11-17 years (mean 11.8 years), with a higher male gender (107/177, 60.4% than female (70/177, 39.6%). Of these CD represents in 54 out of 177 children, with a grade B (b) was the predominant one (24 out from 54)(44.5%). In conclusion, short stature can be the only symptom for celiac disease in children aged between 7-11 years with higher tendency in male than female. The health significance of short stature is to subject children to intestinal biopsy for celiac disease confirmation.

Keywords: *Celiac disease, short stature, villous atrophy, crypt hyperplasia.*

Introduction

Celiac disease (CD), is the commonest cause of malabsorption syndrome⁽¹⁾. It's a chronic inflammatory disorder of immunologically susceptible people, who expressed small intestine damage after a meal rich in gluten especially gliadin^(2,3). The gliadin once gain access to lamina propria, it modifies peptides engulfed and displayed on the surface of antigen presenting cells, which secrete cytokines and start the inflammatory response which will lead to tissue damage⁽⁴⁾. Serological testing during the course of CD reveals antibodies against gliadin and endomysin and transglutaminase⁽⁵⁾. The clinical signs of CD in children appeared once wheat introduced in the diet and are characterized by chronic diarrhea, with a bulky and pale greasy foul smelling stool, and failure to thrive^(6,7). The consequences will be villous atrophy, crypt hyperplasia, and intraepithelial T lymphocytosis⁽⁸⁾. These changes could lead to nutrient malabsorption syndrome^(9,10). The elimination of the condition after removal of diet containing gluten is the absolute confirmation of CD.

Recently, the disease has increased to 1% around the world, affecting children and adults⁽¹¹⁾. Many factors

play different roles in contribution to disease induction, including genetic, environmental and nutritional factors⁽¹²⁾. Although CD is a well-known cause of short stature in children, its diagnosis is often difficult because of more than 200 celiac diseases of different clinical features were reported, and the short stature may be one of the findings. CD is an autoimmune disease involving both gastrointestinal and extra gastrointestinal system⁽¹³⁾. CD could occur as classical, or silent disease and many patients have not diagnosed their condition with subsequent development of intestinal lymphoma⁽¹⁴⁾.

Materials and Method

One hundred and seventy seven children aged 3-17 years with short stature were examined. The following criteria were taken: age, gender, serum antitransglutaminase antibody; and small intestinal biopsy. Serologically positive children for CD were only subjected to small intestinal biopsy.

Tissue samples preparation and morphometric analysis:

Forty four duodenal tissue specimens were collected from serologically positive children, 33male

and 21 females (mean age 3-17 years).

The duodenal biopsies were fixed in neutral buffered formalin and processed for routine histological processing ⁽¹⁵⁾. Sections of (5µm thick) were made and stained with hematoxylin-eosin and used for morphometric analysis.

All parameters of biopsy duodenal samples were measured using the color USB 2.0 digital image camera (Scope Image 9.0- China) which was provided with image processing software. The height of each villus was measured from the top of the villus to the crypt transition and the crypt depth was defined as the invagination between two villi while the width of villi was estimated by measuring the average of the base and tip of the villus, the heights of 20 villi and the depths of 20 crypts were measured per each category, apparent villus surface area was estimated according to ⁽¹⁶⁾. All parameters were set in tables to achieve comparison among different classification of Corazza and Villanacci classification ⁽¹⁷⁾ which has divided the mucosal lesions into 2 categories:

Grade A: Nonatrophic, normal crypt and villous architecture and increased IEL numbers (>25 IELs per 100 enterocytes).

Grade B1: Atrophic, villous to crypt ratio <3:1, but the villi are still detectable and IEL numbers are increased (>25 IELs per 100 enterocytes).

Grade B2: Atrophic and flat, villi are no longer detectable and increased IEL numbers (>25 IELs per 100 enterocytes).The measurements were determined according to the basic principles of morphometric ⁽¹⁸⁾ and earlier morphometric studies of the human intestine ⁽¹⁹⁻²¹⁾.

The small intestinal mucosa parameters were studied at 100x magnification on strictly longitudinally sectioned crypts and villi, and were villi height /µm, villi width/µm, apparent villi surface area/µm², crypt depth/µm, crypt diameter/µm and no. of goblet cells per villus. Morphometric analysis was carried out by an investigator, blind to the age and gender of the subject.

Statistical Analysis

Means and standard errors were calculated for each parameter. Results were statistically analyzed with Mann-Whitney U test with SPSS for Windows 12.0 (SPSS Inc., Chicago, IL, USA).

Results

Figure (1), shows that all examined children were aged between 3-17 years, the most predominant age group were between 11-17 years (98 per 177) (55.4%).

Figure 1: Age distribution of examined children.

Of these children, Males (107 per 177)(60.4%) were more than females (70 per 177) (39.6%).

Micromorphometric measurements and histopathological examination of duodenal biopsy samples represents (54 out of 177 children)(30.5%) (Figure 2).

Figure 2: Percentage of positive CD patients

Thirty three out of 45 (61%) were males, while only 21(39%) females were reported by histopathological examination to be affected with CD (Figure 3).

Figure 3: Gender distribution of CD patients.

From the histopathological and morphometric findings, it is evident that CD children were categorized

according to Corazza and Villanacci classification into B1 category (54/54) (100%).

From Morphometric measurement, it is clear that villi height was significantly reduced in B1(c) when compared to B1(b) and B1(a) ($p < 0.05$). The same picture with villi width, crypt depth, apparent villi surface area were shown in patients with B1(b) and B1(a). Crypt diameter and no. of goblet cells per villus in B1(a) were ($p < 0.05$) higher than those of B1 (b and c) (Figure 4&5).

Figure 4: Diagrammatic representation of the inverse tendency of villi height and crypt depth in category B1 subdivisions in duodenal biopses

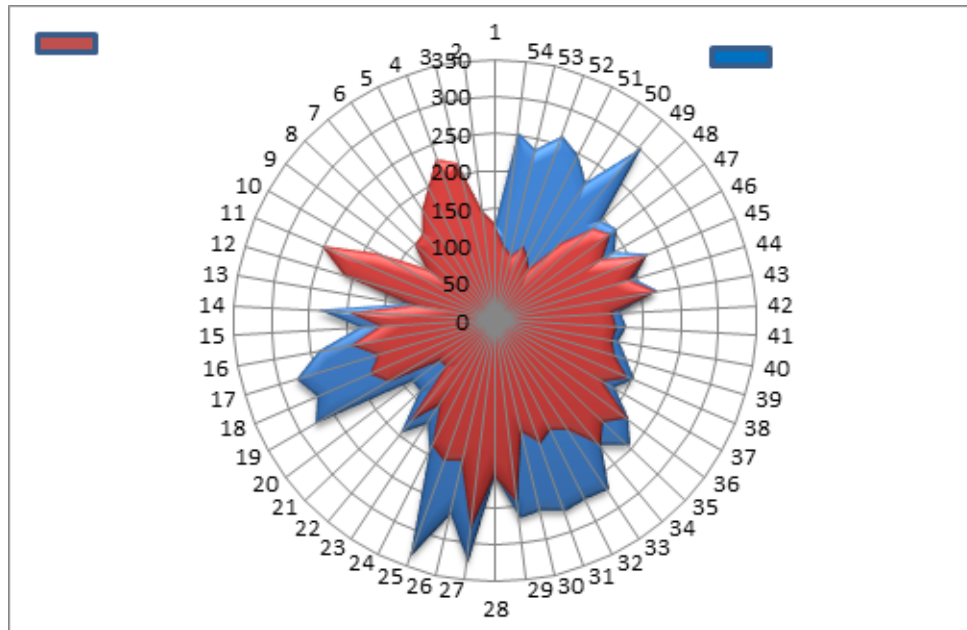

Figure 5: Radar representation of the inverse tendency of villi and crypt depth in category B1 subdivisions in duodenal biopses (from sample 1-12, the ratio 2-3; from sample 13-47, the ratio 1-2; from sample 48-54, the ratio 0-1).

The histopathological section illustrating the three subdivisions of B1 category according to Corazza and Villanacci classification are presented in the following figures:

Figure 6A, show the category B1 (a), with villus height: crypt depth of $< 3-2$. and increased in the number of intraepithelial lymphocytes ($> 25 / 100$ enterocytes).

Figures 6B, show the category B1 (b), show more advanced case of CD with more villus atrophy and broadness of the of the villi with less villus height: crypt depth ($< 2-1$); in addition to increasing in the number of intraepithelial lymphocytes ($> 25 / 100$ enterocytes) and obvious crypt hyperplasia.

Figures 6: A: The category B1 (a), with villus height: crypt depth of $<3-2$. and increased in the number of intraepithelial lymphocytes ($> 25 /100$ enterocytes). X 10⁶

B: The category B1 (b), subtotal villus atrophy and broadness of the of the villi with villus height : crypt depth of $<2-1$; increased in the number of intraepithelial lymphocytes ($> 25 /100$ enterocytes) and crypt hyperplasia. X10⁶

C: Subtotal villus, to almost total villus atrophy; no clear villus architecture; increased in the number of intraepithelial lymphocytes ($> 25 /100$ enterocytes); lymphoma and prominent crypt hyperplasia. X40⁶

The more advanced picture of category B1 according to Corazza and Villanacci classification is seen in figure 6C, in which it appears the subtotal villus to almost total villus atrophy; no clear villus architecture; increased in the number of intraepithelial lymphocytes ($> 25 /100$

enterocytes) and prominent crypt hyperplasia.

DISCUSSION

Celiac disease is a disease of all ages with a predominance of females with overall estimation of

1-2% in Europe and united states, ^(18,19) with 10-20% in first degree relatives ⁽²⁰⁾. In contrast, our findings revealed 33/54 (61%) males were diseased with CD versus 21/54 (39%) for females. This could be attributed to FOXP3 gene mutation (on X chromosome) in CD primarily of children and infants, especially in male children is associated with polyendocrinopathy and immune dysregulation ⁽²¹⁾.

Although serologic testing is recommended before duodenal biopsy in pursuing a diagnosis of CD, the titres are largely correlate with the degree of mucosal damage, especially villus atrophy ^(22,23), but biopsy is recommended when serologic results are non-diagnostic, or because up to 15% of all celiac patients are seronegative CD. Clinical, genetic and histopathology should be done in confirmation process to challenge of lack serum autoantibodies ⁽²⁴⁾.

The new sight for evaluation of the duodenal mucosal lesions in CD patients is the simplest one proposed by Corazza and Villanacci, by dividing them into two categories, nonatrophic and atrophic instead of the currently used Marsh-Oberhuber classification enhances more fruitful communication between pathologists and clinician, in addition to its simplicity, specificity and excitability ⁽²⁵⁾.

Detection of mucosal IgA tissue transglutaminase immune deposits is one of the most sensitive approaches, but Small-bowel biopsy remains the gold standard for diagnosing CD ^(26,27). Small-bowel mucosal biopsy is the standard for diagnosing CD in patient on a gluten-containing diet ⁽²⁸⁾. A presumptive biopsy diagnosis of CD can be made by characteristic findings of intraepithelial lymphocytosis, crypt hyperplasia, and villous atrophy plus confirmation when symptoms resolve on commencing a gluten free diet that return to normalized histology ^(29,30).

It is gluten with its two proteins, gliadin and glutenin, present in wheat, barley and rye are responsible for the toxic effects to coeliac patients. These proteins elicited autoimmune reactions, of theses the production of antibodies against tissue transglutaminase, and anti-endomysial antibodies ^(31,32). During gastrointestinal injury, Gliadin is toxic proteins in wheat which is a substrate of transglutaminase enzyme, provoking T- cell stimulation, ending in cytokines production and other tissue damage mediators, responsible for characteristic histopathological mucosal changes ^(33,34).

Increased IEL numbers represent an expansion of both cytotoxic T cells (60%–70% of the cytotoxic T cells express CD8) bearing the $\alpha\beta$ T-cell receptor, and $\gamma\delta$ T-cell receptor–positive lymphocytes (predominantly CD8–), with the former predominating ^(35,36). The disease is symptomatic and asymptomatic. The symptoms include abdominal pain, bloating, diarrhoea, or constipation. The systemic signs include weight loss, vitamin deficiencies, elevated liver enzyme levels, dermatitis herpetiformis, delayed puberty ⁽³⁷⁾. Refractory celiac disease occurs in adults is the main complication of CD after childhood period caused by continuous ingestion of gluten is likely to be associated with cancer diseases (lymphoma and adenocarcinoma) ⁽³⁸⁾, with great tendency to the oesophagus and large intestine, that could be reduced in gluten free diet ⁽³⁹⁾.

Conclusion

It could be concluded that early diagnosis of celiac disease by regular antibody testing and duodenal biopsy is important in order to prevent it and to prevent misdiagnoses with other autoimmune diseases, since celiac disease is silent and may be symptomatic or asymptomatic.

Association of Periventricular Edema Thickness and Optical Perineal Thickness in Hydrocephalus Non Communications by Magnetic Resonance Imaging Examination

Noor Anita Humaira¹, Sri Andreani Utomo¹, Hari Basuki²

¹Department of Radiology, Faculty of Medicine-Dr.Soetomo General Hospital, Universitas Airlangga, Surabaya, Indonesia, ²Department of Biostatistics and Population, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: Hydrocephalus is a complex neurological disorder that characterized by increased amounts of cerebrospinal fluid and enlargement of the cerebral ventricles also subarachnoid space. Magnetic Resonance Imaging (MRI) is the first choice to diagnose hydrocephalus with better anatomical features. Periventricular interstitial edema is an indication of the presence of hydrocephalus, while Magnification of the diameter in the nerve sheath is an indicator of increased intracranial pressure in humans and apes.

Objectives: To analyze the correlation between the periventricular thickness of edema and optic perineurium thickness in non-communicating hydrocephalus with Magnetic Resonance Imaging (MRI) examination.

Method: The cross-sectional study using secondary data obtained 29 samples that met the criteria from January 2014 to April 2015 which was chosen by consecutive and then analyzed.

Results: Twenty-nine samples consisted of: women 16 (55.2%) and men 13 (44.8%), age <10 months (13.8%), age 10-19 months (34.5%), age 20-29 months (34.5 %), age 30-39 months (6.9%), age ≥39 months (10.3%). The age range of patients between 7 months and 46 months with mean age 21.93 ± 11.35 months. The results of the measurements showed that there was a correlation between the periventricular thickness of edema and the thickness of the optic peri nervus.

Conclusion: There was a correlation between the periventricular thickness of edema and the thickness of the optic peri nervus. The thicker the periventricular edema, the thicker the optic peri nervus.

Keywords : *Periventricular edema, Optic Nerve Opus, Non Hydrocephalus Communicans, Magnetic Resonance Imaging (MRI)*

Introduction

Hydrocephalus is a complex neurological disorder that characterized by increased amounts of cerebrospinal fluid and enlargement of the cerebral ventricles and/or subarachnoid space. Hydrocephalus is remaining an important problem in the world of medicine, especially when correlated with the growth and development of children due to brain growth disorders, so automatic if it was not handled properly and quickly then it will cause

disruption in the growth and more severe development, even case and could be fatal.

Statistically found that a good surgical and medical management was only about 40% of hydrocephalus patients have normal intelligence and about 60% have significant intelligence and motor defects. From these statistical data showed that although with neurosurgical treatment and neurosurgical management also good medical management it turns out that about 60% of patients still have a sequel to meaningful disorders.

Although many are found in infants and children, hydrocephalus actually possible occurs in adults. In infants the clinical symptoms appear more clearly,

Email : sriandreaniutomo48@yahoo.com

making it easier to diagnose. This is because the baby's head is still open so that the accumulation of brain fluid could be compensated by the widening of the skull bones. Infants with moderate and severe hydrocephalus require VP shunt and growth is favorable in 87% of cases¹. Seen by the enlarged diameter of the head of the increasingly larger due to the increase of the pile of cerebrospinal fluid. While in adults, skull bones are no longer able to widen. As a result, no matter how much cerebrospinal fluid is accumulated, it will not be able to increase the diameter of the head.

Prevalence of hydrocephalus 4.65 every 10,000 births. The incidence rate in the world is uncertain. The incidence of infantile hydrocephalus is estimated to be 0.6 every 1,000 births, possibly occur at any age, fetus, perinatal and neonatal. From 2010 data, hydrocephalus tops the Neuropediatric Surgery Division of Dr, Soetomo General Hospital and is in the 7th position of all neurosurgery cases (outpatient and inpatient)².

The characteristic of acute hydrocephalus is the presence of low-density periventricular bands on CT, low on T1, and high on T2 / FLAIR in MRI that reflecting what is described as periventricular interstitial edema³. Shofty et al's 2012 study stated a significant correlation between widening of optic nerve diameter and its envelope with increased ICT in patients with Idiopathic Intracranial Hypertension (IIH) patients compared to healthy patients. Measurements of optic nerve diameter and sheath were performed with MRI 1.5 T axial pieces with T2 sequences at the anterior 10 mm point of the optic foramen⁴.

Neuroimaging is important for the diagnosis and management of hydrocephalus. MRI is the first option for examination to get better anatomic details in diagnosing the cause of hydrocephalus, that allows for the better morphological definition of various central nervous system structures, cerebrospinal fluid space, periventricular edema, and lesions. Various pieces of images could be obtained (axial, sagittal, and coronal); bone structure usually does not interfere with the identification of intrathecal structures, and, like ultrasound, MRI is not the source of ionizing radiation. MRI is also useful for evaluating cerebrospinal fluid flow (CSF) and localization of obstruction in the case of hydrocephalus.

Method

Consecutive sampling was used with the criteria of

patients aged 0-3 years hydrocephalus noncommunicans that diagnosed with MRI examination from January 2014 to April 2015 at the Radiodiagnostic Installation of Dr. Soetomo General Hospital Surabaya. Methods were a measurement of the periventricular thickness of edema and thickness of neural nerve of the optic nerve at sequence T2 or FLAIR, conducted by a researcher under supervision from the supervisor as a consultant of neuroradiology.

Hydrocephalus is a pathological condition due to an imbalance between production and cerebrospinal fluid absorption resulting in ventricular dilatation and increased intracranial pressure^{5,6}. While Hydrocephalus noncommunicans is a circulation of cerebrospinal fluid circulation in the ventricular system itself. Periventricular edema is a low-density periventricular band of T1 in MRI, and high in T2 / FLAIR in MRI, reflecting what is described as periventricular interstitial edema, in this study periventricular edema was measured in the lateral posterior ventricle. The optic nerve diameter is a measure of the diameter of the optic nerve sheath as measured by the head MRI with T2 sequence, measured at 10 mm anteriorly from the optic foramen. The value of the optic nerve sheath diameter is expressed by millimeters (mm). MRI used is MRI 1.5 Tesla with brand Optima MR360w 1.5T.

Furthermore, the results of MRI examinations that have been collected were measured and then arranged in tabular form, and then performed with a correlation test by Spearman. **Results**

This research was conducted to find out the correlation between the periventricular thickness of edema and optic peri nervus thickness in patients with non-communicative hydrocephalus. The total sample was 29 patients in 15 months from January 2014 to April 2015. The research data was obtained in the form of measurement of the periventricular thickness of edema with the thickness of the optic peri nervus in non-communicative hydrocephalus patients.

Distribution of Patients by age group

The mean age of patients was 21.93 ± 11.35 months. The youngest was 7 months old and the oldest was 46. Distribution of patient age is shown in table 1.

Table 1. Distribution of patients by age group

Age category	Frequency	Percentase
<10 Months	4	13.8
10 – 19 Months	10	34.5
20 – 29 Months	10	34.5
30 – 39 Months	2	6.9
≥39 Months	3	10.3
Total	29	100.0

Distribution of Patients by Sex

Based on sex, 16 males and females were 13 patients. In table 2 is shown the results of the distribution of patients by sex.

Table 2 Distribution of patients by sex

Sex	Frequency	Percentase
Male	16	55.2
Female	13	44.8
Total	29	100.0

Periventricular thickness of Edema and Perinervus Optical Thickness

Based on table 3 it was explained that the result of analysis with Spearman correlation shows $r_s = 0.458$ and $p = 0.012$ ($p < 0.05$) which means there was a correlation between the periventricular thickness of edema and optical perinervus thickness. The thicker the periventricular edema, the thicker the optic perinervus.

Table 3. Measurement results of Periventricular Thickness of Edema and Perinervus Optical Thickness

Thickness	N	Median	Minimum	Maximum	Correlation
Periventricular Edema	29	1.04	0.74	Difficult to evaluate (severe HC) 1.43	$r_s=0.458$ $p=0.012$
Perinervus Optical	29	1.01	0.75		

Discussion

This research was conducted for 15 months and obtained 29 patients as samples who meet the criteria of the study sample. Based on that number, the youngest patient aged was 7 months and the oldest was 46 months. Hydrocephalus could occur at any age, fetus, perinatal and neonatal with an incident reported 0.48-0.81 every 1,000 live births⁷.

Based on sex, 29 patients consisted of 16 men (55.2%) and 13 women (44.8%). There was no significant difference in incidence for both sexes⁸. Incidence in male and female sex was the same, except in Bickers-Adam syndrome, X-linked hydrocephalus was transmitted by women and manifested in men⁹.

Hydrocephalus was characterized by cerebrospinal fluid imbalance (CSF) in its formation and absorption, this was manifested by dilatation of the ventricular

system. Approximately 55% of all cases of hydrocephalus were congenital. There were two types of hydrocephalus: communicant and non-communicating with subarachnoid space and the diagnosis could be established by examination of Computed Tomography (CT) and Magnetic Resonance (MR).

Hydrocephalus was not a disease, but a dynamic process that takes place in the size of the ventricular system change¹⁰. Increased water in the brain parenchyma could be detected by both CT and MRI. The CT appears as hypodensity in the periventricular and the ventricular layer becomes unclear. MRI appears to be the hyperintense rim around the lateral ventricle in Fluid Attenuated Inversion Recovery (FLAIR) or proton imaging density¹¹.

Previous research has shown that ultrasonography and MRI could be used to measure the diameter of the optic nerve sheath in normal dogs. Magnification of the diameter of the nerve sheath was an indicator of increased intracranial pressure in dogs. Research on humans and monkeys shows that increased intracranial pressure that measured by increasing in diameter on the optic nerve sheath. Furthermore, measurements of optic nerve sheath diameters in humans by using Magnetic Resonance Imaging (MRI)¹². MRI could help to identify ventricular enlargement due to hydrocephalus by the presence of high-signal halo periventricular on T2-weighted imaging. But there was a high periventricular T2 signal change as a result of the microvascular disease also could be seen¹³.

The diameter of the optic nerve sheath has been found to be a strong predictor of increased intracranial pressure, with high sensitivity and specificity in some studies also in systematic reviews. The increased intracranial pressure was a rapid emergency which has a significant impact on morbidity and mortality¹⁴. Optical nerves and surrounding envelopes could be image and measured on MRI using fat-suppressed T2-weighted sequences¹⁵. From the results, there was a correlation between the periventricular thickness of edema and optical peri nervus thickness. The thicker the periventricular edema, the thicker the optic peri nervus.

Conclusion

There was a correlation between the periventricular thickness of edema and the thickness of optic peri nervus in non-communicative hydrocephalus patients with MRI examination in Dr. Soetomo General Hospital Surabaya.

The result was; there was a correlation ($r_s = 0.458$) between the periventricular thickness of edema and optic peri nervus thickness. The thicker the periventricular edema, the thicker the optic peri nervus.

Outcome of Open Intraperitoneal Dual Mesh Versus on-Lay Mesh for Incisional Hernia Repair

Jassim Mohammed Auib Al Taha

M.B.Ch.B. F.I.C.M.S. Specialist Surgeon, Department of surgery, Al- Fayhaa Teaching Hospital, Basra, Iraq

Abstract

Background : incisional hernia is any abdominal wall gap with or without a bulge in the area of a postoperative scar. There are different methods for treating incisional hernia . Mesh is always used to decrease the recurrence rate to less than 10%. Different types and different methods of mesh hernioplasty.

Objective : to compare the outcome of open intraperitoneal mesh versus on-lay mesh hernioplasty.

Method : this prospective study conducted in Al- Fayhaa Teaching hospital between February 2016 and February 2018. The patients with incisional hernia are divided into two groups . Group A treated by open intraperitoneal optimized composite mesh, and group B managed by on-lay mesh .the patients followed for 24 months following surgery to compare between the two groups regarding , operative time , hospital stay and post operative complications.

Result : eighty patients included in the study . In group A , the mean operative time was (90 ± 10.24 minutes) while for group B was (70 ± 17.53 minutes). The average hospital stay was (3.34 ± 1.27 days) and (5 ± 3.73 days) for group A and group B respectively .seroma developed in 12.5% for intraperitoneal group and 27% for on-lay group. Surgical site infection was 2.5% in group A and 15 % in group B. No patient developed recurrence of hernia in group A , while 7.5 % of group B developed recurrence during the period of follow up.

Conclusion: open intraperitoneal mesh hernioplasty is much better than on-lay method regarding the operative time , hospital stay and post operative complications.

Keywords : *incisional hernia , intraperitoneal , on-lay , hernioplasty.*

Introduction

Incisional hernia is any abdominal wall gap with or without a bulge in the area of a postoperative scar¹. Incisional hernia is common surgical problem and occurs in 2-10% of laparotomies².

The risk factors contributing to the development of incisional hernia include: anaemia, body mass index over $25 \text{ kg} / \text{m}^2$, smoking , chronic obstructive pulmonary

disease^(3,4) , multiple prior procedures , prior incisional hernia and, technical error during repair in addition to wound infection which increases the risk of incisional hernia to 1.9 time⁵ . Repair of incisional hernia have always been a challenging procedure for the surgeon because of the distorted anatomy following previous surgery .

There are different methods of treating incisional hernia .Until 1958 , suturing repair was used , but now is not recommended as it has high recurrence rate 31-54 % . For that reason an another method which is prosthetic mesh should always be used (either open or laparoscopic) to decrease the recurrence rate to less than 10%⁶ . But the mesh has many disadvantages like seroma ,hematoma , infection⁷ ,sinuses , adhesions and recurrence of hernia.

There are different types of meshes like polypropylene (pp), polyester, expanded polytetrafluoroethylene (ePTFE) and combined meshes.

A more recent movement in the design of combined synthetic meshes is to construct a mesh consisting of a polypropylene base coated with absorbable polymers⁸. The main purpose of using combined mesh is to decrease the adhesion between the mesh and the bowel.

In incisional hernia, the mesh should be wide enough to cover the defect in all directions (at least 4 cm wider than the defect) since smaller size may lead to recurrence⁹. The ideal mesh must have good tensile strength, be inert, non-carcinogenic, stable in case of infection and able to develop an inflammatory response and avoid tissue rejection¹⁰. The mesh is placed in a variety of ways. Techniques of mesh placement include on-lay, intraperitoneal and sandwich. In on-lay technique, the mesh is placed over the external oblique fascia. In the intraperitoneal technique, the mesh is placed intraperitoneally. In sandwich technique, one mesh is placed on-lay and one is placed intraperitoneally. It is known that an ideal mesh to be used inside the peritoneal cavity in contact with the bowel needs to have a high reactivity side to promote tissue growth at the abdominal wall and another side with the capacity to avoid adhesion¹¹.

The Parietex composite mesh is made from a composite structure of mono-filament polyester textile on one side and a hydrophilic absorbable collagen film on the other side to decrease the adhesion between the mesh and the bowel.

Aim of the Study

is to compare the outcome of incisional hernia repair between two methods of mesh hernioplasty: open intraperitoneal dual mesh and on-lay mesh repair.

Patients and method

This prospective study was carried out in Al-Fayhaa Teaching Hospital in Basra from February 2016 to February 2018.

Total 80 patients with incisional hernia admitted to the surgical unit as elective cases, divided into 2 groups: group A (n= 40) managed by open intraperitoneal optimized composite mesh (polyester with collagen coated film). The other group is group B (n = 40) managed by on-lay polypropylene mesh. All patients

received the same preoperative antibiotic (ceftriaxone 1 gram intravenously with induction of general anaesthesia and 4000 IU of low molecular weight heparin subcutaneously). Regarding group A the mesh was fixed intraperitoneally by multiple nylon sutures on the collagen side toward the abdominal cavity, while in group B we used (polypropylene) mesh fixed to the anterior rectus sheath. Subcutaneous redivac drain was used for both groups. Post-operative antibiotics were used for 7 days. The patients were followed for 24 months following surgery. In some cases when complications occurred we managed them accordingly. The data were analysed using SPSS statistics software version 23, mean, average and Dunnett multiple comparison test.

Inclusion criteria

1. Midline incisional hernia.
2. The hernial defect less than 10 cm diameter.
3. Body mass index less than 40 kg/m².

Exclusion criteria

1. Emergency surgery (incarcerated hernia).
2. Chronic obstructive pulmonary disease.
3. Immunocompromised patient.
4. Smoker patients.
5. Recurrent incisional hernia.
6. Non midline hernia.

Parameters of comparison

1. Age of the patient.
2. Gender.
3. Duration of surgery.
4. Hospital stay post operation.
5. Drain removal time.
6. Return to the usual activity.
7. Post-operative complications (early and late).

Result

Eighty patients complaining of incisional hernia referred to Al-Fayhaa Teaching Hospital from February

2016 to February 2018 were managed as two groups by using intraperitoneal dual mesh and on- lay mesh.

Regarding the age , patients were divided for five groups as shown in table 1.

Table 1 : The age distribution of patients in both groups.

Age (year)	Group A (intraperitoneal)	Group B (on-lay)
20 _ 29	3	2
30_ 39	15	9
40_ 49	12	14
50 _59	7	10
60 and above	3	5
Total	40	40

Table 2 : gender distribution in both groups.

Gender	Group A (intraperitoneal)	Group B on-lay)
Male	18 (45%)	11 (27.5%)
Female	22 (55%)	29 (72.5%)
	40 (100%)	40 (100%)

In intraperitoneal mesh group 45% (n= 18) were male and 55% (n= 22) were female . On-lay group 72.5% were female. Female forms 63.75% (n= 51) of all patients.

Table 3 : different parameters for comparison.

	Group A (Intraperitoneal)	Group B (on-lay)	P value
Duration of surgery Minute (mean \pm SD)	90 \pm 10.24	70 \pm 17.53	P= 0.001
Hospital stay (Average \pm SD)	Average 3.34 \pm 1.27 days Range 2-6	Average 5 \pm 3.73day Range 3-8	P= 0.05
Time of drain removal	7 day	10 day	P= 0.01
Return to usual activity (median \pm SD	28 \pm 4.32 days	50 \pm 6.75 days	P= 0.05

In group A (intraperitoneal mesh) , the operative time ranged from 60 to 110 minutes with a mean operative time of 90 \pm 10.24 minutes , while in group B (on-lay) the operative time ranged from 50 to 95 minutes with a mean operative time of 70 \pm 17.53 minutes (p= 0.001).

The duration of hospital stay ranged from 2-6 days with an average duration of (3.34 ± 1.27 days) in intraperitoneal group , while in on-lay group the duration ranged from 3-8 days with average of (5 ± 3.73 days) $p= 0.05$.

Table 4 : early and late complications in both groups.

Post operative complications	Group A (Intraperitoneal)	Group B (On-lay)	P value
Early complications			
Seroma	5 (12.5 %)	11 (27%)	<0.05
Haematoma	1 (2.5%)	4 (10%)	<0.01
Surgical site infection	1 (2.5%)	6 (15%)	<0.001
Late complication (Recurrence)	Zero (0%)	3 (7.5%)	< 0.05

Early and late complications were listed in table 4 .seroma developed in 12.5% in intraperitoneal group and 27 % in on-lay group ($p= 0.05$). Haematoma developed in 2.5% and 4 % in intraperitoneal and on-lay groups respectively $p=$.

Regarding surgical site infection developed 2.5 % of group A and 15% of group B ($p= 0.001$).

Recurrence of the incisional hernia which is the late complication was noted in 3 patients (7.5%) in on-lay group , while non of intraperitoneal group developed recurrence during the period of follow up ($p< 0.05$).

Discussion

Incisional hernia is a common surgical problem encountered in clinical practice . The outcome of the surgery is based not only on the technique used but on the experience of the operator, meticulous dissection , tension free repair etc.¹². Repair of incisional hernia is an ongoing challenge in surgical practice and a wide spectrum of surgical techniques have been developed ranging from direct suture technique to the use of various types of mesh to close the defect and strengthening the musculofascial tissues to avoid recurrence ¹³.

When considering the best location for the placement of mesh , a number of features are to be considered. Firstly , technique that avoid the devascularisation of flap will prevent wound complications like infections, flap necrosis, and surgical site infection . Secondly , technical ease and duration of surgery may affect the surgeon's choice ¹⁴.

In our study the mean duration of surgery , in cases underwent intraperitoneal mesh repair was (90 ± 10.24 minutes), while in cases with on-lay mesh repair was (70 ± 17.53 min.) the difference is statistically significant($p= 0.001$) . Other studies showed similar result (Godara et al. ¹⁵ . And Glysteen ¹⁶.)

This difference in time is may be due to more time needed in intraperitoneal method to create wider clear intraperitoneal surface and release the adhesion of previous surgery , while in on-lay method no need for that as the mesh fixed to the anterior rectus sheath. Miller K, et al showed longer time needed for intraperitoneal mesh fixation as compared to on-lay method ¹⁷.

The average duration of hospital stay was 3.34 ± 1.27 days (range 2-6 days)for intraperitoneal group and 5 ± 3.73 days (range 3-8 days) for on-lay group ($p= 0.05$). Other study showed average hospital stay 7 days for intraperitoneal group and 9 days for on-lay group ¹⁸.

Regarding post operative complications, seroma developed in 12.5% and 27% in intraperitoneal and on-lay mesh respectively ($p= 0.05$) , Godara et al study shows similar rate of complication ¹⁵ . Seroma formed in on-lay more than intraperitoneal technique , may be due to that on-lay technique needs more subcutaneous dissection to place the mesh which leads to devitalized tissue and seroma formation.

Other study by Salamone G, Licari L ¹⁹, showed the similar result of our study.

The difference of heamatoma formation is significant

between both groups , it founds in 2.5% and 10% in intraperitoneal and on-lay mesh respectively ($p= 0.01$).

Surgical site infection in intraperitoneal technique was 2.5% while in on-lay technique it was 15% (the difference is statistically significant $p= 0.001$). The superficial location of mesh makes it in danger of infection if there is wound infection. This infection treated by antibiotics and wound dressing and no need for mesh removal. This result agreed with many other studies that found on-lay technique is associated with higher rate of wound infection ^{20,21}.

The recurrence of hernia in our study is 7.5% in on-lay mesh while in intraperitoneal mesh , non of our patients developed recurrence , this result agreed with study done by Vries Reillingh et al .who noticed recurrence of 23% in on-lay technique and no recurrence in intraperitoneal technique ²². Gleysteen found recurrence rate of 20% and 4% on-lay and intraperitoneal mesh respectively ¹⁶. Other studies showed higher recurrence rate with on-lay mesh as compared with intraperitoneal mesh ^{13,23,24}. This lower recurrence rate in Intraperitoneal mesh may be explained that mesh in this place can not be dislodged or ruptured by increasing intra-abdominal pressure , but instead is fixed in place by the same force that caused the hernia.

Conclusion

From our study we concluded that the use of intraperitoneal composite mesh is better than on-lay placed mesh regarding the hospital stay and postoperative complications.

Abstract

The Objective: To assess the knowledge level of teachers' regarding pupils with attention-deficit hyperactivity disorder at Mosul elementary schools.

The Methodology: A descriptive study was applied at Mosul elementary schools in from 18th of January till 4th of June / 2019. The sample involved of (200) teachers working in the selected purposively from elementary schools from Mosul city, (100) teachers from every one side of the city, (10) teachers from each school that selected in this study.

The Result: The socio-demographic characteristic of the study presents that 72% (144) of them females , 35% (70) at age (36-45) years old, 68.5% (137) graduated from institute of teaching , 48% (96) of them have (1-15) years of general experience in the field of teaching, , 81% (162) of them not have any participation in training courses in ADHD between children, 70% (140) of them not have previously reading source of ADHD. The total teachers' knowledge was 75.5 % (151) of them at not acceptable level.

The Recommendations: Continuous extensive special programs, training course and workshops should be design and implement at elementary schools in Mosul City

Keywords: Teachers' knowledge, Attention-Deficit Hyperactivity Disorder in Pupils

Introduction

Attention deficit hyperactivity disorder (ADHD) is represented as physical movements which exceed the normal limit or the acceptable limit, and it shows in the form of a group of behavioral disorders arise as a result of many psychological and organic causes, hyperactivity includes random, involuntary and unsuitable movements appear as a result of organic or psychological causes,

and it is accompanied with an attention deficit (1, 2). Therefore this problem is signified as a very common disorder that result of the diagnosed children pupils' population number with ADHD, there is an abundance of research available on empirically supported methods of identifying and treating ADHD⁽³⁾. In addition, there are professionals from multiple disciplines who aide in diagnosing and treating this disorder⁴. Medical providers, mental health providers, and educators can all play roles throughout the diagnostic and treatment process⁽⁵⁾. The elementary school teachers are the most often that represent the first person have to face these behaviors in the classroom and should be able to make a referral for assessment for ADHD (if the child didn't diagnose yet), because the children with exhibit behaviors become unable to cope with structured school environment, their

peers and their teachers^(6, 7). Worldwide population of children younger than 15 years is 1.8 billion that is 28% of world population is children pupils. Schools play a crucial and formative role in spheres of cognitive, language; emotional, social and moral development of children, there is now growing recognition that schools have significant role in promoting mental health⁽⁸⁻¹²⁾.

The Objectives of the Study

1. To assess the teachers' knowledge levels regarding attention-deficit hyperactivity disorder between pupils at elementary schools in Mosul City.

2. To find out the relationships between the socio-demographic variables and the teachers' knowledge level regarding attention-deficit hyperactivity disorder between pupils at elementary schools in Mosul city

Material and Method

Design of the study: A descriptive study was carried out at the selected elementary schools in Mosul city to assess the teachers' knowledge level regarding attention-deficit hyperactivity disorder between pupils from 18 of January till 4 of June / 2019.

Sample of the study: The sample consisted of (200) teachers working in the selected purposively from elementary schools from Mosul city, (100) teachers from each side of the city, (10) teachers from each school that selected in this study.

Study tool: The questionnaire was constructed and provided for teachers to assess the knowledge which consists of two parts. The first part concerns the demographic information, while the second part was related to the teachers' knowledge in attention deficit hyperactivity disorders. The first section is the teachers' knowledge regarding ADHD in generals, the second section regarding the sign and symptoms, the third sections regarding causes and diagnosis, the fourth sections regarding general managements of students' children, the fifth section regarding the teachers' role in classroom through dealing with ADHD student's children, lastly the sixth section regarding school role through dealing with ADHD student's children.

Results

The table (1) presents that the teachers' knowledge level results regarding ADHD in the right and left side of Mosul city, the result of the teachers' knowledge regarding ADHD at the two side show that at fail and not acceptable level in all items of the teachers' knowledge questionnaire. The table (2) presents that the teachers' knowledge level results regarding ADHD in the Mosul City that content; the teachers' knowledge result regarding ADHD show that all items of the teachers' knowledge questionnaire at fail level except the total teachers' knowledge at not acceptable level.

Discussion

The finding that present in table (1) shows teachers’ knowledge in the right side of Mosul city, that the teachers’ knowledge regarding ADHD in general are 48.0 % of them at fail level of estimate knowledge level, teachers’ knowledge regarding sign and symptoms of pupils with ADHD are 56.0% of them at fail level of estimate knowledge level, teachers’ knowledge regarding the causes and diagnosis of pupils with ADHD are 51.0 % of them at fail level of estimate knowledge level. The teachers’ knowledge regarding the general managements’ of pupils with ADHD are 64.0 % (64) of them at fail level of estimate knowledge level, teachers’ knowledge regarding the teacher roles inside the classroom with pupils having ADHD are 60.0% (60) of them at fail level of estimate knowledge level, teachers’ knowledge regarding the school roles with pupils having ADHD are 64.0% of them at fail level of estimate knowledge level, and lastly the total teachers’ knowledge of the right side of Mosul city are 71.0% of them at not acceptable level of estimate knowledge level. But the left side of Mosul city shows that the teachers’ knowledge

regarding ADHD in general are 40.0 % of them at fail level of estimate knowledge level, teachers’ knowledge regarding sign and symptoms of pupils with ADHD are 46.0 % of them at fail level of estimate knowledge level, teachers’ knowledge regarding the causes and diagnosis of pupils with ADHD are 47.0 % of them at not acceptable level of estimate knowledge level, teachers’ knowledge regarding the general managements’ of pupils with ADHD are 65.0 % of them at fail level of estimate knowledge level. The teachers’ knowledge regarding the teacher roles inside the classroom with pupils having ADHD are 62.0 % of them at fail level of estimate knowledge level, teachers’ knowledge regarding the school roles with pupils having ADHD are 75.0 % of them at fail level of estimate knowledge level, and lastly the total teachers’ knowledge of the left side of Mosul city are 78.0 % of them at not acceptable level of estimate knowledge level. This result agree with Alkahtani (2013), and Safaan et al. (2017) shows in there study that more than half (59.0%) of the studied primary school teachers had poor total knowledge about ADHD compared to only 10.2% of teachers had good knowledge. demonstrates that two thirds of teachers had

poor knowledge about responses of teachers regarding ADHD treatment subscale followed by responses regarding ADHD general information subscale (52.2%) then responses regarding symptoms & diagnosis ADHD subscale (41.6%).^(14, 15). The teachers' knowledge in the Mosul City that the teachers' knowledge regarding ADHD in general are 44.0 % of them at fail level of estimate knowledge level, the teachers' knowledge regarding sign and symptoms of pupils with ADHD are 52.0 % of them at fail level of estimate knowledge level, the teachers' knowledge regarding the causes and diagnosis of pupils with ADHD are 45.5 % of them at fail level of estimate knowledge level, the teachers' knowledge regarding the general managements' of pupils with ADHD are 64.5 % of them at fail level of estimate knowledge level. The teachers' knowledge regarding the teacher roles inside the classroom with pupils having ADHD are 62.0 % of them at fail level of estimate knowledge level, the teachers' knowledge regarding the school roles with pupils having ADHD are 70.0% of them at fail level of estimate knowledge level, and lastly the total teachers' knowledge of Mosul city are 75.5 % of them at not acceptable level of estimate knowledge level. This result agree with Alkahtani (2013) show in his study that teachers' overall percentage score of correct responses (items answered correctly) was reflects poor knowledge of ADHD. Incorrect responses (items answered incorrectly) percentage was indicate misperceptions of ADHD. Don't know responses (items that teachers admitted they just don't know) percentage was point to a lack of knowledge of ADHD among teachers. Teachers' overall percentage scores of the correct, incorrect, and don't know responses are presented graphically^(14,15).

The Conclusion and Recommendation:

According to the results of the present study, the researchers conclude the teachers of the elementary schools in Mosul city do not have appropriate and adequate knowledge regarding the attention-deficit hyperactivity disorder in pupils. There is no significance correlation between the teachers' knowledge and all demographic characteristics except the training courses. According to the results and conclusion of the present study, the researchers recommend the Ministry of Education, Nineveh Education Directorate and ministry of health, Nineveh Health Directorate to increase joint cooperation between them and focusing on the school health system within the school and health center, also in addition to activating the social researcher system in the

elementary school.

Ethical Consideration: before data collection, an official permission was obtained from the Ministry of Education/ Nineveh Directorate , and Written approval of participants was obtained prior to the start of data collection.

Conflicts of Interest: Nil

Antibacterial Properties of New Cement Based Capping Material Prepared from Egg Shell and Biopolymer (Chitosan)

Hemn M. Sarmamy¹, Dara H. Saeed²

¹Lecturer, Department of Pediatric Dentistry, Orthodontics and Preventive Dentistry, College of Dentistry, Hawler Medical University, Irbil, Iraq, ²Assistant Professor, Department of Conservative Dentistry, College of Dentistry, Hawler Medical University, Irbil, Iraq

Abstract

Backgrounds : This study evaluated the antimicrobial properties of a newly prepared, cement-based capping material and biopolymer (chitosan) with Mineral Trioxide Aggregate MTA and Biodentine. **Method:** The antibacterial effects of a set of specimens against *Streptococcus mutans*, *Rothia dentocariosa*, and *Enterococcus faecalis* were evaluated by agar diffusion tests. Thirty disc-shaped specimens (10 of each type of materials; 6 mm in diameter × 2 mm in thickness) were prepared. One specimen for each material was placed on each agar plate, and the plates incubated for 24 h. After incubation, the diameter of the inhibition zone was calculated at three different points and averaged. **Results:** Statistically significant differences were found among new calcium-based capping material, MTA, and Biodentine. An ANOVA test was used to evaluate the effect of materials against each type of bacteria. This revealed that the inhibition zones produced by the new cement based capping material mixture were statistically significantly larger than those produced by the other materials. **Conclusions:** Within the limitations of the experimental methods employed in the present study, the cement-based capping material prepared from egg shells and the biopolymer chitosan has better antimicrobial properties than Biodentine and MTA.

Key words: Egg shell and biopolymer (chitosan), antibacterial , Eggshell

Backgrounds

Streptococci, lactobacilli, and Actinomyces species are the main cariogenic microflora presented on the surface of fissures, smooth-surface coronal caries, or root-surface caries. Members of the mutans group of streptococci spacially, *Strep. mutans* and *Strep. sobrinus* are considered to be the primary etiological causes in the induction of coronal and root caries ¹.

One of the bacteria most frequently involved bacteria in dental caries is *Streptococcus mutans*; it efficiently degrades fermentable carbohydrates to acids, which can demineralize tooth tissue (Van Houte et al; 1991; Brukiene et al; 2005; Konradsson et al; 2006)². Superficial infected dentin contain greater numbers of bacteria compared with deeper dentin. The application of strict anaerobic sampling and cultivation methods

always reveals greater bacterial retrieval, including that the environment of carious dentin promotes the survival of obligately anaerobic bacteria. Thus, species of Propionibacterium, Eubacterium, and Bifidobacterium are predominate microflora of deep carious dentin, including Actinomyces, Lactobacillus, and some streptococci, but rarely *S. Mutans* ³. The antibacterial effect is an important property because killing bacteria is a direct strategy for eliminating the cause of dental caries ^{4, 5}. Dental cements play an important role in assuring a healthy, infection-free oral cavity because they facilitate the sealing of damaged areas. However, it is still likely for infections to appear within these cements, and as such, antimicrobial activity must be one of the essential properties of dental cements ^{6, 7}. Dental cements are greatly used in odontological treatment. However, due to the dangerous nature of some of the materials used and the reduced biological efficiency, newer and safer substitutions are needed, particularly those possessing higher antimicrobial activity than their traditional counterparts ⁸⁻¹⁰.

Coressponding author:

Hemn M. Sarmamy

email :hemn.suleman@hmu.edu.krd

Antibacterial activity and sterilization of carious dentin could be supplied by cements containing calcium hydroxide¹¹. Among the pioneer contaminants of dental cements, there are several types in the oral cavity, such as *Enterococcus*, *Lactobacillus*, and *Streptococcus* species. The inability to prevent these species may lead to tissue invasion with consequential pulpal necrosis and tooth loss. Thus, the search for new compounds that may ameliorate biocompatibility and functionality via enhanced antibacterial properties of cements has gained importance¹². Antimicrobial action and the ability to enhance the formation of mineralized tissue are both dependent on an alkaline pH¹³.

The aim of this study was to compare and evaluate the antimicrobial action changes caused by new capping cement material (prepared from egg shells and biocompatible chitosan) with MTA and Biodentine materials.

Method

In this study, we compared three experimental groups:

- New cement based capping material prepared from egg shells and the biopolymer chitosan (experimental material). The powder to liquid ratio was 1 spoon of powder to 8 drops of liquid; mixing time: 45 seconds, working time: 2 min, setting time: 5.45 min.

- Mineral Trioxide Aggregate (Rootdent, Tehnodent, Russia) (control group).

- Biodentine material (septodont, France) (control group).

The microbiological study was carried out in the Bio[®] Laboratory of Microbiology in Erbil, Iraq.

The antibacterial effects of specimens against *S. mutans*, *Enterococcus faecalis*, and *Rothia dentocariosa* were evaluated using agar diffusion tests as described by Bauer et al.¹⁴. After isolation and identification, a single colony from each type of bacteria was transferred into 5 mL of sterile Brain Heart Infusion BHI broth (Lab, UK) and incubated at 37°C for 24 h. In order to prepare the experimental suspensions, a McFarland 0.5 turbidity

tube was prepared and used to make suspensions of the strains in a brain-heart infusion at approximately 1.5×10^8 organisms/mL, which were flood-inoculated onto the surface of Muller-Hinton agar (Lab, UK) plates¹⁴.

Thirty Petri plates with 20 mL of Muller-Hinton agar were inoculated with the microbial suspensions using sterile swabs that were spread onto the medium. Ninety disc-shaped specimens (30 of each type of materials; 6 mm in diameter \times 2 mm in thickness) were prepared and divided into three groups:

- Group A: 30 experimental specimens composed of calcium-based cement subdivided into:

A1: 10 specimens inoculated with *E. faecalis*

A2: 10 specimens inoculated with *S. mutans*

A3: 10 specimens inoculated with *R. dentocariosa*

- Group B: 30 specimens composed of Biodentine subdivided into:

B1: 10 specimens inoculated with *E. faecalis*

B2: 10 specimens inoculated with *S. mutans*

B3: 10 specimens inoculated with *R. dentocariosa*

- Group C: 30 specimens composed of MTA subdivided into:

C1: 10 specimens inoculated with *E. faecalis*

C2: 10 specimens inoculated with *S. mutans*

C3: 10 specimens inoculated with *R. dentocariosa*

Three discs (one for each material) were placed on each agar plate using sterile forceps and incubated in an aerobic candle jar at 37°C for 24 h. After incubation, the diameter of the inhibition zone was calculated at three different points and averaged. The sizes of the inhibition zones for each material were measured based upon the diameters of the halo of inhibition and the disc's diameter as follows:

Size of inhibition zone = diameter of halo – diameter of the disc (Figures 1–3).

Figure 1: The zones of bacterial growth inhibition against (*Streptococcus mutans*).

Figure 2: The zones of bacterial growth inhibition against (*Enterococcus faecalis*).

Figure 3: The zones of bacterial growth inhibition against (*Rothia dentocaris*).

Results

The antibacterial activities of the tested materials determined by the means and standard deviations of growth inhibition zones for various microorganisms after 24 h are shown in [Table 1](#). All materials showed antibacterial activity. The results of the 24-h incubation revealed that the experimental materials were the most effective against all tested bacterial strains, while the growth zones for the MTA and Biodentin groups were smaller.

Table 1. The diameters (in mm) of the zones of bacterial growth inhibition against the bacterial strains.

Materials	E. faecalis		S. mutans		R. dentocariosa

Discussion

The development and progression of pulpal and periapical diseases, as well as endodontic treatment failure were essentially attributed to Microorganisms. Treatment consequences will depend on the successful elimination of the associated microorganisms and infected tissues¹⁵.

The agar diffusion test is routinely used to explore the antimicrobial properties of dental materials. This method involves placing the tested material on an agar plate inoculated with oral bacteria. Using this method, an inhibition zone around the material is produced. To produce a zone of inhibition, the material needs to ooze a soluble antimicrobial agent. If the amount of the antimicrobial agent removed is not sufficient, the zone of inhibition will not be produced. In general, larger zones

correlate with the concentration and/or potency of the tested bactericide. This also proposes the susceptibility of the tested bacteria to a specific antimicrobial agent, and the size of the inhibition zone can be measured using a graduated ruler^{16–18}.

The bacterial strains used throughout the experiments were *S. mutans*, oral Lactobacilli, and *E. fecalis*. These microorganisms play an important role in dental biofilm formation and in the etiology and progression of caries. *S. mutans* is one of the bacteria most frequently engaged in dental caries. It efficiently degrades fermentable carbohydrates into acids, which can demineralize tooth tissues^{19–21}.

Fransson et al. (2014) consummated that *E. faecalis* reduced the activity of odontoblast-like cells, and it had an inhibitory effect on collagen-1 production. Thus,

it decreases the ability of odontoblasts to induce the synthesis of tertiary dentine²². *E. faecalis* has also been shown to be a highly resistant bacteria in the root canal system, and it plays major role in endodontic treatment failures²³.

The results of this study revealed the effective antibacterial activity of experimental new calcium-based capping material, which showed larger growth inhibition zones of tested bacteria compared to MTA and Biodentine. This may be associated to the liberation of ions and alkalinity of new capping material.

The experimental cement consisted of 70% CaO, 25% MgO, 3% hydroxyapatite (HA), 1.5% bismuth oxide, and 0.5% calcium acetate. Calcium-based cement has an antibacterial effect, and it is a possible candidate for use in pulp capping and cavity lining²⁴. Li et al. (1998) showed that HA has antibacterial properties against cariogenic bacteria. They concluded that it would be best to harness the antibacterial properties of HA by using it as a base in the treatment of carious cavities in order to inhibit residual cariogenic bacteria²⁵.

Tin-oo et al. (2007) found that tubes containing 200 mg or more of HA completely inhibited *S. mutans*, and no bacterial growth was seen. This finding has shown that HA displays solid antibacterial properties. The bacterial growth inhibition could be related to magnesium ions or active oxygen released by MgO into the medium²⁶.

Sawai et al. (1995a) showed that MgO, CaO, and ZnO exhibited strong antibacterial activity. They found that MgO and CaO powders displayed bactericidal effects against Gram-positive and Gram-negative bacteria, while ZnO powder inhibited the growth of Gram-positive bacteria more strongly than Gram-negative bacteria²⁷.

The polycationic structure of chitosan CH is necessary for antibacterial activity. Electrostatic interactions between the polycationic structure and the predominantly anionic components of the microorganisms' surface (such as Gram-negative lipopolysaccharide and cell surface proteins) play a primary role in antibacterial activity, because environmental pH is below the pKa of CH and its derivatives²⁸.

Liu et al. (2006) found that the antibacterial activity of low molecular weight (MW) CH against *Escherichia coli* is higher than that of the high MW CH with the same degree of deacetylation²⁹. *R. dentocariosa* was originally

isolated from dental plaques and caries. It is found in the oral cavity and pharynx of humans where it forms a portion of the normal microflora³⁰. *R. dentocariosa* was seen in over 30% of healthy individuals by an investigation of throat swabs³¹. Furthermore, it can also be extracted from respiratory tract specimens as part of the normal oral flora²⁹.

Biodentine showed some initial bacterial inhibition, but this was significantly lower than that of the new cement based capping material and MTA, which displayed a large spread in data. The fact that Biodentine revealed zones of inhibition implies that Biodentine itself has some definite antimicrobial effects. This might be related to Biodentine's high pH³². Because *E. faecalis* can live in alkaline environments, this may play a role for the smaller inhibition zone of Biodentine against *E. faecalis*. Perhaps the inherent and persistent alkalinity of Biodentine is just enough to smash *E. faecalis*³³. Biodentine powder is composed mainly of tricalcium silicate, calcium carbonate, and zirconium oxide as a radio-pacifier. Meanwhile, liquid Biodentine contains calcium chloride as the setting accelerator and water as the reducing agent. The addition of up to 30% calcium carbonate, calcium sulfate, and calcium chloride resulted in an improvement in the physical properties of tricalcium silicate cement. It also improved the degradability and bioactivity of the resultant material. Calcium silicate hydrate gel, calcium hydroxide and unreacted tricalcium silicate are resulted from the hydration of tricalcium silicate. The antibacterial and anti-inflammatory properties of the calcium hydroxide produced from the tricalcium silicate hydration, mainly due to the high (alkaline) pH of the surrounding environment after it dissolves³⁴⁻³⁵.

Conclusions

Within the limitations of the experimental methods employed in the present study, a number of conclusions can be seen. All tested materials have antibacterial properties against the tested bacteria. Furthermore, the experimental new calcium-based capping material cement showed remarkable antibacterial activity against the bacteria tested, which was comparable to that of MTA and better than Biodentine.

Bow tie Model of Palliative Care as an Early Approach to Providing care for Patients with Heart Failure

Hossein Jafarizadeh¹, Yaser Moradi¹, Alireza Rahmani¹, Amir Mohammad Amini¹

¹Patient Safety Research Center, Urmia University of Medical Sciences, Urmia, Iran.

Abstract

Background & objective: In patients with heart failure due to the complications of the disease and the lack of definitive curative treatment, in the majority of cases, the emphasis is laid on reducing these complications and the symptoms of the disease. Therefore, to manage the symptoms and the complications, and reduce the effect of the disease on the patients' quality of life, in addition to routine care, additional care is required among which palliative care is of great importance. The present narrative review aimed to introduce bow tie model of palliative care as an early approach in care for patients with heart failure. **Methodology:** This study introduces early palliative care for patients with heart failure by reviewing the literature on the bow-tie model. **Results:** Although the bow-tie model Early Palliative Care is an important part of end-of-life care, it is not limited to that stage. It is also applied for patients who are in the early stages of their disease. **Conclusion:** Based on the NYHA New York Heart Association functional classification, patients with heart failure are classified in one of four categories and it seems that bow tie model of palliative care is an effective method of reducing the symptoms, complications, and effect of the disease on the quality of life of the patients especially in the patients of Class I and class II who are in the early stages of the disease.

Keywords: Palliative care, Bow-tie model, Heart failure

Introduction

Nearly 23 million people worldwide and over 5.8 million people in the United States suffer from heart failure¹. Heart failure is also one of the leading causes of disability and death in Iran². In Iran, about one percent of the population over the age of 50 and ten percent of the elderly people over the age of 80 suffer from heart failure^{2,3}, so that regarding the epidemiological transition and the increasing rate of the elderly population as well as the criticality high prevalence of cardiovascular risk factors in both genders, only 4% of the 15-44 age group and 1% of the 45-64 age group had no cardiovascular risk factor, the high incidence and prevalence of heart failure is justifiable as in the not too distant future, it will be more than its present prevalence of 3500 patients per 100,000 population along with a change in population pyramid and the aging of Iran's young people^{2,3}.

Heart failure is a debilitating disease profoundly affecting the functional conditions, quality of life and socioeconomic status of the patients and their families⁴. Furthermore, it impairs the patients' sexual function, occupational and family roles, and social life^{5,6}. Due to the complications of the heart failure and the reduced quality of life, the patients, in addition to medication treatment, require special care to relieve pain and disability, so they can adapt to the existing conditions and apply their ability to continue living and pursue their physical and occupational activities decently⁷.

In patients with heart failure due to the complications of the disease and the lack of definitive curative treatment, in the majority of cases, the emphasis is laid on reducing these complications and the symptoms of the disease. Therefore, to manage the symptoms and the complications, and reduce the effect of the disease on the patients' quality of life, in addition to routine care, additional care is required among which palliative care is of great importance^{8,9}. This is interdisciplinary and patient-centered care, which motivates the patient to continue the care and provides spiritual support, physical comfort and cooperation with the patient's

family to care for patient¹⁰. If we use palliative care in the early stages of the disease, it can lead to positive consequences such as reduced complications, relief from physical and mental stress, and ultimately improvement in the patient's quality of life¹¹. Considering the above, the present narrative review aimed to introduce bow tie model-based palliative care as an early approach in care for patients with heart failure.

Methodology

The present study is a narrative non-systematic review conducted a comprehensive synthesis of published studies on bow tie model-based palliative care in patients with heart failure. To do so, keywords including bow tie model, palliative care, and heart failure were searched in databases of PubMed, Scopus, Google Scholar, and Science Direct using the AND and OR indicators.

Results

After examining the available studies, texts, and specialized websites, the followings explained in order.

Palliative care

Palliative care is an approach that improves the quality of life of patients and their families facing the problems associated with life-limiting illnesses through the prevention and relief of suffering by means of early identification, impeccable assessment, and treatment of pain and other physical, spiritual and psychosocial problems. In fact, from the moment on the diagnosis is established, palliative care helps the patients and their families to cope with the pain, suffering, and complications caused by the disease¹² and emphasizes that more particular attention should be paid to the person with the disease than to those with other diseases. Actually, comprehensive patient care will never be provided without palliative care¹³.

Bow tie model-based palliative care

This care model guarantees the patient survival along with curative treatment and delineates the path of care well, and demonstrates the dual reality of "hope for the best, plan for the worst." Trying to survive is a remarkable reality in this model of care, but the reality of death is also taken into account, and the concepts and pathways existing in this model can be defined by different cultures and implemented with regard to the broad definition of homecare in those cultures^{14, 15}.

Bow tie model was first introduced by Dr. Philippa H. Hawley medical oncologist of Vancouver Cancer Centre and derived from the Canadian Hospice palliative Care Association Model¹⁴. This model places greater emphasis on palliative care and reducing disease complications, and it is not restricted to patients receiving end-of-life care but is also applicable to patients who are in the early stages of their disease¹⁶.

This model emphasizes complementary methods of both palliation and treatment as both concepts are simultaneous and the path of care is not one-sided. The model's name is derived from two symmetrical triangles of "disease management" and "palliative care" that take the form of a bow tie^{14, 15}. This model can be implemented according to the patient's specific circumstances, and the goal of palliative care model is to manage the symptoms and complications of the disease that can improve the patient's quality of life and widen the gap between the onset of disease and disability resulting from its progression. Unlike single-sided triangles, a double-sided triangle of this care model can have all the consequences of a disease, from its diagnosis to the end, which means that survival and death are both acceptable and possible. The shape of each triangle corresponds to the base of the other triangle, indicating that palliative care can be implemented from the moment on the diagnosis is reached or from early stages of the disease and continued with medication therapy for the rest of life. This model suggests that palliative care is not only restricted to the last few months of a patient's life, but also plays an important role early in the course of the disease and during it as well, and potentially survivorship is its main goal¹⁴. In addition, it builds patients' hopes up and reduces their negative emotions such as expecting impending death¹⁷ Fig.1.

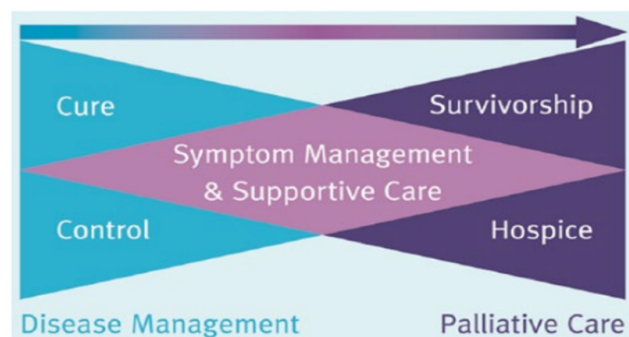

Figure 1: Palliative care based on the Bow tie model, Hawley, 2017¹⁸.

Discussion and Conclusion

In the present model of care, patient recovery is considered as one of the goals of palliative care implementation, and regarding the onset of palliative care early in the course of the disease, the complications are far less severe. On the other hand, with regard to control over the complications of the disease, the gap between the diagnosis and the end-stage of the disease widens so that the patient can spend more time without the adverse and debilitating effects of the disease¹⁴. In a study by Temel et al. 2010, the results indicated that early palliative care has led to improved quality of life, control of depression symptoms, and increased survival of patients with non-metastatic small cell lung cancer¹⁹.

There is currently no comprehensive and inclusive palliative care for patients with heart failure, and there is just limited number of patients whom the care is available for. Furthermore, there is evidence that shows the lack of management and palliative care for the patients in early stages of heart failure^{20, 21}. Therefore, it is essential to adopt early palliative care for patients with heart failure who do not have adequate access to medication and pain relief treatments and also have a low quality of life due to the disease¹¹.

Based on the NYHA functional classification, patients with heart failure are classified in one of four categories and it seems that bow tie model of palliative care is an effective method of reducing the symptoms, complications, and effect of the disease on the quality of life of the patients especially in the patients of Class I and class II who are in the early stages of the disease. Because in this model, unlike previous models where palliative care is utilized solely for patients with a terminal illness, implementation of palliative care begins from the moment on the diagnosis is established and increases along with disease progression according to the patient's needs¹⁴.

Community Acquired Pneumonia; Chest X-Ray Findings in Three Different Times

Kosar Mohamed Ali

Assistant Professor, Department of Medicine, College of Medicine, University of Sulaimani, Kurdistan Region, Iraq

Abstract

Introduction: community acquired pneumonia is common health problem with concerns regarding chest-X-ray findings in different occasions during the disease course. The aim of this study is to compare chest-X-ray findings at presentation, 3 days and 6 weeks after presentation.

Methods: A prospective, observational study was conducted. The consecutive cases of single center were collected from January 2016 to January 2017. The diagnosis was made whenever there was new infiltrate in the CXR with compatible clinical features. All patients with nosocomial infection were excluded from the study. The included data were demographic characters, history, clinical examination, and CXR findings.

Results: The study included 60 patients, 44(73.3%) were male while 16(26.7%) were female. The age of the patients ranged from 19 to 87 years with a mean age of 57.81 years. Chronic obstructive pulmonary disease (COPD) is the most concomitant respiratory disease (11, 18.3%), followed by asthma (9, 15%), and pulmonary fibrosis (9, 15%), other 6 cases (10%) had history of bronchogenic carcinoma, while pulmonary tuberculosis (TB) was found in 3 cases (5%). Cough was the most common presenting symptom which was found in all the cases (60, 100%). Smoking did not correlated with the CXR findings significantly at presentation, 3 days and 6 weeks post complaint (P-value 0.189,0.185 , 0.265 respectively). The most common side of affection was right upper zone which was found in 20 (33.3%) cases. Severity of the CAP significantly related to the pattern of pulmonary involvement which was evident in the CXR (P-value 0.000).

Conclusion: community acquired pneumonia is usually diagnosed by compatible clinical presentation and radiological characteristics. Timing of CXR influences its role in both diagnosis and follow up.

Keywords: *Community acquired pneumonia, chest-X-ray, timing, cough.*

Introduction

Community acquired pneumonia (CAP) is described as the development of symptoms and signs of pneumonia (such as cough, fever of >38.5 C, and respiratory distress) in a patient with a previous healthful condition due to an infection with a microorganism which has been gained outside the hospitals¹. It is a common health problem and a frequent cause of hospitalization². Globally, its incidence ranges from 150 to 1500 cases in each 100 000 persons per year with an annual mortality rate of 0.02%². As far as its clinical presentation varies, the

diagnosis depends on the radiological findings despite of limitation in sensitivity and specificity. The Chest-X-ray (CXR) reveals new parenchymal infiltrate in different pulmonary locations with or without complications like cavitation, lung abscess, or plural effusion^{2,3}. The most common scoring system used to evaluate the severity of the condition is Confusion, Urea, Respiratory rate, Blood pressure, 65 (65-CURB)⁴. The list of the differential diagnosis is long, being atelectasis, underlying vascular and bronchial diseases³.

Due to the crucial relevance of CXR to the condition as a first line diagnostic image in CAP and its critical role as a predictor of the various complications and mortality, it is worthy to examine and interpret CXR findings in different times during the disease period². The aim of this study is to present and discuss the CXR findings

of the cases with CAP in three different occasions (at presentation, day 3 and week 6).

Method

Study design and setting:

A prospective, observational study was conducted. The consecutive cases of single center were collected from January 2016 to January 2017.

Participant selection and data collection:

Those cases with clinical and radiological features consistent with CAP were included in the study. The diagnosis was concerned whenever there was new infiltrate in the CXR with compatible clinical features. The compatible clinical features were defined as fever (temperature more than 38 centigrade) or hypothermia (temperature less than 36 centigrade), dyspnea, pleuritic chest pain, cough, with or without sputum. Findings on clinical examination which were compatible the diagnosis were cyanosis, tachypnea (respiratory rate: more than 25 breaths/minute), use of accessory muscles of respiration, and added sound like wheeze and crackles. All patients with nosocomial infection were excluded from the study. The collection of the data were performed in the form of interview and form. The data included demographic characters, history, clinical examination, and CXR findings. The data used to support the findings of this study are included within the supplementary information file.

Data analysis:

The data were transferred from the forms into the Statistical Package for the Social Sciences (SPSS) after coding. Descriptive analysis (mean, range, standard deviation and percentage) were used to describe the sample. Chi square test was calculated to determine the relationship between categorical data, and paired T-test was analyzed to determine the relationship between the numerical data whenever necessary. Two-tailed fashion was used for all tests. The level of significance was set at 0.05.

Results

The study included 60 patients, 44(73.3%) were male while 16(26.7%) were female (male to female ratios 2.75: 1). The age of the patients ranged from 19 to 87 years with a mean age of 57.81 years and standard deviation of 20.04. Thirty-eight patients (63.3%) were living inside the cities and others (22, 36.7%) came from the rural areas. Regarding smoking history; 23 patients (38.3%) have never smoked, 9 patients (15%) were social smokers, 4 patients (6.7%) were passive smokers, others (24, 40%) were ex-smoker. Among the latter, 14 patients (58.3%) smoked more than 20 pack-years, and 10 patients (41.7%). Forty patients (66.7%) have never drunk alcohol, 12 (20%) were drinker, and 8 patients (13.3) were ex-drinker. Eleven patients (18.3%) had history of recent traveling. Chronic obstructive pulmonary disease (COPD) is the most concomitant respiratory disease (11, 18.3%), followed by asthma (9, 15%), and pulmonary fibrosis (9, 15%), other 6 cases (10%) had history of bronchogenic carcinoma, while pulmonary tuberculosis (TB) was found in 3 cases (5%). Cough was the most common presenting symptom which was found in all the cases (60, 100%), Table 1.

Table 1: Shows the frequency of the symptoms at the time of presentation.

Variables	Numbers (%)
Cough	60 (100%)
Sputum	58 (96.7)
Fever	53 (88.3)
Shortness of breath	29 (48.3)
Chest pain	22 (36.7)
Hemoptysis	13 (21.7)

The most frequent 65-CURB score was score 1, figure1.

Figure 1: distribution of the patients according to the 65-CURB.

Smoking did not correlated with the CXR findings significantly at presentation, 3 days and 6 weeks post complaint (P-value 0.189,0.185 , 0.265 respectively).

The most common side of affection was right upper zone which was found in 20 (33.3%) cases, table 2.

Table 2: chest x-ray findings on presentation.

CXR on Presentation	Number (%)
Right upper zone	20(33.3)
Right middle zone	23(38.3)
Right lower zone	16(26.6)
Left upper zone	7(11.6)
Left middle zone	9(15)

Discussion

Community acquired pneumonia occurs more commonly in male patients. In the study of Bruns et al, 66% of their patients were male⁵. Monkada and colleagues reported 55.5% male predominance ². Even in pediatric population, the picture remains the same. In their prospective study, Michelow, and associates reported a male to female ratio of about 1.7: 1 in pediatric age group ⁶. In the current study, the ratio of male to female was 2.75:1. The high rate of male affection in CAP is not well understood. Smoking may play a role but this argument is challenged by the high incidence of CAP in pediatric population⁶.

Smoking has been recognized as a risk factor of CAP. A person with smoking history has at least two folds increased risk of CAP compared to the healthy population ⁷. Generally, there are three theories behind the increased risk of CAP in the smokers. First, structural and physiological changes induced by the tobacco.

Second, increasing bacterial virulence by the tobacco. Lastly, disturbance of the immune system by the tobacco ⁸. In this study, 35 cases (55%) were either current or ex-smoker. Although there is no comparison group, this may comply with the international standard.

Excessive use of alcohol is another well-known risk factor for development of CAP, it has a crucial impact on the complication and outcome, and it prolongs the hospital stay ¹⁰. In the present study, 20 patients (33.3%) were either current or ex-drinker. Patients with COPD have an increased risk for developing CAP by fourfold. This is independent of smoking history. The increased risk of CAP in cases of COPD is confirmed but the mechanism is not well understood ⁷. In the current study, the most common comorbid disease accompanying CAP was COPD being recognized in 11 patients (18.3%).

The symptoms of CAP include but not limited to cough, hypo or hyperthermia, sputum, lethargy, chest pain, shortness of breath, palpitation and in the severe

form, it may present with disturbed level of consciousness⁵. In the study of Monkada and associates, the most common presenting symptoms were cough (97.8%), shortness of breath (87.5%) and chest pain (63.5%)². In the present study, cough was the most common symptoms found in all the patients (100%). The second most common symptom was sputum (96.7%), followed by fever (88.3%) and shortness of breath (48.3%).

Chest-x-ray is a simple and handy diagnostic image. It is not only used to diagnose CAP but also to exclude other conditions which may present with similar signs and symptoms¹⁰. Timing of CXR is another crucial consideration by some authors^{5,11}. Claessene and associates revealed the low sensitivity and specificity of CXR in the early course of the disease development. They examined the diagnostic accuracy of early CXR in CAP against chest computed tomography scan (CT-scan). In their experiment, CXR illustrated a parenchymal infiltration in 188 patients (61%). The diagnosis initially was categorized as definite in 44.8% of the cases, possible or probable in 53.8%, and it was excluded in 4 patients (1.2%). CT-scan showed a parenchymal infiltration in 40 cases (33%) who were initially labeled as infiltration-free on CXR and it excluded CAP in 29.8% of the 188 patients with parenchymal infiltration revealed by CXR. CT-scan modified the categorization in 187 (58.6%), leading to exclusion of 28.8% and 50.8% definite cases of CAP¹¹.

In the study of Bruns and colleagues, clearance of CXR infiltrate in patients with CAP occurred in the 7th day in 25% of the cases, this ratio increased to the 50% in the fourth weeks of follow up. Findings like high respiratory rate, dullness to percussion, high C-reactive protein (CRP) level, and multilobar disease were shown to be independent predictors for CXR findings in the 7th day of follow up, while only a high CRP level at the presentation was found to be a predictor for delayed clearance of CXR abnormalities in the 28th day¹¹. In the current study, CXR was positive in all of the cases on presentation, at 3 day follow up, 35% showed complete resolution, 25% improved, 31.7% did not reveal any change, while 8.3% deteriorated. At 6 weeks, 55% showed complete resolution, 35% improved, 6.7% did not reveal any change, while 3.3% deteriorated. In both timelines, early pattern of chest involvement on CXR was the predictor of deterioration (the more severe early involvement, the higher chance to deteriorate).

Monkada and his colleagues denied that the CXR findings would expect the severity of the disease and predict and outcome². The result of this study revealed the reverse of this conclusion. Chest-X-ray findings on presentation significantly related to the severity of the score (65-CURB) and consequently, the outcome of the disease.

There are few limitations for CXR in the diagnosis of CAP. First of all, it is almost normal in the early stage of the disease. From this perspective, some authors recommend early chest CT-scan to diagnose and predict the outcome¹¹. Secondly, it necessitates a radiation exposure¹⁰. Thirdly, sensitivity and specificity depend on the quality of the images and experience of the inspectors (interobserver and intraobserver disagreement). Fourthly, there is no correlation between the CXR findings and the etiology of the infection. It does not differentiate viral from bacterial infection³.

In conclusion, CAP is usually diagnosed by compatible clinical presentation and radiological characteristics. Timing of CXR influences its role in both diagnosis and follow up.

Variation of Alkalinephosphatase and Transaminases Levels in Different Trimesters of Pregnancy Iraqi Women

Tariq Hafdhi Al-khayat¹ and Rawaa Muayad Al-Quzweny²

¹Professor, ²Asst.Lecturer, Clinical Bio Chemistry College of Pharmacy, Al-Farahidi University, Baghdad, Iraq

Abstract

The level of enzymes Alkaline phosphatase (ALP) and transaminase (AST & ALT) were measured in 99 Iraqi pregnant women from different areas in Baghdad city and compared with a control group comprising non-pregnant women (29 women). Those pregnant women were classified into three groups according to the semester of pregnancy. (Group I to III). New inclusion and exclusion criteria were applied in this study to increase the specificity. The result revealed a significant increase in the corresponding enzymes ($p < 0.001$) for each trimester of pregnancy when compared with the control group (non pregnant women). There were no significant changes in enzymes activity between group I (first trimester) and group II (second trimester). The significant changes in ALP were observed between group I (first trimester) and group III (third trimester) $p < 0.001$. The same trend was observed between group II (second trimester) and group III (third trimester). The result also revealed insignificant changes in AST/ALT ratio among all the groups including control group ($p > 0.05$).

Conclusion: This study indicates the importance of the establishment of new reference values for the above mentioned enzyme during pregnancy and unsuitability of ALP in liver function test during pregnancy.

Key words: Alkalinephosphatase, transaminases levels, different trimesters, pregnancy Iraqi women.

Introduction

Pregnancy defined as a physiological state which occurs physical change in the reproductive age of a woman. From the time of the reproductive system of a woman changes through the three trimesters of pregnancy. The reproductive system and other systems of the body represented by the renal, endocrine, nervous, cardiovascular, respiratory, gastrointestinal system and hepatobiliary system are also affected. The levels of estrogens (estradiol) and progesterone increase cumulatively during pregnancy^[1]. These sex hormones have effects on hepatic metabolic, synthetic, and excretory functions^[2]. The biliary excretion of bromo sulfo phthalein decreases during late pregnancy and the clearance of some compounds that are secreted into bile may therefore be impaired⁶. The liver has a central and critical biochemical role in the metabolism, digestion, detoxification and elimination of substances from the body^[3].

Liver functions are determined by measuring the concentration of substances produced by hepatocytes or

by estimating the serum content of substances released from these cells as a result of damage and determine the capability of liver to perform metabolic functions like detoxification, conjugation^[4]. Serum aminotransferase assays are the most common laboratory tests for detection of liver diseases and these include aspartate aminotransferase (AST, E.C.2.6.1.1), and alanine aminotransferase (ALT, E.C.2.6.1.2). They are excellent markers of hepatocellular injury^[5]. AST is found primarily in the heart, liver, skeletal muscles, kidney, brain, pancreas, lungs, leucocytes and red blood cell while ALT is found primarily in the liver, kidney, with lesser amount in the heart and skeletal muscles. ALT is thought to be more specific for hepatic injury because it is present mainly in the cytosol of the liver cells and in low concentration elsewhere¹⁵ while AST is both cytosolic (20% of total activity) and mitochondrial (80% of total activity), it is less sensitive and specific for the liver reference^[6]. The pregnant woman's physiological changes to support fetal growth and development. During pregnancy, the serum estrogen and progesterone levels increase progressively and reach a maximum

during the third trimester. These sex steroids have effects on metabolic, synthetic, and excretory hepatic functions^[7]. The increase in plasma volume that occurs during pregnancy leads to haemodilution and decreases the serum protein concentrations. Serum alkaline phosphatase levels increase in late pregnancy because of both a production of the placental isoenzyme and an increase in the bone isoenzymes. It is therefore not surprising that changes in liver function tests (LFTs) occur during pregnancy^[8].

Alkaline phosphatase ALP (E.C.3.1.3.1) is present in practically all tissues of the body, especially at or in cell membranes and it occurs in particularly high levels in intestinal epithelium, kidney tubules, bones (osteoblasts), liver and placenta^[9]. It catalyzes the hydrolysis of phosphate esters in alkaline environment generating an organic radical and inorganic phosphate^[10]. Hepatobiliary disease and bone disease associated with increased osteoblastic activity are linked to increased serum alkaline phosphatase.

The ratio of AST to ALT is of use in Wilson disease, CLD and alcoholic liver disease and a ratio of more than 2 is usually observed. The lack of ALT rise is probably due to pyridoxine deficiency. In NASH the ratio is less than one in the absence of fibrosis on liver biopsy^[11]. In viral hepatitis the ratio is usually less than one. The ratio invariably rises to more than one as cirrhosis develops possibly because of reduced plasma clearance of AST secondary to impaired function of sinusoidal cells^[12]. ALT exceeds AST in toxic hepatitis, viral hepatitis, chronic active hepatitis and cholestatic hepatitis.

Many previous studies dealing with liver function test in different trimesters of pregnancy were carried out. Most of these studies lack specificity because there were no clear exclusion and inclusion criteria involvement. Also the relationship between alkaline phosphatase and transaminase enzymes were elucidated in order to draw some conclusions for the lab. Investigation of those parameters in different trimesters of pregnancy. In this study new introduced **inclusion criteria** :

- 1- 1-All antenatal cases between 18 to 40 years of age.
- 2- spontaneous conception.
- 3- 3-singleton pregnancy.
- 4- No history of hypertension, diabetes or liver

disease.

Also all pregnant women with the following criteria were excluded from our study:

- 1- Known liver disease .
- 2- Hypertensive patients.
- 3- Assisted conception.
- 4- Multiple pregnancy.

Method

Study Design and Subjects

This study was a hospital based cross sectional in vitro study collected specimens at private Hospital, Alkadra'a hospital over a period of seven months (between November 2017 to June 2018). A cross sectional study consists of 102 pregnant women and 31 matched control (age matched non pregnant women).

Among the 102 pregnant women, 32 were in first trimester (within 1-3 month), 34 were in second trimester (within 4-6 month) and 36 were in third trimester (within 7-9 month). Subjects were recruited according to simple random sampling method meeting the selection criteria.

A written consent were taken from the pregnant women and control group before recruiting them in this study.

Blood Sample Collection

A volume of 3 ml of venous blood was drawn from each volunteer using a disposable vacutainer system in Plain and separator serum (SST) tubes vacutainer. Serum or plasma separated within half an hour and stored at -20 C temperature till analysis was carried out.

Analysis of Specimens

Serum alanine transaminase (ALT) activity was measured by modified IFCC UV enzymatic kinetic method. Serum aspartate transaminase (AST) activity was measured by modified IFCC UV enzymatic kinetic method. Serum alkaline phosphatase (ALP) activity was measured by DGKC colorimetric Kinetic method. AST/ALT ratio was also calculated. All biochemical analysis was carried out on spectrophotometer UV/VIS clinical chemistry analyser using kits (LINEAR CHEMICALS)

Results and Discussion

Table (1) : Serum AST,ALT,ALP enzymes in nonpregnant and pregnant women (first, second and third trimester)

All data are expressed as mean ± SD. p value < 0.001 considered as statistically significant .

variables	Controls(non pregnant women) N=29 (mean+ SD)	Cases pregnant women		
		1st trimester N=31 (mean+ SD)	2nd trimester N=33 (mean+ SD)	3rd trimester N=35 (mean+ SD)
AST(U/L) Limited range	15.1 + 5.6 (13.02+17.2)	22.1+ 6.7 (19.6-24.6)	21.3 + 6.8 (18.9-23.8)	20.4 + 5.7 (18.5-22.4)

NS: Non-significant at the level ≥ 0.05

Figure (1): AST level in patients subgroups compared to controls

Figure (2): ALT level in patients subgroups compared to controls

Figure (3): ALP level in patients subgroups compared to controls

The result shown in table(1)(2) revealed a significant increase in the serum levels of AST, ALT and in the successive these trimesters of pregnancy in comparison to the control group. This result agree with Mdhurima Bora,etal in case of ALT, there is gradual increase in 1st , 2nd and 3rd trimester when compared with control non

pregnant group. $P < 0.001$. This supports few studies, a slight increase in ALT and or AST has been found in third trimester [13,14,15]. This may be attributed to hormonal factors that may lead to changes in such enzyme. It is well known that sex steroids have diverse effects on metabolic synthetic and excretory hepatic function.

Some previous studies didn't indicated the differences in the level of those enzymes during pregnancy. such changes in our result to can be attributed to the inclusion and exclusion criteria outlined in our study.

The results also showed a significant increase in ALP level with the progress of pregnancy. This change in the level of the corresponding enzyme can be attributed to the increase rather than elevation of hepatic isoenzyme. In addition to that, there is an increased production of bone isoenzyme with gestational age as a result of fetal bone development .such diversity of the source of serum ALP shows that it is not a reliable or suitable test for liver disease especially during the pregnancy. This results agree with Mdhurima Bora, Arpana Hazarika etal ALP values of the experimental group (all three trimesters). In case of 1st trimester it is significant ($P < 0.05$) and in case of 2nd and 3rd trimester the increase in ALP values become highly significant, $P < 0.001$. This increase during pregnancy is not due to an increase in the hepatic isoenzyme but rather largely due to the production of the placental isoenzyme^[16,17]. During the third trimester there is also an increase in the production of the bone isoenzyme as documented by an increase in its serum level up to six weeks post-delivery.

The revealed that AST/ALT ratio is statistically insignificant. This can be attributed to the fact that there is a concomitant changes in the level of both these two enzymes and This will tend to keep the numerical value of the ratio AST/ALT nearly similar to its value in the control group.

Finally establishment of reference values for aminotransferases is quiet essential for the diagnosis of liver disease and other diseases associated with the changes in the level of these enzymes . in addition to that ,ALP is not suitable for diagnostic purposes in pregnancy and this may be substituted by other diagnostic tools.

Conflict of interest : Nil

Based Assistance Continuum of Care Can Increase Family Independence in Overcoming Health Problems Pregnant-Women

Rita Yulifah

Midwifery Department, Health Polytechnic of Malang

Abstract

Pregnancy is a natural process during pregnancy does not rule out the possibility of problems or complications that can interfere with health. This study is the development of a minimum standard of visits for pregnant-women and the care provider acts as a ball-picker, with the aim of empowering the family to be independent in recognizing pregnancy complications, overcoming minor complaints, meeting nutritional needs, carrying out pregnancy checks and taking blood tablets. Visits are carried out continuously 15 times during pregnancy and communicating until the mother gives birth. This study used experimental design with control. The research subjects were 120 people taken by simple random sampling. Data were collected using observation sheets, then analyzed using the logarithmic-formula (Log^{10}). The results showed an increase in the level of family independence in recognizing complications during pregnancy, family independence in overcoming mild complaints in pregnancy, independence in fulfilling the nutritional needs of pregnant-women, family independence in carrying out pregnancy examinations, independence the family in giving tablets added blood. The average independence change is 37.4%, based assistance continuum of care that is done by conducting intensive visits and more often can increase family independence in overcoming health problems of pregnant-women, able to reduce self care deficits, improve family capacity in meeting demands self care and families are able provide care for pregnant-women independently.

Keywords: *Mentoring, Continuum of Care, Family Independence*

Introduction

Family approach is a community health centers service that combines individual health efforts and continuous first-level public health efforts based on data and information from family health profiles that focus on promotive and preventive efforts. Based on the Regulation of MoH-RI, four priority areas or targets are established: 1-reduction in maternal and infant mortality (MMR and IMR), 2-decreasing prevalence of stunting, 3-prevention of infectious diseases, 4) prevention of non-communicable diseases.¹

MMR and IMR is still a top priority. East Java until 2015 was ranked third with the highest MMR reaching 89.6/100,000 live-births.² Batu is city with the population

of men is 49.33% and 50.67% of women, the general structure of the population tends to refer to the younger age group, the number of fertile couples 4710 and the number of pregnant-women in one year ranges from 1,300 and is expected to increase 1 percent annually, the total coverage of pregnant-women (K4)=95% (target=100%).³

The high maternal mortality rate is made possible by the direct causes of preeclampsia, bleeding, inadequate quality of maternal services, unhealthy conditions of pregnant-women and the determinant factor of 3-Too late in decision making, to health facilities and for help.

The strategy to reduce MMR in the National Medium-Term Health Development Plan 2015-2019 is carried out through the Healthy Paradigm where preventive promotive programs are the main pillar of health by implementing a family-based approach continuum of care since pregnancy. A based approach

continuum of care is needed, given that during pregnancy 15% of complications cannot be predicted. With a-based approach continuum of care during pregnancy, it will be able to care for pregnant-women, not only in physical condition but also in social-mental conditions but also to care for the social health of pregnant-women. Based mentoring Continuum of care is a strategy developed by The Lancet Neonatal Survival Series. The effect of continuity of care by midwives in pregnant-women was 63.0% more likely to experience spontaneous vaginal birth and 23.1% less experienced episiotomy.⁴

This study aims to develop a minimum standard care program for pregnant-women by providing based mentoring continuum of care, emphasizing strengthening preventive, wellness, providing coaching functions, assisting families in solving problems, with the final results of seeing family independence in 1-recognize pregnancy danger signs, 2-deal with minor complaints during pregnancy, 3-fulfill the nutritional needs of pregnant-women, 4-carry out antenatal care, 5-consume blood-added tablets.

Methods

This research was an experimental study with control, namely providing assistance to pregnant-women on an ongoing basis using development assistance modules from maternal and child health books, with population of 120 pregnant-women (60=treatment-groups and 60=control-groups), selected by simple

random sampling.

Data were collected by socializing about mentoring first, then implementing mentoring with stages: 1-implementing mentoring by families, 2-researchers and numerators acting as facilitators and making 15 visits to pregnant-women, 3-the companion conduct a study of the characteristics of pregnant-women and pregnancy, 4-observations on the first and second weeks will be observed in 5 aspects of independence, 5-mentoring starts from the third week to the week before delivery, 6-the facilitator will record the results of the mentoring activities and conduct an evaluation of the mentoring results, 7-the researchers actively communicate, and once a month meet for discussion on mentoring, 8-at the end of the week will be observed conservation of the level of family independence.

The stage of data analysis were: calculating the difference between the average value after being reduced before; do equality by taking the logarithmic value calculated using excel with the formula \log^{10} , then multiplied by 100%, the final multiplication value was used to evaluate effectiveness.

Findings and Discussion

The results and discussion be elaborated on the data obtained.

Table 1. Condition of Mothers During Mentoring

	Intervention			Control	
	Parameter	Amount	Percentage	Amount	Percentage
Increase Body Weight	50-55 kg	32	53.3	23	38.3
	56-60 kg	23	38.3	32	53.3
	61-65 kg	5	8.4	5	8.4
Body-Index	≥20	1	1.7	1	1.7
	21-25	53	88.3	6	10
	26-30	6	10	53	88.3
Systole-Pressure	110	36	60.0	34	56.7
	120	22	36.7	22	36.7
	130	1	1.7	2	3.3
	140	1	1.7	2	3.3
Diastole-Pressure	70	21	35.0	22	36.7
	80	38	63.3	35	58.3
	90	1	1.7	3	5.0

Cont... Table 1. Condition of Mothers During Mentoring

	Intervention			Control	
	Parameter	Amount	Percentage	Amount	Percentage
Complaints most	Nausea, vomiting	1	1.7	3	6.6
	Headache	20	33.3	23	38.3
	Pain Waist	19	31.7	21	35
	Whitish	6	10	7	11.7
