Discussion

Family Independence in Recognizing Pregnancy Complications

At the beginning of the measurement provided an opportunity for family non-independence in recognizing pregnancy complications. The family does not recognize when a pregnant woman experiences severe headaches, suddenly bleeds from birth-canal, excessive nausea-vomiting, swollen-hands and face and blurred-vision are complications of pregnancy but it is normal for pregnancy to be given after assistance sustainably the family is more independent in recognizing the complications that might occur during pregnancy. Families know and recognize signs-symptoms such as severe-headaches, sudden-bleeding from the birth-canal, excessive nausea-vomiting, swollen-hands and face and blurred-vision, which are complications in pregnancy.

During the mentoring, there were four pregnant-women who had to be referred to health facilities because 2 people had increased blood-pressure on the second and third visits, 2 people were due to obesity and high-risk pregnancies with Poedji-Rochyati score of 10-18. Escort until the mother gives birth at 2 people’s health facilities in the hospital, 2 people at the health center, with a healthy mother and fetus.

The independence of the family in recognizing complications between those who were given continuous assistance using the mentoring module had a different effect from the control that used maternal and child health books. The level of independence of the assisted families is higher than the control. During mentoring, the companion acts as a driver, motivator and educator. Direct involvement of the family as a companion plays a role in facilitating the family to quickly recognize the complications.

Family Independence in Overcoming Mild Complaints during Pregnancy

Family independence in overcoming mild complaints during pregnancy shows different results before and after mentoring. Before being given assistance, both the mentoring and control group had the largest percentage in the independent category. Families do nothing if pregnant-women experience nausea vomiting, complain of vaginal discharge and itching on the birth canal, complain of low back pain, cramps in the legs during sleep at night, and difficulty defecating.

During and after mentoring, families are more independent in dealing with minor complaints that occur during pregnancy, namely nausea, mild-headaches, leg-cramps, difficulty defecating and low-back pain.

When the mother experiences nausea-vomiting, the family gives the mother a warm sweet-drink like sweet-tea and prepares and helps give the biscuits before the mother gets up in the morning. The family does not recommend that pregnant-women not use high-heels sandals or shoes, deliver and accompany mothers to take part in pregnancy exercises to avoid low-back pain. When pregnant-women experience cramps in the legs, the family helps the mother to sit and stand. The family immediately takes the mother to the midwife if the mother experiences leucorrhoea or complaints getting heavier.

Family Independence in Fulfilling Nutrition Needs during Pregnancy

The results showed a change in the level of family independence in meeting nutritional needs during pregnancy. Before being given assistance to both the assisted and control group, the family did not know the food that should be given during pregnancy. The food given and eaten by pregnant-women is the same as other family meals, there is no difference in either portion or frequency. If pregnant-women experience nausea-vomiting, the mother has difficulty defecating the family as a normal thing for pregnant-women, so they have not tried to overcome it through food.

After being given assistance, families are more independent in meeting nutrition during pregnancy. Families in fulfilling nutritional needs prioritize foods that contain protein such as fish, eggs, chicken liver and follow recommendations as stated in the mentoring module that is to meet the nutritional needs of quality pregnant-women fulfilling the elements of nutrition, carbohydrates, proteins, fats, vitamins and minerals. The food consumed during companion for carbohydrates is rice and bread. Proteins: tempeh, tofu, eggs, sea fish, fresh fish, chicken and beef; Fat: from cooking oil, Vitamins: spinach, lettuce, mustard greens, broccoli, carrots, kale, pumpkins and fruits. Mothers also drink an average of 6-7 glasses a day.

Family Independence in Conducting Pregnancy Examinations

Family independence in conducting prenatal-care before and after mentoring in both the mentoring and control group showed the same results. Before family assistance has shown independence in carrying out pregnancy checks, the family knows and understands well when knowing signs of pregnancy immediately

brings the mother to the midwife or community health care. During pregnancy, the family brings pregnant-women to check their pregnancy 9 times, which is 1 time at gestational age 1-3 months, 3 times at gestational age 4-6 months and 5 times at gestational age 7-9 months. The family also immediately checks the pregnancy if there are minor complaints that cannot be overcome by themselves and the signs of childbirth.

Family Independence in Consuming Tablets Adding Blood During Pregnancy

Before being given assistance to the independence of the poor family in helping mothers consume tablets plus blood, this was due to a mother's complaint that after taking tablet medicine the blood of the mother felt nauseous and had difficulty defecating.

During the mentoring, the family as a companion assisted by the accompanying coordinator was educated about the importance of consuming blood-added tablets for pregnant-women contributing to family independence in helping to consume tablets with more blood. The results of observations during mentoring, every day pregnant-women routinely take tablets plus blood one tablet before going to bed using warm-water, this is done to avoid possible side effects that arise, namely headache, nausea and difficulty defecating.

The Effectiveness Assistance on of Continuum of Care Family Independence in overcoming the health problems of pregnant-women

It was found that-based mentoring continuum of care had high effectiveness on family independence in overcoming health problems of pregnant-women. Families given assistance have high independence in overcoming health problems. As long as independent family assistance in recognizing complications, the family is able to overcome minor complaints that occur during pregnancy, the family can independently fulfill the nutritional needs, carry out antenatal-care and independently consume blood-added tablets. Families are able to make decisions when they know that an increase in blood-pressure and an increase in body-weight exceed the normal limit by immediately bringing the mother to the nearest health facility, the community health center.

As long as the health assistance of pregnant-women is well monitored, pregnant-women do not experience health problems resulting in pain, 98% of maternal

blood pressure within the normal range, 98% of maternal nutritional status with a BMI between 23-24, high fundus uterine according to gestational age, 98% of fetal heart-rate within normal limits.

The assistance continuum of care is carried out functions in guiding, sustaining, protecting, supporting and empowering functions, namely functioning to guide the assisted family in the decision-making process, enabling and strengthening the assisted family and coping fully or independently when problems occur health for pregnant-women based assistance Continuum of care carried out in this study is mentoring that refers to quality care by using the principle of family-empowerment that is guided and tracks pregnant-women from time to time during the mentoring period, and optimizes family independence in overcoming health problems for pregnant-women.¹ Family empowerment functions as a link between maternal and child care, and the development of a health system approach to strengthening maternal and child health services.⁵ Based mentoring Continuum of care with reference to the quality of care from the results of research effectively increases family involvement as human resources is the potential to empower themselves in achieving independence to solve and overcome health problems for pregnant-women, so as to reduce the incidence of morbidity in pregnant-women, this is appropriate Van den Broek, NR and Graham WJ's opinion that quality care must be at the core of all strategies to accelerate reducing maternal and child mortality.⁶

Mentoring with a-based approach continuum of care during pregnancy, effectively increases family independence in caring for pregnant-women, not only in physical condition but also in social, mental conditions but also caring for the social health of pregnant-women. With based assistance continuum of care, maternal health problems can be overcome, mothers give birth normally, mothers are healthy, babies are also healthy. This is also reinforced by the results of previous studies from McLachlan, HL, Forster, DA and friends, that ongoing care provided by midwives during pregnancy to low-risk women can reduce the rate of Caesarean section.⁴ Case management using continuous care or continuum of care for pregnant-women diagnosed with HIV shows lower results for transmission to infants.⁶

Conclusions

1. Based mentoring continuum of care effectively

increases family independence in recognizing pregnancy complications by 45%.

2. Assistance continuum of care effectively increases family independence in overcoming mild complaints during pregnancy by 36%.

3. The continuum of care is effective in increasing family independence in meeting nutritional needs during pregnancy by 45%.

4. The continuum of care is effective in increasing family independence in carrying out a 22% pregnancy checkup.

5. Mentoring continuum of care effectively increases family independence in giving blood tablets to pregnant-women 39%.

6. Family assistance is Continuum of care effective in increasing family independence in overcoming health problems for pregnant-women.

Overweight and Obesity Associated Factors among High School Students: A Cross Sectional Study in Erbil

Sarhang Qadir Ibrahim¹, Tariq S. Al- Hadithi², Kameran Hassan Ismail³

¹Bsc, Msc in Public Health, College of Medicine, Auvergne University Clermont Ferrand1, France, ²Professor at College of Medicine, Hawler Medical University, Erbil, Kurdistan Region, Iraq, ³Assistant Professor of Community Medicine, College of Medicine, Hawler Medical University, Erbil, Kurdistan Region, Iraq

Abstract

Introduction: The overweight of youth and teens is one of the fundamental issues in the world that seems to be lifestyle and inactivity of the causes of overweight. The purpose of this study was to investigate the causes of obesity / overweight in high school students.

Methods: In this cross-sectional study, 1,000 students in the age range 16-18 years of Erbil, Iraq in 2016-2017 were randomly selected. Data were collected via questionnaire. Data were examined using SPSS 22 for windows and analyzed by appropriate statistical tests.

Results: surveys demonstrated that 30% of youth aged 16 to 18 were overweight or obese. About 30 percent met physical activity guidelines; however, physical activity was not associated with overweight or obesity in this sample. Computer games, watching TV (0.007) and irregular sleep (P-value=0.019) were among other known factors/ affecting obesity/overweight in this study.

Conclusions: According to findings, we concluded that a trend toward being overweight/ obese in youth and there are many factors involved, such as irregular sleep and lack of mobility in overweight.

Key words: *Overweight , obesity , high school students*

Introduction

Overweight and obesity are the fifth leading risk for global deaths Worldwide, about 2.8 million deaths and 35.8 million (2.3%) of global Disability Adjusted Life Years (DALYs) are caused by overweight or obesity¹. According to one US national study, the high prevalence of overweight and obesity during childhood and adolescence has been confirmed in recent decades and currently one child in ten is overweight or obese.² It is stated in one of the studies about 11% of US children and adolescents are classified as overweight (body mass index [BMI] > 95th percentile), and an additional 14% of children and adolescents have a BMI between the 85th and 95th percentiles of the reference population

that places them at risk for becoming overweight^{3,4}. It should be noted that 44% of the diabetes burden, 23% of the ischemic heart disease burden and between 7% and 41% of certain cancer burdens are attributable to overweight and obesity^{5,6}. Data from the third National Health and Nutrition Examination Survey (NHANES III) presented Rapid outbreaks overweight in adolescents⁷. The prevalence of overweight in Iraq is experiencing a shift from underweight to overweight along with rapid socioeconomic and nutritional transition particularly in their area population. Inactivity and obesity are the leading cause of non-communicable diseases. The World Health Organization (WHO) has announced that at least 60 minutes of physical activity are necessary for all children aged 5 to 17 years⁸.

Given the increasing prevalence of overweight in Iraq and the importance of prevention and control of associated factors, we decided to assess the overweight in high school students and its relationship with lifestyle for the first time in Erbil.

Materials and Method

This cross-sectional study, conducted from the 20th of September 2016 to the 10th of March 2017 where students of grade 10, 11 and 12 of public schools (between 16-18 years of age) across Erbil city of Kurdistan region of Iraq were taken as the primary sampling unit.

The sample was collected by multistage cluster sampling technique. Schools are divided into 6 groups according to the municipalities of Erbil city, to cover all quarters of the city. Schools were randomly selected according to the number of students in each region. The total number of selected schools was 32 distributed in the 6 municipalities. Of the 36,777 students in these schools, 1,000 students were randomly selected. From each school a single class was selected randomly; For Data collection from each class was attended by the counseling specialist of the school.

Questionnaire Design:

A questionnaire that was designed by the CDC (Centers for Disease Control and Prevention) was modified and used as data collection⁹. The questionnaire had three parts including demographic information, habits and life style of the students and socio-economic status (SES) that was calculated taking into consideration age, education and occupation of the father, car ownership and house ownership, according to the formula designed by Omer and AL-Hadithi¹⁰ and They were asked to choose between low SES, middle SES, and high SES which is one of the best types of descriptions. For better understanding; the questionnaires were adapted to each school's language of instruction (local Kurdish and also to Arabic language).

After collecting the questionnaires, Data were examined using statistical package for social sciences (SPSS) version 22 (SPSS Inc. Chicago, IL) for windows. Data were analyzed through the use of simple descriptive statistical data analysis approach and inferential data analysis approach. Chi-square test of association was used to assess the association between the prevalence and several risk factors and Fisher's exact test was used instead of the Chi square test when the expected count of more than 20% of the cells of the table was less than 5. P value of ≤ 0.05 was considered as statistically significant.

Ethical Consideration: This research study followed the tenets of the Declaration of Helsinki and written informed consent was obtained from all patients.

All students were assured that their participation in the study was voluntary; they were informed about the purpose of the study; their anonymity and confidentiality were assured. Also an official permission from Erbil General Directorate of Education and from schools' administrations to collect data was obtained.

Results

Total 1000 high school students were analyzed. Among them were 572 women and 428 men with an average age of 16.94 ± 0.79 .

According to Table 1, the prevalence of overweight and obesity in the whole sample was 30% that was significantly higher in men than in women ($p=0.001$). Youth who reported a low socio-economic status were Overweight and obesity higher than those from households with high socio-economic status but this difference was not significant ($p=0.595$). There is no relationship between obesity/overweight with different municipalities ($p=0.418$) and living with parents ($p = 0.836$). Obese caregivers, compared to desirable weight parents, were more likely to have overweight or obese children. The relationship between diabetes and overweight of parents with overweight in youth was also determined that only maternal diabetes was significant in this regard (0.040).

Table 2 shows the effect of dietary habits on overweight and obesity. These results indicate that the rate of eating, Time to eat, and type of food is effective in overweight and obesity. For example, eating food before bed and also eating rice more than once a day is significantly associated with overweight and obesity.

Table 3 examines the degree of sleep and mobility, these results show, Although inactivity is one of the main causes of overweight and obesity, and there is a meaningful relationship, but there is not related to the type of activity. Significant association was detected between the prevalence of Overweight and obesity with regular sleeping as presented which shows also that the prevalence among those who take a nap was significantly higher than the prevalence among those who don't take a nap ($p < 0.001$).

Discussion

In this study to assess the overweight in student, Factors affecting it and its relationship with lifestyle, our estimates of overweight/obesity showed the prevalence of overweight and obesity in the whole sample was 30%. In a study in Tehran, which was conducted on 158 children, this number is reported to be 36%¹¹.

We found that the relationship between socio-economic status and overweight in children was significant, so that by increasing SES, overweight among children increased. In other studies, they have merely examined the economic situation, all of which express the significance of this relationship. In other studies, it was also well-documented that low socioeconomic groups are heavily influenced by obesity^{12, 13}.

The, 66.6% of parents were overweight in our study which coincided with the study of Jeremiah and colleagues; they reported parental obesity about 70%⁹. In general, studies show that children who are at least one of their parents are obese have a higher risk for obesity than parents with healthy weight¹⁴⁻¹⁶.

A study by Patrick et al. showed that those who were overweight had less physical activity¹⁷. According to the results of this study, the relationship between overweight and physical activity was significant but have no significant relationship with physical activity. Low physical activity and reducing energy consumption and reducing the oxidation of fats in the body leads to overweight. Results of the some study showed that the consumption of more fruits, vegetables and protein are seen in children and youth with regular physical activity⁴. But in our Study there was no significant difference related to less use of fiber and vegetables with the overweight.

The results of this study revealed the relationship between sleep and overweight, so that people who had a regular sleep and were napping during the day were less likely to be obese and overweight. The relationship between sleep deprivation and obesity has been studied in epidemiological studies in different countries¹⁸. Sleep deprivation is associated with reduced energy consumption¹⁹. St-Onge and Associates study of 5115 people showed that sleep deprivation is associated with body mass index, body composition and abdominal obesity²⁰.

We concluded that a trend toward being overweight/obese in youth and there are many factors involved, such as irregular sleep and lack of mobility in overweight. It seems that people in terms of diseases and genetic factors should also be compared in future studies.

Abstract

Background: The Central Sulawesi region is one of the areas prone to earthquakes and tsunamis in Indonesia. The low level of knowledge of the community, especially children who are the age most vulnerable to the risk of victims in a disaster. The vulnerability of children to disasters is triggered by a limited understanding of the risks around them, which results in the absence of preparedness in the face of disasters. This study aims to know the influences of disaster counseling with animation video on preparedness students in elementary school in sigi district.

Methods: This research used a quasi-experimental with the pretest-posttest design. 40 respondents, grade IV and V student, were determined by the total quota sampling technique. Data was collected using questionnaires and observation sheets. Data analysis using t-dependent and will be presented in tabular form.

Results: Shows that the average value of respondents' knowledge before video playback (pre-test) is 83.12. Meanwhile, the average value after playing the video (post test) is equal to 92.62. This shows that an increase in the average value of respondents after the video playback. The results of the t-dependent test showed that the animation video method had a significant influence on improving preparedness ($p = 0,000$).

Conclusion: Shows that counseling with animation video method can have a greater influence on the increase in preparedness

Keywords: *Counseling, animation video, Preparedness*

Introduction

In tectonic terms, Indonesia's territory is at the confluence of three active large tectonic plates of the world, namely the Eurasian, Pacific and Indo-Australian

plates. The Central Sulawesi region is one of the earthquake prone areas in Indonesia, because this area is located close to the source of the earthquake which is on land and at sea.¹

Safer schools are needed to protect children's lives during disasters. The concept of school safety is not limited only to prevent the collapse of school buildings during disasters and the safety of teachers and students, but more broadly to achieve a greater goal, namely "disaster risk management", because children play

the role of future generations. Something they have learned about safety today will be useful in developing a “community that is responsive to disaster risk” in the long run. Here is the importance of education about disasters in school safety^{2,3}.

Preparedness is all forms that are carried out to avoid the risk of a disaster that will occur, if a disaster occurs when and if the disaster is still a long time will occur, then preparedness to avoid risk is the best way. Preparedness is any activity prior to a disaster that aims to develop operational capacity and facilitate effective responses when a disaster occurs⁴⁻⁶

This research was conducted by utilizing animated video media that is in accordance with the characteristics of grade IV and V elementary school students, which have begun to understand the cumulative aspects of the material, have the ability to understand how to combine several classes of objects that vary in their level. Besides that students have been able to think systematically about concrete objects and events and students have achieved high objectivity because students have been fond of investigating, trying, and experimenting which are stimulated by probing drives and great curiosity.⁷

Based on the background described above, the researcher conducted a study entitled the effect of video media for earthquake disaster preparedness on the level of student preparedness in SD 2 Talise, Central Sulawesi.

Materials and Method

The research design used was quasi experimental (quasi-experimental) using pre and post test. This research was conducted at Talise Palu Elementary School. The respondents consisted of 40 students, determined by total sampling technique. Inclusion criteria in this study are: 1) Students in grades 4 and 5; 2) have never received a disaster alert counseling.

The extension instrument used to collect data in this study was in the form of animated video media about earthquake disaster preparedness as a learning medium and a questionnaire that had been tested for validity and reliability before to determine the level of respondent's knowledge about disaster preparedness.

The questionnaire will be tested on subjects that are not research samples but have characteristics that are almost the same as research samples that are students in grades IV and V Elementary Schools in Palu.

The time of the research is August 2019. The counseling group with audio-visual media will be given counseling by instructors who have been certified using a 30-minute animated video. Data collection was carried out before and after counseling was given. Data were collected using a questionnaire and observation sheet. Research on the level of preparedness is carried out by asking 20 questions to respondents with a value of 1 for each correct answer and 0 for incorrect or unknowable answers. The assessment based on the preparedness index value used based on Preparedness is grouped into four parameters namely knowledge and attitudes / Knowledge and Attitude (KA), emergency planning (EP), warning system / Warning System (WS) and resource mobilization⁸. The collected data was then analyzed using univariate analysis and bivariate analysis. Univariate analysis was used to determine the characteristics of the respondent's data (including age and sex) and the data of each variable, namely the level of preparedness in each group. Bivariate analysis used to determine differences in the level of preparedness before and after counseling was given to each group using the t-dependent test, the data obtained from subsequent studies will be presented in tabular form.

Written permission was obtained from the Research Ethics Commission of the Tadulako University Medical School. Each respondent is explained in advance about the research procedure to be carried out, and if agreed, the respondent completes the consent form to participate in the research, and begins to take part in the research activities.

Results

Data on the characteristics of respondents by age shown in table 1, shows that all respondents were in the same age group, namely elementary school age. Most respondents (55%) were 10 years old and most respondents were women (52.5%).

Table 1: Frequency distribution of respondent characteristics based on age and gender

Characteristics	Frequency (n)	Percentage(%)
Age		
10 year	22	55
11 year	18	45
Gender		
Male	19	47,5
Female	21	52,5

Table 2: Distribution of Respondents by Level of Preparedness Before video playback

Characteristics	Frequency (n)	Percentage(%)
Sangat Siap(80-100)	30	75
Siap(65-79)	7	17.5
Hampir Siap(55-64)	1	2.5
Kurang Siap(40-54)	1	2.5
Belum Siap(< 40)	1	2.5
Total	40	100

Table 2 shows that respondents who had the most prepared categories were 30 children (75%) before the video screening and the lowest preparedness in the categories of almost ready, less ready and not ready, each with 1 child (2.5%).

Table 3: Distribution of Respondents by Level of Preparedness After video playback

Characteristics	Frequency (n)	Percentage(%)
Very ready (80-100)	38	95,0
Ready (65-79)	2	5,0
Almost ready (55-64)	0	0
Less ready (40-54)	0	0
Not ready yet (< 40)	0	0
Total	40	100

Table 3 shows that respondents who had the highest level of preparedness before the video screening were very ready to be 38 children (95%) and the lowest preparedness in the ready category was 2 students (5%).

Table 4: Effects of Disaster Preparedness Animated Video Screening on the level of disaster preparedness

Variable	Min	Maks	Mean	SD	p
Before Video Screening	30	100	83,12	13,899	0,000
After Video Screening	65	100	92.62	8.085	

Based on the results of the data normality test, it is known that the research data do not meet the criteria for processing by using the T dependent test (parametric test). Therefore, data processing is done by using an alternative nonparametric test that is Wilcoxon test. The comparative distribution of respondents' pre-test and post-test scores and the effect of video playback are listed in Table 4

Discussion

Based on the characteristics of respondents, respondents are elementary school students in grades IV and V whose age range is between 8-12 years. According to Susanto the characteristics of development include developments in cognitive aspects, namely in the concrete operational stage (ages 7-11 years), at the stage These students have started to understand the cumulative aspects of the material, for example volume and amount, have the ability to understand how to combine several classes of objects that vary in their level. In addition, students are able to think systematically about objects and events that are concrete and formal operational stages (ages 11-15), at this stage students are already in their teens, the cognitive development of students at this stage already has the ability coordinate two kinds of cognitive abilities both simultaneously (simultaneously) and sequentially. So that in this study the learning method used video animation which of course can be well understood at the age of 8-12 years.

Based on the research results obtained, it is known that the average value of the respondents before the video screening (pre-test) was 83.12. Meanwhile, the average value after playing the video (post test) is equal to 92.62. This shows that an increase in the average value of respondents after the video playback.

After doing statistical tests using Wilcoxon test obtained p value of 0,000 ($p < 0.05$). The results of this test indicate that there are significant differences regarding the level of disaster preparedness before and after video playback. there is an influence of video animation media on earthquake disaster preparedness on the level of student preparedness at SDN 2 Talise Central Sulawesi.

These results are consistent with what was revealed by Agustiniingsih in an educational journal, that video media can be utilized in the learning process because it can effectively describe the material presented, especially material that is dynamic. (9) According to Munir's theory

the function of animated video can attract attention with the movement and sound in animated video barrel, simplify the appearance of presentations, facilitate the composition of presentations, make it easier to describe a material, to be able to explain something complicated with just pictures or words.

The results of this study are also the same as the research conducted by Wulandari, that there is an influence of the use of video media on the level of preparedness of SMA Negeri 1 Manantwarno students, where there is an increase in student preparedness in the face of an earthquake.

Based on the overall results of the study, it can be seen that the animation of video playback can help to increase one's knowledge significantly, so that this media can be used when providing earthquake disaster preparedness learning by paying attention to more interesting and not boring video quality and the time and environmental conditions when video playback. After the video screening, respondents have at least experienced an increase in earthquake preparedness in the very prepared category. Based on Wells knowledge about preparedness is an effort to reduce the risk and impact of disaster losses, that is knowledge of disasters, actions to prepare, support and rebuild communities after a disaster occurs. Knowledge of disasters is the main key in preparedness¹⁰.

Conclusion

Based on the results of research and discussion that has been described previously, we can get some conclusions as follows:

1. There is an increase in the level of preparedness in the category of very ready, where before giving counseling that is 75% to 95% after being given counseling with animated video media
2. There is an effect of counseling with earthquake disaster prepared video animation media on the level of student preparedness at SDN 2 Talise Central Sulawesi with a p value of 0,000 ($p < 0.05$).

The Influence of Breathing Ball Technique on Length of Labor in Phase I Active in Independent Practice, Midwifery Sriwati

Muliani¹, Hastuti Usman¹, Aspia Lamana¹, Abd Farid Lewa², Andi Ritna Marumu¹, Nasrul³, Anwar Mallongi⁴

¹Lecturer of Department of Midwifery, Health Polytechnic of Palu Health Ministry, Indonesia, ² Lecturer of Department of Nutrition, Health Polytechnic of Palu Health Ministry, Indonesia, ³ Lecturer of Department of Nursing, Health Polytechnic of Palu Health Ministry, Indonesia, ⁴Lecturer of Department of Environmental Health, Faculty of Public Health, Hasanuddin University, Indonesia

Abstract

First stage or first stage of opening takes place from zero opening (0 cm) to complete opening (10 cm). First stage for primigravida lasts 12 hours, while multigravida lasts for 8 hours. Based on the Friedman curve, calculated opening for primigravida 1 cm/hour and opening for multigravida 2 cm/hour. Efforts to determine the speed of labor for the first time were given a breathing ball technique. The purpose of this research is to know the effect of breathing ball on the duration of the first phase of active labor in PMB Sriwati.

This type of research is a pre-experimental study with the one-shot case study. The total sample is 30 respondents, 15 primigravida respondents, and 15 multigravida respondents. Data were analyzed using the Mann-Whitney test. The intervention was given during the first stage of labor during the active phase for 32 minutes, every 32 minutes there were 4 stages of breathing ball, the duration of the duration was 8 minutes, each mother could rest whenever she wanted.

The results of the analysis of the breathing ball technique on the duration of labor in the first phase of labor in the active phase of the p-value of 0,000 <0.05.

The conclusion was that there was a significant influence on the breathing ball technique on the length of labor in the active phase I in the Sriwati Independent Practice Midwife. For midwives, especially in the Independent Practice of Midwife Sriwati to train pregnant women from an early age in performing breathing ball techniques by doing exercises in classes of pregnant women every 2x in a week, and this research can be developed with pain variables in the first phase of active mothers.

Keywords: *Breathing ball, length of labor, active phase*

Introduction

Childbirth is the process of expulsion from the conception that can live from inside the uterus to the outside world. Labor includes a physiological process that allows a series of major changes in the mother to give birth to the fetus from the birth canal⁽¹⁾.

The first stage or first stage of opening takes place from zero openings (0 cm) to complete opening (10 cm). The first stage for primigravida lasts 12 hours, while multigravida lasts for 8 hours. Based on the Friedman curve, calculated primigravida opening 1 cm/hour and opening multigravida 2 cm/hour. For the latent phase from opening 0 to opening 3 cm and the active phase starting from opening 4 cm to 10 cm⁽²⁾.

Pain that may be felt by women during childbirth is quite varied, such as how they respond. For this reason, the labor environment and the support provided by professionals and colleagues, as well as the methods

Corresponding Author:

Muliani

ORCID ID, <https://orcid.org/0000-0003-1139-2620>

used to relieve pain, are important because they can influence reactions during labor and play an important role in the development of symptoms of traumatic stress after childbirth⁽³⁾ which targeted all women scheduled to give birth at Akershus University Hospital in Norway. Questionnaires were given at three different stages: from pregnancy weeks 17 to 32, from the maternity ward, and from 8 weeks postpartum. Data were also obtained from the hospital's birth record. Using structural equation modeling, a prospective mediation model was tested. Results: Posttraumatic stress symptoms were significantly related to both labor pain ($r = 0.23$). While labor pain is a normal process that can cause physiological and psychological stress which is common where 90% of women are accompanied by pain⁽⁴⁾. Breathing ball is one of the non-pharmacological pain relief methods to help mothers cope with labor⁽⁵⁾.

Non-pharmacological methods can relieve pain sensations in a number of ways, by promoting women's well-being, comfort, and sense of control in labor and Breathing ball is one method to help mothers cope with labor and delivery⁽⁶⁾.

According to Surtiningsih et al, (2016) respondents, 40 primigravida mothers with a gestational age of 34 to 35 weeks were divided into 2 intervention groups with breathing ball techniques for 6 meetings and control groups. This technique is very effective in shortening the length of the active phase I with a p-value $0,000 < \alpha 0.05$ and an effect size of 0.6 is also effective in shortening the second time with a p-value of $0.007 < \alpha 0.05$ with an effect size of 0.43. The results of the study concluded that breathing ball effectively shortens the length of the first and second stages of labor in primigravidas⁽⁷⁾.

According to Renaningtyas, et al (2013) the results of the study showed that there was a relationship between pelvic rocking implementation and breathing ball on the duration of I. X counted > X table (13,333 > 9,488), and p-value ($0.01 < 0.05$) by doing pelvic rocking with a breathing ball is able to facilitate labor, especially in the first stage and help mothers experience the time of delivery when the first⁽⁸⁾. Research purposes was knowing the effect of the breathing ball technique on the active time phase I in PBM Sriwati.

Materials and Method

This type of research is a pre-experimental study with posttest only design or also called the one-shot case study. This design treatment or intervention has been

carried out, then carried out measurements (observation) or posttest (02). The sample in this study was normal maternity mothers in gestational age 37 to 42 weeks when I active phase of 15 respondents in the primigravida group and 15 respondents in the multigravida group at the Independent Sriwati Midwifery Practice.

Research Results

Univariate Analysis Results

Table 1 Distribution of Respondents Based on the characteristics of the breathing ball technique at BPM Sriwati, 2019

Characteristics	f	%
Parity		
Primigravida	15	50
Multigravida	15	50
Gestational age		
38 week	6	20.0
39 week	16	53.3
40 week	6	20.0
41 week	2	6.7

Source: Primary Data 2019

Table 1 shows that the number of primigravida and multigravida each was 15 respondents, while the characteristics of respondents based on gestational age were dominated by 39 weeks 16 (53.3%).

The results of the analysis to determine the distribution of respondents based on parity of length of labor in first phase active delivery mothers with breathing ball techniques can be seen in the following table:

Table 2 Distribution of Respondents Based on parity with the length of labor with breathing ball techniques at BPM Sriwati in 2019

Parity	Breathing ball technique			
	fast labor		Prolonged labor	
	f	%	f	%
Primigravida	13	43.3	2	6.6
Multigravida	15	100.00	0	0

Table 2 shows that the distribution of respondents based on parity, the length of labor in multigravida, there were 100% of rapid labor, while the duration of labor in primigravida, there were 2 (6.6%) of respondents who experienced long labor.

Bivariate Analysis Results

The results of the analysis to find out the length of labor by giving breathing technique to first-phase active mothers can be seen in the following table:

Table 3 distribution of labor time in primigravida and multigravida with breathing ball techniques in PMB Sriwati, 2019

Variable		n	Min.	Max.	Mean Rank
Duration of Childbirth	Primigravida	15	2,25	7,42	4,0447
	Multigravida	15	2,15	3,33	2,9553
Z					-5,236
Asymp. Sig. (2-tailed)					0.000

Table 3 shows that the distribution of primigravida length of labor by breathing ball technique using the Mann-Whitney test obtained a minimum time of delivery time is 2.25 hours and a maximum length of 7.42 hours with an average value of -4.0447, while in multigravida obtained the minimum length of labor is 2.15 hours and the maximum length of labor is 3.33 hours with an average value of -2.9557 with a p-value = 0.000 < 0.05. Therefore, the result is that Ha is accepted and Ho is rejected, so it can be concluded that there is an effect of giving breathing ball technique to the duration of the first phase of active labor in Sriwati’s PMB.

Discussion

The Effect of Breathing Ball Technique on the Length of the First Stage of Labor in Active Phase in the Independent Practice of Midwife Sriwati

Based on the characteristics of the respondent’s average gestational age of 38-41 weeks, the highest number of respondents at 39 weeks gestational age. The parity group in primigravida and multigravida each of 15 respondents. WHO⁽⁹⁾ concludes that there is no evidence to support the supine position during the first stage of labor. Based on current findings, it is recommended that women in low-risk labor should be informed of the benefits of an upright position, and be encouraged and assisted to take whatever position they choose⁽¹⁰⁾ while supine positions on an inclusive back should be

avoided⁽¹¹⁾.

There are several potential mechanisms to explain why using a breathing ball can reduce labor pain. The first endogenous mechanism is the gate control theory, which consists of applying light massage to the affected part. This mechanism acts primarily on the sensory component of pain, by blocking part of the nociceptive message in the spine. Based on this theory, breathing ball can provide support for the perineum without putting significant pressure^{(12);(13);(14)}.

This study concludes that clinical implementation of the use of balls during labor can be an effective non-pharmacological intervention in reducing pain perception and improving the experience of childbirth⁽¹²⁾.

The results of breathing ball technique analysis on the duration of labor in the first phase of labor in the active phase based on the Mann-Whitney test obtained a p-value of 0,000 < 0.05 so that the results were obtained that Ha was accepted and H0 was rejected. The results of this analysis can be concluded that there is a significant influence on the breathing ball technique on the length of labor in the first stage of labor in the active phase⁽⁸⁾.

The results of this study are in line with the research of Renaningtyas et al. (2013) in a study entitled “The Relationship of Pelvic Rocking Implementation with Breathing Ball to the Length of First Time in Maternity Mothers”, this shows that the breathing ball technique

can accelerate Kala I delivery compared to only given standard treatment with p-value (0.01 <0.05) Renaningtyas et al, (2013) explains this breathing ball technique is effective because it increases the relaxation of pelvic muscles so that labor is easy and fast⁽⁸⁾.

Likewise the results of research by Tavooni, 2011 suggested that the mean pain score in the Breathing ball group was significantly lower than the average pain score in the control group (P <0.05), but there were no significant differences in the two groups between the duration active phase labor or the interval between uterine contractions (P <0.05)⁽¹⁵⁾.

Research conducted by Zaky at the Labor and Delivery Unit at El-Shatby University Maternity Hospital in Alexandria shows that there is a statistically positive correlation between the effects of birth ball pelvic rocking exercise on the progress of labor in terms of decreasing the interval and increasing the duration and frequency of uterine contractions, cervical dilatation, and decreased fetal head in the study group. While the control group showed little progress with statically significant differences (<0,0001) *. In addition, the control group expressed more pain scores, spending longer duration from the 1st, 2nd and 3rd stage of labor than the study group. The researchers recommend that practicing with birth ball pelvic rocking exercise is recommended as one of the significant modalities to improve labor progress, manage pain, and improve self-control and gain a more satisfying maternity experience⁽¹⁶⁾cervical dilatation and fetal head descent/fifth among the study group. While the control group showed less progress with highly statically significant differences (<0.0001).

The results of data collection conducted in the field found that out of 30 respondents there were 2 respondents who had experienced long labor, this is because respondents were not active in doing breathing ball techniques by only doing 1 round of this technique.

The breathing ball technique can help the mother in an upright position, staying upright when in labor will allow the uterus to work as efficiently as possible making the pelvic plane wider and open. In other words, it can stimulate dilatation and widen the lower door of the pelvis, sit straight on the ball then the gravity of the earth will help the fetus or the lowest part of the fetus to immediately descend into the pelvis⁽¹⁷⁾.

Another study according to Surtiningsih et al, (2016) entitled The Effectiveness of pelvic rocking exercises on the length of time of delivery in primiparous mothers,

respondents 40 primigravida mothers with a gestational age of 34 to 35 weeks. The results showed that the breathing ball technique was effective in shortening the length of the active phase I with a side effect of 0.6 was also effective in shortening the length of the second stage with an effect size of 0.43. From the results of the study concluded that breathing ball effectively shortens the length of the first and second stages of labor in primigravidas⁽⁷⁾.

Breathing ball has been introduced to midwifery settings to facilitate mobilization techniques in women giving birth. This study reports an evaluation of the results of the use of breathing ball in the intrapartum period. The relationship between duration of use and perception of pain intensity has been explored. Although not statistically significant, the clinical significance of a high level of satisfaction must be recognized. Results including the duration of the first and second stages of labor and the way labor were also evaluated⁽¹¹⁾.

This research has explained the effects of pelvic rocking exercises while sitting on Breathing ball during childbirth. His findings indicate that Breathing ball can reduce pain and, increase progress and shorten the stage of labor⁽¹⁶⁾cervical dilatation and fetal head descent/fifth among the study group. While the control group showed less progress with highly statically significant differences (<0.0001).

Obstacles when researching when asking for mother's approval to be a respondent, some of the mothers are not willing to be respondents because they are afraid of the birth ball that researchers use as material for research, there are also mothers who do not want to be respondents because of cultural factors, mothers assume their grandmothers also never do anything like that but during childbirth is fine.

Conclusions and Suggestions

Based on the results of this study, it can be concluded that there is an effect of breathing ball technique on the duration of labor in the first phase of the active maternal phase in the Independent Practice of Sriwati Midwife.

Research needs to be done with more samples and places.

Cardiac Emergency Prevention Through Personal and Environmental Factors

Bambang Guruh Irianto¹, Loetfia Dwi Rahariyani²

¹Associate Professor, Department of Electromedical Engineering, Poltekkes Kemenkes Surabaya,

²Associate Professor, Department of Nursing, Poltekkes Kemenkes Surabaya

Abstract

Cardiovascular disease is the number one cause of death for non-communicable diseases. There are many types of cardiovascular disease, but the most common and well-known one is Coronary Heart Disease. Those who are diagnosed with coronary heart disease need to always be vigilant since it is highly possible for them to experience the cardiac emergency at any time, which can cause death. This study aims to determine how the efforts to prevent coronary heart disease patients against cardiac emergency through personal and environmental factors. The results of this study are expected to improve the quality of health services in coronary heart disease patients and increase the efforts of preventing cardiac emergencies in the patients with coronary heart disease independently. There were 118 patients with a medical diagnosis of coronary heart disease as the sample of this study. It utilizes the observational analytic method with cross sectional research design. The analysis technique used was variance or component-based Structural Equation Modeling (SEM). The results showed that there were coronary heart disease patients who had suffered from the disease for more than 1 (one) year (87.3%), had comorbidities: hypertension or diabetes mellitus (85.6%), had experienced a chest pain (79.7%), had a hereditary factor of heart disease (69.5%), and had a healthy lifestyle (69.9%). The results of the structural model analysis between personal factors and environmental factors indicate that there is a significant influence on preventing the cardiac emergencies.

Keywords: *cardiac emergency; personal; environmental*

Introduction

In Indonesia, non-communicable diseases increase every year causing more than 36 million people to pass away (63% of all deaths)⁽¹⁾. The number one cause of the death for non-communicable diseases in general is cardiovascular disease. It is a disease associated with the heart and blood vessel abnormalities. There are many types of cardiovascular disease, but the most common and well-known one is Coronary Heart Disease. Coronary Heart Disease is a heart function disorder due to lack of blood in the heart muscle caused by the narrowing of the coronary arteries. It is clinically characterized by the chest pain or discomfort feeling in the chest. Sometimes, there is a heavy pressure in the chest while climbing /

doing strenuous work, walking in a hurry or walking too far. It is defined as coronary heart disease if someone has been diagnosed with angina pectoris and / or myocardial infarction by a doctor, or has never been diagnosed with coronary heart disease but has experienced symptoms / history of the chest pain / feeling of pressure, severe / discomfort in the chest, pain / discomfort in the middle of the chest / front left chest / which spreads over the left arm, pain / discomfort in the chest felt while climbing / climbing stairs / walking in a hurry, and pain / discomfort in the chest which disappears when stopping the activity / taking a rest⁽²⁾. Sudden deaths caused by the heart disease represent about 25-30 percent of all cardiovascular deaths, and are estimated to cause 70,000 to 90,000 deaths each year⁽³⁾. The cardiovascular system is very vital, therefore it should always be treated in order to stay healthy and be able to function normally. The prevalence of heart disease (doctor diagnostics) at all ages by province in 2018 is 1.5 million.

Those who are diagnosed with coronary heart disease need to always be vigilant since it is highly possible for them to experience the cardiac emergency at any time, which can cause death. The phenomenon of sudden death was the only manifestation of disease in almost half of all subjects with myocardial infarction(4),(5). Most sudden deaths occur before the patient is hospitalized(3). The results of this study indicate that the patients with coronary heart disease are at risk of having a heart attack in any kind of situations(6). The death occurs due to the patients not getting any help or handling late. When a cardiac emergency arrest occurs, the patients must immediately get help either from themselves or others because if they are not treated immediately, they can get into a worse condition or death. The cardiac emergency can occur anywhere, and at any time. Sometimes it happens when the patient is alone.

An effective approach to prevent the cardiac emergencies must be undertaken for individuals at risk followed by risk factor control(7),(8). Therefore, the patients must be treated thoroughly since they are diagnosed with the coronary heart disease. It is not only about the treatment, but they must be able to prevent, anticipate and help themselves in the event of an attack, so they can avoid the death.(9)

This study aims to determine the efforts of preventing the coronary heart disease patients against cardiac emergencies through personal and environmental factor approaches. The results of this study are expected to improve the quality of the health services in coronary heart disease patients and increase the efforts of preventing the cardiac emergencies in the patients with coronary heart disease independently.

Materials and Method

The subjects in this study were 118 patients with a medical diagnosis of coronary heart disease. Research location was Polyclinic of Cardiovascular, Dr. Soetomo Hospital, Surabaya, a tertiary referral hospital that prioritizes broad sub-specialist and sub-specialist services. Time of research was July to August 2017.

This research utilized observational analytic method; a research approach without intervening the population in data collection. The analytic intended in this study was an explanation of the influence between variables. This study applied a cross sectional design where all variables were measured at the same time. These were the variables that influence the process of prevention of cardiac emergency, including personal factors and environmental factors (Figure 1).

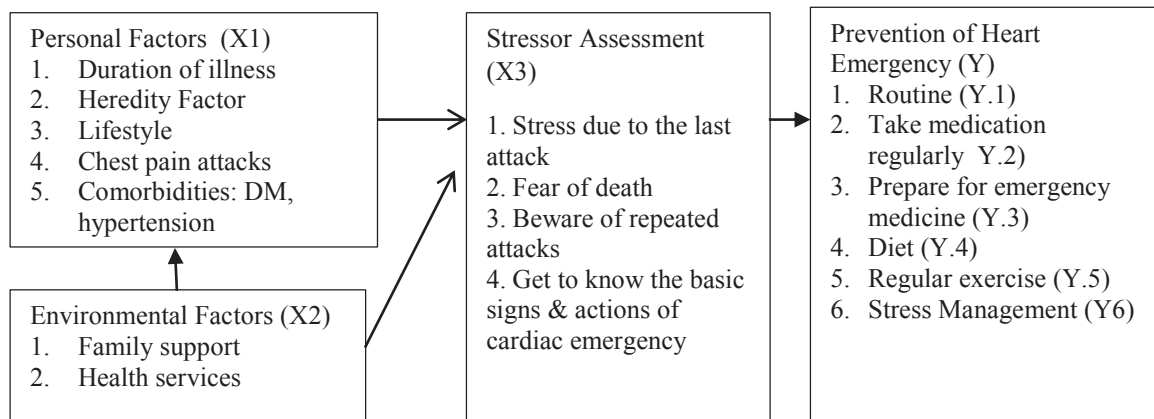

Figure 1. Research Conceptual Framework

The data were collected using a closed questionnaire and analyzed descriptively and inferentially. The results of the observations on 118 will then be analyzed. The analysis technique used is a structural equation model of variance or component-based Structural Equation Modeling (SEM).

Results

Personal factors in this study were measured through 5 indicators, namely: duration of illness, chest pain, presence of comorbidities, hereditary diseases and lifestyle. The complete data can be seen at Table 1.

Table 1. Distribution of Personal Factors in Coronary Heart Disease Patients

No.	Indicators	Frequency	Percentage
1	Duration of illness		
	<1 year	15	12.7
	>1 year	103	87.3
2	Chest pain attack		
	Experienced chest pain	94	79.7
	Not experienced chest pain	24	20.3
3	Comorbidity		
	There is comorbidity	101	85.6
	There is no comorbidity	17	14.4
4	Hereditary disease		
	There is a hereditary disease	82	69.5
	There is no hereditary disease	36	30.5
5	Lifestyle		
	Unhealthy	35	29.7
	Healthy	82	69.9

The results showed that there were Coronary Heart Disease patients who had suffered from the disease for more than 1 (one) year (87.3%), had comorbidities: hypertension or diabetes mellitus (85.6%), had experienced a chest pain (79.7%), had a hereditary factor of heart disease (69.5%), and had a healthy lifestyle (69.9%).

Environmental factors are constructed by two indicators: family support and health services which can be seen in table 2.

Table 2. Distribution of Environmental Factors in Coronary Heart Disease Patients

Indicators	Category						Total	
	Good		Fair		Poor			
	n	%	n	%	n	%	n	%
Family Support	65	55.1	35	29.9	18	15.3	118	100
Health Services	49	41.5	17	14.4	52	44.1	118	100

The results of the 2 indicators of the environmental factors showed that half (55.1%) of Coronary Heart Disease patients received a good family support, while the health service indicator was more in the unfavorable category.

The results of the analysis to see the measurement model (outer model) by testing the construct validity and construct reliability are shown in Table 3.

Table 3. The Results of Convergent Validity Test

Latent Variable	Indicators	Convergent Validity Test		
		Loading Value	T-Statistics Value	Validity
Personal Factor (X1)	Duration of illness	0.902	44.976	Valid
	Chest pain attacks	0.804	17.082	Valid
	Heredity factors	0.777	13.688	Valid
	Comorbidities	0.827	17.021	Valid
	Lifestyle	0.7050	13.178	Valid
Environmental factor (X2)	Family support	0.909	26.638	Valid
	Health services	0.743	9.757	Valid

The convergent validity test results explain that the factor loading value of the indicator is >0.5 and all indicators are significant for measuring the factor variables (T-statistic is more than 1.96). The conclusion of the analysis is that the above indicators are valid for measuring the latent variables and showing the criteria of goodness of a measurement model (outer model).

Structural model analysis is performed to examine the effect of the exogenous factors on the endogenous factors. The value used as a reference is the T-table value (109; $0.025 = 1.96$) with margin of error (α) = 5%. The results of the full significance test are explained in the following table.

Table 4. Significance Test Results on the Structural Model (Inner Model)

Path	Path parameter coefficient	Test of		Influence
		Relationship Significance		
		T-Statistics	T-Table	
(X1) Personal factor → (X3) Stressor assessment	0.215	2.099	1.96	Significant
(X2) Environmental factor → (X3) Stressor assessment	0.309	3.374	1.96	Significant
(X2) Environmental factor → (X1) Personal factor	0.374	5.221	1.96	Significant
(X3) Stressor assessment → (Y) Cardiac Emergency Prevention	0.273	3.179	1.96	Significant

Based on the structural model test results using the T test, all the T-statistic values are greater than the T-table. The conclusion is that there is a significant influence between exogenous factors and endogenous factors.

Discussion

The majority of coronary heart disease patients have been suffering from this disease for more than a year and have experienced chest pain. The acute coronary syndrome is caused by the imbalance between myocardial oxygen demand and supply which causes cell death and myocardial necrosis. The pain is experienced due

to lack of oxygen in the heart muscle. If this condition is not resolved immediately, it will cause arrhythmia that is very likely to occur the cardiac emergency⁽¹⁰⁾. Suffering from particular pain for a long time and having experienced chest pain is an unfavorable condition since it can have a psychological impact on the patient. It may cause boredom for individuals to undergo therapy. The

experience of chest pain is an unpleasant condition for the patient and a stressor⁽¹¹⁾. The psychological disorders experienced by the coronary heart disease patients will affect the treatment, especially in undergoing the treatment of the regular diet. The majority of the patients have comorbidities such as hypertension, diabetes or hyper cholesterol. Hypertension is one of the factors causing coronary heart disease. The 50% of myocardial infarction suffer from hypertension and 75% of them suffer from left ventricular failure due to the hypertension⁽¹²⁾. High and persistent blood pressure will cause direct trauma to the coronary artery walls. Diabetes is one of the predispositions to vascular disease. Men who suffer from diabetes have a 50% higher risk of illness than normal people, while women have a double risk⁽¹³⁾. Hypercholesterolemia is a major factor in coronary heart disease. The blood cholesterol level is affected by the daily composition of food. The patients who have comorbidities have a higher risk of experiencing cardiac emergency. Therefore, the intensive care needs to be done such as taking medication regularly, controlling blood sugar, maintaining the blood pressure, and choosing a healthy lifestyle⁽¹⁴⁾. In addition, the patients who experience diabetes or hypertension are at risk for coronary heart disease^{(14),(15),(16)} Several studies have shown that genetic factors predispose to the sudden death⁽⁴⁾. In recent years, the cardiovascular disease inherited due to genetic basis reaches more than 50% and can cause sudden cardiac death⁽¹⁶⁾.

Family support is necessary in treating coronary heart disease patients, especially in terms of taking medication regularly, doing routine medical check-ups at the hospital, helping to provide food according to the patients' diet, and supporting regular exercise. The results showed that half of the Coronary Heart Disease patients have good family support. This support is needed for the patients to take care of themselves better and avoid the cardiac emergencies. The coronary heart disease patients have to take the medication regularly and have a healthy lifestyle. They need to get an intensive care by doing routine medical check-ups which include blood pressure, blood sugar, and blood fat levels⁽¹⁴⁾. Furthermore, half of the coronary heart disease patients do not have good family support. Therefore, they try to overcome their health problems independently. The family does not provide support for regular medical check-ups to the hospital in which the patients need to go alone and take care of themselves. This condition is not good since they need support from the family to live

a life with the illness. The deaths from coronary heart disease can be prevented up to 80% by regular medical check-ups⁽¹⁴⁾.

The results of the research on the health services received by the patients with coronary heart disease showed that more than half of them stated that the services provided were not good. It is related to the lack of health education received by the patients with coronary heart disease, especially in terms of indications and symptoms of the heart attacks, as well as actions that must be taken when an attack occurs. The discussion results with the experts indicate that there is no Standard Operating Procedure (SOP) related to the health education for coronary heart disease patients from both the nursing and medical professions. Some of the doctors or nurses have conducted the health education, limited to their abilities and to answer the patient questions. If the patient does not give any question, the doctor or nurse does not give explanation, so the counseling varies both in quality and quantity.

Based on the results of the structural model analysis between personal factors and environmental factors, the T-statistic value (3.374) is greater than the T-table (1.96) which means that there is a significant influence between personal factors and environmental factors in preventing cardiac emergencies.

Conclusion

Patients with coronary heart disease are at risk for recurrent attacks of chest pain that can lead to cardiac emergencies. The personal factors including the duration of illness, chest pain attacks, the presence of comorbidities and hereditary diseases, as well as the environmental factors in the form of family support and good health services are very influential in the treatment of coronary heart disease patients to prevent the cardiac emergencies.

Abstract

Cronobacter sakazakii is a member of Enterobacteriaceae family and it is a food-born pathogenic bacteria which can cause several diseases for human and animals. The present study focused on the isolation of this species from clinical specimens from different sexes and ages in addition to hospital environments specimens and then investigation of *cpa.* and *zpx.* genes. The specimens have been taken from group of hospitals in Al-Nasiriyah city (center of Thi-Qar province- south of Iraq). The identification was done by both phenotypical methods and confirmed by API. 20 E. system. Then investigation of *cpa.* and *zpx.* genes by conventional PCR.

Out of 400 specimens (100 from each Burn humans, stool of patients with diarrhea, urine with UTI. in addition to hospital environments specimens) there were 16 (4 %) of specimens gave positive for *C. sakazakii* included : 4 from 100 burns specimens (4%), 6 from 100 stool specimens (6%), 0 from 100 urine (0%) and 6 from 100 hospital environments specimens (6%). The 16 isolates have been tested for presence of *cpa.* and *zpx.* genes by PCR., a number of 13 (81.25%) and 16 (100%) gave positive for these genes respectively. This species was exist in the clinical specimens and can cause diarrhea and burn infection in the area of study with ratio equal to what obtain by other researchers. Additionally this species considered hazardous because of having the *cpa.* and *zpx.* genes.

Key words: *Cronobacter sakazakii*, *cpa.*, *zpx.*

Introduction

Cronobacter sakazakii is one member of Enterobacteriaceae family which characterized by *gram-negative, rod-shaped*, facultative anaerobic, motile with a peritrichous flagella.⁽¹⁾ Firstly, it was identified and named as “yellow pigmented *Enterobacter cloacae*” by Urmenyi and white-Franklin (1961).⁽²⁾ The Japanese bacteriologist “Riichi Sakazakii” reclassified it (in 1980) as new species -*Enterobacter sakazakii*- based on genotype and phenotype classification.⁽³⁾ In 2007 it has been re-ranged in new genus called *Cronobacter* based on revised taxonomy.⁽⁴⁾ From 2008-2012, the genus *Cronobacter* subjected to more revisions which now consists of 7 species: *C. sakazakii*, *C. dublinensis*, *C. malonaticus*, *C. muytjensii*, *C. condimenti*, *C. turicensis*, and *C. universalis*⁽⁵⁾.

This organism is lactose fermenter bacteria with pink-mucoid colonies on MacConkey agar. It can be

identified with a typical non-diffusible yellow pigment colonies on Tryptic Soy Agar (TSA.) at 25°C and can also be grow on Eosin Methylene Blue (EMB.) and deoxycholate agar.⁽⁶⁾

C. sakazakii can be isolate from different sources such as: environments (e.g., domestic environments and manufacturing plants), clinical sources (e.g., cerebrospinal fluid, blood, and sputum), food (e.g., cheese, meat, and vegetables), and animals (e.g., rats and flies).

C. sakazakii is emerging foodborne pathogen which has been classified as sixth most common cause of nosocomial infections and antibiotic resistant strains.⁽⁷⁾ International Commission of Microbiological Specifications for Foods,⁽⁶⁾ considered *Cronobacter* as pathogenic organisms threatening human live and causing serious diseases,⁽⁶⁾ as well as World Health Organization

(WHO) recognized all *Cronobacter* species a pathogenic microorganisms.⁽¹⁾ The mortality rate with *Cronobacter* infections ranged between 40– 80%. This species is life-threatening for all human age groups (premature neonates, infants and immunocompromised adults) which can cause septicemia, meningitis and necrotizing enterocolitis. Urinary tract infection and diarrhea have also been recorded in addition to neurological sequelae. Patrick *et al.*, (2014).⁽⁸⁾ mentioned that the majority of *Cronobacter* infections are in the adult population, especially those suffering from serious underlying disease or malignancy.

C. sakazakii has a group of virulence factors, but these factors remain poorly studied.⁽⁹⁾ Recent studies by improved DNA-based techniques have identified many virulence factors in *C. sakazakii* such as seven O-serogroups and eleven proteolytic enzymes. Among the virulence-related proteins, outer membrane proteins (*ompA* and *ompX*) are involved in the colonization of the gastrointestinal tract and may have roles in helping the organism penetrate the blood–brain barrier.⁽⁹⁾ *Cronobacter* plasminogen activator (encoded by *cpa*. gene) is an outer membrane protein provides resistance against the bactericidal activity of serum, activates plasminogen, and inactivates alpha2- antiplasmin. Other virulence factor is Zinc-metalloprotease (encoded by *zpx*. gene) which causes cell deformation and cells rounding.

Genes in the area of current study (Thi-Qar province – south of Iraq), though there was a study by.⁽¹⁰⁾ which studied isolation of *C. sakazakii* from different sources and identified by phenotypic methods. Therefore, this work aimed to investigate the incidence of *C. sakazakii* in clinical and hospital environments specimens and detection of *cpa*. and *zpx*. genes.

Methodology

Four hundred specimens (included 100 specimens from each: Burns, Stool with diarrhea, Urine with UTI. and Hospital environment) were collected from Thi-Qar province (south of Iraq) hospitals: Bint-El-Huda Hospital, Al Hussein Educational Hospital and Mohammed Al Moussawi Hospital. The specimens were tacked by media swabs and transported to laboratories of college of sciences- Thi-Qar university in a cool box within 1-2 hours.

Pre-enrichment procedure

The methods of culture and isolation of *C. sakazakii* were done, the specimens were pre-enriched by mixing 25 ml/g sample with Buffered peptone water (BPW). Mixed well and incubated at 37°C for 24.0±2.0 h.

Isolation of *C. sakazakii*

After pre-enriched, all specimens were cultured on MacCokey agar (*C. sakazakii* lactose fermenter) for 37°C for 24 h. Then the pink – mucoid (lactose fermenter colonies) were sub-cultured on Tryptic Soy Agar (TSA) and incubated at 25 °C for 48-72 h. (colonies appeared as yellow pigmented) and chromogenic selective media- *Enterobacter sakazakii* Isolation Agar (ESIA.) was used, *C. sakazakii* appear as green- bright blue colonies.

Identification of *C. sakazakii*

The isolates were tested by microscopic examination under light microscope (which appear gram negative bacilli). Then tested by conventional biochemical methods as Oxidase test, Catalase test, Triple Sugar Iron (TSI. – A/A with gas production and no H₂S), Urease test, IMViC. test (Indole, Methyl-red, Voges-Proskauer and Citrate), Motility test and DNase test. Then this identification was confirmed by API. 20 E. system.

*Note: all used media were Oxiod / England except ESIA. Media.

Detection of *cpa*. and *zpx*. genes

After plasmid extraction, Cpa. and BAM. primers were used to detection of *cpa*. and *zpx*. genes respectively by PCR. technique for all identified isolates. The used primers for this purpose.

The primers were processed according to manufacturing instructions. The total volumes of reagents and premix tubes contents which used in the PCR amplification were 20 µl, included: 1 µl from each forward and reverse primers, 3 µl from DNA. template and 10 µl free water.

The results of virulence genes amplification have been visualized by 1% agarose gel electrophoresis (0.25 gm of Agarose powder in 25 ml of (1x) TBE. buffer) at 70 V. for 45 min, a ladder with 100-2000 bp. Has been used with genes electrophoresis.

Results

Total isolates of *C. sakazakii* were 16 out of 400 (4%) specimens, included : 4/100 burns specimens

(4%), 6/100 stool specimens (6%), 0/100 urine (0%) and 6/100 hospital environments specimens (6%), as shown in table (1):

Table (1): The number and percentages of *C. sakazakii* isolates

Clinical specimens	Number of specimens	Number of <i>C. sakazakii</i> isolates (%)	Percentage / 16
Burn	100	4 (4 %)	25 %
Hospitals environment	100	6 (6 %)	37.5%
Stool	100	6 (6 %)	37.5%
Urine	100	0 (0 %)	0 %
Total	400	16 (4 %)	100%

Phenotypic identification

-Morphological examination:

Isolates of *C. sakazakii* were lactose fermenter, pink color with thick center and mucoid colonies after 24 hrs. of incubation at 37 °C. with MacConkey agar. The isolates showed slight yellow–golden yellow pigmented colonies on TSA. agar and showed two types of colonies with ESIA. agar: typical colonies (small green to blue-green colonies) and non-typical colonies (slightly transparent and violet colonies), as shown in figure (1), The *C. sakazakii* isolates appeared as gram-negative rod shape under light microscope.

Figure (1): Morphological examination of *C. sakazakii*

Biochemical identification:

Biochemically, *C. sakazakii* isolates have been

identified by a list of testes (TSI., Catalase, Oxidase, Urease, IMViC. & Motility) and confirmed by API. 20E. system. The results of these tests showed in table (2) below:

Table (2): *C. sakazakii* biochemical tests and its results

Tests		Results
TSI.		A/A, G.*
Catalase		+
Oxidase		-
Urease		-
IMViC.	Indole	V*
	Methyl-red	-
	Voges- Proskaur	+
	Citrate	+
Motility		+
DNase		-

*A/A : acidic/acidic, G: gas (O₂). *V: variable.

C. sakazakii is considered a pathogenic bacterium and is necessary to focus on this bacterial species because of their own high virulence factors which constitute a threat to humans and animals. Its diagnosis show high similarity with other Enterobacteriaceae member's (as *Citrobacter* spp. and *Enterobacter* spp.) which lead to difficulty in diagnosis and do not rely on one type of methods; therefore the in present study the identification was done by using of morphological, biochemical and API.20 E..

The current study is the first in the study area, as well as the global studies with such design is very few where most local and global studies have been focused in isolation of the *C. sakazakii* from milk samples and food. There were some local studies isolated these organism from some clinical specimens. The results of current study in comparison with these locally studies indicated to the variation in isolation rates from one region to region and form time to time, where lower than results of study by⁽¹¹⁾ who obtained 16% of *C. sakazakii* isolates from clinical specimens from ALImamain Al-Kadhumain Medical City, Baghdad/Iraq, lower than results of study by⁽¹²⁾ who detected 9% of *C. sakazakii* isolates from clinical specimens from various hospitals of Najaf/Iraq.

The current results slightly higher than⁽¹⁰⁾ in Thi-qar province/Iraq who obtained one isolate (2%) of *C. sakazakii* from 50 specimens from patients stool with diarrhea, other study by⁽¹³⁾ in Thi-qar province reported 2% of *C. sakazakii* from stool of patients and a study by⁽¹⁴⁾ in Al-basrah city obtained 0 % from patients stool. In mexico: 0.33% in Hospitalized Nursing Infants Associated with the Consumption of Powdered Infant Formula (Two Cases of Hemorrhagic Diarrhea Caused by *Cronobacter* .⁽¹⁵⁾

Investigation of *cpa.* and *zpx.* genes :

Figure (2) show the extracted plasmid After DNA, the results of virulence genes investigation by PCR. technique revealed that 13 isolates (81.25) were positive for *cpa.* gene and all 16 isolates (100%) were positive for *zpx.* gene, as shown in figures (3 and 4).

Figure (2): Extracted plasmids DNA.

Figure (3): *cpa.* gene amplification from plasmid

Figure (4): *Zpx.* gene amplification from plasmid

The present study focused on the some important virulence genes which carried on the bacterial plasmids, these are: *cpa.* gene (*Cronobacter* plasminogen activator) and *zpx.* Gene (zinc containing metalloprotease).

A *cpa.* gene encodes by *cpaF* and *cpaR* primer was obtained in 13 (81.25%) of present isolates. This results agree with most previous studies by⁽¹⁶⁾ who recorded 60 % of a novel isolate of *C. sakazakii* have *cpa.* gene using an in vitro blood brain barrier model,⁽¹⁷⁾ 100% of *C. sakazakii* from clinical sample have *cpa.* gene,⁽¹⁸⁾ revealed 100% of *C. sakazakii* from some food and dust samples have *cpa.* gene and Almajed 2015, obtained (85%) of *cpa.* gene in *C. sakazakii* from clinical samples. In contrast disagree with⁽¹⁹⁾ who recorded *cpa.* gene (28%; 12/43) in *C. sakazakii* from different sources.

The *pESA3* encodes for the outer membrane protease *Cpa.* (which is responsible for serum resistance), this protease resistance against complement-dependent killing of serum by cleaving complement components C3. and C4b. This process leads to converting plasminogen

to plasmin, which then activate of other proteolytic enzymes, including matrix metalloproteinases, resulting in degradation of the tight junctions of microvascular endothelial cells. The bacteria will be able to migrate to peripheral tissue and invade the CNS.⁽²⁰⁾ Cpa. help bacteria to avoid serum-mediated killing together with the persistence within macrophages and other phagocytic cells gives the organism an advantage so it can survive in the blood stream, multiply, cause bacteraemia, and potentially reach vital organs such as the brain and the meninges. Degrading the components of the tight junctions resulting in the migration of the bacterial cells leading to more damage to the infected organ or tissue.

Zpx. gene encodes by BAM122 and BAM123 primer was obtained in 16 (100%) of isolates. This result agree with⁽¹⁸⁾ who revealed (100%) of *C. sakazakii* from some food and dust samples have *Zpx*. gene.

Zpx. is one of the important virulence factors that cause and associated with many diseases, In 2007, a study performed by.⁽²¹⁾ discovered a cell-bound zinc-containing metallo-protease (*Zpx*.) and showed that it is interact with the protease substrate azocasein, which led to rounding of Chinese hamster ovary (CHO.) cells in tissue culture.⁽²¹⁾ In addition to its a key role in allowing *Cronobacter* to disrupt the cellular junctions of the GI tract or CNS. leading to either NEC. or meningitis, respectively. In 2008, Hunter *et al.* performed a study using an infant rat model that implicated over-expression of interleukin-6 (IL-6) and the *Zpx* protein to playing a key role in the pathogenicity of *Cronobacter* spp. associated NEC infection.⁽²²⁾

Conclusion

C. sakazakii do exist and can be isolated from clinical sources (from sites of infections such as stool of patients with diarrhea and burns) as well as from the environment of hospitals not just from their natural sources. Difficulty of its diagnosis by the conventional methods due to some variations in the results of some recognized biochemical tests as indole according to its strains. There is no limited age for the patients infected with these organism contrary to most references which confirmed that “these bacteria affect newborns and infants only”. *C. sakazakii* in the present study is human-health thereat due to presence of virulence genes.

Abstract

Hemorrhoidal disease is one of most common anorectal disease and surgical hemorrhoidectomy remains one of most common operation in general surgery. The aim of the present study is to compare between conventional Milligan-Morgan hemorrhoidectomy and ligasure hemorrhoidectomy in treating patients with 3rd and 4th degree hemorrhoids. This randomized control trial was conducted at Alfayhaa teaching hospital during 2016 to 2018. The 3rd and 4th degree hemorrhoid patients (n=60, age 16-70 years) were randomly divided into two groups based on the surgical procedure, i.e. ligasure hemorrhoidectomy (n=30) and conventional hemorrhoidectomy (n=30). In ligasure hemorrhoidectomy, operative time, pain score on the 1st operative day and 1st week, duration of wound healing were 12.2 ± 03 , 4.1 ± 05 , 5.3 ± 02 min and 3.1 ± 02 , respectively. While in the conventional hemorrhoidectomy, it was 23.3 ± 02 , 6.2 ± 03 , 2.1 ± 09 min and 4.4 ± 07 , respectively. In ligasure hemorrhoidectomy 15 patients didn't have blood loss, 10 patients had a mild blood loss and 5 patients had a moderate blood loss. While, in conventional hemorrhoidectomy all patients suffered from blood loss, i.e. 14 patients have mild blood loss and 11 patients have blood loss. In conventional hemorrhoidectomy postoperative bleeding, necrosis, residual disease and anal _____ stenosis _____ were 19.2 ± 03 (p<0.001); 02.5 ± 01 (p<0.01); 08.9 ± 08 and 01.5 ± 01 , respectively. While, in ligasure hemorrhoidectomy postoperative bleeding, necrosis and residual disease were reduced to 07.3 ± 07 ; 00.0 ± 00 and 04.9 ± 09 , respectively. Anal _____ stenosis _____ was found to be increased to 06.4 ± 06 as compared to the conventional hemorrhoidectomy. Ligasure hemorrhoidectomy is better than conventional hemorrhoidectomy in terms of less operative time, less intraoperative pain and less postoperative complication and earlier wound healing and return to daily work hence higher patient satisfaction.

Keywords: Ligasure hemorrhoidectomy, conventional hemorrhoidectomy, postoperative complication, residual disease

Introduction

The hemorrhoid is a common anorectal disease characterized by distal displacement or enlargement of anal cushion¹⁻³. Abnormal destructive changes and dilated vascular channel in the supporting tissues in the anal cushion are reported by the various authors⁴⁻⁵. Ample of literature available on the association of the tissue inflammation and hyper perfusion state of anorectal region.

Hemorrhoidal disease reported in approximately 5% of the general population, especially after age 40 years of age, due to normal anatomical component of anal canal and the treatment is indicated in symptomatic cases⁶. On the bases of hemorrhoids degree of prolapse and appearance, it can be graded in to four degrees⁷. They are known as Goligher's classification. IN the first-degree hemorrhoids (grade I), the anal cushions are bleed but do not show any sign of prolapse. The second-degree hemorrhoids (grade II) include anal cushions prolapsation through the anus on straining however it reduce spontaneously. In the third-degree hemorrhoids (grade III), anal cushions prolapse through the anus on exertion or straining and it involve manual replacement into the anal canal. In the fourth-degree

hemorrhoids (grade IV), the formed prolapse remains out at all times and is irreducible. However, the variation in the 4th stages are also seen in many patients. Incarcerated internal hemorrhoids, elevated numbers of incarcerated, thrombosed with or without hemorrhoids involving circumferential rectal mucosal prolapse are a few variations observed among the patients⁸. In the present study we focused on the 3rd and 4th degree of hemorrhoids.

Many surgery options are available for the patients based on the hemorrhoids degree, age, complications etc⁹⁻¹¹. The main and ultimate treatment for 3rd and 4th degree hemorrhoids is hemorrhoidectomy¹². Traditional Milligan Morgan hemorrhoidectomy is open surgical procedure in which the hemorrhoid pedicle is ligated by transfixing suture. This may lead to postoperative complications, mostly pain, bleeding and wound infection¹³. Many surgeon believes that by avoiding vascular pedicle ligation, the chance of secondary bleeding can be decrease⁹⁻¹³. Because it may lead to ischemia and necrosis. Additionally, if sutures are applied deeply, then they can also cause firm scarring at anus later on. To avoid this problem, ligasure are used by the practitioner. In this surgery procedure, the transfix vascular pedicle of hemorrhoids are not used instead they seal them by Ligasure. The Ligasure vessel sealing system is a bipolar electro thermal device which seals blood vessels by a calculated arrangement of pressure and radio frequency. With is background, in the present study, we aim to compare between conventional Milligan-Morgan hemorrhoidectomy and ligasure hemorrhoidectomy in treating patients with 3rd and 4th degree hemorrhoids.

Material and Method

This randomized control clinical study was carried out at the Alfayhaa teaching hospital during a period from may 2017 to may 2018. The study enrolled 60 patients diagnosed with 3rd and 4th degree hemorrhoids. They are randomly divided into two groups i.e. ligasure hemorrhoidectomy treated patients (n=30) and conventional Milligan Morgan hemorrhoidectomy treated patients (n=30).

The inclusion criteria were patients above 16 year age with diagnosed 3rd and 4th degree hemorrhoid. Patients with previous anal surgery, anticoagulant therapy, immunosuppressed patients and under 16 years were excluded from the study. All patients were subjected to

history taking, clinical examination and investigations, including complete blood count, coagulation profile, liver function tests, kidney function test, fasting blood sugar, ECG, anoscopy or sigmoidoscopy. Before the surgical procedure, cefalosporine (1gm) were given intra-venously to the both groups.

Surgery procedure for ligasure hemorrhoidectomy

The hemorrhoidal complex is grasped by Allis clamp with artery forceps. So that skin elevation can be seen at the junction between hemorrhoid and peranal skin. The ligasure device was applied. The dissection was started in this plane, with sparing the sphincter in anal canal till the pedicle of hemorrhoid appear. The pedicle of hemorrhoid can be sealed twice to ensure it is devascularized and reduced postoperative bleeding. A similar procedure was done for 2nd and 3rd hemorrhoids with skin bridges between them. The anal pack was used if needed.

Surgery procedure for conventional (Milligan-Morgan) hemorrhoidectomy

The anal retractor was introduced to visualize the surgical field. Allis artery forceps were placed on the external component at the three main sites. Traction on these prolapse the internal components, relevant two artery forceps were grasped in the palm of left hand and the index finger extended anally to define the triangle of exposure. The mayo scissors were used to incised the skin. The external component was dissected off the underlying superficial external anal sphincter and separated the internal component from underlying internal anal sphincter, continually narrowing down the pedicle, and transfix and ligate the pedicle. The operation then proceed for the another two hemorrhoids. Hemostasis is checked and anal pack is used to ensure hemostasis.

Statistical Analysis

The data were represented as a mean and standard error. The statistical analysis was perform by one way analysis of variance (ANOVA).

Results

The Age of the patients ranged between 16 and 70 years old with a mean 38.9 years. Regarding Sex, male patients in the study were 20 representing 66.66%. Female patients were 10 representing 33.33% of patients

participated the study in the conventional group and male patients were 23 representing 76.66%, and female patients 07 representing 23.33% of patients in Ligasure group (Table 1).

Table 1. Gender wise variation of patients

	Conventional	Ligasure
Male	20 (66.66%)	23 (76.66%)
Female	10 (33.33%)	07 (23.33%)

Table 2 reveals features of hemorrhoids as compared between ligasure and conventional hemorrhoidectomy methods regarding operative time. In ligasure and conventional hemorrhoidectomy the operative time were 12.2 ± 03 and 23.3 ± 02 min. In ligasure and conventional hemorrhoidectomy, the pain score on the 1st operative day were 4.1 ± 05 and 6.2 ± 03 . The pain score on 1st week postoperative were 5.3 ± 02 and 2.1 ± 09 min in ligasure and conventional hemorrhoidectomy. While, duration of wound healing were 3.1 ± 02 and 4.4 ± 07 in ligasure and conventional hemorrhoidectomy.

Table 2. Feature of ligation and conventional hemorrhoidectomy method

	Ligasure hemorrhoidectomy	Conventional hemorrhoidectomy	p value
Operative time (min)	12.2 ± 03	23.3 ± 02	0.001
Pain scores 1st day	4.1 ± 05	6.2 ± 03	--
Pain scores 1st week	5.3 ± 02	2.1 ± 09	--
Duration of wound healing	3.1 ± 02	4.4 ± 07	--

Table 3 shows the variation of intraoperative blood loss in both groups. In ligasure hemorrhoidectomy 15 patients didn't have blood loss, 10 patients had a mild blood loss and 5 patients had a moderate blood loss. While, in conventional hemorrhoidectomy all patients suffered from blood loss, *i.e.* 14 patients have mild blood loss and 11 patients have blood loss.

Table 3. Variation of blood lost during operation

	Ligasure hemorrhoidectomy	Conventional hemorrhoidectomy
No blood loss	15 (50.00%)	00 (00.00%)
Mild blood loss	10 (33.33%)	14 (63.33%)
Moderate blood loss	05 (16.66%)	11 (36.66%)

Table 4 shows complications from hemorrhoidectomy in comparison between two surgery procedure. In conventional hemorrhoidectomy postoperative bleeding, necrosis, residual disease and anal stenosis were 19.2 ± 03 ($p < 0.001$); 02.5 ± 01 ($p < 0.01$); 08.9

± 08 and 01.5 ± 01 , respectively. While, in ligasure hemorrhoidectomy postoperative bleeding, necrosis and residual disease were reduced to 07.3 ± 07 ; 00.0 ± 00 and 04.9 ± 09 , respectively. Anal stenosis was found to be increased to 06.4 ± 06 as compared to the conventional hemorrhoidectomy.

Table 4. Complications

Complication	Ligasure hemorrhoidectomy	Conventional hemorrhoidectomy	P value
Bleeding	07.3 ± 07	19.2 ± 03	0.001
Necrosis	00.0 ± 00	02.5 ± 01	0.01
Residual disease	04.9 ± 09	08.9 ± 08	--
Anal stenosis	06.4 ± 06	01.5 ± 01	--

Discussion

Now a day also conventional hemorrhoidectomy was recommended to many patients showing irreducible and symptomatic piles¹⁴. However, many reports are available about the comparison of conventional hemorrhoidectomy and recent more advance surgery procedure¹⁴⁻¹⁸. The comparison of conventional hemorrhoidectomy with ligasure hemorrhoidectomy were also reported by many researchers¹⁶⁻¹⁸.

In the randomized trials on the 850 patients, significant improvement in wound healing, postoperative pain, and time off work was reported with comparable complications and postoperative bleeding in both ligasure and conventional hemorrhoidectomy¹⁷. However, in the present study no significance improvement was observed in the wound healing as compared to conventional hemorrhoidectomy. Kraemer et al.¹⁹ reported Ligasure haemorrhoidectomy reduces in the postoperative pain and slide improvement in radiofrequency in 4th stage piles patients as compared to stapled haemorrhoidectomy. Our study is accordance with this report.

Mastakov et al.¹⁸ reported that the ligature hemorrhoidectomy was a more effective treatment than other hemorrhoidectomy surgery procedure. The study was based on the eleven trials of 1046 patients and their large meta-analysis. The complication incidence was also reported to be very low¹⁸. In the present study, ligature hemorrhoidectomy found to be reduce operative time, postoperative pain in 1st day and 1st week as compared to hemorrhoidectomy surgery procedure.

In the prospective multicentric randomized trial (n=273), LigaSure treatment showed significant improvement in faster return to work, shorter operating time with reduction in postoperative pain. However, complication occurrence and postoperative bleeding

was non-significant differs¹⁶. About 50% patients did not show any blood loss after surgery. The data is accordance with the previous reports.

Conclusion

Ligasure hemorrhoidectomy is found to be an effective method as compared to conventional hemorrhoidectomy in terms of less intraoperative pain and operative time, and less postoperative complication and earlier wound healing with the maximum frequency of return to daily work.

Women's Reactions and Health Disorders Caused by Abuse During the Pregnancy-Postpartum Period

Rosmala Nur¹, Siti Ika Fitriasyah¹, Anwar Mallongi²

¹Department Public Health, Faculty of Public Health, Tadulako University, Palu Street Soekarno-Hatta KM. 9. Palu, Central Sulawesi, 94117 Indonesia, ²Department Environmental Health, Faculty of Public Health, Hasanuddin University, Indonesia

Abstract

The purpose of this study was to determine women's reactions to violence, and reproductive health problems as a result of violence, during the pregnancy-puerperal period. The study was conducted in two villages of central Sulawesi: Sunju Village in Sigi Biromaru Regency and Tanjung Batu Town in Donggala Regency. The main population of interest was married women of childbearing age who were pregnant, in the puerperal period, had been pregnant, had given birth a maximum of 2 years previously, or who had experienced violence in the past. The data collection was completed through structured interviews, in-depth interviews, observations, and a Focus Group Discussion (FGD). The results showed that women who are victims of violence generally go to traditional midwives for childbirth, while women in town in general go to rural midwives. The typical response of wives to reproductive health problems is silence, and this is the first choice of reaction for victims of violence in villages and cities. However, if the violence is considered to endanger the health and safety of their lives, women in the village generally report the violence to a customs agency called "Pabisara Ada", while women in town choose to fight or avoid it, rather than to report their husband's actions.

Keywords: reproductive health; responsibility; violence

Introduction

The ideal conditions desired by women for healthy reproduction are liberation from pain and disease, the ability to perform and enjoy safe sex activities, the ability to have descendants and undergo pregnancy and childbirth safely, the ability to regulate fertility without compromising their health, and the ability to go through their pregnancy with a healthy baby and mother¹. The prevalence of violence towards pregnant and nursing women has increased over time. In the study area there were 71 cases of violence in 2010–2012, which increased to 91 cases in 2013–2015³. Pregnancy demands extra attention and awareness by the husband, both physically and mentally; however, many women experience violence during this time. Data shows that in the period from 2010 to 2012, there were 11 cases of violence towards expectant mothers, and this increased to 27 cases in 2013 to 2015³. In this paper, we seek to understand the reaction of women to violence, and the prevalence of health disorders caused by violence during the pregnancy-puerperal period.

Materials and Method

This study was conducted in Sunju Village (rural area) in Sigi Biromaru Regency and Tanjung Batu Town (urban area) in Donggala Regency, Central Sulawesi. When the study was conducted, Sunju Village and Tanjung Batu Town were included in Donggala Regency. Now, they have been separated; Sunju Village is included in Sigi Biromaru Regency and Tanjung Batu Town is included in Donggala Regency. Samples were taken from married women of childbearing age who were pregnant, in the postpartum period, had experienced pregnancy and child birth within the last 2 years, or who were suffering from violence at the time. This study had 94 respondents. Data were collected through interviews, focus group discussions (FGD), and observations.

Results

Responses of Women to Reproductive Health Problems

In Table 1, it can be seen that the total number of

victims seeking care from a midwife was 39.7%.

Table 1. Places where help was sought for reproductive health problems.

Place of Treatment	Sunju		Tanjung Batu		Total	
	n	%	n	%	n	%
	1	2	3	4	3	4
Traditional midwife	16	44.4	8	21.7	24	32.9
Doctor	1	2.8	6	16.2	7	9.6
Village midwife	11	31	18	48.6	29	39.7
Health Center	6	16.2	5	13.5	11	15.1
Not looking for treatment/ Self-treatment	2	5.6	0	0	2	2.7
Total	36	100	37	100.0	73	100

This phenomenon can be understood by that fact that almost all villages have a midwife who can be reached by the public. According to Adrina⁵ and Hakimi et al.⁶ the victims chose a village midwife because of the short distance required to travel to them. In addition, this type of midwife is deemed to meet the needs of pregnant women in terms of having knowledge and equipment that is modern and sophisticated than that of traditional midwives, thereby giving a general feeling of safety. These data are supported by qualitative data, including statements such as the following by Mrs. SW (31 years of age), from interviews and the FGD:

“At that time, I was arguing with my husband. I was heavily pregnant, and then his body banged me against the wall and then he dragged me. I was bleeding at that time. Yes, I was taken by my neighbor to midwife’s house, because I thought the traditional midwife had no medicine to stop the blood. I was given some medications there, then the midwife injected me, she said that it was to strengthen the pregnancy, yeah, thank God the bleeding stopped.”

In addition to the fact that the traditional midwives are able to keep secrets, women generally assumed that the cost of the treatment given by traditional midwives would also be cheaper:

“If we asked for help at the traditional midwife, she just asked to buy cigarettes, sometimes I bring 3 liters of beans or rice, while in the midwife I could pay up to 40,000Rp or more.”

Several other women (Mrs. Ng, Mrs. Dika, and Mrs. HJR) explained that they were

usually assisted by traditional midwives because they offer comfort and advice to them:

“Ina made me comfortable, she first asked, what’s wrong with you my daughter, then we were entertained by her, if we felt pain, or dizziness, she always advised, then she gave therapy as well so we felt calm. She prayed for us.”

Traditional midwives also seem to care about the pregnancy complications experienced by women.

Several advantages of this midwife were noted by the women in this study. Village midwives often provide an opportunity for victims to make several payment installments. Mrs. Neni (26 years old) stated

“Midwife is preferred, although it is a bit pricey. The payment can be repaid at the health center. Midwives can also be approached easily both day and night, while health center services is confined only in the mornings.”

Reproductive health services through midwives not only treat complications of pregnancy or bleeding, but they also help with childbirth and venereal diseases and provide contraceptive services. Some women said that they had a normal childbirth; some had babies born prematurely. Mrs. Sisi (32 years old) stated

“Since my husband had slapped me, I often had a fever. At the time, I returned from the market after

trading. When I arrived home, I washed, mopped, then I cooked. Immediately my body felt limping at all. I took Vitamin C. Not long after that, I felt that there was blood coming out of my womb, then I went to midwife's house. "

In addition to the above forms of help, midwives can treat venereal diseases, as expressed by Mrs. Jm (28 years old). She was reluctant to go to the health center because it was considered disgraceful:

"My genital was swollen. She said that it was like that, genital was swelling and itching. I went to traditional midwife and she fetched the bark of Java, then laced with areca and betel, and cooked it. She then taped it in my genital parts. For one month I treated it regularly and eventually my genital is dry and does not itchy anymore.

Especially for abortion services, it seems that traditional midwives and midwives in the village have the same view. They steadfastly refuse to perform abortions if they are asked for help. Abortions are very difficult to talk about openly. Mrs. An (30 years old) from Tanjung Batu Town, who had an abortion, expressed the following in an interview:

"I aborted my pregnancy in a place that is located quite far from here. Its location is in the Pasang Kayu, North Mamuju, West Sulawesi.

The low control of women over their reproductive rights, especially in terms of the decision to have an abortion, is certainly not new in the community, which embraces the values of the patriarchy¹⁰⁻¹².

Women may be pressured by their husband or the surrounding community, while at the same time the facilities and the support they need is not available. Related to this discourse, although provisions for abortions exist in Clauses 1 and 2 of the Health Act No. 23 of 1992, the opportunity to have an abortion is only available in the case of an emergency, as an attempt to save the lives of pregnant women or their babies. These provisions need to be reviewed. These conditions often mean that women's needs are neglected, as stated by Catherine A. McKinnon:

"Policy on abortion is never explicitly approached contextually, namely by taking into account the circumstances of the time a woman is impregnated by her partner, that is, in the circumstances specified by

gender inequality that, as a result, women are forced to have sexual relationship."

Another place women use for reproductive health services is the health center. An assortment of reasons for this were expressed by the respondents, for example, Mrs. Mila (32 years old) from Sunju Village stated

"If I got sick, I tried to go to traditional midwife first, but if I was not cured, I would go to the health center."

Most respondents said that they rarely go to the health center because of remoteness and limited service time. Mrs. Neni (26 years old) recognized the problem as follows:

"Health center are quite far from here. It is also open only until 11 o'clock, so if we were sick in the evening then the least is we should go to the midwife or call traditional midwife."

Although the respondents tended to have a number of grievances, it seems that not much can be done by health workers in health centers given the limited availability of medicines, the lack of understanding about women's reproductive health, and the tendency to consider the complaints of women as not being important. Often, the answer given to the respondents was, "never mind Ma'am, you will be cured if you have been given a drug". In addition to the services of health workers being less friendly, health center services also tend to be complicated and slow to access.

3.2. Respondent's Responses to Violence

Respondents reported an assortment of reactions to violence. The reactions of victims of violence were classified into four categories: silence, avoid, resist, and report. In general, respondents' reactions to violence were affected by the impact they experienced. If the violence experienced was considered mild, respondents generally tended to be silent or avoid it, whereas when the impact was painful, the victims tended to complain, resist, and report^{19,20}.

This facility has long existed in the village, so the villagers affected by violence are likely to know the details of the reporting procedure or complaint process. Meanwhile, in Tanjung Batu Town, there are no indigenous village councils. In the town, although silence was shown to be the preferred response, the percentage of respondents who reported quite a lot of resistance was 20.7%; however, in the village it was

only 13.1%. This is due to the fact that awareness of respondents of their rights has begun to increase.

Table 2. Respondents' reactions to violence in Sunju Village and Tanjung Batu

Respondents Reaction to Violence	Sunju		Tanjung Batu		Total	
	n	(%)	n	(%)	n	(%)
	1	2	3	4	3	4
Silent	15	41.7	28	48.3	43	45.7
Resist	5	13.9	12	20.7	17	18.1
Report	12	33.3	6	10.3	18	19.1
Avoid	4	11.1	12	20.7	16	17.0
Total	36	100.0	58	100.0	94	100.0

The places to report or complain included the village traditional council, the headman, police, friends, family, and neighbors. Table 3 shows that, in general, the respondents complain to a friend (39.1%). This is because friends can keep conflicts secret and help find a solution before the incident gets worse

Table 3. Places used to report or seek protection by respondents.

The Place to Report for Seek Protection	Sunju		Tanjung Batu		Total	
	n	(%)	n	(%)	n	(%)
	1	2	3	4	3	4
Village Traditional Council	10	27.8	0	0.0	14	14.9
Headman	4	11.1	9	15.5	15	16.0
Police	0	0.0	7	12.1	7	7.4
Neighbors	2	5.6	4	6.9	6	6.4
Friends	14	38.9	23	39.7	33	35.1
Family	6	16.7	15	25.9	19	20.2
Total	36	100.0	58	100.0	94	100.0

In the town, the place used to report or complain tended to be family (25.9%). This was possibly because violence was reported to cause severe problems, such as husbands getting remarried and women getting slapped. In general, this occurred more in the town. A neighbor of a respondent (Mrs. Leni, 42 years old) confirmed that view. She argued that tackling a violent husband could result in major problems, such as the husband remarrying or giving a beating; thus, for minor issues, in general, the woman will just cope herself.

This reinforces the findings of Khaeruddin²¹ and Hayati⁶, that the service of law enforcement officers in the handling of women victims of violence is not adequate, which makes victims reluctant to report

violence to the authorities^{22,23}.

Conclusions

Silence is the common reaction of respondents in both villages and towns to violence. However, if violence is considered to endanger their health and safety, the village respondents generally report it to the customs agency "Pabisara Ada", while respondents in the town prefer to fight or avoid it than report it.

Handling of violence by pregnant women in the two regions remains piecemeal. In the town, the management of violence against pregnant women is done by police. The services provided tend to be convoluted, take a long time, and are costly, with inadequate facilities and

handling by officials who are not sensitive to gender issues.

Abstract

Age of First Marriage is the age at which a person is legally and biologically married for the first time. According to UNICEF, the percentage of women who decide to get child marriage in the world throughout 2016 is 12 million. Southeast Asia and Asia-Pacific are the highest in the number of child marriage. In Southeast Asia, Indonesia ranks second highest for child marriage. The purpose of the study was to determine the factors associated with the age of first marriage in young women in West Marawola Sub-District. This research was categorized as quantitative research with *cross-sectional* approach. The population was young women aged 10-24 in the West Marawola Sub-District with a percentage of 988 people taken as the sample (*Proportionate Stratified Random Sampling*). The analysis was conducted using univariate and bivariate analysis at a confidence level of 95% (). The chi-square test results showed that Knowledge ($=0,001$), Parental Support ($=0,000$), Culture ($=0,040$), and Family Planning Instructor ($=0,037$) are related to the Age of First Marriage. It is expected that this research is able to socialize the age of marriage, so that young women can delay their marriage.

Keywords: *Age of first marriage, Knowledge, Parental Support, Family Planning Instructor.*

Introduction

Child marriage is a marriage conducted a couple in not ideal age, either men or women, when they are not in ideal age, if a marriage is still held, it can be said as child marriage. The government program, in this case the BKKBN (National Population and Family Planning Board), said that the ideal age for marriage is 21 years old for women, and 25 years old for men.¹

Globally, it is estimated that 12 million women decide to get child marriage in the world. Southeast Asia and Asia-Pacific are the highest in the number of child marriage. In Southeast Asia, Indonesia ranks second highest for child marriage as 1 in 3 children gets child marriage. There is a relationship between child marriage and poverty and the low education opportunities.²

In Indonesia, the average age of first marriage (UKP) is 20 years, and this has not yet reached the targets of the National Population and Family Planning Board (BKKBN) for at least 21 years old for women and 25 years old for men.³

In Central Sulawesi Province, the average Age of First Marriage is 19 years old from the percentages of 459,795 couples of childbearing age in total, with the percentage for married wives <21 years old of 57.29% and the percentage of married husbands <25 years old of 21.34%. Central Sulawesi ranked the second highest for age of first marriage in Indonesia (BPS, 2017). Sigi was one of the highest average age of first marriage of 19.96 years old with a percentage of married wives <21 years old was 59.08% and a percentage of married husbands <25 years old was 25.67%. The age of first marriage in Marawola Barat District was the highest, with a total of 1,427 couples of childbearing age, the percentage of married wives <21 years old was 73.56% and the percentage of married husbands <25 years old

was 76.45%⁴.

Materials and Method

This research is categorized as an analytical survey research with a quantitative approach. This research used *Cross-Sectional* design, where the cause or risk variables and the consequences or cases that occurred in the research object were measured or collected at the same time.

The population in this study was young women aged 10-24 years, as many as 988 people in Marawola Barat Sub-District, Sigi Regency, Central Sulawesi Province. There were 91 respondents taken as the sample of the research using the Slovin formula. The sampling was conducted using *Proportionate Stratified Random Sampling* or simple random sampling, which used certification technique.

Results

Based on the research conducted in West Marawola Sub-District, the characteristics of respondents can be seen in the following table:

Table 1: Characteristics of Respondents

Characteristics	F	%
Age		
10-12 Years Old	1	1.1
13-15 Years Old	10	11.0
16-18 Years Old	34	37.4
19-21 Years Old	25	27.5
22-24 Years Old	21	23.1
Total	91	100.0
Age of first marriage		
<21 Years Old	78	85.7
≥ 21 Years Old	13	14.3
Total	91	100.0
Educational Background		
Elementary School	11	12.1
Junior High School	45	49.5
Senior High School	33	36.3
University	2	2.2
Total	91	100.0
Parents' Educational Background		
Not Graduated from Elementary School	2	2.2
Elementary School	14	15.4
Junior High School	51	56.0
Senior High School	24	26.4
Total	91	100.0

Most of respondents have Junior High School Education with a percentage of 49.5%, and most of their parents have Junior High School Education with a percentage of 56.0%. Factors related to the age of first marriage in female teenagers in Marawola Sub-District:

Table 2: Factors related to the age of first marriage in female teenagers in Marawola Sub-District

Good	17	69,4%	7	30,6%	24	
Total	78	85,7%	13	14,3%	91	

Of 36 people who have good knowledge, there are 25 people (69.4%) got married at the age of <21 years. The statistical test resulted in $\rho = 0.001$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between knowledge and Age of First Marriage in West Marawola Sub-District.

The data in table 2 shows that from 70 people who give parental support to their children, there are 66 people (94,6%) have their children married at the age of <21 years. While from 21 people who give less parental support to their children, there are 12 people (69.4%) have their children married at the age of <21 years. The statistical test resulted in $\rho = 0,000$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between Parental Support and Age of First Marriage in West Marawola Sub-District.

The data in table 2 shows that from 55 people (92.7%) who have a good cultural support, there are 51 people (92.7%) got married at the age of <21 years. While from 36 people (75.0%) who have a poor cultural support, there are 27 people (75.0%) got married at the age of <21 years. The statistical test resulted in $\rho = 0.040$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between culture and Age of First Marriage in West Marawola Sub-District.

The data in table 2 shows that 67 people accompanied by the bad PLKB (Family Planning Instructor), there are 61 people (91.0%) got married at the age of <21 years. While from 24 people accompanied by the good PLKB (Family Planning Instructor), there are 17 people (69.4%) got married at the age of <21 years. The statistical test resulted in $\rho = 0.037$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a

relationship between PLKB and Age of First Marriage in West Marawola Sub-District. child marriage⁹

Discussion

Knowledge and Age of first marriage

Knowledge is the result of knowing from humans who simply answered the “*what*” questions happen after they conduct imaging on a particular object.⁵

The statistical test resulted in $\rho = 0.001$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between knowledge and Age of First Marriage in West Marawola Sub-District. There were more respondents with the Age of First Marriage < 21 years who have poor knowledge compared to those who have good knowledge.

This research is in line with the research conducted by Priyanti *et al.*⁶ which, based on the results of Chi-Square analysis, found a significance level of $\rho = 0.001 < 0.05$ which statistically proved that there is a relationship between knowledge of respondents and child marriage.

The results of this research are in line with the research conducted by Dwinanda *et al.*⁷. Based on results of the analysis on the analysis on the respondents with poor knowledge, from 55 respondents who have good knowledge, there were 14 respondents (87.5%) got child marriage and 2 respondents (12.5%) did not get child marriage.

From 36 respondents with good knowledge, there were 25 people (69.4%) got married at the age of < 21 years and 11 people (30.0%) got married at the age ≥ 21 years. This is because they already know about the risks of child marriage, which has an impact on their future, now and in the future. The results are in line with the study conducted by Smith *et al.*⁸ that there is no relationship between knowledge and the high rate of child marriage in the Philippines.

Parental Support and Age of first marriage

In society, there are some parents or family members who consider child marriage as a common phenomenon. There are many parents in traditional societies still believe that investing in a girl’s education is wasteful, as she is only going to get married and being a housewife in the future. This concept is strongly influencing the illiterate fathers, fathers with lower level of education have a higher tendency to have their daughters conduct

The statistical test resulted in $\rho = 0,000$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between Parental Support and Age of First Marriage in West Marawola Sub-District. This research is in line with the research conducted by Desiyanti¹⁰, that from 34 respondents (68.0%) stated parental support to their daughters to get child marriage as it will improve their economy and to have the better economy, because their daughters will be supported by their husbands who have great capital that raises an understanding that the marriage of their daughters will improve the economy of the parents.

The results obtained at the location of the study showed that from 70 people who give parental support to their children, there were 66 people (94.6%) have their children get married at the age of < 21 years as it is dominated by economic factors. Parents who cannot afford to pay for their living and school sometimes make their children to decide to get child marriage. This study is also in line with the research conducted by Naveed & Butt¹¹ on poor families with low education level that parents do not have the resources to send their daughters to school. Parents choose to let their daughters get married as early as possible to set free from responsibility.

Culture and Age of first marriage

Child marriage is a behavior learned by adolescents from the environment in which they live. The environmental influence in question is the existence of values and norms that develop in the community related to the existence of a young woman and the concept of marriage¹².

The culture of child marriage is a culture that has become customary law and is still preserved nowadays which is carried out in several ways, such as arranged marriages, spells (witchcraft), and prohibition the younger sibling to get married before the older sibling to avoid the older sibling to be a spinster, as if the younger sibling wants to get married before the older one, there must be dowry offered to the older sibling and so on.¹³

The statistical test resulted in $\rho = 0.040$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between culture and Age of First Marriage in West Marawola Sub-District. It is similar to the research conducted by Desire¹⁴ in Myanmar that support for child marriage is influenced by the

surrounding environment. The environmental influence in question is the existence of values and norms that develop in the community related to the existence of a young woman and the concept of marriage.

From 55 people (92.7%) who have a good cultural support, there were 51 people (92.7%) got married at the age of <21 years. This is predominantly because the customary law is still upheld by the people in West Marawola Sub-District, if there is a couple is dating and tends to do negative things, they will be forced to get married soon and pay fines or customary sanctions apply in accordance with the provisions and the severity of the violation. As stated in the research conducted by Rahardjo & Imron¹⁵, it becomes a culture for young women to get child marriage since the environment and their peers experienced it.

Family Planning Instructor and Age of first marriage

The Family Planning Instructor (PKLB) is the spearhead of the Population, Family Planning and Family Development program that is given full duty, responsibility, authority and rights by authorized officials to carry out counseling, giving service, evaluation and development of the National Family Planning³.

The statistical test resulted in $\rho = 0.037$, so that $\rho < 0.05$, thus, H_0 in this study was rejected, means that there is a relationship between PLKB and Age of First Marriage in West Marawola Sub-District. This research is in line with the research conducted by Astuti, E (2014), The Role of Family Planning Instructor (PLKB) in Population Growth Control in Sungai Dama Village, Samarinda Ilir Sub-District was running poorly because there were still many people who do not understand the importance of KKBPK and the performance of PLKB was not maximal due to the lack of socialization and improvement of skills for the community, especially for adolescents, concerning reproductive health and child marriage.

The results obtained from the location of study showed that 67 people accompanied by the bad PLKB (Family Planning Instructor), there were 61 people (91.0%) got married at the age of <21 years. This is because the PLKB did not socialize the KKBPK programs, especially for the youth-friendly programs, related to reproductive health, preparation of family life, the far distance between each village, and the notion that information is not needed in West Marawola Sub-District.

This research is also in line with the research conducted by Mengistu¹⁶ in Ethiopia, that the Performance of Healthcare Personnel in disseminating information is very important, and it could be measured how many officers reach the goal of changing perspectives and behaviour in the success of Population, Family Planning and Family Development programs especially for the Maturity of Age of Marriage¹⁷.

Conclusions and Suggestions

Knowledge, parental supports, culture, and family planning instructors became the factors related to the age of marriage in young women in West Marawola Sub-District, so that it requires special attention from the government to embrace and provide awareness for young women, to provide opportunities and facilities in accessing information through KIE Maturity of Age of Marriage and to improve coordination related to cooperation with BKKBN in increasing public knowledge about the maturity of age of marriage.

Abstract

Maternal mortality rate in Sigi Regency in Central Sulawesi is quite high at 309 per 100.000 live births. The study aimed to determine the effect of knowledge on Antenatal Care (ANC), early detection of high risk and pregnant women postpartum behavioral care, reproductive health disorders, and to determine which factors are the most salient of these variables. The study was an analytical observational research with a population of 180 pregnant women and a sample of 180 pregnant women. Data was collected from February 2018 to June 2018 by interview using questionnaire, observation and FGD. Data analysis used was *Chi Square* at significance level of $p < 0.05$.

The research results showed that the mother's level of knowledge on *Antenatal Care* was low at 58.88%; the level of knowledge on early detection of high risk pregnancy was low at 56.66%, mother's behavior in pregnancy treatment was also poor at 55.55%, and prevalence of respondents with reproductive health disorders was 57.7%. Knowledge on ANC, early detection of high risk pregnancy, and mother's behavior in prenatal care had significant relations with reproductive health disorders ($p < 0.05$). Maternal knowledge becomes the most influential variable to maternal reproductive health disorder with P value = 0,001. It was found out that lack of mother's knowledge on antenatal care and late detection of high risk pregnancy, as well as behavior during pregnancy-*puerperal* period contributed to adverse reproductive health of women. and led to an increase in maternal and infant mortality rates in Sigi district of Central Sulawesi. As an intervention, the study recommends increased women's literacy in pregnant-*nifas* treatment as a preventive effort in improving women's reproductive health.

Keywords: *Pregnancy-Puerperal Period, Antenatal Care (ANC), Early Detection of High Risk, Healthy Behavior, Reproductive Health*

Introduction

To reduce maternal mortality significantly, early detection and treatment of pregnant women at risk should be improved, especially in primary service facilities. Therefore, early detection by health workers on risk factors and complications, as well as adequate treatment as early as possible, are necessary¹.

Factors causing high mortality rate can be direct and indirect. Direct causes are bleeding, preeclampsia, infection, and pregnancy complication². Indirect causes of MMR and IMR include completeness and accuracy in implementing Antenatal care, poor administration

of iron tablet and examination of hemoglobin which causes anemia in pregnant women³, poor knowledge of symptoms of high risk^{4,5}.

The purpose of the present study was to determine the relation between mother's knowledge on Antenatal Care (ANC), high risk early detection, as well as healthy behavior in pregnancy-*puerperal* treatment, and reproductive health disorders, and which factors are most influential on the three variables.

Materials and Method

This was an analytical observational study. The

research was performed in the working area of Tinggede Public Health Center, which covers 3 villages, i.e. Sunju, Tinggede and South Tinggede Villages from February 2018 to June 2018.

The following information were culled from the participants' medical records available at the Public Health Centers: personal identity, frequency and regularity of prenatal care (antenatal care ANC), immunizations, detection of high risk, number of abortions in the past activities during antenatal care, diet.

Additionally, a questionnaire consisting of 75 questions about knowledge of prenatal care (ANC), high risk pregnancy detection and mother's behavior during pregnancy that impacts reproductive health. Interviews were conducted during the prenatal care of mothers at the Tinggede Public Health Center of the three villages usually at 8:00 am to 12:00 pm. The researcher also observed the pregnant woman's home environment by going to the subjects homes in the afternoon until evening, and during Saturdays and Mondays every week.

Statistical analysis using chi square were performed on the relationship of the variables.

Population and Sample

The population was all pregnant women (second pregnancy) who have a child under two years old totaling 180 subjects. The sampling technique was total sampling.

The data collection was conducted through a series of measurements:

Measurement of knowledge on ANC using questionnaire with the indicators of Pregnancy

examination, Checkup frequency, Height measurement and weight, Blood pressure measurement , Measuring Upper Mid Arm, Measuring Height of Fundus Uteri, and TT Immunization

Measurement of knowledge on **early detection of high risk pregnancy using questionnaire** with the indicators of Too young to be pregnant (≤ 16 years old), Too slow to get pregnant, Too fast to get pregnant again (≤ 2 years), Too old to be pregnant (≥ 35 years old), Too long to be pregnant again (≥ 10 years old), Too many children (4 or more), Too old (≥ 35 years old), Too short (< 145 cm), Previous miscarriage, Previous birth involving (Being pulled by forceps/vacuum, Reaching into placenta, Administration of infusion/transfusion, and breech pregnancy).

Measurement of **healthy behavior in pregnancy treatment** using questionnaire with the indicators of Balanced daily menu, Favorite dishes and fruits, Hand washing habit, Bathing habit, Habit of wearing footwear, length of working hour and rest.

Measurement of **Reproductive health disorders using questionnaire with the indicators of** Bleeding, Infection, Miscarriage, Pregnancy complication, Fever/seizure, Premature birth, Low birth weight, Infant mortality.

Data Analysis

Univariate data analysis were performed for all study variables. Chi-square test was used to examine the correlation between independent variables and dependent variables (bivariate and multivariate). The level of significance was $p < 0.05$.

Results

Table 1. The relation between knowledge on ANC, early detection and high risk pregnancy, Healthy behavior in pregnancy treatment and reproductive health disorders

Variable	Reproductive health disorders				Total		P value
	Experienced		Not Experienced		N (180)	% (100)	
	n (104)	% (57.7)	n (76)	% (42.3)			
Knowledge on ANC							
Low	72	67.9	34	32,1	106	58.88	0.001
High	32	43.2	42	56.8	74	42.12	

Knowledge on early detection and high risk pregnancy							
Low	68	66.6	34	33.4	102	56.66	0.015
High	36	46.1	42	53.9	78	43.34	
Healthy behavior in pregnancy treatment							
Not healthy	68	68.0	32	32.0	100	55.55	0.015
Healthy	36	45.0	44	55.0	80	44.45	

Pregnant women who had unhealthy/poor behavior in pregnancy and puerperal treatment and reproductive health disorders were 68% and those who had healthy behavior in pregnancy and puerperal treatment and reproductive health disorders were 45%. Meanwhile, those who had no reproductive disease and had unhealthy/poor behavior were 32% and those who had healthy behavior were 55%.

Figure 1.. Distribution of Mother's Behavior In Pregnancy-Postnatal Care Percentage

Table 2 shows maternal behaviors in prenatal care of pregnant women. Checking for pregnancy is highest (measuring height and weight, and measuring the height of the uterine fundus, which is a component of the examination performed at the first visit) with a value

of more than 90%. The lowest was treating nipples for breast milk (0%), resting habits (0%), regular taking of iron tablets (7%), tetanus toxoid immunization (9%) and Hb checking habit (13%).

Multivariate Data**Table 2. ANC Multivariate Test Results, Early Detection of High Risk, Mother Behavior, and Reproductive Health Disorders**

No	Variables	Model 1			
		P	B	OR	95% CI
1	ANC Knowledge	0.002	1.024	2.785	1.478 – 5.249
2	Early Detection Knowledge	0.535	0.574	0.563	0.092 – 3.458
3	Healthy Behaviour	0.111	1.474	4.369	0.714 – 26.731

The results of multivariate analysis showed that the most influencing variables of reproductive disorder were knowledge of ANC. Mothers who had knowledge of ANC had 2 times less higher risk for having reproductive disorder compared to mothers who had no good ANC knowledge.

Discussion

Table 1 shows that pregnant women with poor knowledge generally had reproductive health disorders (bleeding, infection, seizure, hypertension, low birth weight (LBW) and miscarriage) at 67.7%. Their low knowledge affected their health behavior, especially in the utilization of antenatal care, i.e. pregnancy examination, compliance in drinking Fe tablet, HB examination, counseling, etc.. This research indicated the importance of iron supplement during pregnancy, knowledge about anemia and iron-rich food during pregnancy. Educating antenatal women on the importance of consuming Fe tablet and regular taking of the iron supplement will help prevent bleeding⁶.

Moreover, there are many factors causing low knowledge on the importance of ANC services, including low level of education^{7,8}. Mother's level of knowledge affects information acceptance and attitude change, thus enhancing or lacking knowledge on nutrition for both women and fetus. Knowledge and access to antenatal care can lead to healthy condition of the mothers and healthy fetal growth. Educational attainment factor had significant relation with reproductive health of pregnant women and ability to look for knowledge on pregnancy-periperal treatments.

Further, the research results also showed that knowledge on early detection of high risk pregnancy

had significant relation with reproductive disorders with $p = 0.015$ ($p < 0.05$). Low knowledge level on early detection of high risk pregnancy made pregnant women and their families unaware of the symptoms of high risk pregnancy. This finding is consistent with Risk,⁹ study found that knowledge on preeclampsia affects maternal and infant mortalities. Women with high risk pregnancy require closer attention from their families and health care providers because they may not be able to distinguish these symptoms.

Table 1 shows that low knowledge of pregnant women led to risk of reproductive health disorders (bleeding, infection, seizure, hypertension, low birth weight (LBW) and miscarriage) at 66.6%. One's level of education is related to knowledge on many things, e.g. rationality in thinking, attitude and consideration of different factors, including early detection of high risk and their own high risk Rosmala-Nur¹⁰, and Abdullah¹¹ found that one's knowledge impacts the economic, social cultural, and political activities, as well as asserting women's rights to reproductive health in a patriarchal society.

Education level also determined how readily a pregnant woman absorbs and understands knowledge on early detection of high risk. Low education leads to limited knowledge on early detection, e.g. too young, too old for birth, too many children, short body height, etc., leading to pregnancy complication, bleeding, anemia, premature birth and even infant death. These findings were similar with the study of¹² which shows significant relation between low knowledge and reproductive health (e.g., bleeding) in pregnant women.

Anemia prevention affects incidence of postpartum bleeding according to Sulastri, Arina Maliya and Maliya study¹³. Education and socialization on health by health workers to get optimal level of health are still very necessary, especially in developing countries such as Indonesia as found by Mubasyiroh R, Tejayanti T¹⁴, and Rosmala-Nur and Mallongi¹⁵.

Another factor which affected low healthy behavior among pregnant women was husband's lack of support to the wife during pregnancy and puerperal periods. Rosmala-Nur¹⁰ found that low husband's participation among pregnant women whose reproductive rights weren't met were due to husband's domination in decision making in the family.

Furthermore, in Table 2 vividly shows that healthy behaviors during pregnancy such as pregnancy checking, measuring height and weight, measuring blood pressure, Measuring Upper Mid Arm, measuring height of fundus uteri, TT immunization, regular taking of Fe tablets, HB checking habits, consuming varied healthy side dishes and fruits, hand washing habits, bathing habits, footwear habits, adequate resting habits, not smoking and drinking alcohol, and treating nipples for breast milk impacted healthy outcome for both mother and child. Among the different healthy practices, the lowest behaviors were treating nipples for breast milk (0%), resting habits (0%), regular taking of Fe tablets (7%), TT immunization (9%), and HB checking habits (13%). All of these factors impacted maternal reproductive health. Pregnant women who do not have time to rest, work hard during pregnancy accompanied by not regularly taking Fe tablets were at risk for bleeding which affects the incidence of maternal deaths.

Routinely performed ANC are also useful for facilitating the passage of mutual trust between pregnant women and health workers, thereby cultivating a shared sense of responsibility for keeping pregnancy healthy until the birth process¹⁶. Thus if the expectant mother has no knowledge of ANC, it will affect her behavior during pregnancy and utilizing the pregnancy related services. The results of this study were in accordance with study revealed that one of the risk factors of maternal mortality is incomplete implementation of ANC among pregnant women because of lack of knowledge in the utilization of ANC services.

Pregnant women should have knowledge that high-risk pregnancies can be detected if they routinely submit

to prenatal care and check-ups. Included in this service is early detection of danger signs, as well as providing information about efforts to maintain pregnancy and prepare for the birthing process. High risk pregnant women are among those who suffer maternal deaths if not detected at the outset¹⁷⁻¹⁹. Thus it can be concluded that lack of knowledge of Antenatal Care (ANC) is a variable that greatly impacts the occurrence of reproductive health disorders in the regency of Sigi Biromaru, Central Sulawesi.

Conclusion

Pregnant women's level of knowledge on ANC and early detection of high risk and pregnant women's behavior in pregnancy-puerperal treatment affected reproductive health disorders such as bleeding, infection, seizure, hypertension, low birth weight (LBW)) and led to increased mortality and infant mortality rates in the research areas of Tinggede Public Health Center, Sigi Regency, Central Sulawesi.

The Influence of Wedge Sea Hare (*Dolabella auricularia*) Extract and Papaya Juice on Hemoglobin (Hb) and Ferritin Levels of Mice Strain (Balb / C) with Anemia

Sultan Akbar Toruntju¹, La Banudi¹, Purnomo Leksono¹, Mochammad Rahmat², Wa Ode Salma³

¹Senior Lecturer of Department of Nutrition, National Health Polytechnic of Kendari, ²Senior Lecturer of Department of Nutrition, National Health Polytechnic of Jakarta II, ³Lecturer of Faculty of Medicine, University of Haluoleo, Kendari

Abstract

The aim was to see the effect of wedge sea hare extract and papaya juice, on Hemoglobin and Ferritin levels of Mice Strain (BALB / c).

Method, True Design Experiment with Control Group, has been used. Mice were divided into 5 groups, each group 5 tails, reserves 5 tails. Intervention of mice was given a solution of collaborative compounds (a mixture of sea rabbit extract with papaya juice) for 21 days, with the distribution of the following doses: Group A, Control (-), Group B, Control (+), Fe tablets 0.65 mg / kg BW, Group C, dose treatment = 100 mg / kg BW of mice / day, Group D, dose treatment = 150 mg / kg BW of mice / day, Group E, dose treatment = 250 mg / kg BW mice / day. Blood is taken before and after treatment 21 days. Data Analysis using a Paired t-test and ANOVA statistical tests.

The results, statistical tests showed a significant difference in hemoglobin levels that were significant in the three treatments, between before and after treatment, with $P < 0.05$. This means that the administration of wedge sea hare extract and papaya juice can increase Hemoglobin levels in anemia mice, where there is a tendency to increase the average hemoglobin level along with the large dose of treatment given. Besides, it is also due to the presence of primer metabolic substances in papaya juice, such as vitamin C, Beta carotene, Calcium, Potassium, and Phosphorus.

Conclusion, there is a different increase in hemoglobin levels in the three forms of treatment between before and after treatment. This means that there is a significant effect of giving collaborative compounds to Hemoglobin levels in mice.

Keywords : *Wedge sea hare, Hemoglobin, Ferritin, Wedge Sea Hare extract, Papaya Juice.*

Introduction

The Basic Health Research in 2007 showed that the national prevalence of anemia (in urban areas) was 12.8%, of which 70.1% were IDA. This number increased to 21.7% in 2013,¹⁴. This showed that the biggest proportion of anemia is IDA. IDA, in general, may not be known and felt by children or parents, but its effect causes a decrease in aerobic endurance which will have a decreased physical ability to disrupt the child's growth and development itself,²⁰.

Wedge sea hare is a food source of animal protein that is not widely known by the public. Recent research has found that wedge sea hare is very rich in amino acids such as aspartic acid, glutamate, and glycine, moreover, the amino acid arginine which is an essential amino acid for growing children,^{8,17}. Providing food sources of vitamin C and β -Carotene greatly influences the mechanism of action of Fe in forming hemoglobin,²¹.

Hb is an element that contains Fe Fero (Fe 2+) as the main element of Hb. This Hb is present in erythrocytes, where each Hb is bound to one protein (globin) and four molecules of heme. Hb levels are often used as

indicators of anemia,⁶. Ferritin is an intact form of Fe deposits. Serum ferritin is an excellent indicator of iron reserves unless there are symptoms of inflammation and malignancy,². The objective of this research was knowing the effect of giving wedge sea hare extract, papaya juice, on Hb and Ferritin levels in Mice Strains (BALB / c) with anemia.

Materials and Method

Pre-clinical study research design, True Experiments with Control Group Design. Mice divided into 5 groups, each group of 5 animals, reserve 5 animals. The total number of samples was 30. The following groups of procedures form the treatment:

Group A = Control (-) given aquades

Group B = Control (+), Fe tablets 0.65 mg / kg BW / day,¹⁵

Group C = Treatment I, Collaborative fluid of wedge sea hares, papaya juice, dose = 100 mg / kg BW of mice / head / day = 0.75 mg / day

Group D = Treatment II Dose = 150 mg / kg BW = 2.25 mg / day

Group E = Treatment III Dose = 250 mg / kg BW / mice / day = 3.25 mg / day,

Experimental Animals (Mice strain BALB / c):

Mice weighing 25-35 grams/head, aged 8-12 weeks, healthy and free of pathogens, obtained from mice experimental animal farmers in the city of Kendari. Implementation of this research trial as a basis using the “Research Guidelines for Evaluating the Safety and Efficacy of Herbal Medicines” according to WHO standards.

Adaptation of Experimental Animals

Mice before being treated were acclimatized for 1 week. This process was carried out indoors with sufficient air circulation, the room temperature was maintained at standard conditions, ie 28 ± 2 °C, and humidity of 50 ± 10 % with a room lamp that has a cycle of 12 hours on and 12 hours off.

Sample size

The sample size was calculated using a modification of the Federer formula: 45 each test group consisted of

6 mice,¹¹.

Federer’s formula:	3n	≥ 18
(t-1) (n-1)	≥ 15	n
(4-1)(n-1)	≥ 15	≥ 6
3 (n-1)	≥ 15	Information :
3n-3	≥ 15	t = number of test groups
		n = sample size per group

The ideal sample size according to the Federer formula above was 6 or more mice. Thus, the total number of mice in all 5 test groups was 25.

Research design: *The pretest and posttest control group design*

The Making of wedge sea hare extract and papaya Juice

1. The making process of wedge sea hare extract

Wedge sea hare is gastropods living in shallow areas where there are algae. Wedge sea hares were taken from the coast of Toronipa, Soropia District, Konawe Regency. Wedge sea extract before being made, first rinsed 5-7 times to reduce salt levels, then dried without direct sunlight.

2. Making Papaya Juice

Papaya was taken from the Mandonga Mall market, Kendari City. Both papaya juice and wedge sea hare extracts were made in the Biopharmaca laboratory, Faculty of Pharmacy, Haluoleo University, Kendari. Thickening papaya was washed, peeled, cut into 10 x 7 cm sizes and blended until crushed, then filtered.

3. Making Combined Extracts (Collaborative Fluids)

After wedge sea hare and papaya extract were obtained, then preparations were made. The extract was then made into 4 comparisons between wedge sea hare and papaya juice, as followed :

1. 1.5 grams: 40 grams

- 2. 2.0 grams: 30 grams
- 3. 2.5 grams: 20 grams
- 4. 3.0 grams: 10 grams.

Then each of these comparisons was dissolved in Na-CMC until the volume became 100 mL.

Intervention Implementation (Provision of wedge sea hare extract and papaya juice)

1. Pathological Treatment of Anemia

The pathological treatment was through the administration of NaNO₂ with a dose used in each mice that is 3.75 mg dissolved in 1 ml of distilled water. The dose given was 0.3 ml/mice/ day,²⁰. This was done for all groups of mice.

2. Treatment (wedge sea hare extract and papaya juice)

Feeding mice must be careful because they must meet their nutritional needs and fluids. The need for food for mice ranges from 2-4 grams/day of dry matter or approximately 20% of body weight, while the water needs are only 3 ml/day. Collaborative fluids in this study were given orally using a gavage needle through a sonde⁵.

3. Initial and final blood sampling/examination:

Taking too much blood in small animals, causing hypovolemic shock, stress and even death. Blood sampling that was not according to the rules, caused anemia in experimental animals.

Results

a. Homogeneity Test

Table 1: Description of Homogeneity Test from the results of initial blood tests of mice (before treatment).

Variables	Number of samples	Mean Hb level (mg / dl)	Standard Deviation
Control (+)	5	5.88	3,7
Control (-)	5	3.90	0.88
Treatment-1	5	4.70	0.15
Treatment-2	5	4.60	0.34
Treatment-3	5	4.80	2.02

P-Value = 0,421

ANOVA statistical test showed a significance level $\alpha > 0.05$, H_0 was accepted, there was no difference in mean Hb levels between groups.

b. Hemoglobin levels before and after the intervention

Table 2: Mean Hb levels before and after treatment

Group	Hb Level	
	Before	After
Control (-)	7,42 + 3,39	8,30 + 2,22
Control (+)	4,00 + 0,83	11,76 + 2,67
Treatment-1	5,90 + 3,16	13,10 + 1,45
Treatment -2	6,00 + 3,30	13,06 + 1,39
Treatment -3	6,22 + 5,02	14,40 + 1,68

Table 2, there was a mean increase in Hb levels before and after treatment. In the treatment group, both treatments one, two and three increased Hb levels, compared with negative controls ($P < 0.05$). The mean increased in the three treatments was higher than the increase in positive controls (given iron folate capsules).

Table 3: Mean difference in hemoglobin levels before and after treatment

Group	Mean difference in Hb level	
	Difference	Standard Deviation
Control (-)	0,88	+ 3,25
Control (+)	7,76	+ 1,37
Treatment-1	7,20	+ 1,39
Treatment -2	7,06	+ 1,49
Treatment -3	8,18	+ 1,68

Table 3 showed the difference in Hb levels before and after treatment, where treatment groups one and treatment two had a difference in Hb levels that almost resembled positive control (iron-folat etablets) of 7.76 gr/dL, while in treatment three, instead, it exceeds positive control, which is 8.18 gr /dL.

4. Ferritin Levels

The results of the laboratory examination of Ferritin levels in this study could not be displayed as Hb levels, because the results of the examination showed un iformity among all groups, namely with a value < 0.500 µg/L.

Inferential Analysis

Paired t-test

Table 4: Paired t-test statistical test results:

Group	Mean	t – test	Sig (2-tailed)
Control (-)	-4,02	-1,74	0,155
Control (+)	-7,76	-6,45	0,003
Treatment-1	-7,20	-3,65	0,022
Treatment-2	-7,66	-12,38	0,000
Treatment-3	-8,66	-7,78	0,001

Table 4 showed the mean difference between the treatment group and the control group, both in treatments one, two and three ($P < 0.05$).

Discussion

Wedge sea hares are gastropods that are incorporated into the genus *Dolabella*, living in shallow areas where there are algae. Stated that wedgesea hares favor *Cladophora* green algae, *Cymodocearotunseagrass* data, and *Sargassumcristaefolium* brown algae species,²². The characteristics of this animal have a pair of tentacles found in the dorsal part. The ventral part of the wedge sea hare has a shell that covers the purple ink glands. Purple ink glands in wedge sea hares are used to protect against danger.

The compound in Rabbit Sea Extract

Phytochemical examination results prove that rabbit sea hare extract in this study contained several secondary metabolic active compounds, such as Saponin Flavonoids and Tannins. Research by Uffelle S.A. reported that active phytochemical compounds, namely flavonoids and tannins were very involved in hematological processes,²⁰.

Compounds in Papaya juice

In the Indonesian Food Composition Table-(2018), fresh papaya contains several primary metabolic nutrients such as vitamin C, Beta carotene, Thiamin, and the minerals Ferum, Calcium, and Potassium. A study explained that Fe absorption is strongly influenced by things such as the level of Fe deficiency, the level of body Fe availability, gastric acidity, the availability of vitamin C, the presence of Phosphate and Fitat,¹⁹. Hoffbrand & Moss explained that for the formation of hemoglobin, iron is transported by transferrin proteins to erythroblasts in the bone marrow, bound to globin proteins, assisted by vitamin B6 which is a coenzyme and vitamin C which plays a role in reducing ferric iron (Fe^{3+}) to ferrous (Fe^{2+}) in the small intestine,⁷. This reduction process causes iron to be easily absorbed for hemoglobin synthesis,¹⁵.

The collaborative compound of hemoglobin formation

This was likely the effect of the collaboration compound in three doses which can increase the Hb level, which exceeds the effect of the iron folate capsule, ie at a dose of three (250 mg/kg BW). The protein of wedge sea hare did not differ much in the research of Abdullah et al, which stated that the protein content of *Anadara antiquate* is 12.89%,¹. The protein content of wedge sea hare is greater than *Pleuroploca trapezium* 10.348%,⁴. The high protein content of wedge sea hare showed that wedge sea hare can be used as an alternative food source of beneficial animal protein.

Hemoglobin level difference

Table 2 showed that there was an increase in the average Hb level in mice in the treatment group, both one, two and three treatments, especially when compared to negative controls ($P < 0.05$). The mean increase in the three treatments was higher than the increase in positive controls (given iron folate). This proved that the treatment of wedge sea hare extract and papaya juice (collaboration fluid) influences the formation of Hb levels. Purwaningsih S reported that these wedge sea hare, besides containing several nutrients as primary metabolic sources such as amino acids, fatty acids, and minerals, also contained many secondary metabolic substances such as Flavonoids, Saponins, and Tannins, through the results of phytochemical tests,¹¹.

Foods that contain iron and protein are needed for the formation of hemoglobin, including consuming food sources of animal protein from the sea such as fish, shellfish and wedge sea hare. Consumption of wedge sea hare is highly recommended because in addition to being a source of animal protein is also a source of minerals such as Fe, Cu, and Zn. Purwaningsih S stated that wedge sea hares contained 12.49 + 0.34% protein, mineral 23.02 + 3.23%, fat 0.87 + 0.55%, where the amino acid value of wedgesea hare is very good from other sea animals,^{13,19}

Results of statistical tests Table (5-4) in which there were significant differences in mean Hb levels in the three treatments, $P < 0.05$. This means that the administration of collaborative fluids can increase hemoglobin levels in anemic mice, there is a tendency to increase the mean hemoglobin level along with the large dose of treatment given. The formation of Hb will run smoothly if a sufficient number of triggers is available, the absorption rate of Fe,³. The availability of Fe in the body will greatly affect the formation rate of Hb and Erythrocytes. Hb is a protein with a molecular weight of 64,450 is a red pigment, which functions to carry globular oxygen, where each molecule contains 5% heme-containing iron and 95% globular polypeptides. This pigment is a chromogen which has 4 metal pyrrole groups¹⁶.

Conclusion

Giving several doses (100 mg / kg body weight, 150 mg / kg body weight, and 250 mg / kg body weight) of wedge sea hare extract on hemoglobin levels in mice (BALB / c) that have anemia showed an increase in the mean level of hemoglobin along with the magnitude the dose given. This is because the collaboration of many secondary metabolic phytochemical compounds from wedge sea hares that work together with the primary metabolic compounds of papaya extract can synthesize the formation of heme which can stimulate hemoglobin levels.

The Relation between Psychological Empowerment and Job Satisfaction among Nurses

Rifaie Yaseen Hameed Al-Hussein

Assistant Professor, Ph.D. Community Health Nursing, Northern Technical University, Technical Institute of Mosul, Nursing Department, Nineveh, Iraq

Abstract

Background- Empowering employees is an essential factor to reduce workplace stress, whereas its role in enhancing job satisfaction among employees is through perceived job obligation, and reducing stress. Aim- The present study endeavored to determine the relationship between Psychological Empowerment and Job Satisfaction among nurses. Methods and Materials- Cross-sectional, descriptive and correlational study design carried out for a period from 5th of September/2017 till 30th of May/2018 at five hospitals in Mosul/Iraq. Non-probability sampling technique and accidental sampling method were depended to select (317) nurse as a sample of the study. An interview was the method through which data were gathered. Two instruments were used to collect data; Psychological Empowerment questionnaire “PE”, and Minnesota Job Satisfaction questionnaire “JS”. Mean, Standard deviation and stepwise regression analysis were used to present the findings of the study. Findings- Total Psychological Empowerment and Total Job Satisfaction and their domains had an acceptable level, from another side, Total Psychological Empowerment and its domains had significant relations with Total Job Satisfaction and its domains.

Keywords: *Psychological Empowerment, Job Satisfaction, Nurse.*

Introduction

Nurses consider a vital part in the health care system, play a profound role in its efficacy, effectiveness, and promotion of patient health, whereas, any health agency can't dispense his/her⁽¹⁾.

Empowerment can be seen as an organizational initiative to grant staff an autonomy in order to reduce the sense of helplessness and remove the formal obstacles in the regulatory environment⁽²⁾, while the person's experience of self-motivation that forms the point of view of his/her is known as psychological empowerment⁽³⁾, it motivates employees to do well⁽⁴⁾, and composes of many domains; mean, competence, self-determination, and impact⁽⁵⁾.

The individual's cognitive attitude or affective reaction toward job is known as job satisfaction, it is

the extent of love and belonging the employees have to their work, the increased sense of importance of work and improvement of achievements⁽⁶⁾, the perceptions in regard to job performance, the contribution of positive meaning values and positive consequences for the organization, the desire to develop work personalities and skills⁽⁷⁾, and they tend to be high self-confidence⁽⁸⁾.

However, scholars recognize that job performance enhances employee empowerment that can encourage employees to operate beyond the norm and achieve jobs in an accommodating manner. Empowering employees is an essential factor to reduce workplace stress^(2,9), while its role in enhancing job satisfaction among employees is through perceived job obligation, and reducing stress⁽⁷⁾.

The present study endeavored to determine the relationship between Psychological Empowerment and Job Satisfaction among nurses.

Material and Method

Cross-sectional, descriptive and correlational study design carried out for a period from 5th of

September/2017 till 30th of May/2018 at five hospitals in Mosul/Iraq. Non-probability sampling technique and accidental sampling method were depended to select (317) nurse as a sample of the study depending on such criteria (providing bedside nursing care, having a tenure in the current place ≥ 5 years, presenting at work during gathering data and didn't engage in management or leadership position at the study period). An interview was the method through which data were gathered; each interview lasted 20-30 minutes. Two instruments were used to collect data; Psychological Empowerment questionnaire "PE" which is used to measure the level of four dimensions; (Meaning= 3 items, Competence=3 items, Self-determination=3 items, and Impact=3 items), the scores of each item had five options ranged from (strongly disagree=1 to strongly agree=5) ⁽⁵⁾, and Minnesota Job Satisfaction questionnaire "JS" which is used to measure respondent's level of satisfaction at their job, it consists of (20) items categorizes as two dimensions, Intrinsic Job Satisfaction "IJS" (12 items) and Extrinsic Job Satisfaction "EJS" (8 items), the scores

of each item had five option ranged from (strongly dissatisfied=to strongly satisfied=5) ⁽¹⁰⁾.

The means of scales and their domains had been calculated by summation of their items and divided by the number of items. A higher score (mean) means a higher degree of each of them. Content validity of scales was measured by exposing them to five experts in the nursing field, whereas, their few essential corrections were undertaken in the final drafts, while reliability analysis for the scales yielded a Cronbach's alpha of 0.79 for Psychological Empowerment scale and 0.83 for Job Satisfaction. Mean and Standard deviation as a descriptive statistic was used to review the levels of measured variables (PE, and JS), while stepwise regression analysis was used to evaluate the impact of criteria variable on multiple prediction variables.

According to the administrative rules, informal permission was obtained from the respondents prior to starting data collection.

Findings

Table (1): Descriptive statistics of PE, and JS and their domains:

Variable	Mean of Scores	Minimum	Maximum	Mean	Standard Deviation
PE (Total);	36	32	60	47.59	6.58
Meaning	9	8	15	12.47	1.87
Competence	9	6	15	12.68	2.07
Self-Determination	9	4	15	10.97	2.92
Impact	9	4	15	11.47	2.41
JS (Total);	60	40	80	61.93	8.47
Intrinsic	36	26	50	38.14	5.31
Extrinsic	24	13	34	23.79	4.06

Table (1) demonstrates that the means of Total Psychological empowerment and its dimensions were above the means of scores of the scale, while the total means of JS and their aspects were around the means of scores of the scale.

Table (2): Regression Findings for Job Satisfaction (JS)with respect to Psychological Empowerment (PE)

Model ⁽¹⁾	Adj. R ²	B	t. Value	F.	β

<i>(6)Predictor (Constant)=TPE DV=EJS **P. ≤ 0.001</i>					
PE=Psychological Empowerment; DV= Dependent Variable; IJS=Intrinsic Job Satisfaction; EJS=Extrinsic Job Satisfaction; TJS=Total Job Satisfaction; TPE=Total Psychological Empowerment					

Table (2) reveals that Psychological Empowerment as a total and its dimensions are highly significantly correlated with Job Satisfaction and its dimensions.

Discussion

Empowerment gives a power of decision-making to employees, making employees own their work and thus increase commitment. When employees have high levels of perceived Psychological Empowerment, view their work as meaningful, acquire skills and competencies needed, have the impact on actions in their work environment, provide a high level of autonomy, feel to influence the work outcomes, they perceive themselves as effective, see their work as important, and be more attached to their organizations⁽¹¹⁾. In line with many previous studies^(5,7,12,13,14,15,16), and inconsistent with another study⁽¹⁷⁾ were the results of the present study, while other studies agreed partially, for, they found that nurse's competencies had the most importance, and self-determination and impact dimensions had the lowest^(7,18,19,20). Nurses' Psychological Empowerment means as a total and as all dimensions in the present study were higher than means of scores of the scale (Table-1) which indicates that nurses' values and behaviors were, to some extent, in accordance with the work goals and nurses' capabilities and requirements of work.

Job Satisfaction means in the present study has been around the means of scores of the scale, whereas Intrinsic Job Satisfaction is best than Extrinsic Job Satisfaction (Table-1). A previous study found that the respondents of their study had moderate positive perceptions of job satisfaction⁽⁷⁾, while another study pointed low job satisfaction among their respondents⁽²⁾. If nurses are satisfied with intrinsic factors more than extrinsic factors, they can satisfy themselves interiorly more than the satisfaction promote from their environment and supervisors. This finding is in agreement with the view of many previous studies^(6,21). This is an important issue for any organization, for individuals who have a high level of Job Satisfaction generally have a positive attitude towards their work and vice versa⁽²²⁾, in another word, if employees are dissatisfied and they see a chance to work in other organization, they will leave an organization without a sense of guilt⁽²³⁾.

The empowerment of employees increases the effectiveness and satisfaction of employees, reduce job-related strain^(18,24,25,26), shapes employees' perceptions of their jobs, and eventually leads to high job satisfaction⁽²⁾. Total Psychological Empowerment is significant and

positively correlated with TJS and its dimensions IJS and EJS as 0.579, 0.613 and 0.407 respectively. The coefficient of determination (R^2) presents that TPE predicted the variation of TJS, IJS, and EJS as 33.3%, 37.4%, and 16.3% respectively. From another hand, all PE dimensions present significant and positively correlated with TJS and with its dimensions, while self-determination was the best one in predicting TJS, IJS, and EJS as 27.8%, 32.1% and 12.8% respectively (Table-2). In line with these results were the results of previous studies^(2,27,28,29,30,31,32,33,34,35), on the other hand, another study found that Psychological Empowerment explains about 33.5% of the variation in Job Satisfaction⁽³⁶⁾, also it concluded that Meaning, Competence, and Impact were positively related and significant in predicting Job Satisfaction, while, regarding Self-determination, it is suggested that satisfying a psychological need will lead to Job Satisfaction, also he found that Psychological Empowerment explains about 33.5% of the variation in the Job Satisfaction. A previous study found that when employees feel active in their work, they build a sense of job satisfaction. From another side, when individuals feel that they are highly competent to carry out their tasks, their job satisfaction will be better. Individuals are empowered when they have a tendency to attach more value and importance to their work, their Job Satisfaction level is increased, their success and contribution to work will be greater⁽³⁷⁾. As a result for their study, they found that all dimensions of Psychological Empowerment explained 42% of the variance in the Intrinsic aspect of Job Satisfaction, and 30% of the variance in the Extrinsic aspect of Job Satisfaction, Meaning significantly influenced the Intrinsic Job Satisfaction " $\beta=.25, p=.01$ ", Self-Determination and Impact had a significant effect on Intrinsic Job Satisfaction " $\beta=.28; p=.01; \beta=.22, p=.01$ ", and Extrinsic Job Satisfaction " $\beta=.23; p=.01; \beta=.26, p=.01$ ". Meaning relatively had the greatest relationship " $r=0.451; p<0.01$ " with satisfaction. The weakest correlation was between Impact and Job Satisfaction " $r = 0.285; p<0.01$ ". Previous study results indicated that overall Psychological Empowerment comprising Meaning, Competence, Self-determination, and Impact explained 22% of the variance in Job Satisfaction. The Beta calculations showed the highest variation as explained by Meaning " $\beta=0.436$ " and the next as explained by Self-determination " $\beta=0.183$ ". The next relatively lowest ones were Competence and Impact having the same beta scores " $\beta=0.102$ ". The coefficient of determination R^2 was calculated as 0.41, which means that 41% of the variation in Job Satisfaction

was explained by the variation in overall Psychological Empowerment^(26,38).

Conclusions

The study concluded that;

* Total Psychological Empowerment and Total Job Satisfaction and their domains had an acceptable level.

* Total Psychological Empowerment and its domains had significant relations with Total Job Satisfaction and its domains.

Recommendations :

* Staying away from centralism in the formulation and decision-making in regard to patient care and giving priority to the nurse and supporting his/her decisions.

* Creating a therapeutic environment that balance between the nurse's habits, traditions, and values with the patient's needs and care, improving the nurse experience, performance and expertise and fostering his / her authority, power and self-worth.

Conflict of Interest: Non

Source of Findings: Non

Ethical Clearance: This research was carried out with the patient's verbal and analytical approval before the sample was taken.

Abstract

Objectives: A prospective study carried out in Kirkuk city from 15th of January 2019 to 10th of April 2019, included 45 women who were enrolled in assisted reproductive technology (ART) programs in infertility Centre /Kirkuk, Iraq. **Patients and method:** All women were subjected to the basic fertility work-up at the infertility center which consists of history taking, physical examination, ovulation detection, evaluation of tubal patency and uterine cavity. The average age of the included women ranged between 20 and 42 years old. All women were enrolled in short protocol type of IVF/ICSI cycle and they had normal menstrual cycles. Nearly 5 ml of follicular fluid was obtained from all women undergoing ICSI for estimation of follistatin level by ELISA technique. **Results :** The present study showed that 31.1% (14 of 45) of women underwent ISCI technique became pregnant and 68.9% were non-pregnant (31 of 45). The highest mean of age were recorded among pregnant women compared with non-pregnant women (32.21 ± 6.68 v.s 31.80 ± 5.38 year) although the result was non-significant ($P > 0.05$). The highest mean of BMI were recorded among non-pregnant women compared with pregnant women (23.92 ± 1.55 v.s 25.36 ± 1.99 kg/m²), the result was significant. The highest mean level of follicular fluid follistatin evaluated in pregnant compared with non pregnant (10.20 ± 0.30 v.s 9.83 ± 0.58 ng/ml) although the result was high significant difference ($p < 0.05$). The study showed that there was negative correlation of follicular fluid follistatin level with age in pregnant women ($r = -0.3$), with positive correlation of with age in non-pregnant women. **Conclusions:** There was a highly significant relation of follicular fluid follistatin with pregnancy outcomes after ICSI.

Keyword: Follistatin; Follicular Fluid; ICSI; Infertility; Pregnancy

Introduction

Infertility is a disease of the reproductive system. According to the World Health Organization definition, it is defined as the failure to achieve a clinical pregnancy after two years of regular unprotected sexual intercourse without contraception, the woman has not become pregnant (there is no other reason, such as breastfeeding or postpartum amenorrhea) ⁽¹⁾. The chance of having a baby is 85%-90% in a year and the rest(10-15)% is infertile because it depends on the length of sexual exposure, frequency of coitus, and couple's age ⁽²⁾. Nowadays, progress in assisted reproductive technology (ART) has enabled the clinicians to treat many types of infertility. Assisted reproduction is a complicated process involving multiple stages like ovarian stimulation, ovum

pick up, then fertilization of these oocytes, embryo cleavage and implantation⁽³⁾. Intra-cytoplasmic sperm injection (ICSI) refers to the technique of assisted reproduction, include injecting a single sperm into the center (cytoplasm) of the egg ⁽⁴⁾. ICSI is a well-established treatment for most types of infertility, including long-standing infertility due to tubal disease, endometriosis, unexplained infertility, and even some mild forms of male factor infertility and cases of failure with respect to in-vitro fertilization (IVF) cycles^(5,6). Follistatin (FSH-suppressing protein) is a cysteine-rich monomeric (single chain) glycoprotein with molecular weight of 39-kDa and is an important binding protein for inhibins and activins⁽⁷⁾. For this reason the activities of follistatin on the oocyte maturation depend on their

autocrine and paracrine effects in follicular fluid than their serum levels⁽⁸⁾. Follistatin not only worked as an activin binding protein but also regulator of hormone secretion from the pituitary gland and degraded the activin from the circulation⁽⁹⁾. Because it localized within the human fallopian tube, endometrium and placental tissues, Therefore this proteins have been proposed as potential sensitive and specific markers to monitor the progress and outcome of pregnancy⁽¹⁰⁾. Follistatin levels increased during the course of pregnancy and decreased rapidly postpartum this mean increasing maternal serum FST levels are associated with healthy pregnancies and It could be altered in a status of failed pregnancy^(11,12). The aim of the study was to evaluate follistatin level in follicular fluid and correlate the results with pregnancy outcome in women undergoing intra cytoplasmic sperm injection (ICSI).

Material and Method

A prospective study carried out in Kirkuk city from 15th of January 2019 to 10th of April 2019, included 45 women who were enrolled in assisted reproductive technology (ART) programs in infertility Centre for IVF in International center/Kirkuk, Iraq. All women were subjected to the basic fertility work-up at the infertility center which consists of history taking, physical examination, ovulation detection, evaluation of tubal patency and uterine cavity. The average age of the included women ranged between 20 and 42 years old. All women were enrolled in short protocol type of IVF/ICSI cycle and they had normal menstrual cycles.

Nearly, 5 ml of follicular fluid was obtained during ovum pick up from all women undergoing ICSI, Follicular fluid was collected from the dominant follicles (>18 mm) after(34 to 36) hr. of HCG hormone administration. The samples were placed into sterile test tubes, centrifuged at 3000 rpm for 15_20 minute and the obtained follicular fluid was aspirated using mechanical micropipette and transferred into clean test tubes which labeled and stored in deep freeze at -20 c for biochemical measurement. After approximately two weeks of embryo implantation 2ml of blood sample was taken to assess pregnancy status.

Statistical Analysis

Computerized statistically analysis was performed using Mintab ver 18.0 statistic program. Comparison was carried out using Chi-square (X²)and T test for determination of the P. value (P<0.05: significant).

Findings

The present study showed that 31.1% (14 of 45) of women underwent ICSI technique became pregnant and 68.9% were non-pregnant (31 of 45), Table 1.

Table 1: Distribution of women in the study according to pregnancy after ICSI

	All patients	Pregnant	Non pregnant
Number	45	14	31
Frequency	100%	31.1%	68.9%

Figure 1 shows that the highest mean of age were recorded among pregnant women compared with non-pregnant women (32.21± 6.68 v.s 31.80±5.38 year) although the result was non-significant (P: > 0.05). The highest mean of BMI were recorded among non-pregnant women compared with pregnant women (23.92 ± 1.55 v.s 25.36±1.99 kg/m²), the result was significant.

Figure 1: The mean of age and BMI of pregnant and non-pregnant women.

The study showed that the highest mean level of follicular fluid follistatin was found in pregnant compared with non-pregnant (10.20±0.30 v.s 9.83±0.58 ng/ml), the result was high significant difference (p: < 0.05). Table 2.

Table 2: The level of follicular fluid follistatin in pregnant and non-pregnant women.

Follistatin level (ng/ml)	Pregnant	Non pregnant	P. value
In follicular fluid	10.20±0.30	9.83±0.58	< 0.05

The study showed that there was negative correlation of follicular fluid follistatin level with age in pregnant women, with positive correlation of follicular fluid follistatin level with age in non-pregnant women, Figure 2 and Figure 3.

Figure 2: Correlation between follicular fluid follistatin level and age in pregnant women.

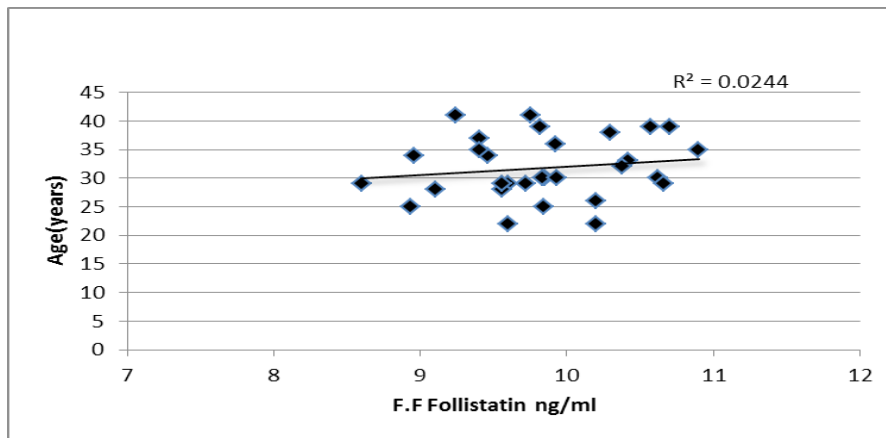

Figure 3: Correlation between follicular fluid follistatin level and age in non-pregnant women.

Discussion

Data presented in this study included 45 women under IVF process and yield two groups (successful and non-successful pregnancy). The overall pregnancy rate for all patients of current study was 31.1%. in International IVF center in kirkuk. In consistent with our result, Al-Ubodi *et al* ⁽¹³⁾ found that the pregnancy rate of women after ICSI was 28.89%. several study also indicated that pregnancy rates were only 30%–40% ⁽¹⁴⁻¹⁶⁾. Also the pregnancy rate by Orvieto *et al* ⁽¹⁷⁾ was 31.25%. This difference between these findings may be related to the environmental condition such as the level of air pollution ⁽¹⁸⁾.

In the current study, the highest mean of age were recorded among pregnant women compared with non-pregnant women (unsuccessful ICSI) (32.21± 6.68 v.s

31.80±5.38 year) although the result was non-significant (P: > 0.05) and the highest mean of BMI were recorded among non-pregnant women compared with pregnant women (23.92 ± 1.55 v.s 25.36±1.99 kg/m²). These findings were close to that reported Ahmeid (5), who found that mean age of pregnant women was 32.18 year and 30.36 year for non pregnant women, his study also found that the mean of BMI was 22.9 (kg/m²) for non-pregnant and for the pregnant group was 22.55 (kg/m²). Al-Dujaily et al (7) also found that there was no significant statistical difference between the mean age of pregnant (31.5 yeas) and non-pregnant women (31.0 year). Additionally, Gultekin (19) showed that the mean age women under IVF a was 31.3 year. Many women choose to get pregnant later in life, waiting until their mid-30 or later to begin trying(4). The younger age of women seeking IVF in developing countries, including

Iraq, could be explained in the context of social habits where most families have the desire to have children immediately after marriage (8).

Most studies to date report decreased pregnancy success in obese patients treated with in vitro fertilization (IVF). In agreement with our findings, Hussein et al (20) found that IVF results showed that positive pregnancy occurred in women BMI 22.55 (kg/m²) whereas negative pregnancy was 22.9 (kg/m²) with a significant differences between pregnant and non-pregnant women (P <0.05). Sarais et al (21) showed that overweight and obese BMI women have a statistically significant lower live birth rate. Lauritsen et al (22) showed that obese women had a significantly longer mean period of infertility and more an ovulatory infertility (P<0.01) compared to normal weight women. Our findings were disagree with Rhodes et al (23) who revealed that pregnant group mean BMI was 25.1 (kg/m²) and non-pregnant group was 25.0 (kg/m²) with no significant difference (P >0.05). Due to body mass index (BMI) has an adverse effect on reproduction, overweight women have a higher incidence of menstrual dysfunction and anovulation, possibly because of altered secretion of gonadotropin releasing hormone, sex hormone binding globulin, ovarian and adrenal androgen, and luteinizing hormone and also because of altered insulin resistance (24). In assisted reproduction, however, there are many reports on the effect of obesity on oocyte quality, embryo development, lower number of mature oocytes, lower implantation and pregnancy rate (25) .

In agreement with the current results, studies done by Gultekin (19) and Köninger et al (26) found that the level of intrafollicular follistatin was higher pregnant women rather than non pregnant women after ICSI process. As well as, Lau (27) and Jeppesen et al (28) revealed that follistatin showed highly significant elevation in follicular fluid of pregnant women. Chang et al (29) showed that follistatin levels increase in the follicular fluid with the increasing growth of the follicle, a mechanism for decreasing activin activity. Level of FST increased in good quality oocyte compared with poor quality due to follistatin play role in folliculogenesis, oocyte maturation and embryogenesis(embryo development to oocyte) (30). The follistatin had a role on the oocyte grade and it was necessary for the oocyte maturation. As a result, the level of the follistatin directly affected the oocyte and embryo quality(31). In vitro study done by Jorgez et al (32) on the mouse showed that the foliculogenesis was paused and the infertility was appeared by the lack

of follistatin. Wakatsuki et al (33) found that porcine follicular fluid contained extremely high follistatin level (5.6 mg/L) due to follistatin originally isolated from porcine ovarian follicular fluid.

Conclusions

There was a highly significant relation of follicular follistatin and pregnancy after ICSI.

Conflict of Interest: Nil

Source of Findings: Self

Ethical Clearance: This research was carried out with the patient's verbal and analytical approval before the sample was taken. According to this approval, all the samples were collected and the tests were carried out. A copy of the results of the tests was then given to the patients

Serum α -Klotho Level in the Patients Subjected to Hemodialysis in Association with Lipid Profile

Hibah Hasan Ibrahim¹, Mutaz Sabah Ahmeid², NihadKhalawe Tektook³, Hashim Abdulsattar Jabar⁴

¹Kirkuk health directorate, Kirkuk City, Iraq, ²M.B.Ch.B, M.Sc, Ph.D in clinical Biochemistry, College of Medicine, Tikrit University, ³Ph.D in immunology, Middle Technical University- College of Medical & Health Technology-Baghdad- Iraq, ⁴B.Sc, M.Sc in Chemistry, Department of Biochemistry, College of Medicine, Tikrit University, Iraq

Abstract

Background: Klotho, is a protein associated with life extension plays a important role in kidney disease progression, anti-aging, anti-oxidation, modulation of ion transport, and development of disturbed mineral metabolism. The aim of the study was to measure Soluble α -Klotho(SAKL) levels in chronic kidney disease(CKD) patients before and after dialysis in relation with Lipid profile. Methods: This short-prospective hospital-based study was done in the Department of Chemistry and Biochemistry, College of medicine, Tikrit University, Tikrit, Iraq. The study was carried out for 30 patients subjected to Hemodialysis recruited from Tikrit Teaching Hospital, hemodialysis unit between 1st December,2018 and 1st April,2019. The study also included 30 adult persons looks healthy with no prior medical or family history of CKD as a control participated in this study.The levels of SAKL and lipid profile were measured in the serum of 30 patients, before and after Hemodialysis and compared with controls. Results: The study revealed increased in the SAKL level in CKD patients before dialysis compared to healthy control group, and decreased in group of CKD after dialysis compared to control group. Furthermore, there was a significant positive correlation of SAKL level with serum Triglyceride and Very low density lipoprotein cholesterol(VLDL-C) in CKD patients before dialysis. Conclusions: There was a highly significant relation of SAKL with lipid abnormality in CKD patients under hemodialysis.

Keyword: Soluble α -Klotho; chronic kidney disease; hemodialysis; Lipid profile.

Introduction

Chronic kidney disease (CKD) describes abnormal kidney function and/or structure. It is common, frequently unrecognized and often exists together with other conditions such as cardiovascular disease(CVD) and diabetes (1). CKD is a global health burden estimated to affect up to 15% of adult populations and is independently associated with increased CVD risk similar to the risk of diabetes mellitus or coronary heart disease(2). This risk increases as CKD advances and is evidenced by worsening excretory function, usually manifest as declining glomerular filtration rate, and increasing proteinuria(3). The increased cardiovascular risk associated with end-stage renal disease(ESRD) has been well established, and estimated cardiovascular mortality rates are 10- to 100-fold higher among dialysis patients than age- and sex-matched individuals in

the general population. Hemodialysis(HD) should be starting when indicated by the impact of symptoms of uraemia on daily living, or biochemical measures or uncontrollable fluid overload, or at glomerular filtration rate (GFR) of around 5-7 mL/min/1.73 m² if there are no symptoms.This syndrome leads to death unless the toxins are removed by renal replacement therapy, using dialysis or kidney transplantation(2,4).

Dyslipidemia is a major risk factor for cardiovascular morbidity and mortality and is common among patients with CKD. Lipid profiles vary widely in these patients, reflecting the level of kidney function and the degree of proteinuria. Several factors contribute to the development dyslipidemia associated with chronic renal impairment(5).Patients with CKD have a reduction in the activity of lipoprotein lipase and hepatic triglyceride lipase. Hypercholesterolemia in nephrotic syndrome

is thought to be a result of increased production and decreased catabolism of lipoproteins(6).

Klotho exists in both membrane-bound and secreted(S.Klotho) forms, the latter of which may exert vasculoprotective effects. It enhances endothelial nitric oxide production and thereby improves endothelium-dependent vasodilatation and it is an endogenous inhibitor of vascular calcification, as shown in recent studies in vitro and in CKD mice in vivo(7). So, the aim of the study was to measure SAKL level in CKD patients before and after dialysis in relation with Lipid profile.

Patients and Method

This short-prospective hospital-based study was done in Tikrit city-Iraq between 1st December,2018 and 1st April,2019. The study included 30 adult patients with chronic kidney disease who underwent Kidney dialysis unit at Tikrit Teaching Hospital and their age range were between 18-80 years. They were clinically diagnosed by nephrologist as ESRD patients (on hemodialysis), based on their history, clinical examination, renal function tests and other laboratory tests, undergoing hemodialysis twice weekly. The study also included 30 adult persons looks healthy with no prior medical or family history of CKD as a control participated in this study. Blood samples were collected from CKD patients before dialysis and 4 hours after dialysis. All blood samples were centrifuged and the obtained sera were aspirated and labeled for determination of serum Klotho were measured by enzyme-linked immunosorbent assay (ELISA) kit supplied by (MYBIOSOURCE, USA), and lipid profile including Total cholesterol, Triglyceride, High density lipoprotein cholesterol(HDL) were measured by colorimetric method using kits provided by Biolabo (France) according to the manufacturer manual instruction. Furthermore, Very low density lipoprotein(VLDL) and LDL levels were assessed using the following equation:

$$\text{VLDL-C (mg/dl)} = (\text{Triglycerides} / 5)$$

$$\text{LDL-C (mg/dl)} = [\text{Total cholesterol}] - [\text{HDL-C}] + [\text{TG}]/5$$

Statistical Analysis

Computerized statistically analysis was performed using SPSS Software version 23.3 statistic program. Comparison was carried out for determination of the P. value (P<0.05: significant).

Finding

Relation of SAKL and lipid profile in CKD patients before and after hemodialysis and control group.

Results presented in Table 1 shows increased in the SAKL (pg/ml) level in CKD patients before dialysis compared to healthy control group. While the decrease in SAKL level was recorded in group of CKD after dialysis compared to control group, although the result was non-significant (p>0.05). Our study showed that the higher mean level of Total cholesterol was recorded in the control group (168.60±46.03 mg/dl), followed by CKD patients before dialysis and patients after dialysis (131.94±75.44 and 98.23±54.25 mg/dl) respectively with significant differences among the groups, Also the higher mean level of TG was documented in the control group (158.50±74.92 mg/dl), followed by CKD patients before dialysis and patients after dialysis (95.43±50.48 and 87.77±44.51 mg/dl) respectively with significant differences among the groups.

The study showed that the higher mean level of HDL-cholesterol was recorded in the control group (65.60±34.16 mg/dl), followed by CKD patients after dialysis and patients before dialysis (33.80±19.93 and 31.87±11.67 mg/dl) respectively with significant differences among the groups, Also the higher mean level of VLDL-cholesterol was recorded in the control group (31.70±15.05 mg/dl), followed by CKD patients before dialysis and patients after dialysis (19.13±10.12 and 16.97±8.89mg/dl) respectively with significant differences among the groups (P<0.05).Furthermore current study showed that the higher mean level of LDL-cholesterol was found in CKD patients before dialysis (81.93±73.41mg/dl), followed by the control group (74.63±48.25 mg/dl) and the lowest mean level was in patients after dialysis (54.23±51.06 mg/dl). Although there were no significant differences among the groups (P>0.05).

			Good	Poor

Pa: P value between control group and before dialysis, Pb : p value between control group and after dialysis. SAKL: Soluble α -klotho, T.Ch: Total cholesterol, TG: Triglycerides, HDL: High-density lipoprotein cholesterol, VLDL: Very low-density lipoprotein cholesterol, LDL: Low-density lipoprotein cholesterol, SD: Standard deviation.

Correlation between SAKL and parameters of CKD patients before and after hemodialysis

The study showed no correlation between SAKL

and cholesterol in CKD patients before dialysis (Figure 1) and no correlation with cholesterol after dialysis.

Figure 1: Correlation between SAKL and Total cholesterol in CKD patients before hemodialysis.

Current study showed a positive correlation of SAKL with S. TG in CKD patients before dialysis (Figure 2) and negative correlation with TG after dialysis.

Figure 2: Correlation between SAKL and S. TG in CKD patients before dialysis.

The study showed a negative correlation of SAKL with HDL-C in CKD patients before dialysis and no correlation with HDL-C after dialysis .

Our study showed a positive correlation of SAKL with VLDL-C in CKD patients before dialysis (Figure 3) and negative correlation with VLDL-C after dialysis.

Figure 3: Correlation between SAKL and VLDL-C in CKD patients before dialysis.

The study showed no correlation of SAKL with LDL-C in CKD patients before and after dialysis.

Discussion

Soluble α -Klotho

In recent years, emerging evidence suggests that the SAKL could serve as an early biomarker for CKD (8). In agreement with our findings in studying the elevation of SAKL in CKD patients before dialysis, Devaraj et al (9) registered an elevated level of SAKL in patients with CKD before dialysis when comparing with control group. Also, Shimamura et al (10) reported higher levels of SAKL in stage 5 CKD compared with healthy individuals. Akimoto et al (11) and Hage et al (12) also agreed with our current findings and reported that SAKL level was significantly higher in patients with CKD as comparing with healthy control.

The study was disagreed with studies done earlier by Seiler et al (13) and Hu et al (14), who indicated that SAKL levels had no elevation in pre-hemodialysis CKD patients. Although this difference from our results may be due to the difference in the stage of CKD which showed a different levels of SAKL (low level in 1st stage and high level in the 5th stage of CKD) (9). The decreased level of klotho may be due to its downregulated after kidney injury and intensive renal damage (12).

In the present study, reduction in SAKL level was recorded in group of CKD after hemodialysis compared to control group. In agreement with this findings, study done by Asai et al (15) demonstrated that SAKL was reduced in CKD patient after dialysis. Also, Shimamura et al (10), Koh et al (16) and Sakan et al (17) agreed with our result, they revealed a reduced α -Klotho in CKD patients specially after dialysis, and indicated a reduced production of klotho in human chronic renal failure kidney patients with CKD after hemodialysis. Furthermore, Golembiewska et al (18) and other studies agreed with our findings, reported that reduced SAKL in plasma of CKD and ESRD patients on hemodialysis when comparing with elevated SAKL in pre-dialysis patients.

On the other hand, the current result was disagreed with some studies with contradictory results showed that soluble α -Klotho levels were not differed in CKD patients (12,13).

The decreased of SAKL in CKD patients after dialysis have some explanations. Kidney is a major organ to maintain soluble Klotho homeostasis by two ways, One is to cleavage membrane-bound α -Klotho

in the renal tubular epithelial cells and release into circulation and the second is to eliminate redundant and unnecessary soluble α -Klotho from circulations into the urinary lumen through renal proximal tubules by transcytosis (16). This mechanism clarify the reduction of SAKL after HD in same patients who have elevated SAKL before HD. In addition, there are indications that urinary Klotho measurement is more closely linked to residual renal nephrons and that the significance of serum and urine measurement should be investigated. Therefore, there are still few reports indicating whether Klotho levels can be used as prognostic factors for CKD (19).

Correlation of SAKL with Lipid Profile

It is well known that patients with impaired renal function exhibit significant alterations in lipoprotein metabolism resulting in the development of severe dyslipidemia and this is attributed to the non-traditional risk factors in patients with ESRD, such as, inflammation, oxidative stress, anemia, malnutrition and endothelial dysfunction that have been proposed to play a central role in lipid metabolism abnormalities. The lipid abnormalities often accompany and aggravate the renal disease, thereby favoring the acceleration of atherogenesis and progression of cardiovascular disease (1,6).

The study showed that there was positive correlation of SAKL with Triglyceride and VLDL-C in CKD patients before dialysis and negative correlation with HDL-C in CKD patients before dialysis. Furthermore a negative correlation of SAKL with TG and HDL-C in CKD patients after dialysis and no correlation of SAKL with cholesterol and LDL-C after dialysis. There were very few studies on the relation between SAKL and lipid profile. From these studies, Seiler et al (13) studied that the level of SAKL in patients with chronic kidney disease and found that there was positive correlation of SAKL with LDL-C. Yu et al (20), showed that no correlation occurred of α -Klotho with Total cholesterol and LDL-C in CKD patients. In pathological conditions, including CKD, renal tubular epithelial cells may be exposed to ox-LDL. Oxidized modified lipoproteins have been identified in human kidney tissues, injurious actions of ox-LDL include induction of inflammation, oxidation and apoptosis, all of them processes associated with progression of renal disease. Studies in hypercholesterolemic animal models showed that renal injury was accompanied by increased oxidative

stress and inflammation, changes that may decrease Klotho expression, as previously reported(21). On the other hand, Pan et al (22) showed positive correlation of SAKL with LDL and negative correlation with HDL in patients with diabetes mellitus.

Conclusions

There was a highly significant relation of SAKL with lipid abnormality in CKD patients under hemodialysis.

²Ph.D. Medical Microbiology, College of Medicine, Tikrit University, Iraq

Abstract

A cross-sectional hospital based study was done from November 2017 to February 2019 including 240 patients with chronic renal disease (168 males and 72 females) whose ages were between 15-75 years and they admitted to hemodialysis unit of Kirkuk general hospital. The study also included 50 individuals of blood donors as control group. Ten ml of blood were collected by vein puncture each patient and control enrolled in this study, blood were injected in blood culture bottle sterilely for isolation of bacteria causing bacteremia, with detection of CTX-M-G2 and Van A genes by real time PCR. The study showed that 32.25% of HD patients have positive blood culture while no one of blood donors have a positive blood culture. The highest rate of isolated bacteria from HD patients (51.28%) was G-ve bacteria comparing with G+ve bacteria, while 42.86% of isolated bacteria from patients with UTI was G+ve bacteria. although the result was non-significant relation. The highest rate of bacteria isolated from HD patients (25.65%) was *S. aureus* followed by *E. faecalis* (17.95%). The study showed that 80% of *S. aureus* isolates who were resistant to ceftriaxone were positive for CTX-M-G2 gene comparing with 20% haven't CTX-M-G2 A gene. The highest rate of ceftriaxone resistant *S. faecalis* (77.78%) were positive for CTX-M-G2 gene comparing with 22.22% haven't the gene, although the results was non-significant. The study showed that the highest rate of ceftriaxone resistant *K. pneumoniae* (63.64%) were positive for CTX-M-G2 gene comparing with 36.36% haven't the gene. The study showed that 77.78% of *S. aureus* were positive for Van A gene comparing with 22.22% haven't Van A gene. The highest rate of vancomycin resistant *S. faecalis* (69.23%) were positive for Van A gene comparing with 30.77% haven't the gene. The study showed that all vancomycin resistant *K. pneumoniae* were negative for Van A gene. It was concluded that Most *S. aureus* and *E. faecalis* isolates were positive for CTX-M-G2 and vanA gene and most *Klebsiella* spp. isolates were harbored CTX-M-G2 gene.

Keyword: Bacteremia;; hemodialysis, Blood culture; CTX-M-G2; Van A

Introduction

Chronic kidney disease is a worldwide public health problem with an increasing incidence and prevalence, poor outcomes, and high cost. Outcomes of chronic kidney disease include not only kidney failure but also complications of decreased kidney function and cardiovascular disease(1). Current evidence suggests that some of these adverse outcomes can be prevented or delayed by early detection and treatment(2). The major outcomes of chronic kidney disease, regardless of cause, include progression to kidney failure, complications of decreased kidney function, and cardiovascular disease(CVD) (3). Increasing antimicrobial resistance

is a worldwide concern. The prevalence of resistance of blood borne isolates is increasing and it also varies in accordance with geographical and regional location(4). The infection caused by multidrug resistance (MDR) organisms is more likely to prolong the hospital stay, increase the risk of death, and require treatment with more expensive antibiotics(5). The widespread use of vancomycin has led to increased number of infections by vancomycin resistant enterococci, which could transfer via plasmids the above resistance to *S. aureus*(6,7). The aim of the study was to isolate bacteria casing bacteremia in hemodialysis patients and molecular detection of CTX-M-G2 and Van A genes by real time PCR

Material and Method

A cross-sectional hospital based study was done from November 2017 to February 2019 including 240 patients with chronic renal disease (168 males and 72 females) whose ages were between 15-75 years and they admitted to hemodialysis unit of Kirkuk general hospital. The study also included the control group who were matched to the patients, included 50 individuals (blood donors). Ten ml of blood were collected by vein puncture using vacutainer syringe from each patient and control enrolled in this study, 10 ml of blood were injected in two 5 ml blood culture bottle sterilely (5 ml for aerobic and the other was for anaerobic culture) for isolation of bacteria causing bacteremia, blood is sampled directly into two aerobic and one anaerobic blood culture bottles containing culture broth.

Bacterial susceptibility test to antimicrobial agents.

Disk diffusion test were employed in the present study and it was carried out according to the modified Kirby-Bauer method. Pure inoculum were obtained by selecting pure colony from an agar plate and suspended in broth to achieve a turbid suspension, and allowing the culture to achieve good active growth, as indicated by observable turbidity in the broth.

Extraction of bacterial DNA

In this study, to view and determine the gene expression of isolated bacteria from HD patients responsible for resistance to ceftriaxone and vancomycin. The isolated bacteria (*S. aureus*, *E. faecalis* and *K.*

pneumonia) which represent examples to most resistant bacteria, these bacteria were cultured separately on the Muller-Hinton agar with and without ceftriaxone and vancomycin for quantitative and qaulitative detection of CTX-M-G2 and Van A genes. According to manufacture instructions of ZR Fungal/Bacterial DNA MiniPrep™ kit (Zymoresearch, California- USA). The DNA is isolated and purified and then detected by using real-time PCR (Sacace Biotechnology-Italy) through out detection of the following primers:

A. CTX-M-G2 gene:

CGTTAACGGCACGATGAC
CGATATCGTTGGTGGTRCCA

B. VAN A gene:

CTACTCCCGCCTTTTGGGTT
TTCACACCGAAGGATGAGCC

Statistical analysis

Computerized statistically analysis was performed using Mintab ver 18.0 statistic program for determination of the P. value (P<0.05: significant).

Findings

The study showed that 32.25% of HD patients have positive blood culture while no one of blood donors have a positive blood culture. The study was highly significant (P :0.00001), (Table 1)

Table 1: Results of blood culture among the study groups.

Results of blood culture	HD patients		Blood donors	
	No.	%	No.	%
Positive	78	32.5	0	0
Negative	162	67.5	50	100
Total	240	100	50	100

P<0.05

The study demonstrated that the highest rate of isolated bacteria from HD patients (51.28%) was G-ve bacteria comparing with G+ve bacteria (Table 2).

Table 2: Types of isolated bacteria among study groups.

Results of blood culture	HD patients	
	No.	%
Gram positive	38	48.72
Gram negative	40	51.28
Total	78	100

The study showed that the highest rate of bacteria isolated from HD patients (25.65%) was *S. aureus* followed by *E. faecalis* (17.95%) and the lowest rates was 2.56% for each of *S. warneri*, *S. hominis* and *A. cloaca*. (Table 3).

Table 3: Distribution of isolated bacteria among study groups.

Isolated bacteria from blood culture	HD patients	
	No.	%
<i>Staphylococcus aureus</i>	20	25.65
<i>Enterococcus faecalis</i>	14	17.95
<i>Klebsiella</i> spp.	13	16.67
<i>Escherichia coli</i>	10	12.82
<i>Pseudomonas aeruginosa</i>	6	7.69
<i>Salmonella typhi</i>	6	7.69
<i>Proteus mirabilis</i>	3	3.85
<i>Staphylococcus warneri</i>	2	2.56
<i>Staphylococcus hominis</i>	2	2.56
<i>Acinetobacter cloaca</i>	2	2.56
Total	78	100

The study showed that 80% (16 of 20) of *S. aureus* isolated from HD patients were positive for CTX-M-G2 gene (gene responsible for ceftriaxone resistance) comparing with 20% haven't CTX-M-G2 gene, the result was highly significant ($p < 0.1$), the highest rate of *S. faecalis* (77.78%) were positive for CTX-M-G2 gene comparing with 22.22% haven't the gene, although the results was non-significant ($P > 0.05$), the highest rate of *K. pneumoniae* (63.64%) were positive for CTX-M-G2 gene comparing with 36.36% haven't the gene, although the result was non-significant (Table 4).

Table 4: Molecular detection of CTX-M-G2 gene resistance to ceftriaxone.

Bacteria	Total No.	No. of resistant isolate	CTX-M-G2				P. value
			Present		Absent		
			No.	%	No.	%	
<i>S. aureus</i>	20	20	16	80	2	20	0.001
<i>S. faecalis</i>	14	9	7	77.78	6	22.22	0.08
<i>K. pneumoniae</i>	13	11	7	63.64	4	36.36	0.15

The study showed that 77.78% of *S. aureus* isolated from HD patients were positive for Van A gene (one of the genes responsible for vancomycin resistance) comparing with 22.22% haven't Van A gene, the result was significant ($P < 0.05$), the highest rate *S. faecalis*

(69.23%) were positive for Van A gene comparing with 30.77% haven't the gene although the result was non-significant ($P > 0.05$), The study showed that all vancomycin resistant *K. pneumoniae* were negative for Van A gene, (Table 7).

Table 5: Molecular detection of Van A gene resistance to vancomycin.

Bacteria	Total No.	No. of resistant isolates	Van A gene				P. value
			Present		Absent		
			No.	%	No.	%	
<i>S. aureus</i>	20	18	14	77.78	4	22.22	0.018
<i>E. faecalis</i>	14	13	9	69.23	4	30.77	0.16
<i>K. pneumoniae</i>	13	6	0	0	6	100	0.014

Discussion

The study showed that 32.25% of HD patients have positive blood culture while no one of blood donors have a positive blood culture. The study was highly significant. In agreement with this result, Hassoon et al (1) demonstrated that 40% of the blood samples of patients under hemodialysis was positive for blood culture. In agreement with the current results, Villalon et al (2) demonstrated that non significant difference was occurred in positive blood cultures of HD patients regarding G+ve and G+ve isolated bacteria and the main microorganisms isolated in blood culture were *Staphylococcus aureus* and *Pseudomonas aeruginosa*. Additionally, Mohsin (3) found that Gram negative microorganisms accounted for 61.5% of the events and Gram positive microorganism accounted for 38.5% and *Staphylococcus aureus* was the most common microorganism. In the study of Parameswaran et al (4), 64% of the pathogens causing CRBSI were Gram-positive and 36% were Gram negative and the commonest pathogen causing bacteremia in HD patients was *S. aureus* 40%, *Pseudomonas aeruginosa* 16%, coagulase negative staphylococci 8%, *E. coli* 8%, *Klebsiellapneumoniae* 8%, and *Acinetobacterbaumannii* 4%. Dalgaard et al (5) identified that the most common causative microorganisms in hemodialysis patients, were *Staphylococcus aureus* (43.8%) and *Escherichia coli* (12.6%). The most common isolates reported in

other studies vary from *S. aureus*, *E.coli*, *Pseudomonas* and *Klebsiella* and *Salmonella* and *Enterobacter cloacae* bacteremia and the source of this bacteria was contaminated saline (6,7). While, Gauna et al (8) found Gram-positive cocci formed 27.7% of blood culture positive of patients with ESRD, also revealed that *Staphylococcus aureus* accounted for most of the gram-positive infections. Other studies indicated that bacteremia due to hemodialysis caused mostly by Gram positive *S. aureus* and non-fermenting Gram-negative bacilli, such as *Acinetobacter baumannii* and *Pseudomonas aeruginosa*, which are difficult to treat because they are highly resistant, can cause outbreaks of nosocomial infection, and are often associated with high mortality rates (9,10). Hassan et al (11) indicated that most *S. aureus* isolates harbor CTX-M antibiotic resistance gene and PCR technique is a fast, practical and appropriate method for determining the presence of antibiotic-resistance genes. Al-Marzooq et al (12) reported that, CTX-M genes was detected in 91.3% Malaysian multidrug-resistant *K. pneumoniae* isolates. Our finding was in agreement with most recent studies in Asia and worldwide(13,14). Moreover, Kpoda et al (15) reported a dissemination of CTX-M genes in ESBL producing Enterobacteriaceae and 58% of *Klebsiella* had CTX-M- gene. Mathlouthi et al (16) reported the distribution of CTX-M gene was 51.7% in *Klebsiella* isolated from hospitals in Tunisia and Libya. In a similar study in Burkina Faso Ouedraogo

et al (17) reported CTX-M-1 and 2 groups as dominant in hospitals acquired infection. This is in line with the reports of Ibrahim et al (18). In regard of vancomycin resistance, several studies reported that The most common isolated *E. faecalis* was with *vanA* genes (19). Most VRE outbreaks in human populations are attributed to the *vanA* and *vanB* gene clusters (20). Saadat et al (21) demonstrated that 82.53% of VRSA *S. aureus* isolates were detected with *vanA* gene. Banerjee et al (22) also found a high rate of *vanA*-VRSA strains *S. aureus* isolated from post operative pus sample. In June 2002, the World's first reported clinical infection due to *S. aureus* with high resistance to vancomycin (VRSA) (vancomycin MIC>128 µg /ml) was diagnosed in a patient in the USA, this isolate contain the *vanA* genes from enterococci and the methicillin-resistance gene *mecA*(23). Bamigboye et al (24) also demonstrated that, significant rate of *S. aureus* VRSA isolated from different clinical samples were contain the *vanA* genes. The responsible mechanism for vancomycin resistance in these strains has been found to be the acquisition of resistance plasmids carrying *vanA* or *vanB* operon. The similar VRSA isolate in Europe was reported from Portugal in 2013, and this isolate carried *mecA* and *vanA* genes probably acquired from VRE that coinfecting the patient from whom the isolate was recovered(25). During the past decade VRSA did not spread rapidly and there were only a few reports of this superbug. Until the end of 2012, 33 cases of *vanA*-type VRSA have been reported worldwide: 13 from the United States, 16 from India, 3 from Iran (2 from Tehran, 1 from Mashhad) and 1 from Pakistan(26). Limited spread of VRSA is attributed to the highly-costly *vanA* operon for *S. aureus*, which can be acquired from enterococcal conjugation(27,28,29).

Conclusion: Most *S. aureus* and *E. faecalis* isolates were positive for CTX-M-G2 and *vanA* gene and most *Klebsiella* spp. isolates were harbored CTX-M-G2 gene.

Assessment of Butchers Attitudes and Practices Toward Food Safety in Thi-Qar governorate in Iraq

Sameeha Naser Abed¹, Zahraa Zuhir¹

¹Department of Community Health Techniques, Kut Technical Institute, Middle Technical University, IRAQ

Abstract

Objectives: To assess of attitudes and practice of butchers in Thi-Qar governorate regarding food safety and to find out any association of different variables with practices and attitudes. **Methodology:** A descriptive cross – sectional study to assess the attitudes and practices of butchers. The data collection extended from the February 2018 and April 2018. each. The sample of (57) butchers was selected from (26) small slaughter houses in Thi-Qar governorate who agreed to participate were included in this study. **Results:** A total of fifty seven (57) butchers were selected as a sample size for this study. 46(80.7%) were in the age of <30 and from the urban area. Most of butchers interviewed were married (52.6%). Based on length of experience of butchers, The highest proportion of them (59.6%) were in the length of experience (≤ 5) and the highest percentage of butchers were in the level of intermediate (31.6%). The overall attitudes and practices on food safety was poor, (67%) and (91%) respectively. **Conclusions:** There was high poor attitudes of food safety in of butchers. As an overall, nearly three quarters of the butchers having poor practice scores relating to food safety.

Key words: food safety, personal hygiene, butchers , practices , attitudes .

Introduction

Although food is indispensable for maintaining the life on the earth(1), it can also cause food borne diseases(2) which are important public health issues worldwide(3), such diseases cause about 2.2 million human deaths annually(2,4). In this respect, meat is a major component of the food and therefore, is the important animal protein resource which is essential for life and health (5). Notwithstanding the slaughtering of animals is typically considered to be economic activity which increasing meat supply, and others products such as skin and leather, there is an increasing enteric pathogens and contaminate environment also(6,7). As one indication of the force of the hitch, it is approximated that about 27 to 38% of foodborne diseases outbreaks contribute to poor personal hygiene (8). Food safety is a social responsibility (9) and a basic need for public health in developing countries in the twenty first century (10). as well as developed world (11). Moreover, it plays numerous, critical roles to in maintaining a human's overall health (9). It has been defined as science and an international concern that is prevents from unsafe food and food borne diseases (12,13). Different factors within the poor hygiene practices such as do not washing hand

(14), do not wearing of protective clothing, unclean of butchery equipment, as well as transporting the meat in unclean container and others factors can lead to meat contamination (15) and these factors are considered to be the major risk factors to increase foodborne illness (16). More specifically, good personal hygiene and food handlers training are prerequisites for food safety. In addition it can play an important role in the effective prevention contaminated of food . (17,18,10). All of the above mentioned issues that relate to pollute the environment are common among Abattoirs (19). These conditions are better enhanced when butchers consistently pay attention to promoting personal hygiene. Hence literature regarding attitude and practice of hygiene and food safety among abattoir workers is limited (20), the present study aimed at assessing attitude and practice of food safety among butchers in Thi-Qar governorate.

Material and Method

Place of study : The study was conducted in Thi-Qar governorate. Twenty six small slaughter houses

Study sample: The sample selection was convenient sample. Butchers present in the small slaughter houses at the time of conducting the study. The sample of (57)

butchers was selected from (26) small slaughter houses in Thi-Qar governorate who agreed to participate were included in this study.

Design&time of Study:A descriptive cross – sectional study to assess the attitudes and practices of butchers .The data collection extended from the February to April 2018.

The data collection: The data collection was by interview of a previously designed questionnaire constructed by the investigator after intensive review of relevant literatures and evaluated by a panel of experts. The items of questionnaire included 28 close ended questions, including different statements concerning the attitudes and practices of various aspect of food safety arranged in the following parts:

Part I: Demographic information sheet; four items, included demographic characteristics like age, gender, marital status, occupation, residence,experiences years.

Part II: practices on food safety (12 question) : Butchers were required to respond with yes or no , for practices, scores which were assigned for response in practices as related to 2- point type likert scale and scored as (2) for yes, (1) for no. The potential range of general questionsscores was12-24; Poor practice was defined as scores of 12-17, and good practice as 18 and more

Part III: Attitude towards food safety(16 question): Butchers were required to respond with agree or disagree , for attitudes, scores which were assigned for response in attitudes as related to 2- point type likert scale and scored as (2) for yes, (1) for no..The potential range of general questionsscores was16-48; Poor attitude was defined as scores of 16-23, and good attitude as 24 and more.The subjects were informed about the study objectives during the face to face interview, the subjects responses through the employment of the application of the constructed interview as mean of data collection.

Statistical Analysis

The approach to data consisted of two steps (descriptive and analytic statistic). Tables (Frequencies, and Percents), arithmetic mean, and standard deviation were used in order to analyze . Fisher exact test was

used to determine the significant statistical association between qualitative and quantities demographic characteristics that include age group gender, education level, marital status and practices and attitudes towards food safety and assess the results of the study under application of the statistical package (SPSS) ver. (24.0). P value was used as ≤ 0.05 as the level of significance for the test of significance.

Findings

The result of this study as explained above is presented in three forms, thus, Demographic characteristic, practices and attitudes. Therefore, the result and analysis are as follows;A total of fifty seven (57) butchers were selected as a sample size for this study The demographic information of butchers as presented in Table 1 below. Based on the age of butchers , 46(80.7%) were in the age of <30 while 11(19.3%) were in the age of ≥ 30 . However, study published from Nigeria done by O. A. Olowoporoku (2016) show a prominent age groups of study were age group <40years (93.3%)(21). Concerning the residenceof butchers , 46(80.7%) were from the urban area while 11(19.3%) were from the rural area.Similar findings were seen in study of Junaidu Yakubu M et al (2013). in Nigeria. It was noticed that about eighty of the butchers interviewed were residence in urban area (20). Most of the butchers interviewed were married (52.6%), followed by single (38.6%), and the lower percentage was others (8.8%). Based on length of experienceof butchers , The highest proportion of butchers) 59.6%) were in the length of experience(≤ 5) and this is in accordance with other study done by Mirembe BB et al (2015) in Uganda(22). In regard to education level, the highest percentage of butchers were in the level of intermediate (31.6%) followed by primary level)26.3%) and secondary level (14%). While both illiterate and institute and more education level was 10.3%. Very few of butchers were reading and writing (7%).This finding is contrary to the study of KhelkarTuneer and TiwariMadhavi (2015), which found the majority of butchers were illiterate (76%)(23).

Table 1: Distribution of butchers by Demographic characteristic.

Variable		Frequency	Percent
Age	<30	46	80.7
	≥30	11	19.3
Residence	Urban	46	80.7
	Rural	11	19.3
Marital	single	22	38.6
	Married	30	52.6
	others	5	8.8
Length of Experience	≤5 years	34	59.6
	>5 years	23	40.4
Education level	Illiterate	6	10.5
	Read and write	4	7.0
	Primary	15	26.3
	Intermediate	18	31.6
	Secondary	8	14.0
	Institute & Higher	6	10.5

The figure (1) represent the practices of butchers regarding food safety , The overall practices on food safety was poor. (67%) had poor practices of food safety while (33%) had good practices.This finding is supported by Magda A. Latif et al (2014), who found the generally poor practices on food safety has been demonstrated in their study(17).

Figure 1 : Distribution of butchers by practices of food safety

The figure (2) represent the attitudes of butchers regarding food safety , The overall attitudes on food safety was poor.(91%) had poor attitudes toward food safety while only (9%) had good attitudes.This finding is contrary to the study of Magda A. Latif et al (2014)

who evaluated of food safety knowledge, attitudes and practices among Abattoir Workers’ in Khartoum State in Sudan and concluded that the overall attitudes were well (17).

Figure 2 : Distribution of butchers by attitudes toward food safety

Table 3 shows the association between the socio-demographic characteristics, and practices levels of butchers involved in the study, with their reported involvement in food safety. As shown in Table 3, marital status and age were found to be statistically significantly associated with practice. It is also observed that residence, length of experience and education level were found to be not statistically significantly associated with practice .

	Others	Count	1	4	5	
		%	20.0%	80.0%	100.0%	
Length of experience	≤5	Count	4	30	34	0.638

Conclusion

There was high poor attitudes of food safety in butchers. As an overall, nearly three quarters of the butchers having poor practice scores relating to food safety. There was significant relation between practice of food safety with age and marital status of butchers. Residence and education level were found to be statistically significantly associated with attitudes. The findings should be used for further strengthening food safety programs to help butchers be healthier and to enhance their educational outcomes.

Ethical Clearance: Before collecting data, necessary approvals and official permissions were obtained from butchers in The-Qar governorate. The purpose of the study was clearly explained to the butchers before filling the questionnaire.

Conflict of Interest: Nil

Nutritional Status for Patients with Hypertension in Hemodialysis Units at Baghdad Teaching Hospital

Shaymaa M. Hussein

Adult Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Millions of people are affected by chronic kidney disease (CKD) every year, as a result of various health conditions and diseases. The poor nutritional status considered communal among the dialysis patients and lead to opposed consequences, patients who have diabetes or hypertension often go without diagnosis by kidney disease due to poor medical follow-up. This study aims to assessing the socio-demographic data and the nutritional status for patients with hypertensive who undergone hemodialysis, in which an approach of assessment was applied to achieve the mentioned objectives. A descriptive (cross-sectional) design study was conducted during November 15th, 2018 to May 9th, 2019. A purposive (non-probability) sample of 100 patients with hypertension were selected. Data were collected through the use of the questionnaire format by recording the data from patients' charts and dialysis machine. Data were analyzed through the application of descriptive and inferential statistical approaches by using Statistical Package for Social Science (SPSS) version 20.0. The most patients were old age (≥ 62 years); they're evenly distributed for male and female. The highest percentages of the study sample have low educational attainment; almost patients have normal body mass index, and the highest percentage of them have stage 2 hypertension. The major percentage of patients have anemia, an elevated level of serum phosphors, blood urea and serum creatinine, respectively. Finally, the study results revealed the patients weren't smoking and they weren't having DM. Based on this, Establishing of nutritional health style for patients with hypertension on hemodialysis and activate the dieticians' role in hemodialysis units.

Keywords: *Nutritional status, Hypertension, Hemodialysis.*

Introduction

Millions of people are affected by chronic kidney disease (CKD) every year, as a result of various health conditions and diseases, It also can occur when patients fail to take prescribed medications for chronic diseases or because of a poor financial situation that prevents patients from seeking treatment^[1]. The National Kidney and Urologic Diseases Information Clearinghouse stated in 2010, that more than twenty millions of Americans had CKD^[2]. By the US Renal Data System in 2009, data were collected on patients with kidney diseases recorded that there was a 3.3% increase in the treatment of kidney diseases by hemodialysis, peritoneal dialysis, transplants, and other approaches yearly. The incidence of kidney diseases increased among Asians by 8.3%, African Americans by 1.1%, Native Americans by 9.9%, and Caucasians by 3.5% during 2008 to 2009,^[3]. This study aims to assessing the socio-demographic data and

the nutritional status for patients with hypertensive who undergone hemodialysis.

Material and Method

A descriptive (cross-sectional) design study was conducted to achieve the study objectives. The study was carried out during November 15th, 2018 to May 9th, 2019. The study was conducted at Baghdad teaching hospital. A purposive (non-probability) samples of 100 adults with hypertension were selected, those patients undergone thrice weekly treatment at hemodialysis units. A questionnaire designed and constructed to achieve the study objectives. The validity was determined through the use of panel of (6) experts, they were faculty members from College of Nursing\ University of Baghdad, to investigate the clarity, relevancy, and adequacy of the questionnaire. The experts' suggestions were taken into consideration and modifications were employed

and the final constructed instrument was completed for conducting study. The reliability was determined through the use of Test- retest through the computation of Pearson Correlation Coefficient ($r = 0.86$). The questionnaire consisted of three parts: the first contained socio- demographic characteristics: age, gender, educational attainment, marital status, occupation, financial status, and residence; the second part contained clinical data: BMI, blood pressure)BP(, Hb, PCV, S. Potassium, S. Phosphor, B.urea, S.creatinine, and S.Albumine; the third part contained the medical history such as: smoking, suffering from diabetes, heart and coronary arteries diseases, intestinal disorders, taking anti-hypertensive medications and food limitations due

to the disease. The data have been collected through utilizing the direct interviewing approach. Time from 10 – 15 minutes for each patient was taken to accomplish the questionnaire. The data were collected when the patients on the dialysis machine, the readings of BP was obtained from the machine monitor. The latest date of diagnostic tests results were obtained from the patients' charts, the patients' height and weight were measured through the tool in the dialysis units used for this purpose. The BMI calculated through an equilibrium $BMI = \frac{Weight}{Height^2}$. Data analysis was employed through the application of descriptive and inferential statistical approaches by using statistical package of social science (SPSS) version 20.0.

As presented in table (1), in term to the age and gender the results revealed that the patients were fifty percent for each male and female. These findings go along with the study [4] that stated the gender were male and female evenly distributed in their study.

A twenty nine percent of them were aged (62) years and more, with a mean age of forty nine years old and four months, which reflect that the older adults have been affected with kidney disorders more than young people regardless if they were being male or female. This result of old age go along with two studies[5],[6] which stated that the age of the patients were older than fifty five years old. In regard to the mean age, a study [4] that reported the mean age was (47.4) years for the patients which considered near to this study outcome. The samples of the study were equally distributed (50%) for each males and females. These findings reflect the effect of HD on the nutritional status for both males and females patients equally.

A highest rate (22%) of the patients were primary school graduated, this reflect they have low educational

level. This study outcomes go along with two another studies[7],[8] that reported the patients have lack of education who attending in the dialysis centers.

The majority (89%) of the patients were married; these findings opposed to the study results [9] that reported majority (74%) of the samples were single.

More than half of the study samples have sufficient monthly income; this perhaps indicates that the poor financial status hasn't an effect on the patients' health-related condition. While the study results [1] has been showed that un sufficient financial status has an effect on patients condition and leads to failure of taking prescribed medications and prevent patients from seeking treatment for chronic diseases.

A forty nine percent of the patients were free job; these results showed there is no effect of occupation on nutritional status. A major (94%) were lived in urban areas, this may refer to the people who lived in urban more prone to be affected with renal diseases and hypertension.

Table 2. Biochemistry Characteristics of the Study Sample

Variables	Frequency	Percent	Mean

Total	100	100.0	
9- S.creatinine			
Normal range	1	1.0	8.4
More than normal range	99	99.0	
Total	100	100.0	
10- S. Albumin			
Less than normal	27	27.0	4.040
Normal range	66	66.0	
More than normal range	7	7.0	
Total	100	100.0	

In term to BMI, table (2) showed that (39%) have normal BMI, this result are opposite to the another studies results [10],[11] which stated that the patients have low BMI and this is considered a risk factors for death in kidney diseases. Another study [12] reported that the patients have high level of MBI (>22 kg/m²) and this is associated with increased the morbidity.

The results of patients reveal they have a stage 2 systolic hypertension which formed a (45%). A (34%) were stage 2 diastolic BP readings also, a study [13] revealed that increasing frequency of hypertension lead to increasing the epidemic of cerebrovascular diseases. This study results opposite with study [14] that reported a temporary reduction in BP during the dialysis nutritional examination for patients with hemodialysis.

In relation to Hb and PCV for the study sample, less than normal value formed the majorities (89% and 97%) respectively; this indicates the reduction in kidney functions of erythropoietin secretion by the adrenal glands. This study results corresponds with systematic review, carried out in the United States [15] presented that patients on dialysis having anemia and it should be treated.

In regard to the potassium level, it was within the normal level for more than half (65%) of the study sample. A study [16] stated that as the potassium acceptable upper limit is (5.3 mmole/l) and potassium level (6.0 mmole/l) is considered hyperkalemia and responsible for (3%- 5%) deaths in hemodialysis patients.

The study results show that a (63%) have had elevated level of phosphors due to disturbance in the kidney functions.

In this study the B.urea and S.creatinine levels were elevated for the patients (97% and 99%) for each, respectively, these outcomes go along with a study [9] that mentioned the elevated B.urea and S.creatinine levels for patients on hemodialysis.

In relation to the S.Albumin level, a (66%) of the samples have normal values. The study results [17] revealed that patients in dialysis having hypoalbuminemia due decrease protein intake or due to inflammation process. While another study [18] revealed that a higher levels of S.Albumin is due to an increase in protein intake over time or higher dietary protein intake, also study [19] shown the elevated albumin level in hemodialysis patients due to oral nutritional intake and parenteral nutrition during dialysis.

Table 3. Clinical Characteristics of the Study Sample

Variables	Frequency	Percent
1- Smoking		
Yes	14	14.0
No	86	86.0
Total	100	100.0
2- Having Diabetes Mellitus (DM)		
Yes	25	25.0
No	75	75.0
Total	100	100.0
3- Having Heart Diseases		
Didn't have	88	88.0
Angina	1	1.0
MI	1	1.0
Atherosclerosis	2	2.0
Heart Failure	8	8.0
Total	100	100.0
4- Hypertension Medications		
Yes	90	90.0
No	10	10.0
Total	100	100.0
5- Having an Intestinal Diseases		
Didn't have	85	85.0
Cereal Diseases	1	1.0
Irritable Bowel Syndrome	14	14.0
Total	100	100.0
6- Limitations of Food		
Yes	85	85.0
No	15	15.5
Total	100	100.0

Table (3) presented that the majority (86%) weren't smoking; these findings indicate that smoking may not disrupting the kidney functions and doesn't matter whether the patients on hemodialysis were being smoking or not.

In relation to having DM, the findings revealed that (75%) weren't have DM, a study results [20] weren't resemble to this study results; which stated that a lot of hemodialysis patients have DM.

The results showed (88% and 90%) haven't heart diseases and they're taking hypertension medications regularly, respectively. The results of Epidemiology of Diabetes Intervention and Complications/ Diabetes Control and Complications Trial study[21]indicated that reduced use and reduced antihypertensive drugs prescription can lead to reduction in cardiovascular likelihoods and reduce hypotension for patients during hemodialysis.

In regard to food limitations that lead to decrease the elevated BP, the majority (85%) were followed food limitation, this results go along with study results [22] that implemented different dietary approaches included low and limiting total dairy fatty foods, saturated fat, and cholesterol to stop hypertension. These approaches lead to decrease BP.

Conclusions

1. The study findings showed male and female evenly distributed, and the most patients were old age.

2. The study findings reflecting the patients have low educational attainment; they're a primary school education,

3. The results showed that more than half having sufficient financial status, and the majority of the samples were lived in urban areas, this may refer to living in urban areas may be more prone to hypertension.

4. The highest percentage have normal BMI, and most of them have stage 2 hypertension.

5. The major percentage of the patients have anemia, this is appear through the findings of low Hb and PCV value as a result of disturbed kidney functions.

6. The study results reflecting an elevated level of S.phosphors, B.urea and S.creatinine, respectively due to disturbance in normal kidney functions.

7. The major percentage of the samples weren't smoking and they weren't have DM, this may be a good sign for patients with hypertension who undergoing hemodialysis.

Recommendations

1. Establishing of nutritional health style for patients with hypertension on hemodialysis.

2. Activate the dieticians' role in hemodialysis units.

Relation of Epstein Barr virus with Interleukin-6 Level among Women with Breast Cancer in Ramadi City

Arkan Abdullah Abbas¹, Israa Hashim Saadoon¹

¹Department of Microbiology, College of Medicine, Tikrit University, Tikrit, Iraq

Abstract

The study aimed at evaluating the relation of Epstein Barr virus (EBV) with level of interleukin-6 (IL-6) in women with breast cancer. The study was carried out in Ramadi city from 12th of January to 12th of September 2018, and included a total of 95 breast cancer women who admitted to oncology clinic of Ramadi Teaching Hospital whose ages were between 25-70 years. Patients were investigated for detection of EBV by using Real Time PCR and interleukin-6 (IL-6) by ELISA technique. The rate of breast cancer women with EBV was 29.47%. The highest rate of breast cancer women was within the age group 40-49 years with no significant relation between breast cancer and age. The study showed that the highest means of IL-6 level (151.50 pg/ml) were found in breast cancer women without EBV. The highest rate of breast cancer women was from rural areas.

Keywords: Breast cancer, EBV, IL-6, Ramadi.

Introduction

Breast Cancer (BC) is one of the most important neoplasia among women. It was recently suggested that biological agents could be the etiological cause (1). Epstein-Barr virus (EBV) is a ubiquitous in that infecting more than 90% of adult population worldwide. Epstein-Barr virus has been linked to the development of variety of human malignancies. Epstein-Barr virus and human papilloma virus (HPV), which are DNA viruses, were reported to be linked with 38% of all virus-associated cancers (2). A viral etiology for several malignancies has been suggested. One of the risk factors for development of breast carcinoma, which is the leading malignancy in women all over the world, is proposed to be a viral infection; hence recognition of the causative issues is essential for proper management (3).

Elevated interleukin 6 (IL-6) and interleukin 10 (IL-10) serum concentration, are strongly associated with breast cancer and correlate with clinical stage of disease. Interleukins may stimulate cancer cells growth and contribute to locoregional relapse as well as metastasis (4). Interleukin-6 plays an important role in the process of inflammation, particularly in the transition from acute to chronic inflammation. In breast cancer, IL-6 has been shown to inhibit the growth of cancer cells but promote the development of metastases (5,6).

Material and Method

Across-sectional study was carried out in Ramadi city from 12th of January to 12th of September 2018, and included 95 women with breast cancer whose ages were between 25-70 years old. These patients admitted to oncology clinic of Ramadi Teaching Hospital.

Blood samples were taken from breast cancer women. Samples were examined by immunological methods, enzyme linked immuno sorbent assay (ELISA) for detection interleukin-6 (IL-6) and molecular technique (Real time PCR) which included DNA amplification of Epstein Barr virus based on the specific primers.

Seven and half ml of blood was collected by vein puncture using vacutainer tubes from each patient enrolled in this study. Blood samples were placed into two sterile test tubes, in one of them 2.5 ml of blood was put in test tube containing anticoagulant ethylene diamine tetra acetic acid (EDTA) and used for DNA extraction of EBV. The second part of sample (5ml) was placed in plain tubes left for 30 minutes at 37 °C then was centrifuged at 3000 round per minute (rpm) for 15 minutes then the clot was removed and the remain re-centrifuged at 3000 rpm for 10 min and the obtained sera were then aspirated using automatic micropipette and transferred into two clean test tubes, for serological

tests. Label was fixed on each test tube which then stored in deep freeze at -20°C for late serological testing for determination the level of IL-6 by using ELISA technique.

For DNA extraction, kit was purchased from Gene Aid(USA) company for molecular detection of EBV by Real Time PCR using Anatolia Gene Works(Turkey). Detection of IL-6 was done by using ELISA kit Elabscience (China), which depends on the Sandwich-ELISA principle.

Statistical Analysis

Computerized statistically analysis was performed using T-Test probability. The P value >0.05 was

considered statistically significant, and for result which its P value was less than 0.01 was considered highly significant, while for those which its P value greater than 0.05 was considered statistically non-significant.

Finding

A total of 95 breast cancer women, their age ranged between 20-89 years old, were investigated for detection of EBV by using real time PCR and estimation the level of IL-6. The present study revealed that EBV was found in 29.47% of women with breast cancer, as shown in Table 1.

Table 1: Frequency of EBV in women with breast cancer.

EBV	Breast Cancer Women	
	No.	%
Positive	28	29.47
Negative	67	70.53
Total	95	100

The current study showed that the highest rate of EBV infections (12.63 %) was found in women with breast cancer within the age group 40-49 years, as shown in Table 2.

Table 2: Distribution of EBV infection in women with breast cancer according to their age.

Age Group (Years)	No. of Women with Breast Cancer Patients	EBV Infection	
		No.	%
20-29 (No:0)	2	0	0
30-39 (No:3)	19	5	5.26
40-49 (No:15)	43	12	12.63
50-59 (No:38)	23	9	9.47
60-69 (No:27)	5	1	1.05
70-79 (No:6)	1	0	0
80-89 (No:6)	2	1	1.06
Total (No:95)		28	29.47

The present study revealed that there was a negative correlation between EBV infection and age of women with breast cancer, but the difference was statistically non-significant (R value: -0.132), as shown in Figure 1.

Figure 1: Negative correlation between EBV infection and age of women with breast cancer.

The present study revealed that the highest rate of women with breast cancer and EBV infection was from rural areas, as shown in Table 3.

Table 3: Distribution of EBV infection according to residence of women with breast cancer.

Residence	No. of Patients	EBV Infection	
		No.	%
Rural	51	14	14.73
Urban	44	14	14.74
Total	95	28	29.47

The present study revealed that the mean of IL-6 was higher in women with breast cancer without EBV infection as compared with those infected with EBV, as shown in Table 4.

Table 4: Relation of EBV infection with level of IL-6 among women with breast cancer.

EBV Infection	No. of Women with Breast Cancer	IL-6		P value
		Mean	SD	
+ve	28	76.46	±70.71	0.74
-ve	67	81.61	±62.69	

The present study revealed that there was a positive correlation between EBV infection with IL-6 among women with breast cancer but the difference was statistically non-significant between them (R value: 0.084).. Figure 2.

Figure 2: Positive correlation between EBV infection with IL-6 among women with breast cancer.

Discussion

Breast cancer is a public malignancy and a major cause of morbidity in women. The present study revealed that EBV was detected in 29.47% of women with breast cancer. Numerous studies have reported a relationship between EBV and breast cancer. Zekri et al (7) revealed that EBV was found in 28% of Iraqi women with breast cancer and 45% of Egyptian. Lorenzetti et al (8) indicated that 31% was positive for EBV and in agreement with 31% to 52% EBV association which described in several geographic locations (9,10,11,12,13,14,15). Preciado et al (10) revealed that EBV was detected in 31% of tumor samples analyzed. No EBNA-1 labeling was obtained from samples without tumor. Fawzi et al (11), reported that EBV-DNA has been detected in 20% of breast cancer samples, using PCR targeting sequences specific for the Bam HI-W region of EB and refutes all studies that deny the relationship between breast cancer and Epstein-Barr virus infection (16,17).

The current study showed that the highest rate of EBV infections (12.63 %) was detected in those within the age group 40-49 years. Richardson et al (18), showed that the mean age of breast cancer women was 48 years with most in the 40-54 year age-group. It has been reported that the rate of EBV infection was higher in women less than 50 years than those older (19). According to American Cancer Society, age of the patient is an important factor both for the occurrence and management of the cancer with 95% of all new breast cancer cases occur in women aged 40 years (20). Al-Khafaji (21) revealed that the peak frequency was

recorded in the age of 50 years. The results reported that risk of breast cancer increases with age (22). Epstein – Barr virus [EBV] in Arab countries including Iraq was with high rate of infection (23). Epstein –Barr virus infection was linked with the development of breast cancer (24). However, other study was carried out in Taiwan detected EBV in 6.5% to 35.25% in breast cancer tissue (25). In addition, EBV detection rate in breast cancer tissue was the lowest in USA (18.27%) and the highest in Asia (35.25%) (26).

The current study revealed that the highest rate of women with breast cancer was from rural areas. The study of epidemiology of breast cancer in Indian women showed that the higher breast cancer is the major cause of morbidity and mortality among females ranking number one among females in Indian metropolitan cities like Delhi, Kolkata, Pune and Thi'puram, Bangalore and Mumbai and in Northeast. Factors as marital status, location (urban/rural), BMI, breast feeding, waist to hip ratio, low parity, obesity, alcohol consumption, tobacco chewing, smoking, lack of exercise, diet and environmental factors were major risk factors in India leading to increasing incidence cancer. Activities play a role among urban and rural women in the development of breast cancer. The more time spent on household activities further reduced the breast cancer risk (27).

The present work revealed that the means of IL-6 level was higher in women with breast cancer without EBV infection than those with EBV infection. Cytokines may play a role in pathophysiology of neuropsychiatric of the immune and neuro-endocrine

system. Pro-inflammatory cytokines have been associated with depression in persons with cancer during treatment and fatigue in survivors of breast cancer (28,29). Victoret al(30) confirm the association of levels IL-6, and IL-10 in breast cancer patients with or without receiving chemotherapy. In breast cancer, high levels of the inflammatory cytokine IL-6 have been associated with disease survival and treatment resistance (31,32). A study on interleukin-6 gene promoter and influence of -174G/C polymorphism on breast cancer revealed that there was no association or trend of association between -174G/C polymorphism of IL-6 promoter gene and breast cancer diagnosis or prognosis(33).

Conclusions

The study concluded EBV may play a role in the development of breast cancer and may be an etiology or it may induce immunosuppression that enhance the development of breast cancer. The mean age of breast cancer women was 54.5 years, The highest rate of breast cancer women was within the age group 40-49 years, with no significant relation among breast cancer patients and their age concerning EBV infection. There was a highest rate of rural than urban residence among breast cancer women, concerning EBV infection. The mean of IL-6 level was higher in women with breast cancer without EBV than those with EBV infection.

Assessment of Nutritional Status of Under Five Years Children in Relation to Their Birth Space in Shirqat City

Enas AbdulYaseen¹, Nahid Ahmed Hassan¹

¹Depts. Community medicine, College of Medicine, Tikrit University, Iraq

Abstract

Background: Nutritional status of children who are less than 5 years old is of significant regard as the beginning years of life are important for best development. Childhood malnutrition occurs due to several reasons, but spacing of birth is frequently unnoted even if it is accompanied with stunting which reflect chronic malnutrition. **Aims:** To assess the nutritional status of children less than 5 years old, and its relationship with birth interval, and associated factors. **Materials and Methods:** It was a cross sectional study was carried on children of 0-5 years age groups of both sexes. Data was collected using predesigned and pretested questionnaire, face to face interview with the mothers and anthropometric measurements of children were performed. **Results:** Most of undernourished children were with birth space less than 24 months. The frequency of stunting and wasting was the highest among children with birth interval less than 24 months, it was (14.5%) and (6.8%) respectively as compared to those with birth interval 24-59 months were frequency of stunting and wasting was found to be the lowest, it was (11.2%) and (2.2%) respectively. **Conclusion:** This paper draws attention to significant linkages between birth spacing and child nutritional status. Most of undernourished children were with birth space less than 24 months.

Keywords: birth interval, nutritional status, under five.

Introduction

Nutritional status and the health of child population is a true indicator of the overall health and economic development of the community. Children that are under 5 years old are considered the most vulnerable sector of the community, and malnutrition among this sector is one of the important health problems in developing countries(1) ,Birth spacing might have an impact on the nutritional status of the child as it leads to preterm delivery. Mothers cannot easily regain their nutritional stores if a pregnancy occurs early after the previous birth, that leads to low birth weight and preterm birth. Birth spacing effects on the nutritional status of the child extend after pregnancy and to infancy as a result of early weaning and insufficient practices of alternative feeding, usually because of a new siblings birth in a short interval. Mothers who have adequate spacing for their

pregnancies are capable to give their children essential nutrition for development success.(2)Interpregnancy interval (IPI) or birth to pregnancy interval(BTP), is defined as the period between a live childbirth and the beginning of the next pregnancy. (3) The World Health Organization (WHO) recommended that couples should rest for at least (2-3 years) between births in order to lower adverse maternal and child health outcome. Some studies found positive relationship, some negative, and some display no effect at all(4)

Material and Method

It was a cross sectional study conducted in the period from the first of November 2018 to the end of April 2019. Simple random sampling was used to choose the study subjects if he/she met the inclusion criteria. Verbal permission was obtained from Al-Shirqat primary health care sector before dealing with the children and their caregivers and from parents of the study subjects after explaining the aim of the study and procedures. In this study anthropometric measurements were used to assess nutritional status because they provide satisfactory results within the available resources. Data management

and analysis were done using manual statistical method. Chi-square test was used to test the significance in this study. The level of significance was estimated with 95% confidence interval and p value <0.05.

Findings

Out of 339 study subjects 131 (38.6%) had birth space of less than 24 months, majority of children 133 (39.2%) had birth interval of 24-59 months, and 75 (22.1%) children had birth space of more than 59 months (Table 1).

Table(1) :Distribution of children according to their birth interval.

Birth interval	Male(175)	Female(164)	Total(339)
>24 months	68(38.85%)	63(38.41%)	131(38.64%)
24-59 months	69(39.42%)	64(39.02%)	133(39.23%)
>59 months	38(21.71%)	37(22.12%)	75(22.12%)

Most of undernourished children were with birth space less than 24 months. (Figure1).

Chi-square=1.3 df=2 p-value=0.5

Figure (1): Association between child nutritional status and birth interval

Some children who are stunted could be also underweight and/or wasted at the same time. Similarly, children who are wasted and/or underweight may be stunted also. A child either stunted, underweight or wasted or any combination of the three was considered as having malnutrition which comes to be 67 (19.7%). The frequency of stunting and wasting was the highest among children with birth interval less than 24 months, it was (14.5%) and (6.8%) respectively as compared to

those with birth interval 24-59 months were frequency of stunting and wasting was found to be the lowest, it was (11.2%) and (2.2%) respectively. The frequency of underweight was the highest among children with birth interval 24-59 months, it was (9.7%) compared to those with more than 59 months birth interval. This finding was statistically insignificant. (Table 2).

Table (2) : Association between child nutritional status and birth interval.

Birth interval	Total children	Height for Age		Weight for Age		Weight for Height	
		Stunted Normal		Underweight Normal		Wasted Normal	
<24months	131(38.64%)	19(14.50%)	112(85.49%)	12(9.16%)	119(90.83%)	9(6.87%)	122(93.12%)
24-59months	133(39.23%)	15(11.27%)	118(88.72%)	13(9.77%)	120(90.22%)	3(2.25%)	130(97.74%)
>59months	75(22.12%)	10(13.33%)	65(86.66%)	4(5.33%)	71(94.66%)	2(2.66%)	73(97.33%)
Total	339(100%)	44(12.97%)	295(87.02%)	29(8.55%)	310(91.44%)	14(4.12%)	325(95.87%)

Chi-square=0.59 chi-square=1.03 chi-square=4.03 ;

Df=2 df=2 df=2; p-value=0.744 p-value=0.59 p-value=0.133

Among 339 children, 44 (12.97%) were stunted,29 (8.55%) children were underweight and 14 (4.12%) children were wasted. Males were comparatively more malnourished than females. (Table 3).

Table(3) :Distribution of study population According to Nutritional Indicators.

indicators	Male No. (%)	Female No. (%)	Total No. (%)
Stunting	24 (54.54%)	20 (45.45%)	44 (12.97%)
Underweight	18 (62.06%)	11 (37.93%)	29 (8.55%)
Wasting	8 (57.14%)	6 (42.85%)	14 (4.12%)

As per WHO chart: Cut-off is considered as <2 sd

In the study sample, the result of malnutrition by the combinations of birth interval with birth order indicate that the predominance of being malnourished were higher in the combination of birth order 2-3 and <24 months of birth interval (57.5%) in comparison to combination of birth order 2-3 and >59 months (5%) in particular. There were significant differences in the association of birth spacing with malnutrition by birth order (p- value <0.05). (Table 4).

Table (4): The relationship of birth spacing with malnutrition according to birth order.

Birth order	Malnutrition by birth interval (in months)			Total Malnutrition
	<24	24-59	>59	
2-3	23 (57.5%)	15 (37.5%)	2 (5%)	40 (59.70%)
4-5	5 (25%)	6 (30%)	9 (45%)	20 (29.85%)
≥6	2 (28.5%)	3 (42.85%)	2 (28.57%)	7 (10.44%)
Total	30 (44.77%)	24 (35.82%)	13 (19.40%)	67 (100%)

Chi-square=16.22 Df=4 P-value= 0.002

Discussion

The current study found increased frequency of stunting and wasting among children with birth interval less than 24 months as compared to those with birth interval >24 months. The association between birth interval and stunting, underweight and wasting was found to be statistically insignificant (p -value > 0.05). These results correspond with similar findings from other studies which found increased odds of stunting among children with birth interval less than 24 months as compared to children with birth interval 36-59 months(2) Other study conducted in Bangladesh revealed increase prevalence of stunting among children of birth interval less than two years, the study found significant association between birth interval and stunting. Also the study shows a negative relation between intervals more than 48 months and stunting(5) ,Study from India, Shahjada et al (2014) found that the majority of malnourished children were with birth space less than 24 months. It observed that the prevalence of stunting, underweight and wasting was the highest among children with birth interval less than 24 months and this study showed a positive association between the length of birth interval and child nutritional status(6) ,The current study found that the frequency of stunted children, underweight and wasting was higher in male children than females. This finding was studied and explored by researchers who suggested some explanations. It is expected that male children are more affected by environmental strains than females(7,8).This finding also agrees with a study conducted in Somalia, where it was found that more males had malnutrition than females as their numbers are very in the community(1)

A possible explanation for this result could be due to the fact that males have a tendency to be actively playing outside the house as compared to girls who are always at home spending most of their time eating. The current study found that children with birth interval less than 24 months were more likely to be malnourished in the birth order 2-3 than those with \geq 24 months of birth interval. The result of the present study shows that the children of lower birth order and longer birth interval were less malnourished than those with higher birth order and shorter birth interval. Birth spacing comes to be less effective on a higher birth order to reduce childhood malnutrition. This finding is supported by a similar result from previous study (9) ,Overall, our results suggest that high percentage of malnutrition among low birth order children could be avoided with the improvement of

birth spacing as better nutritional outcome seen among children with lower birth order and longer birth interval. Zajonc (1976) revealed that the negative effect of birth order can be reversed by longer birth interval (10). Although, the finding suggest that the combination of lower birth order(2-3) and lesser birth interval (<24) that often considered as a result of lack of family planning, adversely affects child's nutritional status.

Conclusions

1. This paper draws attention to significant linkages between birth spacing and child nutritional status. Most of undernourished children were with birth space less than 24 months.
2. Males are comparatively more malnourished than females.
3. The predominance of being malnourished were higher in the combination of birth order 2-3 and less than 24 months birth interval.

Recommendation

- Community and health facility-based birth spacing educational programs are required to enhance birth spacing and encourage post-partum birth control use.
- Health providers and health workers should be educated about informing and counseling women on birth spacing.
- For women who want to get a next pregnancy after a live birth, wait at least 2 years before attempting to become pregnant.
- Strengthening and improve quality of prenatal care services and intensive awareness programs has to be arranged to increase its utilization.

Detection of blaCTX-M gene in Klebsiella sp. Causing UTIs in Al-Yarmouk Teaching Hospital

Marwan Majeed Ibrahim¹, Ammar Hameed Howaidy², Abeer Nahy Hamdy³

¹CABM Internal Medicine, College of Medicine, Tikrit University, Tikrit, Physician at Al-Yarmouk teaching Hospital, Iraq, ²Urologist, College of Medicine, Fallujha University, ³Assist Pprof. Department of Gynecology & Obstetrics, College of Medicine, Tikrit University, Iraq

Abstract

Background : Klebsiella sp. causes a wide range of bacterial diseases like pneumonia, UTI and sepsis. Therefore, this study was done to assess the prevalence and molecular characteristics of Klebsiella sp. in 50 samples of men and women isolated from Iraqi patients which was suffering from urinary tract infection (UTI) compared with (10) of healthy individuals. All samples were collected from Al-Yarmouk teaching hospital/Baghdad during January – March 2019. Identification of bacterial isolated were done by using manual cultural procedures and VITEK 2 automated (bioMérieux, France) system, while antibiotic sensitivity test of Klebsiella sp. was achieved by Kirby-Bauer and MIC testing was made by VITEK 2. The creation of ESBL was phenotypically distinguished by twofold plate cooperative energy test as assigned by to the CLSI rules. Location of bla-quality encoded CTX-M was seen by customary P.C.R system. Out of fifty separates of K. Pneumonia, 26% were planted generation of ESBL utilizing CDT, the MIC utilized with diverse anti-infection agents in this investigation, 13 (26%) of secludes by utilizing VITEK2 AST-GN30 which exhibited that, all disconnects were totally impervious to every one of ceftazidime, cefepime and ceftriaxone with MIC (≥ 16 - ≥ 64) $\mu\text{g/ml}$, and the outcome demonstrated that 61.53% separated of ESBL production were delicate carbapenem with MIC (≤ 0.25) $\mu\text{g/ml}$. Furthermore, PCR examine uncovered that 4 (30.76)% of the ESBL creating isolates harboured blaCTX-M gene.

Keyword : Molecular study ; virulence genes ; Klebsiella sp.; urinary tract infections (UTIs)

Introduction

In human body, the urinary system is a usually sterile and far from the colonization of normal by innate epithelial barrier and the antibacterial action of the bladder mucosa and the excretion of urine. However, urinary tract infections (UTIs) are represent principal infectious diseases, occurred in all individuals and all age groups (1).

Globally, more than 6 million physician clinics were visits in year due to UTI by two-thirds by women (2). Numerous revision submitted that daily sexual relation have a role in occurrence of bacterial vaginosis. this might be sexually transmitted by sex or by therapeutic routs especially when males suffered from these infection though they applied to heavy program of treatment (3,4).

Urinary tract infections are an important health problem for millions of individuals each year (5). Notwithstanding the common obtainability of antibiotics, it stills the second most public bacterial infection in the population, and not forget that in women more frequent infected with UTI than men (6,7).

The majority of UTI infection occurs with exposure to Klebsiella, it account about 6 to 17% of all nosocomial UTIs and reveal high occurrence in patients with risk, e.g., DM patients. Klebsiella causing UTIs are clinically can not be distinguished from UTIs of other origins. So, the aim of this work was to study the role of virulence gene associated with Klebsiella sp. causing UTI in Baghdad hospital (8).

Material and Method

Collection of samples:

Sample of urine were gathered as aseptically as conceivable in sterile holders (general containers or pee packs). mid-stream examples were gathered from the UTIs patients and the control person. All examples were gathered from Al-Yarmouk showing emergency clinic/ Baghdad during January – March 2019. The gathered examples were moved to the research center inside 20 minutes of accumulation.

Cultivation

A calibrated loop measures 0.01ml of urine, using one plate of each a MacConkey and blood agar, the loop touched to center of plate in such a manner and as mentioned in in standard bacterial cultivation procedures in order to produce isolation colonies. “The plates were incubated at 37oC overnight” and examined on the following day for growth. Colonies were counted on each plate. Colonies were morphologically studied on MacConkey agar and blood agar by using a magnifying lens, As well as biochemical tests.

Sensitivity Test To Antimicrobial Agents:

Disc diffusion test (Kirby-Bauer) was used as initial susceptibility test because of its ease of performance, reproducibility and proven values as a guide to antimicrobials therapy. All *Klebsiella* sp. secludes were societies on MacConkey agar. The antimicrobial helplessness of these detaches was finished by Kirby-Bauer technique and VITEK 2 framework as indicated by the Clinical and Laboratory Standards Institute (CLSI) rules. CLSI guidelines (9). The MIC for phenotypically ESBL creating segregates was gotten.

ESBL Production

Emulsions that are potential ESBL producers were isolated by preliminary examination using a nutrient broth to adjust the density of the vaccine equal to the density of the McFarland sour criteria 0.5 was performed in all isolates presumed to be an ESBL. In this test, Ceftazidime tablets alone and in combination with clavulanic acid (10)

Extraction of DNA

Beta-mercaptoethanol was added to the DNA restricting support to a last weakening of 0.5% (v/v) i.e., 500 µl/100 ml (2).

1. A measure of 100 mg (wet weight) bacterial cells that resuspended was included up to two hundred µl of

water or isotonic cushion, added (750) µl of this Lysis Solution to the cylinder 2 (Figure 3.4).

2. Secure in a dot blender fitted with a 2 ml cylinder holder gathering and procedure at 10,000 x g for five minutes.

3. The ZR BashingBead™ Lysis Tube was centrifuged in a microcentrifuge at 10,000 x g for 1 minute.

4. 400 µl supernatant was moved to a Zymo-Spin™ IV turn channel (orange top) in a gathering tube and centrifuged at 7,000 x g for 1 minute.

5. A measure of 1,200 µl of bacterial DNA restricting cushion was added to the filtrate in the accumulation tube from Step (4).

6. A measure of 800 µl of the blend from Step (5) was moved to a Zymo-Spin™ IIC Column 3 in an accumulation cylinder and axis at (10,000) x g for one minute.

7. Dispose of the move through from the Collection Tube and rehash Step (6).

8. 200 µl of DNA pre-wash cushion was added to the Zymo-Spin™ IIC segment in another accumulation tube, then centrifuged at (10,000 x g) for 1 minute.

9. 500 µl DNA wash support was added to the Zymo-Spin™ IIC section and axis at 10,000 x g for 1 minute.

10. The Zymo-Spin™ IIC segment was moved to a clean 1.5 ml microcentrifuge cylinder and include 100 µl DNA elution cradle legitimately to the segment lattice, centrifuged at 10,000 x g for 30 seconds to elute the DNA.

Detection of CTX-M genes :

identified phenotypically in resistant isolates of *Klebsiella* sp. by CTX-M genes by used primers targeting blaCTX-M gene. amplification mixture of PCR was prepared according to manufacturer's instructions (Intron, Korea).

A- Primers:

In amplification CTX-M gene, used primers which listed in Table- 1, below:

Table 1: primersequences for detection of blaCTX-M genes(14)

CTX-M gene	Sequence(5'-3')	product Size (b.p)
F R	CGCTTTGCGATGTGCAG ACCGCGATATCGTTGGT	550

Statistical Analysis

Statistical tables including observed frequencies with their percentages and Graphical presentation by (bar - charts) as well as Chi-Square (χ^2) for calculation of P. value ($P < 0.05$: significant).

Finding

In this study, 26% of Klebsiella isolates were ESBL producers as used by CDT methods. Number 13 of Klebsiella sp. Isolate was differed from other isolates in view of cephalosporin resistance. 100% of Klebsiella spp were with MIC above 16 for CFT and more than 64 MIC for the both antibiotics. Some of Klebsiella sp. Isolates with MDR were resistant to imipenem & meropenem with level of 16Mg of MIC/

Figure 1: Typical combination disk method with +ve result.

In this work, all Klebsiella isolates were non-susceptible to CAZ accompanied with increasing in clear zone around CZC. Additionally, majority of isolates extended antibiotic betalactames processing were recovered from urine samples and lowest rate of them were considered MDR due to stability against 10 discs and as mentioned in Table below.

Table 2:Antibiotic susceptibility of ESBL producing Klebsiella sp. isolates

Isolate number	VITEK 2 system result of MIC									
	Imepenem	ciproloxacin	gentamycin	Ceftaz	Amp.	ceftriaxone	tobramycin	meropenem	FEP	LEVO
1	R*1	R*4	R*1	R*2	R*3	R*1	R*1	R*1	R*2	R*1
2	S*1	R*4	R*1	R*3	R*3	R*2	R*1	S*1	R*2	S*1
3	S*1	R*4	R*1	R*2	S*1	R*2	R*1	S*1	R*2	S*1
4	R*1	R*4	R*1	R*2	R*3	R*2	R*1	R*1	R*2	R*1

R*1*: MIC equal or more 16 Mg/ml

R*2: MIC equal or more 64 Mg/ml

R*3 : MIC equal or more 32Mg/ml

R*4: MIC equal or more 4 Mg/ml

S*1 : MIC equal or lese that 0.25 Mg/ml

Additionally, CEF resistant Klebsiella isolates were further underwent molecular evaluation for ESBL pheonotype using specific procedure for detection of blaCTX-M and according to manufacture instructions. It was observed by above PCR technique that 30.76% of Klebsiella isolates (the 4 MDR isolates) were virtually harboured blaCTX-M genes.

Figure 2: Agarose gel was stained by Ethidium bromide to show amplification of PCR out product with blaCTX-M gene (550 bp) primers for Klebsiella sp. extracted DNA.M: 100 bp average size reference marker. Lane 1: K1 shows positive result with blaCTX-M gene Lane 2: K2 shows positive result with blaCTX-M gene. Lane 3: K3 shows negative result with blaCTX-M gene. Lane 4: K4 shows positive result with blaCTX-M gene. Lane 5: K5 shows negative result with blaCTX-M gene. Lane 6: K6 shows positive result with blaCTX-M gene.

Discussion

The vast majority of the diseases are procured in clinic setting therefore, it is accounted for to be the among the 10 most normal nosocomial pathogen in different examinations(9). Nowadays, Klebsiella pneumoniae diseases are entangled by increment in Extended Spectrum Beta Lactamase (ESBL) producing segregates(10,11). Subsequently, this examination is being led with the target to find out the commonness of ESBL delivering Klebsiella pneumoniae in different clinical examples and to find out their affectability design(12). Flare-ups of ESBL-delivering living beings have been depicted. Asymptomatic patients colonized with ESBL-delivering K. pneumoniae can fill in as stores for this pathogen with resulting persistent to-tolerant spread through the hands of medicinal services laborers. What's more, sullied persistent consideration things and fake fingernails worn by human services laborers have been involved in transmission(9). Most examinations have exhibited a poor adherence to contamination control strategies as a significant factor. Flare-ups of ESBL-delivering K. pneumoniae in NICUs have been outstanding for high assault rates and huge quantities of colonized infants(1,2). The neonates at most serious hazard for colonization are those with a more extended length of remain, a lower evaluated gestational age and additionally a lower birth weight.(11,13). Studies directed in Ghana have announced K. pneumoniae as a noteworthy pathogen in charge of UTI (14). A research center based across the nation reconnaissance of antimicrobial obstruction in Ghana by Opintan and collaborators announced that K. pneumoniae spoke to 1.06% of every bacterial disease and 1.4% of Gram-negative bacilli (11). Another study showed an expanded K. pneumoniae opposition of 118.9% of Gram-negative microscopic organisms in their investigation on MDR bacterial diseases in a showing medical clinic(15). Notwithstanding the risk presented by multidrug safe Gram-negative microscopic organisms in social insurance, there is lack of sub-atomic the study of disease transmission ponders. This examination, which structures some portion of a more extensive investigation on the atomic profile of Gram-negative ESBL pathogens in a patient of private clinic, portrays the clonal genealogies, anti-infection resistome and plasmid replicons of a sub-set of K. pneumoniae with protection from the second and third-age cephalosporins utilizing entire genome sequencing (14).

Ceftazidime is one of type of 3rd generation cephalosporin used commonly for the treatment K. pneumoniae related infections. Nevertheless, high rate of resistance toward ceftazidime is occurred continuously in clinical managing of infection with these isolates. In the current study, an elevated rate of ceftazidime resistance was detected in patients infected with Klebsiella sp. , This result similar to results obtained by Aheret al(4) showed ceftazidime resistant Klebsiella. additionally, isolates producing ESBL were with high rate of resistance to all antibiotics tested as compared with non- ESBL producer, other revealed a resistance to aminoglycosides fluoroquinolones, and methoprim in organisms producing ESBL(5). The development and polyclonal spread of CTX-M-delivering K. pneumoniae as happened among detaches with various hereditary foundations. This speculation appears differently in relation to discoveries with respect to KPC-delivering K. pneumoniae: clonal spread of KPC-delivering (K. Pneumoniae) segregates having a place with the ST258 heredity was seen by Zachar Czuket al(7).

In clinical strains, the CTX-M-encoding qualities has normally been situated on plasmids that differ in size from (7 -160) kb(2). Plasmid-intervened transmission of CTX-M qualities in Enterobacteriaceae that includes a few motile hereditary components has portrayed (7,9). given strength of CTX-M-15 genotype, among hereditarily heterogeneous (K. Pneumoniae) secludes, the examination additionally suggests the same level exchange of a hereditary component conveying blaCTX-M among K. pneumoniae disconnects. Second, the CTX-M-delivering K. pneumoniae study disconnects displayed high paces of protection from gentamicin and trimethoprim-sulfamethoxazole as percentage (68 and 96%) respectively , so antibiotic medication as 80%, notwithstanding protection from ciprofloxacin (88%) and piperacillin-tazobactam (64%) as portrayed beforehand (16).

Conclusion

In this study, the high rate of beta lactamases production of Klebsiella sp. is necessary to avoid treatment failure condition and need to adopt appropriate control measures to reduce the ESBL. Also, usefulness of PCR technique for detection ESBLs and their effect on antimicrobial resistance. Remarkably, 41.67% of bacterial isolates have three of cephalosporine β -lactamase genes and this could be due to the common used of cephalosporine for treatment.

Alterations in Antioxidants and Trace Element with Interleukin 6 Level in β Thalassemia Major Patients

Janan I. Mohammed¹, Shihab A. Al-Bajari¹, Motaz A. AL. Akashe¹, Alaa N. Totanjee¹

¹Mosul Technical Institute, Northern Technical University, Mosul, Iraq

Abstract

β -Thalassemia major is an inherited blood disorder caused by drop or total absence of beta globin chains. Patients with this blood disorder are repeatedly needed to blood transfusion to survive. There are many experimental and clinical evidence that suggested that the oxidative stress and free radical plays an important role in thalassemia. The aim of the present study was to investigate the level of antioxidant enzymes and trace element with interleukin 6 in β thalassemia major patients. The blood samples were obtained from 50 patients (30 with β -thalassemia major and 20 healthy controls). The serum levels of MDA, GSH, Vitamin (E, C), trace element (Fe, Zn, Cu, Se) and antioxidant enzymes (SOD, CAT, GPx) and interleukin 6 were analysed using conventional methods. The results showed that the level of MDA, Fe, Cu and interleukin 6 were significantly increased ($P < 0.05$), whereas the activities of GSH, Vitamin (E, C), trace element (Zn, Se) and antioxidant enzymes (CAT, GPx) were decreased significantly ($P < 0.05$) in β -thalassemia major patients compared with healthy control. This results suggested that the β thalassemia patients disease activity and progress could be investigated by determining the oxidative stress marker, trace element and interleukin 6 levels.

Key words: *Thalassemia major, Oxidative stress, Trace element, Interleukin 6, Vitamins.*

Introduction

Alpha and beta thalassemia are known to be the most common types of thalassemia disease. The beta thalassemia major is found the very severe form that is required a repeated blood transfusions and treatment by desferrioxamine injections (1), Despite a such treatments could increase the patients' life span, however, it is related with a variety of complications, such as endocrine, skeletal metabolic, immunity, growth disorders. The trace elements and oxidative stress are detected as a consequence of high level of iron storage in the body and that might cause an oxidative stress. Though, some studies were suggested the damage caused by the endogenous free radical in thalassemia (2), the oxidative stress is the balance interruption among oxidants and reluctant in the body due to excessive production of both peroxides and free radicals caused cellular and tissue damage in the body, and this damage caused an oxidative stress and decrease the total antioxidant capacity (3). The production of the reactive oxygen species (ROS) that has the ability to react with all biological molecules such as lipids, proteins, carbohydrates and DNA, and exert a cytotoxic effects on

cellular components. Hence, increase ROS and impaired antioxidant defense are contributed for the initiation and progression of Beta thalassemia major disorder. The ROS activates is also diverse the damaging processes in cells, including oxidation of intracellular and surface components of the red blood cells in β thalassemia major patients (4). The antioxidants complex is Enzymatic antioxidants including catalase, superoxide dismutase and glutathione peroxidase, Superoxide dismutase and non-enzymatic antioxidants including glutathione vitamin A, C and E), and all are protect the key biological sites from oxidative damage and scavenge free radicals and other reactive oxygen species (ROS) (5). The trace elements play an important role in building of proteins, enzymes and complex carbohydrates to contribute in the biochemical reactions. Additionally, trace elements such as Zinc, Selenium, Magnesium, Manganese, and Copper are cofactors or structural components of antioxidant enzymes (6). In Beta thalassemia patients, the selenium element and glutathione peroxidase enzyme are observe an important protecting role of cell membranes from oxidative damage (7). Interleukin 6 (IL-6) it has a broad effect on immune and non-immune system related cells

and is often exhibit hormone-like characteristics that affect the homeostatic processes (8), and it has context-dependent pro- and anti-inflammatory properties. Several cytokines have been found at the chronic inflammatory sites, such as periodontitis autoimmune diseases, thyroiditis and arthritis. Also, there is an suggestion IL-6 is overproduced in thalassemia diseases (9).

Material and Method

This study was conducted in Al-Mosul governorate, a 50 patients (30 with β -thalassemia and 20 were healthy controls) with age range (10-15) years old. The serums were collected by incubation the blood sample tubes in a water path at 37°C for 10 minutes, and then centrifuged at 13000xg using cooling centrifuge for 10 minutes. The supernatants were then collected and stored at -20 freezer (10).

serum Interleukin 6: The Interleukin 6 was analyzed by using ELISA technique (Eagle Biosciences, USA Kit) (11)

serum Malondialdehyde: The malondialdehyde levels was analyzed by method described by Yao-Yuan (12) .

serum Glutathione: The GSH concentration in serum was analyzed according to (13).

serum Vitamin C: The Ascorbic acid is oxidized by copper to form a dehydroascorbic acid and

diketogulonic acid. These products were treated with 2,4-dinitrophenylhydrazine (2,4-DNPH) to form the derivative bis-2,4- dinitrophenylhydrazone.(14).

serum Vitamin E: The Vit E was analyzed according to Emmerie-Engel reaction in which the tocopherols reduce ferric ion to ferrous ion, then it reacted with α, α' -dipyridyl give a red-orange color with absorbance at 520 nm.(15)

serum Superoxide dismutase activity: (SOD) activity was measured by colorimetric assay (16). We used commercially available colorimetric method (Randox Laboratories Ltd, UK).

serum Catalase activity: Catalase activity was estimated by the method of Aebi (17). Catalase can degrade hydrogen peroxide which can be measured directly by the decrease in the absorbance at 240 nm.

serum Glutathione peroxidase activity: Gpx activity was measured by the method (18).

serum trace elements: Zinc, Selenium and Copper were analyzed by atomic absorption spectrometry.

Statistical analysis: All data were reported as mean and \pm SEM. The statistical significance was assessed using Student's t-test. The P value less than 0.05 was accepted as the data were significantly different.

Finding

Table1: Descriptive data of studied for β -thalassemia patients and control individuals.

Parameters	Control N=20	β -thalassemia patients N=30
Age (Years)	11 \pm 2.3	12 \pm 4.4
Sex (Male/Female)	10/10	15/15
BMI (Kg/m ²)	15.51 \pm 1.23	16.1 \pm 1.45
Duration of β -thalassemia (years)	--	7.4 \pm 2.4

Serum levels of MDA showed significant difference between β -thalassemia and control group ($p < 0.05$). It was significantly increased in the β -thalassemia group when compared with control group. Per oxidative damage of lipids is indicated by the increase in serum MDA and significant decreased antioxidant defiance GSH & Vitamin when compared with control group ($p < 0.05$) are shown in Table-2.

Table 2: The levels of serum oxidative stress marker in β -thalassemia patients and control groups.

Parameters	Control N=20	β -thalassemia patients N=30
MDA (μ mole/L)	2.66 \pm 0.32	5.43 \pm 1.2*
GSH (μ mole/L)	12.95 \pm 0.56	7.31 \pm 1.1*
Vitamin C (μ mole/L)	44 \pm 2. 17	31 \pm 2.2*
Vitamin E (μ mole/L)	21.4 \pm 1.5	13.2 \pm 1.4*

Data are reported as mean \pm SD. *P<0.05 compared to control (Student t-test).* significant.

Table-3 showed that β -thalassemia patients significantly decrease significantly in glutathione peroxidase (GPx) and Catalase (CAT) level in serum compared with control groups (p<0.05). While superoxide dismutase (SOD) no significantly increase compared with control groups (p<0.05).

Table 3: The levels of serum Activity enzymes and Interleukin 6 in β -thalassemia patients and control groups

Parameters	Control N=20	β -thalassemia patients N=30
CAT (U/ML)	3.1 \pm 0.64	2.7 \pm 0.7*
GPx(U/ML)	0.67 \pm 0.11	0.55 \pm 0.09*
SOD (U/ML)	6.82 \pm 2.1	7.14 \pm 1.7
Interleukin 6 (pg/ml)	1.99 \pm 0.12	2.5 \pm 0.13*

Data are reported as mean \pm SD. *P<0.05 compared to control (Student t-test).* significant.

The mean serum trace element (Zn , Cu , Se) levels are shown in β -thalassemia patients were significantly lower than control group, while (Fe) was significantly higher in serum than control group (Table-4).

Table 4: The levels of serum trace element in β -thalassemia patients and control groups.

Parameters	Control N=20	β -thalassemia patients N=30
Zn (μ g/dl)	107 \pm 5.2	69 \pm 1.4*
Cu (μ g/dl)	107 \pm 3.3	173 \pm 2.4*
Se (μ g/dl)	82 \pm 2.2	69 \pm 1.3*
Fe (μ g/dl)	89 \pm 4.3	163 \pm 2.9*

Data are reported as mean \pm SD. *P<0.05 compared to control (Student t-test).* significant.

Discussion

A significant increase serum iron proves patients have severe anemia due to ineffective erythropoiesis which is primary reason for iron overload and blood transfusion is secondary to it ⁽¹⁹⁾. The results showed a significant lowering in Serum GSH levels in patients which was in agreement with many studies in normal and human diseases individuals ⁽²⁰⁾. Shekhar study showed a significant decrease of antioxidants, GSH in patients of low level of hemoglobin in red blood cells in beta thalassemia ⁽²¹⁾. GSH is an essential antioxidant for recycling of vitamin E and C and is very powerful in helping the body fight against the free radicals ⁽²²⁾. GSH also participates in the cellular defense system against oxidative stress by scavenging free radicals and reactive oxygen intermediates. Decrease in GSH level in patients increases the sensitivity of cells to oxidative stresses ⁽²³⁾. Patne et al., found a significantly increasing of MDA in serum in β -thalassemia patients compared to healthy control ⁽²⁴⁾. MDA and acrolein ($\text{CH}_2=\text{CHCHO}$), potentially toxic agents which spontaneously formed from aminoaldehydes, and induce oxidative stress in mammalian cells ⁽²⁵⁾. In β -thalassemia syndromes, decreased or impaired biosynthesis of beta-globin leads to accumulation of unpaired alpha-globin chains. Moreover, the iron overload in β -thalassemia patients generates oxygen-free radicals and peroxidative tissue injury and elevated MDA ⁽²⁶⁾. Vitamin C and E were significantly decreased in patients with β -thalassemia compared to healthy subjects. similar result was obtained by Dissayabutra et al. (2005), who showed a significantly lower in vitamin C and E levels in patients. This decrease may be due to multiple blood transfusion are at risk in iron overload and high oxidative. GPx This antioxidant enzyme belongs to a group of antioxidant selenoenzymes that protects the cells from damage by catalyzing the reduction of lipid hydro peroxides ⁽²⁸⁾. The reduction in GPx activity associated with enhanced oxidative stress in β -thalassemia may be related to increased H_2O_2 levels ⁽²⁹⁾. The present study indicates a significant decreasing of CAT activity. The activity levels of CAT were significantly decreased in β -thalassemia males and females patients than in healthy subjects ⁽³⁰⁾. Therefore, a significant decrease in the levels of CAT indicated protection against oxidative stress ⁽²¹⁾. Also no significant increase in SOD activity in patients compared with healthy subjects. In the present study, the activity of Erythrocyte SOD was no significantly ($P>0.05$) increased as compared to controls. Erythrocyte SOD scavenges superoxide radicals to form

hydrogen peroxide and protects the cell membrane from its damage. Increased Erythrocyte SOD activity may be due to blood transfusion and increase in the proportion of younger erythrocytes, as a compensatory mechanism after increased oxidative stress ⁽³¹⁾. A significant increase ($p<0.001$) in serum iron was observed in beta thalassemia major when compared with controls. The patients have severe anemia due to ineffective erythropoiesis which is primary reason for iron overload and blood transfusion is secondary to it. Thus, increased iron may increase the potential of oxidative injury to erythrocytes and cell organelles ⁽³²⁾. Interleukin 6 (IL-6) is an interleukin that acts as both a pro-inflammatory cytokine and an anti-inflammatory myokine. In humans, it is encoded by the IL6 gene ⁽³³⁾. In addition, osteoblasts secrete IL-6 to stimulate osteoclast formation. Smooth muscle cells in the tunica media of many blood vessels also produce IL-6 as a pro-inflammatory cytokine. IL-6's role as an anti-inflammatory myokine is mediated through its inhibitory effects on TNF-alpha and IL-1, and activation of IL-1ra and IL-10 ⁽³⁴⁾. IL-6 stimulates the inflammatory and auto-immune processes in many diseases such as β -thalassemia ⁽³⁵⁾. Diabetes ⁽³⁶⁾ atherosclerosis ⁽³⁷⁾ and multiple myeloma ⁽³⁷⁾. Thus, IL-6 concomitantly regulates proinflammatory and antiinflammatory activities and contributes to both the development and the resolution of the acute inflammatory response ⁽³⁵⁾. Tabatabaei et al reported that 84.8% of thalassemia major patients had zinc deficiency. They emphasized that the cause of zinc deficiency in these patients was due to insufficient zinc of dietary intake ⁽³⁷⁾. Yazdih et al showed that the serum concentration level of zinc in thalassemia patients ($37\pm 1.9\text{mg/dl}$) was lower than in control group and there was significant difference statistically. They recommended zinc supplement for thalassemia patients ⁽³⁵⁾. They suggested that the etiology of zinc deficiency is malnutrition and inadequate zinc intake. They advise administration of zinc supplement ⁽³⁶⁾. In this study, the β -thalassemia major patients showed low levels of serum Se in comparison with the control group. These findings are comparable to the results reported by other studies ⁽⁷⁾.

Conclusion

This study indicates that in patients with β -thalassemia impairment of the antioxidant enzymes (GPx, CAT, SOD) along with essential trace elements (Se, Cu, Zn) minerals in order to reduce the extent of oxidative damage and the related complications in β -thalassemia major associated with elevated iron and

plasma levels of lipid peroxidation.

Abstract

Background: Currently, obesity affects almost a third of the world's population. Traditionally, anthropometric measures such as waist circumference or body mass index (BMI) were used to quantify total obesity. aim of this study to estimation the relation between Overweight BMI with and without regular exercise among secondary school students in Tikrit City. **Patients and methods:** cross-sectional descriptive epidemiological study was carried out to estimate the relation between Overweight BMI with and without regular exercise in secondary school students in Tikrit city among 153 students (80 girls and 73 boys) and study the relationships between them. **Results:** In current study, male who doing exercise 1-2 times weekly 44.83% less than non- doing as percentage 55.17% ,so 11/23(47.83%) from female do exercise 1-2 times weekly, while in male 13/29(44.83%) do exercise 1-2 times weekly.as well as 8/23(34.78%) from female do exercise 3-4 times weekly, while 9/29(30.03%) in male do exercise regularly, In male 7/29(24.14%) do exercise more than 4 times weekly, while 4/23(17.39%) from female do exercise more than 4 times weekly.and female 16/23(69.57%) do exercise for 0-30mins, while in male 15/29(51.72%) do exercise for 0-30mins. also 6/29(20.69%) in male do exercise for 30-60mins, In male 8/29(27.59%) do exercise for more than 60mins, also 16/49(32.66%) had a overweight BMI and 22/49(44.9%) had a central obesity. **Conclusion :** Most of the students have a normal BMI and a normal waist-to-height ratio and among secondary school students (34%) only have regular exercise, from them (46.15%) doing exercise 1-2 times weekly.

Keywords: Overweight; BMI ; regular exercise ; secondary school students ; Tikrit city

Introduction

The obesity and overweight prevalence in both children and adolescents is considered as pandemic problem worldwide⁽¹⁾. By participating in regular exercise programs, can estimated that about approximately (22.0 million) overweight and obese people worldwide may reduced BMI⁽¹⁾, So According to WHO about three hundred million are defined as obese (BMI>30kg/m²) and one billion are overweight (BMI >25kg/m²)⁽²⁾.

Obesity is causing by an imbalance in the consumption of calories that derived from food comparing to the expenditures via exercise and body activity⁽¹⁾. About 5% of the world's deaths caused by overweight and obesity ,so the Physical inactivity concenter as fourth leading risk factor for mortality in the world and (6%) of deaths globally⁽³⁾, as well as low in movement behavior, there are indications of a significant increase in youth with weight concerns and an increased in negative body image as adolescents progress⁽⁴⁾.

Exercise recipes for obese people follow the same framework for the condition; intensity; forever; and the frequency has been explained. The amount of exercise which needed to lose weight is too large to be increased⁽⁵⁾.

Patients and Methods

Cross-sectional study was used to assess Overweight BMI with and without regular exercise in secondary school students in Tikrit city, collected 153 cases of both gender from secondary school students (Ibn-almotam ,Al-Khansaa and Al-Mustansrya), during the 1st of November to the 1st of January.

Finding

In figure-1 illustrates that male who doing exercise 1-2 times weekly 44.83% less than non- doing as percentage 55.17% .

Figure (1): - Illustrates secondary school student (male gender) who are doing regular exercise weekly

Figure (2): - Illustrates secondary school student (female gender) with who are doing regular exercise weekly

Figure (3): - Illustrates secondary school student (both gender) with their percent of how many times they do exercise weekly

This figure illustrates that 11/23(47.83%) from female do exercise 1-2 times weekly, while in male 13/29(44.83%) do exercise 1-2 times weekly.

Also 8/23(34.78%) from female do exercise 3-4 times weekly, while 9/29(30.03%) in male do exercise regularly, In male 7/29(24.14%) do exercise more than 4 times weekly, while 4/23(17.39%) from female do exercise more than 4 times weekly.

Figure (4): - Illustrates secondary school student (both gender) with their percent of duration taken to complete exercise

This figure illustrates that female 16/23(69.57%) do exercise for 0-30mins, while in male 15/29(51.72%) do exercise for 0-30mins. Also 7/23(30.43%) from female do exercise for 30-60mins, while 6/29(20.69%) in male do exercise for 30-60mins, In male 8/29(27.59%) do exercise for more than 60mins.

Figure (5): Illustrates secondary school student (both gender) with their percent of daily drinking glasses of water.

This figure shows that 48/80(60%) of females drinking less than 4 glasses of water, while in male 39/73(53.42%)

Table (1): - Body mass index (BMI) score of the secondary school students involved in the study with a positive family history.

BMI	Male		Female		Total
	Number	Percents	Number	percents	Number(%)
18.5>	4	17.39	1	3.85	5 (10.2%)
18.5-25	5	21.74	9	34.62	14 (28.57%)
25-30	8	34.78	8	30.77	16 (32.66%)
>30	6	20.09	8	30.77	14 (28.57%)

This table shows that 16/49(32.66%) had a overweight BMI.

Table (2): - waist-to-height ratio of secondary school students involved in the study with a positive family history

waist-to-height ratio	Male		Female		Total
	Number	Percents	Number	percents	
>0.5	7	30.34	6	23.08	13 (26.53%)
0.5-0.6	9	39.13	13	50	22 (44.9%)
0.6<	7	30.34	7	26.92	14 (28.57%)

This table shows that 22/49(44.9%) had a central obesity.

Discussion

Current study showed that male who doing exercise 1-2 times weekly 44.83% less than non- doing as percentage 55.17% ,regular exercise can lead to noticeable changes in BMI for overweight and obese people ⁽¹⁾, Sherwood, 2001 are recommended the sport is in individual who are overweight and obese ,this type of sport is highly recommended ⁽⁶⁾.

It has been associated with increased symptoms of depression and anxiety in college students and adolescents⁽⁷⁾.

As well as about (47.83%) from female do exercise 1-2 times weekly, while in male (44.83%) do exercise 1-2 times weekly, but this results disagreement with Hassan et al., who showed, only(1%)has a good level of daily physical activity , whilst 86.7% has low daily physical activity⁽⁸⁾.

Man students had higher physical activity than women students,the results indicate that this variable is associated with BMI among man participants, While these aren't the case with women, although it is believed that normal weight are more active than overweight or obese participants,whilst not the case with women, Although this is not the case in women, it is believed that normal weight are more active than obese participants ⁽⁹⁾.

So Otomo explained to lose weight, exercise more effective than other interventions⁽¹⁰⁾.Proven aerobic weight loss(66.78)%, so percentage the Cholesterol as(27.67%) and fat(86.42%),therefore significant effect of low impact aerobics, weight loss, fat percentage

and levels of cholesterol in women with obesity. This study also reveal that male (40%) doing exercise more than female (29%) and this is agree with another study occurred in Al-Najaf Al-Ashraf City⁽⁸⁾.

Conclusion

- Most of the students have a normal BMI (55.56%) and a normal waist-to-height ratio (67.32).
- Among secondary school students (34%) only have regular exercise, from them (46.15%) doing exercise 1-2 times weekly.

Conflict of Interest : None.

Genotyping Diversity of *Escherichia coli* isolated from UTI in Iraqi Patients

Tabarek Saeb Sabri¹, Amal A.Kareem¹

¹Middle Technical University ,College of Health and Medical Technology/Baghdad

Abstract

Background *Escherichia coli* (*E. coli*) is the predominant uropathogen isolated in acute, community-acquired uncomplicated UTIs in adults and children. **Pateints and Methods:** A total of (150) clinical samples (Urine) where collected from the patients at admission to the hospital in a sterile container. A loopful of uncentrifuged urine samples was cultured onto blood agar, MacConkey agar, HiCrome UTI Agar and EMB media, the diagnosis of *E.coli* bacteria was confirmed by using VITEK 2 system. Antimicrobial susceptibility testing of *E. coli* isolates was carried out against the antibiotics by Disc Diffusion Method ,ERIC PCR used for determined genotyping diversity. **Results:** *E.coli* showed antibiotic resistant to Garamycine (86%), Ciproflaxcin (66%), Ceftriaxone (46%) and Rifampcine (100%). The biofilm formation result showed out of 50 *E. coli* isolate (12%) were weak biofilm formation, (72%) were moderate biofilm formation and (16%) were strong biofilm formation. Genotyping by ERIC-PCR (Enterobacterial Repetitive Intergenic Consensus) of 50 *E.coli* isolates subjected to ERIC-PCR, 47 isolates have amplications ranging from 700 to < 3000bp The generated banding profile showed highly polymorphic DNA fragments in these 47 isolates **Conclusion** : : *E.coli* resistance to Garamycine (86%), Ciproflaxcin (66%), Ceftriaxone (46%) and Rifampcine (100%). The biofilm formation result 50 *E. coli* isolate (12%) were weak biofilm formation, (72%) were moderate biofilm formation. Genotyping by ERIC-PCR (Enterobacterial Repetitive Intergenic Consensus) of *E.coli* isolates subjected to ERIC-PCR, 47 isolates have amplications ranging from 700 to < 3000bp The generated banding profile was highly polymorphic DNA fragments in these isolates.

Key Words: *E.coli* ,UTI , ERIC PCR, Biofilm, genotype

Introduction

E. coli is a gram negative bacilli of the Enterobacteriaceae family, and it is commonly found in the intestines of warm-blooded animals. Most strains of *E. coli* are harmless, but some strains cause food poisoning, diarrhea, and urinary tract infections . Many bacteria can cause infection in the urinary tract. In fact, 80 to 90% of urinary tract infections in the world are caused by *E. coli* Extraintestinal pathogenic strains of *E. coli* that cause urinary tract infections in humans are known as uropathogenic *E.coli*¹. Urinary tract infections (UTI) are the most common bacterial infections which are characterized by bacterial colonization of the urinary system and often occur in women of all age groups. The strains of uropathogenic *E. coli* are the most common pathogens isolated from UTI patients and often originate from the intestinal flora. The most common UTI symptom is dysuria which may be moderate or severe . In addition to common symptoms of the lower UTI, patients with the

upper UTI or pyelonephritis may experience flank pain, fever, or nausea and vomiting . *E. coli* is responsible for 80–90% of UTIs; the remaining UTIs are caused by *Staphylococcus saprophyticus*, *Citrobacter*, *Klebsiella*, and *Enterobacter*². In various human diseases induced by *E. coli*, pathogenic *E. coli* is generally divided into two main categories: diarrheagenic *E. coli* and extraintestinal pathogenic *E. coli* which have two major pathotypes, uropathogenic *E. coli* and neonatal meningitis *E. coli* Extraintestinal bacteria can colonize different sites and cause various infections outside the gastrointestinal tract, with the urinary tract being most commonly affected³. Knowledge of the epidemiology of microbial populations is important in the field of medical microbiology. It is possible to identify infection reservoirs, examine the prevalence of hospitalization infections, and identify the type of microbial pathogenic agents via molecular typing¹. Molecular typing can be used to identify nosocomial infections and infection

reservoirs and also to isolate specific genotypes in conjugation with a specific bacterium. Besides, it gives us more knowledge about the principles of epidemiology, evolution, and spread of many bacterial diseases⁴. With the development of molecular biology techniques, We believe that Enterobacterial repetitive intergenic consensus-polymerase chain reaction (ERIC-PCR) methods could resolve the genotypes of the large number of O antigen serotypes, thereby enabling identification of an appropriate immunogenic strain. These researchers determined the sequence distribution and copy numbers on chromosomes for ERICs and showed interspecies specificity. This technique can be used in strain typing of ETECs based on their unique numbers and sizes of pattern⁵.

Patients and Methods

A total of (150) clinical samples (Urine) were collected from the patients at admission to the hospital in a sterile container. A loopful of uncentrifuged urine samples was cultured onto blood agar, MacConkey agar, HiCrome UTI Agar and EMB media, the diagnosis of *E.coli* bacteria was confirmed by using VITEK 2 system (Biomérieux, France). Disc Diffusion Method (Kirby-Bauer Method) used to determine AB sensitivity test⁶. Biofilm assay using (microtiter plate method)⁷. The oligonucleotide primers supplied by Integrated DNA Technologies Company (IDT) / USA. PCR using ERIC primers ERIC-IR CATTAGGGGTCCTCGAATGTA ERIC-2 AGTAAGTGACTGGGGTGAGCG was used to identify strains⁸. The PCR tubes were transferred to the

thermal cycler to start the amplification reaction according to specific program for the gene. PCR amplification programs were Initial Denaturation 94°C 3 min, Denaturation 94°C 1 min 40, Annealing 55°C 1 min, Extension 72°C 5 min, Final Extension 72°C 10 min.

Finding

Distribution of *E. coli* Isolates According to Gender:

According to the gender, the incidence of *E. coli* isolates among patients with UTI showed a remarkable difference in percentage of *E. coli* isolation. It was noticed that the percentage of *E. coli* isolation was high in females (90%) in comparison with males (10%), as shown in table (1). This result agrees with many studies as well as with local study by Basima⁹ in Baghdad City, who recorded that *E. coli* was isolated with a percentage of (81.8%) from female with UTI and (18.2%) from male. This higher frequency of UTI caused by *E. coli* in females than males is due to several causes, such as the shortness of the female urethra and close proximity of the perianal region of the urethral meatus to the vagina and anus and alternations in vaginal microflora that play a critical role in encouraging vaginal colonization with coliforms which may lead to UTI¹⁰. On the other side, this study disagrees with Tawfiq¹¹, that showed the bacterial cultivation had revealed positive results in (54.5%) of males and (45.5%) in females¹². The UTI in female is influenced by several risk factors such as; marital status, number of child, operation history, delivery methods and other factors¹³.

Figure (1): The isolation of *Escherichia coli* according to the gender.

Distribution of clinical states with *Escherichia coli* according to age groups:

The clinical samples of present study were recovered from patients their age ranged from 17 to 64 years.

Figure (2): The isolation of *Escherichia coli* according to the age group.

The study recorded more than half of the isolation rate in UTI state was among the age (30-39) years and (40-49) years with (26%), while other local study have reported (30.51%) with age (>35 years) with UTI caused by *E. coli*¹³. And other study in Nigeria have reported (22.4%) with age (>45) years with UTI caused by *E. coli*¹⁴. Other study in Ethiopia have reported (20.6%) with age (36-45) years with UTI caused by *E. coli*¹⁵.

Disc Diffusion Test (DDT):

Antimicrobial susceptibility tests were done for all *E. coli* isolates (50 isolates) by using the disk diffusion method (Kirby-Bauer Method) against 4 different clinically important antimicrobials (Ceftriaxone, Ciprofloxacin, Gentamicin, Rifampicine) (Appendix III). These isolates showed different susceptibility toward antimicrobials used in this study. The susceptibility to different antimicrobials was determined depending on¹⁶.

The result illustrated in Figure (3) show a high resistance level of *E. coli* isolates to most of the antimicrobials. The present study showed a highest resistance to Rifampicine (100%) and Garamycine (86%). Other findings revealed that *E. coli* isolates had resistance to Ciproflaxcine (66%) and The lower percentage of resistance was recorded to Ceftraxone (46%). All isolated *E. coli* show resistance to one or more antimicrobial agents.

Figure (3): Percentage of resistant *E. coli* isolates against some antibiotics.

Rifampicine is the first “broad spectrum” Rifampicine are components in the first-line treatment of bacterial infections, As with many antibiotics, the clinical utility of these therapeutics has declined due to the increased incidence of antibiotic resistant bacterial pathogens, Resistance to the rifamycin family of antibiotics commonly occurs in clinical isolates as a result of point mutations in the antibiotic’s target¹⁷. The study findings showed that all *E. coli* isolates were resistant to Rifampicine with percentage (100%).The resistance level of *E. coli* against gentamicin was obtained in this study (86%). while the result of present study is lower than the result obtained by¹².

in Ethiopia have reported that resistance was (67.7%). And other study in Mexico have reported (50%) done by¹⁷. Another study obtained by ¹⁸. in Mongolia, who found that resistance was (44%).The study showed resistance to Ciproflaxcine with percentage (66%) other study in Ethiopia have reported (57.7%) done by ¹⁰. while the result of present study is lower than the result obtained by ¹⁹. in Mongolia, who found that resistance was (42%).The ciprofloxacin are an important class of antibiotics prized for their large spectrum of activity and ease of use in oral versus parental forms, but emerging resistance to these antibiotics is limiting their usefulness ²⁰. Ceftriaxone is a third-generation cephalosporin class used to treat infections caused by Gram negative bacilli especially *E. coli* ²¹. The low resistance level of *E. coli* against Ceftraxone was obtained in this study (46%) other local study in Zakho have reported (52%) done by ²².

Biofilm-forming ability of 50 *E. coli* isolate

Biofilm formation has been described as an important virulence factor in various pathogenic bacteria causing human UTI.A total 50 *E. coli* isolated from UTI were divided into three groups : weak, moderate, strong biofilm formation(figure 4).The result showed out of 50 *E. coli* isolate (12%) were weak biofilm formation, (72%) were moderate biofilm formation and (16%) were strong biofilm formation, This study disagree with ²³. in Iran who found the biofilm formation was seen in 100% of isolates, of which (48.6%) were strong, (11.4%) were moderate .

Table (1): Biofilm Formation results using plate method depending on OD Value.

Biofilm -forming ability	Mean (%)	Percentage%
weak	0.0985	(12%)
Moderate	0.1623	(72%)
strong	0.3017	(16%)

<0.120 Weak biofilm producer ; 0.120-0.240 Moderate biofilm producer; >0.240 Strong biofilm producer

Genotyping by ERIC-PCR of *Escherichia coli* isolate from UTI cases:

Figure (4): Analysis of ERIC genotyping of *E. coli* isolates on agarose gel (1%) at 5 V/cm for 1 hour. Lane(L): 3000bp DNA Marker. A - Lane(+,-):control isolates from the present study isolates. Lane (1-17) showing ERIC-PCR fingerprint of *E.coli* isolates; B- Lane (18-34) showing ERIC-PCR fingerprint of *E.coli* isolates; C- Lane(L): 3000bp DNA Marker. Lane(+,-):control isolates from the present study isolates. Lane (35-50) showing ERIC-PCR fingerprint of *E.coli* isolates.

Of 50 *E.coli* isolates subjected to ERIC-PCR, 47 isolates have amplications ranging from 700 to < 3000bp (figure 4). The generated banding profile showed highly polymorphic DNA fragments in these 47 isolates (4, 12, 13, 14, 15, 16,17).ERIC-PCR was formerly reported in clinical isolates of *E. coli* in India by ²⁴,and by have been recorded in ¹. ERIC was also recorded in other type of *E.coli* such as enterotoxigenic *Escherichia coli* (ETEC) ⁵.

Phylogenetic Analysis:

In molecular typing phylogenetic tree, there were 100% matching in several strains as showing in figure

(5), such as (9&16) who both showed moderate biofilm production, while in antibiotic strain number 9 was moderate to Ciproflaxcine, while strain 16 was resistant to all antibiotics.Strain number (43&49) also where identical, strain 43 showed strong biofilm production while 49 showed weak biofilm production, strain 43 was resistant to all antibiotics and strain 49 was moderate to Ciproflaxcine and Ceftraxone.Strain number (40&47) both where moderate biofilm production, strain 40 was resistant to all antibiotics, while 47 was moderate to Ciproflaxcine and Ceftraxone.Strain number (41&44) both where moderate biofilm production, and both were resistant to all antibiotics.

Figure (5): Neighbor-joining trees based on ERICgene molecular typing .

Conclusion

1- *E. coli* isolation was high in females than with males and more than half of the isolation rate in UTI state was among the age (30-39) years and (40-49) years.

2- High resistance level of *E. coli* isolates to most of the antimicrobials and highest resistance to Rifampicine and Garamycine .

3- *E. coli* isolate (12%) were weak biofilm formation, and (72%) were moderate biofilm formation and Of 50 *E. coli* isolates subjected to ERIC-PCR, 47 isolates have amplications ranging from 700 to < 3000bp .

4- In molecular typing phylogenetic tree, there were 100% matching in several strains , such as (9&16) who both showed moderate biofilm production, while in antibiotic strain number 9 was moderate to Ciproflaxcine, while strain 16 was resistant to all antibiotics. Strain number (43&49) also where identical, strain 43 showed strong biofilm production while 49 showed weak biofilm production, strain 43 was resistant to all antibiotics and strain 49 was moderate to Ciproflaxcine and Ceftraxone..

Abstract

Diabetes mellitus is a progressive catastrophic medical condition, associated with serious acute and chronic complications. Despite the significant improvement in the diagnostic techniques, it is estimated that up to 50% of diabetic patients are unaware of their disease, especially those with type 2 diabetes mellitus. The impaired fasting glucose, defined as fasting blood glucose 70-100 mg/dl, has been recognized as a major risk factor for the development of type 2 diabetes mellitus. Aim of the study: To investigate the use of HbA1c as an alternative to fasting blood glucose (FBG) in the diagnosis of impaired fasting glucose. Materials and methods: The study involved apparently healthy individuals, attended a private medical laboratory for routine medical checking. Two aspects were followed, dividing participants into 4 groups, group 1 with normal FBG, group 2 with FBS 100-125 mg/dl, group 3 with HbA1c < 5.7%, and group 4 with HbA1c of 5.7%-6.4 %. Group 1 and 2 were investigated for FBS, while group 3 and 4 were investigated for HbA1c. Results: A total number of 312 subjects were included in the current study, with a variable number of individuals in each group. The results of HbA1c were statistically compared with the results of FBG. The sensitivity of HbA1c in the diagnosis of impaired fasting glucose was 80%, and the specificity was 66.4% only while the positive and negative predictive values were 81.4% and 64.6% respectively.

Conclusion: HbA1c should be used with caution in the diagnosis of impaired fasting glucose.

Keywords: prediabetes; HbA1c; IFG; sensitivity; specificity.

Introduction

Diabetes mellitus represents a major global health problem of increasing prevalence. It is associated with a high incidence of morbidity and mortality due to its both acute and chronic complications. Many conditions are known to increase the risk of development of diabetes mellitus, primarily type 2, the most important of which is the presence of impaired fasting glucose (IFG)⁽¹⁾. Prediabetes represents an intermediate state between normal hemostasis of glucose and frank diabetes mellitus; it is classified into two primary forms, impaired glucose tolerance (IGT) and the impaired fasting glucose. According to the American Diabetes Association (ADA), IFG is defined as fasting blood glucose (FBG) 100-125 mg/dl while IGT is defined as a blood glucose of 140-199 mg/dl 2 hours after a 75 g oral glucose⁽²⁾. The prevalence of prediabetes is widely variable with an expected increasing prevalence in the

foreseeable future. It is estimated that the prevalence of prediabetes is within the range of 9-40%⁽³⁾. Many factors are claimed to affect the distribution of prediabetes including age, sex, and ethnic group; for example, IGT is more frequent in women than in men whereas IFG is more prevalent in men⁽⁴⁾. The progression of prediabetes into frank diabetes mellitus remains a universal concern regardless the exact definition of prediabetes, 5-10% is the annual incidence of development of diabetes mellitus in subjects with prediabetes, and within 10 years, 70% of them will develop diabetes mellitus⁽⁵⁾. To some extent, prediabetes can be considered as a discreet medical condition that is associated with specific physiological changes and specific complications⁽⁶⁾ including retinopathy, nephropathy, neuropathy, and cardiovascular complications⁽⁷⁾.

Diagnosis of prediabetes is not uniform until the time being, the World Health Organization (WHO) defines

prediabetes as either:

- IFG: when FBG \geq 110 mg/dl and $<$ 126 mg/dl, with 2h post-load glucose of $<$ 140 mg/dl (if measured).
- IGT: when FBG $<$ 110 mg/dl, and 2h post-load glucose \geq 140 mg/dl and $<$ 200 mg/dl.

The ADA has applied slightly different criteria; for IGT, the same cut-off has been applied, while for IFG, a lower cut-off has been used (100-125 mg/dl). Furthermore, ADA has added HbA1c for the definition where a level between 5.7%-6.4% will indicate prediabetes⁽⁹⁾. Many disadvantages are present with applying these criteria for the diagnosis of prediabetes, of these disadvantages is the poor reproducibility of the results with day to day variation of 15% in respect to FBG and up to 46% in respect to 2-hour post-load glucose concentration making misclassification relatively common⁽¹⁰⁾. Besides, the progression to diabetes mellitus has been observed in subjects with levels of blood glucose concentration of less than the prediabetes level, making the full benefit of the prediabetes concept under the current definition questionable⁽¹¹⁾. Furthermore, the addition of HbA1c to the definition of prediabetes has its own disadvantage due to the so many factors that might affect the measured level of HbA1c.

Modalities of treatment of prediabetes include lifestyle modification, bariatric surgery, and pharmacological therapy, including various groups of antidiabetic drugs, where metformin has been intensively used for this purpose⁽¹²⁾.

Materials and Method

The current study was performed at a private clinical laboratory during the period between 20th October 2018 to 15th April 2019. It involved the estimation of FBS and HbA1c for adult individuals who attended the laboratory for routine checking. A total number of 312 apparently healthy adults were randomly selected after applying the exclusion criteria. All participants have been questioned about any current or previous diseases or any current medications. Other information included age, weight, and height.

Informed consent was obtained from all individual participant included in the study.

For each participant, BMI was calculated; FBS, HbA1c, complete blood count, blood urea, serum creatinine, and serum ALT were estimated.

The exclusion criteria were:

1. Patients with diabetes mellitus of any type, regardless of his treatment.
2. Patients on drugs that might affect blood glucose level, emphasizing on steroid, and thiazide.
3. Patients with endocrinal disorders, with or without treatment.
4. Patients with anemia of any type.
5. Patients with acute illness, including a psychiatric one.
6. Pregnant females.

The history and laboratory results were used to apply these criteria.

FBG of 70-99 mg/dl was regarded as normal.

Impaired fasting glucose was defined as FBS 100-125 mg/dL.

Reference range of HbA1c was 4.8 - 5.6 %.

The participants were grouped according to their sex, BMI, FBS, and HbA1c, followed by statistical evaluation of these groups.

The main laboratory devices used were:

Tosoh G7 for assessment of HbA1c using HPLC technique.

SelectraproS for biochemical tests.

finding :

A total number of 312 subjects were involved in the current study fulfilled the selective criteria. Sex distribution of the studied group was as follows:

- Male: 121
- Female: 183

BMI was calculated according to the following equation:

BMI=

Table 1: The distribution of BMI of the studied group.

BMI	Number	Percentage
<25	119	38%
25-30	112	36%
30-35	81	26%

Mean BMI was 27.3 kg/m²; the distribution of individuals according to BMI is shown in table 1.

Table 2: Number and percentage of participants according to their FBG and HbA1c.

FBS (mg/dl)	Number	Percentage
<100	110	35
100-125	202	65
HbA1c (%)		
<5.7	218	73
5.7-6.4	94	27

The participants were classified according to their FBS and HbA1c into further groups as shown in table 2.

Table 3: Groups of participants according to their combined results of FBG and HbA1c.

Result	Number	Percentage
FBS 100-125 with HbA1c >5.7%	162	80
FBS 100-125 with HbA1c <5.7%	40	20
FBS <100 with HbA1c >5.7%	37	33.6
FBS <100 with HbA1c <5.7%	73	66.4

The results of the current study have shown that only 162 individuals with FBS of 100-125 mg/dl had HbA1c 5.7-6.4%, while the other 40 individuals with FBS of 100-125 mg/dl had HbA1c <5.7%. At the same time, the results of the current study have shown that only 73 individuals with FBS <100 mg/dl have HbA1c <5.7%, while the other 37 individuals with FBS <100 mg/dl have HbA1c >5.7%, as shown in table 3.

Accordingly, and using FBS as a reference, the sensitivity and specificity of HbA1c in the diagnosis of IFG will be as follows:

Sensitivity =

= 80%

Specificity =

= 66.4%

Positive predictive value =

= 81.4%

Negative predictive value =

= 64.6%

In the estimation of the effect of BMI on HbA1c and IFG, the results of the current study have shown that individuals with BMI >25, and HbA1c >5.7% were 61 of 94 (65%), while individuals with BMI ≥25 and FBS >100 were 141 of 202 (70%), but despite the percentage of these two groups are very close, the individuals are not the same in the two groups.

At the same time, the results of the current study have shown that individuals with BMI ≥25 and HbA1c <5.7% were 143 of 218 (66%) while individuals with BMI >25 and FBS < 100 were 80/110 (73%), again, the individuals are not the same in these two groups as might be expected.

For those with a BMI of < 25, and in the scope of their blood levels of FBG and HbA1c, it was noticed that individuals with BMI <25 and HbA1c ≥5.7% were 33 of 94 (35%) while individuals with BMI <25 and FBS ≥100 were 61 (30%).

Likewise, individuals with BMI <25 and HbA1c <5.7% were 75 (34%) while individuals with BMI <25 + FBS < 100 were 30 (27%). Using SPSS version 21, there was a significant correlation between BMI and HbA1c level, while there was no significant correlation between BMI and FBG.

Discussion

Evaluation of glycated hemoglobin (HbA1c) in blood represents evidence about the individual’s mean blood glucose levels during the previous two to three months, which represents the expected half-life of red blood cells (RBCs). Logically, HbA1c level should be directly related to the mean glucose level in healthy individuals, diabetic patients, and in our case, individuals with IFG, but in fact, this is not always the

rule especially in individuals with IFG as we will discuss here.

The increasing evidence about the poor reproducibility of both FBG and HbA1c necessitate a persistent evaluation of their use in the diagnosis of IFG; furthermore, the comparison between these two markers has not reached the final destination; this is why searching for a new biomarker is persistent.

Taking the result of FBG as a reference, the current study has shown that the sensitivity of HbA1c in the diagnosis of IFG is 80% and the specificity of it is 66.4%. Accordingly, It is obvious that HbA1c carries an accepted sensitivity rate in the diagnosis of IFG, but unfortunately, a relatively low specificity. At the same time, the positive and negative predictive value of HbA1c in the diagnosis of IFG were 81.4% and 64.6% respectively. The vast number of studies that thoroughly investigated this subject have shown a significant variation, although most of them have suggested a precaution with the use of HbA1c for this purpose. Fangjian Guo, in his large study that has included 5359 individuals between 2005 and 2010, has shown a poor sensitivity of HbA1c for detection of IFG (35.4%) with better specificity (64.9%)⁽¹³⁾.

A much higher result has been revealed by Pedapati Radhakrishna and his group, where the sensitivity was 81%, and the specificity was 80%⁽¹⁴⁾. Another similar study has shown a sensitivity of 62% and specificity of 77%⁽¹⁵⁾. The most surprising results have been demonstrated by Nicole R. Pinelli, and his colleagues where the sensitivity was extremely low (14%), while the specificity was extremely higher (91%)⁽¹⁶⁾.

A summary of other similar studies is shown in table 4 with mentioning of positive and negative predictive value when available.

Table 4: Examples of similar studies with the sensitivity and specificity of each one.

Study	Sensitivity (%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
Current study	80	66.4	81.4	64.6
Fangjian Guo et al(13)	35.4	64.9		
Pedapati Radhakrishna et al(14)	81	80		
A. Bhansali et al(15)	62	77	57	55

Cont... Table 4: Examples of similar studies with the sensitivity and specificity of each one.

Nicole R. Pinelli(16)	14	91		
M. Norberg et al(17)	90	42	8	
Arnold M. et al(18)	40-58	73-84		
Zhang Y et al(19)	35.2	86.4		

Despite the significant variation in the results of these studies, and many others as well, nearly all the results are pointing to a common conclusion which suggests a relatively poor correlation between HbA1c level and diagnosis of IFG.

Conclusion

The results of the current study suggest that:

1. HbA1c should be used with caution in the diagnosis or exclusion of IFG.
2. There is a significant impact of obesity on the level of HbA1c.

Evaluation the Serum Level of Melatonin in Iraqi Patients with Polycystic Ovarian Syndrome

Ahmed Abduljabbar Hameed¹, Mutaz Sabah Ahmeid²

¹Obstetrics and Gynecology of alzahra'a Hospital, Almosyab City, Iraq, ² M.B.Ch.B., M.Sc., Ph.D. in clinical biochemistry, College of Medicine, Tikrit University, Iraq

Abstract

Background: Polycystic Ovarian Syndrome(PCOS) is one of the most frequent gynecological endocrinopathy that occur in premenopausal females, with a predominance range from 6%to10% among women of reproductive age.Melatonin (N-acetyl-5-methoxytryptamine), an neurohormone synthesized from the aromatic amino acid tryptophan mainly by the pineal gland of humans.The important of melatonin in human reproduction is still unidentified. A numerous study suggests that melatonin and reproductive hormones are closely related. This concept is based on observation of influence melatonin on sex steroid production at different stages of ovarian follicular maturation as melatonin receptors have been demonstrated at multiple sites in ovary and in intrafollicular fluid. **Aim :**The study aim to evaluate the role of melatonin in women with polycystic ovarian syndrome. **Materials and Methods:**A prospective cross-sectional study was designed taking 60 PCOS patients and 30 controls women whose ages were between 15-35 years old, from beginning of January 2019 to ending of April 2019. These patients admitted to obstetrics and gynecology unit at Babylon teaching hospital. And Five ml of blood sample was taken on day 2 of menstrual cycle by vein puncture from each subject enrolled in this study .Blood samples were collected between 07:00am – 08:00 am, and placed into sterile test tubes to serum melatonin estimation.**Result:** The study showed that there is the significant difference betweenPCOS women and the control group concerning melatonin level,and the highest mean of melatonin was occurred in PCOS women (61.21 ± 13.78 vs. 28.61 ± 6.73). And also This study showed that there were the higher means of melatonin in PCOS women with positive family history than PCOS women with negative family history (66.56 ± 11.25 vs. 59.26 ± 14.21) with significant relation. **Conclusions:** Women with PCOS have significant increase of serum melatonin in PCOS women. And also thisstudy could open the way for therapeutic role of melatonin in treatment of PCOS women.

Keyword : Melatonin ; Iraqi patients ;Polycystic Ovarian Syndrome

Introduction

Polycystic Ovarian Syndrome(PCOS) is one of the most frequent gynecological endocrinopathy that occur in premenopausal females⁽¹⁾, with a predominance range from 6%to10% among women of reproductive age⁽²⁾. It is characterized by hyperandrogenism (male hormone in female), menstrual disturbance, excess body and facial hair (hirsutism), acne, temperament disorder, endometrial cancer in addition, severe physiological disturbance are commonly detected among women with PCOS; for example, abdominal adiposity, inflammation, and infertility^(3,4,5). Polycystic ovarian syndrome diagnosis is based on two of the following three findings: Oligo- or anovulation, polycystic ovaries under ultrasonography,

and clinical or biochemical signs of hyperandrogenism⁽⁶⁾. Polycystic ovarian syndrome etiology and pathogenesis is still unknown, but some causative factors play important role in this syndrome such as hormonal disorders, adipose tissue dysfunction, oxidative stress have been blamed, but definitive consensus has not been reached⁽⁷⁾. However, in recent years, insulin resistance (IR) has been reported to play an important role in the progression of PCOS^(8,9,10). PCOS may present with metabolic abnormalities such as insulin resistance (IR) and visceral obesity at a young age. Long-term exposure to these abnormalities during fertile life may increase the reverse impacts and expose these women to higher risks of metabolic syndrome (MetS), cardiovascular diseases (CVDs) and type II diabetes mellitus (T2DM)

(11). While, melatonin (N-acetyl-5-methoxytryptamine), an neurohormone synthesized from the aromatic amino acid tryptophan mainly by the pineal gland of humans⁽¹²⁾. As a neurohormone, melatonin has numerous important physiological function and regulates varieties of central and peripheral actions related to circadian rhythms and reproduction. It act as a broad-spectrum antioxidant, powerful free radical scavenger, anti-inflammatory agent, potential immunoregulator, anticarcinogenic effector, sleep inducer, and regulator of the circadian rhythm in the body⁽¹³⁾. The important of melatonin in human reproduction is still unidentified. A numerous study suggests that melatonin and reproductive hormones are closely related⁽¹⁴⁾. This concept is based on observation of influence melatonin on sex steroid production at different stages of ovarian follicular maturation as melatonin receptors have been demonstrated at multiple sites in ovary and in intrafollicular fluid. Also several studies found that increased of melatonin concentration in serum of women with PCOS, and also indicating a feedback mechanism due to reduced melatonin concentration at the level of ovarian follicles. This could interpretation role of melatonin in the pathogenesis of PCOS⁽¹⁵⁾. The study aim to assess the role of melatonin in women with polycystic ovarian syndrome. Objectives: Clarify the relation of serum melatonin in PCOS women and the control group and Evaluate the association some clinical symptoms in PCOS women.

Materials and Method

Study design: A prospective cross-sectional study was designed taking 60 PCOS patients and 30 controls women whose ages were between 15-35 years old, from beginning of January 2019 to ending of April 2019. These patients admitted to obstetrics and gynecology unit at Babylon teaching hospital. An interview was carried out with these patients using questionnaire form designed by the investigator including their demographic characteristics, age, weight, length, BMI... etc.

Study population:

Inclusion criteria for selection of cases women:

The Rotterdam European Society for Human Reproduction and Embryology/American Society for Reproductive Medicine (ESHRE/ASRM) this criteria was used to diagnose PCOS and women with presence of any two of the following three features were included in the study:

- Menstrual disturbance or irregular.
- Clinical and/ or biochemical hyperandrogenism (hirsutism, acne, and alopecia)
- Polycystic ovaries morphology under ultrasound (more than 12 follicles in one or both ovaries, 2-9mm in diameter and/ or increased ovarian volume more than 10 ml).

Inclusion criteria for selection of controls women:

- Regular menstrual cycle
- Normal androgen, without (hirsutism, alopecia, and acne)
- Absence of polycystic ovary morphology under ultrasound
- Normal biochemical parameters including (S.Melatonin).

Exclusion criteria: All patients with metabolic or endocrinology disorders including thyroid disorder, diabetes mellitus, hypertension, Cushing's syndrome, acromegaly, premature ovarian failure, virilising adrenal or ovarian tumors, and history of using contraceptive through last of sex months were excluded from this study.

Sampling: Five ml of blood sample was taken on day 2 of menstrual cycle by vein puncture from each subject enrolled in this study .Blood samples were collected between 07:00am – 08:00 am, and placed into sterile test tubes, after blood clotting, centrifuged at 2500 RPM for 15 minute then clot removed and remain re-centrifuged at 2500 RPM for 10 minute and the obtained serum were aspirated using mechanical micropipette and transferred into clean test tubes which labeled and stored in deep freeze at -20 c for serum melatonin measurement.

Statistical Analysis

Computerized statistically analysis was performed using SPSS statistic program version 16.1. Comparison was carried out using; Chi-square(X^2) and T-Test probability (P value).

Finding

Comparison of age in PCOS and Control women.

A total of 60 PCOS women and 30 non PCOS women (control group) were examined for (melatonin).

Their age range group were between (15-35) years, showed in Table 1.

Table 1: Comparison of age in PCOS and Control women.

Age	PCOS group	Control group
No.	60	30
Mean	24.25	23.63
SD	5.12	4.06
P- Value	NS	

Comparison of melatonin level with PCOS women.

The study showed that there is the significant difference between PCOS women and the control group concerning melatonin level, and the highest mean of melatonin was occurred in PCOS women (61.21 ± 13.78 vs. 28.61 ± 6.73), showed in Table 2.

Table 2: Comparison of melatonin and PCOS.

Serum Melatonin (ng/ml)	PCOS group	Control group
No.	60	30
Mean	61.21	28.61
SD	13.78	6.73
P- Value	< 0.05	

Comparison of Melatonin with Family History in PCOS women.

This study showed that there were the higher means of melatonin in PCOS women with positive family history than PCOS women with negative family history (66.56 ± 11.25 vs. 59.26 ± 14.21) with significant relation, showed in Table 3.

Table 3: Comparison of melatonin and family history in PCOS.

Melatonin	Negative family history	Positive family History
No.	44	16
Mean	59.26	66.56
SD	14.21	11.25
P- Value	< 0.05	

Discussion

PCOS with Age :

Our study it was found that there was no significant difference between PCOS women and control group concerning age (24.25 ± 5.12 vs. 23.63 ± 4.06), Table 3.1, and Figure 3.1. This agreement with (Guilherme

Barbosa, *et al.*)⁽¹⁶⁾ study, that found PCOS affects women of childbearing age without higher prevalence by ethnic groups, but the signs and symptoms may differ by ethnicity. And disagreement with (Chhabra,*et al.*)⁽¹⁷⁾ who reported that PCOS varies with age but continues to be more common among women aged less than 35 years than in those above 35 years, this finding could be

attributed to that the women in that age are physiological active concerning the fertility and ovulation.

Melatonin level with PCOS.

The study showed that there is the significant difference between PCOS women and the control group concerning melatonin level and the highest mean of melatonin was occurred in PCOS women compared with control group (61.21 ± 13.78 vs. 28.61 ± 6.73), Table 3.2, and Figure 3.2.

Melatonin is normally synthesized in the ovary, as both melatonin synthesizing enzymes AANAT (arylalkylamine N-acetyltransferase) and HIOMT (hydroxyindole-O-methyl transferase) are present in ovarian tissue⁽¹⁸⁾. The study by (Tenorio,*et al.*)⁽¹⁹⁾ found that, the presence of melatonin receptors in the follicular cells of rats and mice, suggests possible melatonin production in the ovary. Its well-documented role as an antioxidant may be associated with follicular development and oocyte quality, interfering in processes such as oocyte maturation and ovulation⁽²⁰⁾. Melatonin, synthesized by the ovary, may be released into the follicular fluid. However, the capacity of melatonin detected in the ovary and preovulatory follicular fluid is derived from the circulation. There may be a reduction in the uptake of melatonin from circulation into the ovarian follicles of PCOS cases due to anovulation and increased number of atretic follicles and consequently serum melatonin concentration may increase in PCOS as a feedback response to decreased follicular concentration⁽¹⁵⁾. This study agreement with (Murcia-García,*et al.*)⁽²¹⁾, Experimental studies with female rats and hamsters reported that removal of the pineal gland leads to a decrease in melatonin levels with consequent premature vaginal opening, ovarian hypertrophy, increased cornification of vaginal cells and chronic anovulation, effect that can be reversed after administration of melatonin⁽²²⁾. The reduction of melatonin ovary can decrease embryo implantation, as well as interfere with pregnancy when rats are subjected to short photoperiods, showing an increase in melatonin levels accompanied by depressions in follicle stimulating hormone (FSH) and reduction in follicle development, becoming anestrous⁽¹⁹⁾. And also with (Woo,*et al.*)⁽²³⁾ study, found the expression of receptors for melatonin MT1 and MT2 has been identified in human reproductive tissues, including the mammary epithelium, myometrium, ovary and granulosa-luteal cells. In females, the influence of melatonin on the reproductive

function can be inferred from studies that indicate that high levels of melatonin cause amenorrhea⁽²⁴⁾, disturbance in gonadotropin secretion and the secretion of prolactin in response to the photoperiod⁽²⁵⁾. Studies have suggested that melatonin has a role in ovarian physiology, given that high concentrations of melatonin have been detected in follicular fluid⁽¹⁹⁾.

Melatonin and Family History in PCOS women.

The study showed that there is the significant difference between positive family history and negative family history concerning melatonin level and the highest mean of melatonin was occurred in positive family history compared with negative family history in PCOS women (66.56 ± 11.25 vs. 59.26 ± 14.21), Table 3.3 and Figure 3.3.

Our result agreement with (Sirmans,*et al.*)⁽²⁶⁾ study, that found family history of PCOS is a risk factor for PCO. Based on the clustering of cases in families, PCOS is considered to be a heritable disorder. A high prevalence of PCOS or its feature among first-degree relatives is suggestive of genetic influences. A increased prevalence of PCOS is associated with a number of condition. A history of weight gain often precedes the development of the clinical features of PCOS, and following healthy lifestyle has been shown to reduce body weight, abdominal fat, reduce testosterone, improve insulin resistance, and decrease hirsutism in women with PCOS. And also with (Begum,*et al.*)⁽²⁷⁾ study, that found The presence of a genetic component to PCOS and familial clustering of reproductive and metabolic abnormalities results in increased risk of PCOS among first-degree relatives of PCOS patients. This is evident agree with our study results where participants with a positive family history of PCOS carried little higher risk of development of PCOS.

Conclusions

- 1- There was significant increase of melatonin in PCOS women.
- 2- There was significant increase of melatonin with positive family history in PCOS women.

Relation of Some Heavy Metals with Male Infertility

Hussein M. Ali¹, Qater, Al-Nada A. Kanaem², Mohammad Oda Selman³

¹Al-wasti hospital / Ministry of Health, ² College of Health and Medical Technics, Middle Technical University, Baghdad, Iraq, ³Al-Nahrain University/ high institute of infertility diagnosis and assisted reproductive technologies

Summary

Background: Infertility is defined as a failure of achieve a pregnancy after one year and more of regular unprotected sexual intercourse. The exposure of reproductive system especially the testis to heavy metals has also been associated with male infertility. A large number of metals are toxicants to the reproductive system. **Patients and methods:** Study was performed at the high institute of infertility diagnosis and assisted reproductive technologies in Al-Nahrain University and the Poisoning consultation center / specialized surgeries hospital in the Medical city during the period from November 2018 to April 2019. A total number of 150 men were enrolled in this study who were divided into two groups, the patient and the normal control groups. The patient group included 100 men aged between 20-50 years. The second group included 50 healthy men who have at least two children without any previous history of systemic diseases as a control group. Heavy metals and trace element concentrations were estimated for all the study groups in this study. The aim of current study are evaluation of some trace element concentrations, in serum and whole blood of infertile men and healthy controls. **Results:** The heavy metals Cu, Pb and Cd showed a highly significant increase ($p < 0.01$) in the serum and blood of infertile men ($159.77 \pm 8.49 \mu\text{g/dl}$, $24.18 \pm 4.30 \mu\text{g/dl}$, $0.31 \pm 0.10 \mu\text{g/dl}$) respectively when compared with their concentrations in healthy control men ($125.14 \pm 10.12 \mu\text{g/dl}$, $15.74 \pm 2.69 \mu\text{g/dl}$, $0.16 \pm 0.03 \mu\text{g/dl}$) respectively. The mean levels of Zn showed a highly significant decrease ($p < 0.01$) in the serum of infertile men ($70.82 \pm 9.48 \mu\text{g/dl}$) compared to its mean level in the healthy control group ($95.70 \pm 11.41 \mu\text{g/dl}$). **Conclusions:** this study concluded that some heavy metals were shown to be an indicators for men infertility.

Keywords: heavy metals infertility male reproductive.

Introduction

Infertility was defined as inability to conceive after one year of regular unprotected intercourse⁽¹⁾. Infertility is an ever increasing phenomenon in the modern urban societies⁽²⁾, and generally, infertility affects about (10-15%) of the couples in the world. The cause of infertility in about (10%) of cases remains unexplained, and the couples are designated as normal infertile couples⁽³⁾. Male infertility is a common disorder that affects approximately (50%) of infertility cases in the world⁽⁴⁾. Male fertility depends upon the coordination between neural and hormonal mechanisms or between male reproductive system and these mechanisms. Thus, any hindering of at least one of these mechanisms will result in infertility⁽⁵⁾. The trace elements are micro nutritive elements that exist in minute quantities within the body mass and they are either important via playing different functional roles in the body or non-essential

elements with negative effect on the human body even at very low concentrations⁽⁶⁾. Heavy metals are usually dense elements with potential toxicity, especially in environmental context⁽⁷⁾. They can be naturally obtained from the earth crust, and became concentrated because human activities. Heavy metals can enter human tissues via food, inhalation and manual handling⁽⁸⁾. Skin contact absorption, for instance soil contact, is another possible source of body contamination by heavy metals⁽⁹⁾. Because they are difficultly metabolized, toxic heavy metals can bioaccumulate in human's body⁽¹⁰⁾. Those heavy metals may combine with and interfere with the vital cellular element functions⁽¹¹⁾. Because of sperm's oxidative damage and testicular apoptosis, exposure to heavy metals has also been associated with male infertility⁽¹²⁾. Increase in fertility associated with higher miscarriage rates have been noted in the partners of men working in lead battery factories, indicating harmful effects of heavy metals on reproductive success⁽¹³⁾.

Materials and methods:

Study was performed at the high institute of infertility diagnosis and assisted reproductive technologies in Al-Nahrain University and the Poisoning consultation center / specialized surgeries hospital in the Medical city during the period from November 2018 to April 2019. A total number of 150 men were enrolled in this study who were divided into two groups, the patient and the normal control groups. The patient group included 100 men aged between 20-50 years. The second group included 50 healthy men who have at least two children without any previous history of systemic diseases as a control group. Heavy metals and trace element concentrations were estimated for all the study groups

in this study. Frozen serum was allowed to thaw at room temperature, and assessment of inorganic elements Zn and Cu was performed by Flame atomic absorption spectrophotometry, while Cd was measured by graphite furnace atomic absorption spectrophotometry.

Finding

results indicated that 78 (78%) of the 100 cases had abnormal zinc levels, while 22 (22%) of them had normal zinc levels in comparison with the control group which showed that 46(92%) had normal zinc levels and only 4 (8%) had abnormal zinc levels, with a highly significant difference using the Monte Carlo test MCP < 0.01. As shown in table (1).

Table (1) Descriptive statistic & MCP test between cases and control of serum zinc

Zn Level	Cases		Control	
	No.	percentage%	No.	percentage%
Normal	22	22	46	92
Abnormal	78	78	4	8
Total	100		50	100

Cu Level	Cases		Control	
	No.	percentage%	No.	percentage%
Normal	20	20	50	100
Abnormal	80	80	0	0.0
Total	100	100	50	100

Table (2) Descriptive statistic & MCP test between cases and control of serum copper

While results in table (2) demonstrated that 80 (80%) of the 100 cases had abnormal copper levels, and 20 (20%) of them had normal copper levels when compared with the control group which showed that all the 50(100%) control group had normal copper levels, with a highly significant difference using the Monte

Carlo test MCP < 0.01.

Results of blood lead level estimation in table 3 showed that 33 (33%) of the 100 infertile patients had abnormal lead levels, and 67 (67%) of them had normal leadlevels, while all the control group 50 (100%) had normal lead levels, with a highly significant variation

using the Monte Carlo statistical test $MCP < 0.01$.

Table (3) Descriptive statistic & MCP test between cases and control of blood lead

Cd Level	Cases		Control	
	No.	percentage%	No.	percentage%
Normal	49	49	50	100
Abnormal	51	51	0	0.0
Total	100	100	50	100

Results of blood cadmium level estimation showed that 51(51%) of the 100 infertile patients had abnormal cadmium levels, and 49 (49%) of them had normal cadmium levels, while all the control group 50 (100%) had normal cadmium levels, with a highly significant difference using the Monte Carlo statistical test $MCP < 0.01$ as illustrated in table 4.

Table (4) Descriptive statistic & MCP test between cases and control of blood cadmium

Pb Level	Cases		Control	
	No.	percentage%	No.	percentage%
Normal	67	67	50	100
Abnormal	33	33	0	0.0
Total	100	100	50	100

Table (5): Descriptive statistics and t-test between patient group and control group regarding (Zn µg/dl, Cu µg/dl, Pb mg/dl, Cd µg/dl).

	Groups	N	Mean ±Std.	t-test	P-Value	C.S
Cu	Cases	100	159.77±8.49	22.065	.000	P<0.01(HS)
	Control	50	125.14±10.12			
Zn	Cases	100	70.82±9.48	14.140	.000	P<0.01(HS)
	Control	50	95.70±11.41			
Pb	Cases	100	24.18±4.30	12.684	.000	P<0.01(HS)
	Control	50	15.74±2.69			
Cd	Cases	100	0.31±0.10	10.478	.000	P<0.01(HS)
	Control	50	0.16±0.03			
	Control	50	450.35±131.27			

All the above results discern great variation in levels of heavy metals between the infertile male group and the control group suggesting that heavy metals have effect on male infertility. Results agreed with⁽¹⁴⁾who mentioned in a scientific literature a lot of data on the negative influences of the toxic metals on the human body⁽¹⁴⁾.⁽¹⁵⁾found increase in Cd and Cu concentrations in the serum of infertile men comparison with the control group⁽¹⁵⁾. Inhalation or dermal absorption of heavy metals can significantly increase blood heavy metal levels⁽¹⁶⁾. These findings were consistent with the other studies conducted in Baghdad, Beirut and Al-Najaf which demonstrated that the blood levels of lead, cadmium & other heavy metals were increased among many workers^(17&18&19).as depicted in table 5, the mean serum copper concentration in infertile men group was 159.77 ± 8.49 $\mu\text{g/dl}$, which was significantly higher than the mean serum copper concentration of the healthy control group 125.14 ± 10.12 ($p < 0.01$). Results agreed with⁽¹⁵⁾ who found a significant increase ($p \leq 0.05$) in the concentration of Cd and Cu in the serum of infertile men in comparison with the control group. However, many human studies found negative correlations between Cu quantified in the body and spermatozoa quality parameters such as morphology, motility and viability⁽²⁰⁾.⁽²¹⁾Indicated that high doses of Cu had negative effects on sperm motility⁽²¹⁾. Similar results were reported by⁽²²⁾ in human spermatozoa in Cu accumulation⁽²²⁾. Also showed that serum zinc concentration in infertile men group was 70.82 ± 9.48 $\mu\text{g/dl}$ which was a highly significantly lower than serum zinc of the healthy group 95.70 ± 11.41 ($p < 0.01$). This result was compatible with⁽²³⁾ who showed that serum zinc levels of patients with abnormal seminal fluid parameters were lower than those who have normal seminal fluid parameters⁽²³⁾, and similar to the results of⁽²⁴⁾ who showed significant variation between serum zinc of infertile group & fertile group⁽²⁴⁾. The most rapidly growing organs in the body are the gonads, and zinc metallo-enzymes are the vital enzymes involved in protein and nucleic acid synthesis, therefore, zinc deficiency can result in severe testicular damage, decreases of testicular weight, gonads dysfunction and seminiferous tubule shrinkage⁽²⁵⁾.Data demonstrated in table 5 showed that the mean blood lead concentration in infertile men was 24.18 ± 4.30 $\mu\text{g/dl}$, which was significantly higher than its concentration in the healthy control group 15.74 ± 2.69 ($p < 0.01$). These results were compatible with a study of⁽²⁶⁾ who found a highly significant variation between their study groups⁽²⁶⁾.And with⁽²⁷⁾ who found high levels of lead in the

infertile men in comparison with the controls⁽²⁷⁾. And also with⁽²⁸⁾ who found that Pb levels were significantly higher in infertile males ($p=0.001$) when compared with the control group⁽²⁸⁾. Our results were also compatible with the results of⁽²⁹⁾ which showed that seminal and blood plasma cadmium as well as blood plasma lead levels were significantly higher ($p < 0.01$) in azospermic and oligospermic men in comparison with normospermic men⁽²⁹⁾. Results shown in table 5 indicated that mean blood cadmium concentration in the infertile male group was $(0.31 \pm 0.10$ $\mu\text{g/dl}$), which was significantly higher than its mean concentration in the healthy control group $(0.16 \pm 0.03$ ($p < 0.01$). Our results were compatible with⁽²⁹⁾ who reported that seminal and blood plasma cadmium as well as blood plasma lead were significantly higher ($p < 0.01$) in azospermic and oligospermic men when compared with normospermic men⁽²⁹⁾. However,⁽³⁰⁾ observed significant correlations between blood cadmium levels, volume of semen and immature forms of spermatozoa suggesting the need of further studies on blood and semen cadmium levels⁽³⁰⁾. These results were in agreement with⁽¹⁵⁾ who showed a significant increase ($p \leq 0.05$) in the serum concentration of Cd and Cu in infertile group which included azospermia & oligospermia in comparison with the control group⁽¹⁵⁾.

Conclusions

The heavy metals Cu, Pb and Cd showed a highly significant difference in the serum and blood of infertile men compared to the healthy control men, indicating that the alteration in heavy metal metabolism may be related to the development and even progress of infertility among men. The mean levels of Zn showed a highly significant decrease in the serum of infertile men compared to the healthy control group, indicating that the alteration in zinc metabolism may be related to the development of infertility among men. Concentrations of heavy metals during the progress of life of infertile men were higher than those in healthy men. According to the results of the present study, all heavy metals were shown to be indicators for men infertility. The heavy metals should be monitored routinely in male infertility, which could be helpful in improving the general health conditions and reducing progression of the disease.

Abstract

Objectives: The present study designed to investigate the Immunological role of toll-like receptor-7,IL-17A and IL-10 in sera of 66 Chronic Renal Failure CRF patients at IBN-SINA center for Dialysis in Diyala governorate - Iraq.**Methods:** Sandwich Enzyme Linked Immuno-Sorbent Assay(ELISA) technique were used in this study to evaluate concentration of TLR-7 ,IL-17A and IL-10 between study groups.**Results:** The findings of the present study demonstrated that significantly increased level of TLR-7 in the CRF group (0.24±0.05 ng/ml) compared to controls (0.02 ±0.08 ng/ml), the findings revealed a significant association between CRF and IL-17A serum level in the studied groups,There was a significantly increased level of IL-17A in the CRF group (6.50±1.37 pg/ml) compared to controls (2.19±0.32 pg/ml) also decreased level of IL-10 in the CRF group (26.20 ±5.16 pg/ml) compared to controls (79.27±23.44 pg/ml).**Conclusion:** These findings concluded that TLR-7 , IL-17A and IL-10 might have a role in CRF pathogenesis.

Keywords: Chronic Renal Failure, TLR-7, IL-17A, IL-10, Pro-inflammatory cytokines.

Introduction

The kidneys are paired organs that lie on the posterior wall of the abdomen behind the peritoneum on either side of the vertebral column ^[1] . The kidneys are able to maintain Fluids, electrolytes, and regulate blood pressure ^[2] . Renal failure (RF) is the condition in which the kidney is unable to remove the final metabolites from the blood and regulate fluids, electrolytes, and acid balance in extracellular fluid ^[3].(CRF) occurs when the kidneys are destroyed or decreased functions for at least 3 months (Glomerular Filtration Rate (GFR) <60 ml / min / 1.73 m ² ^[4] .The severity of CRF is directly proportional to diabetic disease and hypertension, and the most serious complication of chronic renal insufficiency is the risk of cardiovascular disease (CVD), as the blockage of the arteries, which has a negative effect on the kidney, leads to further deterioration of kidney function ^[5] . many pathogens in patients with CRF

include: Immune disorders such as glomerulonephritis , Metabolic Disorders such as diabetes, Renal vascular disorders such as atherosclerosis, Injuries Infections such as tuberculosis, Urinary Tract Obstruction such as Renal Calculi and Congenital and hereditary disorders such as polycystic disease and congenital nephropathy ^[6] .Toll-like receptors (TLRs) have recently emerged as a key component of the innate immune system that detect microbial infection and trigger antimicrobial host defense responses, TLRs activate multiple steps in the inflammatory reactions that help to eliminate the invading pathogens and coordinate systemic defenses In addition, TLRs control multiple dendritic cell functions and activate signals that are critically involved in the initiation of adaptive immune responses ^[7] . When triggering TLR, signals are generated transcription factors that stimulate expression of genes that encode cytokines, enzymes, antimicrobial, and phagocytes^[8] . Acute Renal Failure (ARF) caused by Injuries, drug interactions or toxicity is identified and generated by biological memory. This process is not simple and may take several weeks. Pro-inflammatory cytokines are generated with an increase in the circulatory flow , (TLR-7 and TLR-9) play a role in increasing the severity

of the injury and if this continues to progressively lead to the chronic stage of this disease [9]. (IL-17A) is a pro-inflammatory cytokine produced by natural killer cells (NK cell), neutrophils, macrophages, dendritic cells (DCs), mast cells plasma cells and Thelper17 (Th17) [10]. IL-17A has is pleiotropic cytokine which play a role in development of atherosclerosis, hypertension, diabetic nephropathy, ischemia-reperfusion injury, fibrosis, glomerulonephritis, nephrotic syndrome and acute renal rejection [11].(IL-10) is an important Homodimer anti-inflammatory agent known as the human Cytokine Synthesis Inhibitory Factor (CSIF), the length of each subunit 178 amino acid [12].(IL-10) is a pleopetric multifunctional cytokine that affects the immune response and inflammation, It also reduces the expression of T Helper(Th1) and Major Histocompatibility Complex Antigens (MHC II) and enhances the survival and proliferation of B cells and production of antibodies , also inhibits cell differentiation and(DCs) maturation [13]. Renal failure may increase inflammatory responses through a number of mechanisms, including immune response, which include increased concentration of pro-inflammatory cytokines and reduced levels of anti-inflammatory cytokines, as well as antioxidants and increased acute phase proteins [14]. Therefore, the aim of the present study is to assess the presence of innate immunity represented by TLR-7 serum level and cytokines (IL-17A and IL-10) in the pathogenesis of CRF patients.

Materials and Methods

Patients

Sixty-six Iraqi CRF patients (24 females and 46 males) were enrolled in this study with age mean ± standard deviation (SD)(48.1 ± 14.3years). They referred to Ibn-Sina center for dialysis, Baqubaa Teaching

Hospital. during the period beginning of October 2018 to end of March 2019 for treatment after diagnosis by the specialist physician in Ibn-Sina Center . In addition to patients, 22 apparently healthy individuals (11 females and 11 males) with no clinical symptoms or a family history for CRF were enrolled in the study as a control group with the age mean ± SD (37.1 ± 12.6 years). The study was permitted by the local ethics committee of the Health ministry, Baqubaa Teaching Hospital. In addition to the informed permission that was obtained from the study volunteers.

Methods

Five milliliters of venous blood was dropped from all the study volunteer groups. The withdrawn blood amount was separated in test tubes to collect serum for immunological examination, the blood left to clot at room temperature(25°C), then the tubes were centrifuged for 10 minutes, and the sera were separated in Eppendorf tubes. The sera of studied groups were tested to assess the level of TLR-7 (ABBEXA company, UK), IL-17A and IL-10 (PEPPROTECH Company/ UK), by using Sandwich ELISA technique.

Statistical Analysis

The data were analyzed by using the IBM SPSS computer program version 24 and expressed as mean ± SD, one-way ANOVA table, and Pearson’s two-tailed. The statistical significance level was set at (P < 0.05),(P≤ 0.01),(P≤ 0.001).

Finding

In the present study, Table 1 showed the level of TLR-7 in the sera of CRF patients and healthy control groups.

Table 1: Toll-like receptors7 level in the studied groups

TLR-7 Level ng/ml (mean±SD)	
CRF Patients	Healthy Control
0.248±0.057***	0.08±0.021***

*** significant differences (P ≤ 0.001).

When comparing (TLR7) with sex for CRF patients, we found that the level in males was higher than in females with significant difference between the two groups (P≤ 0.01), Table 2 showed the levels of TLR-7 in the sera of patients .

Table 2: Toll-like receptors7 level in CRF patients

TLR-7 Level ng/ml in CRF patients (mean±SD)	
Males (42)	Females (24)
0.528±0.264**	0.219± 0.351**

** significant differences (P ≤ 0.01).

The results of the present study showed a significant increase in the level of the IL-17A in people with CRF comparing with control group ,Table 3 showed the level of IL-17A in the sera of CRF patients and healthy control groups.alsoresults showed a significant decreased in levels of IL-10 for patients with CRF compared to healthy control group where we found an increase in the concentration of this cytokine ,Table 3 showed the level of IL-10 in the sera of CRF patients and healthy control groups.

Table 3: Interleukin-17 A and 10 level and in the studied groups

IL-17 A Level pg/ml (mean±SD)	
CRF Patients	Healthy Control
6.50±1.37*	2.19±0.32*
IL-10 Level pg/ml (mean±SD)	
26.20 ±5.16***	79.27 ±23.44***

* significant differences (P ≤ 0.05). *** significant differences (P ≤ 0.001).

When comparing IL-17A with sex, the level in males was decreased compared with females with no statistically significant difference (P>0.05), as shown in Table 4.

Table 4: IL-17A level in CRF patients

IL-17A Level pg/ml in CRF patients (mean ± SD)	
Males (42)	Females (24)
5.75 ± 9.43NS	7.81± 13.79NS

NS No significant differences (P > 0.05).

When compared with the sex of the infected, IL-10 was found to be higher in males than in females and no significant difference between the two groups (P >0.05) As shown in Table 5 .

Table 5: IL-10 level in CRF patients

IL-10 Level pg/ml in CRF patients (mean ± SD)	
Males (42)	Females (24)

NS No Significant differences ($P>0.05$)

Discussion

The results of TLR-7 level in the studied groups showed that there was a significantly increased level ($P \leq 0.001$) in CRF group compared to healthy control group (0.248 ± 0.057 ng/ml vs. 0.08 ± 0.021 ng/ml, respectively). This finding matched the findings of other studies that referred to high levels of TLR7 in sera of patients with CRF compared to healthy control is clearly indicative of presence infections due to the vulnerability of the immune system as they have increased chances of Bacterial infection are identified by cells of the immune system that are derived by the secretion of TLR-7,9,4,2 receptors that stimulate the phagocytosis and secretion of inflammatory cytokines [15]. Elevated levels of TLR-7 in sera may indicate the immune system's response to inflammation and kidneys damage in patients with CRF who are constantly dialysis.

The level of TLR-7 may be associated with age, This finding matched the findings of other studies [16]. showing a high level of this receptor in the younger and middle age groups and generally decrease in aging. This high level may be associated with other diseases such as rheumatoid arthritis (RA), hepatitis C [17], immunodeficiencies, atherosclerosis and asthma [18]. The reason for decreasing level of this receptor may be attributed to the weakness of immunological mechanisms as a result of aging or may be affected by patterns and methods of life and smoking in addition to the duration of the incidence of kidney failure, where it is noted in

young groups that the incidence of kidney failure and the number of dialysis that was conducted less than age groups over 50 years.

The results of the present study showed a significant increase in the level of the IL-17A in people with CRF comparing with control group , The results were agreed with other study [19] as one of the pro-inflammatory cytokines, the reason for its rising is due to the higher frequency of the allele in the group of patients than the control group ,that the genetic differences of IL-17A may thus have an effect in The development of renal failure and its increased secretion by T cells due to inflammation[20,21].

These findings were agreed with previous studies indicated increased IL-17A concentration with age, showing that IL-17A was involved in the inflammatory process as a causative agent for aging diseases, and recent studies have enhanced the association of Th17 with age, These cells may contribute to significant changes in immune function [22].

The results of our study were agreed with [23] showed a significant decreased in levels of IL-10 for patients with CRF who are constantly undergoing dialysis compared to healthy control group. The absence of significant difference in level of IL-17A and IL-10 in CRF patients for both sexes may be due to immune defense mechanisms may be somewhat similar regardless of sex as the interaction within the body activates the

immune cells responsible for the immune response in the sera of patients, and the sex is not affected by the level of cytokines in the body [24,25].

Conclusion

TLR-7, IL-17A and IL-10 might have a role in CRF pathogenesis.

Protective Immunity against Virulence Uropathogenic Escherichia Coli in Mice

Hussam Sami Awayid¹, Saif Ali Mohammed¹, Adnan Kamel Shebeeb¹

¹Depart, Medical Laboratory, Technical Institute -Kut, Middle Technical University; ²Depart, Medical Laboratory, Technical Institute -Bagubah, Middle Technical University, Baghdad, Iraq

Abstract

Infection in the urine tract is more dominant as a medical condition around the world in the hospital and society, especially from young women and pregnant women. The reason for disease the first is uropathogenic Escherichia coli, which has several agents that help in the development that disease in addition to its the capability to stick on a host epithelial cell in urine tract with an assembly the biofilm, which is the most important factor for the disease. Therefore, a vaccine was made for these local isolates to avoid recurrent urinary tract infection and to obtain protective immunity by a laboratory mouse model. After isolation and diagnosis of 90 positive isolates using chrome agar diagnostic from women with urinary tract infection from hospitals in middle Iraq to Wasit province for the period from Jan. 2019 to Apr. 2019. All isolates were tested to detect virulence factors. One isolate was chosen for the determine LD50, immunization and vaccine model, then to estimate the antibody (IgG) level during immunization in the serum of mice at 6 weeks. Results proved that isolates showed positive (71.11%) biofilm, (23.33%) α -hemolysin, (31.11%) serum resistance, and (41.11%) MRHA and (5.55%) MSHA, while LD50=(1×10^{10}). There are highly significant differences when using isolate in the level of IgG reaches the high peak ranged (749.1 \pm 20.4) in 6 weeks as compared with control. The results showed that the local vaccine for this isolation provided preventive protection by inducing a protective immune response in mice to protect against infection.

Keywords: humoral immune response, E.coli, Virulence factors, LD50.

Introduction

When uropathogenic E. coli (UPEC) have the capability to step inside the host urine tract with reaches to 10^6 colonies per ml urinary tract infection occurs, and As a result of the infection, several diseases may develop, including acute, chronic, recurrent and bacteriuria infection⁽¹⁾. After a period of urinary tract infection, the bacteria begin to enter the latency state, which will be the future and express recurrent urinary tract infection resulting from the reactivation of the bacteria to have factors that help it in addition to that the lack of correct diagnosis of this infection will expose the patient to a serious medical condition⁽²⁾. UPEC characterized by the possession of several virulent factors have a close role in the continuation of colonization and the occurrence

of the pathogenesis of the urinary tract, and the biggest remarkable agents are biofilm, hemolysin, and fimbriae⁽³⁾. Fimbriae There are two types according to immune classification through special receptors which are mannose resistance hemagglutination (MRHA) and mannose sensitive (MSHA)⁽⁴⁾. The multiple virulence factors of the E. coli strains shown during the urinary tract infection are dangerous to the patients' lives. It is therefore necessary to develop a protective immune response by a vaccine against these bacteria and their virulent agents⁽⁵⁾. Therefore, the research aims to provide a suitable vaccine for local isolates from hospitals in middle Iraq to the E. coli bacteria which have harmful factors and reduce the cost of importing ineffective vaccines and avoid the side effects of antibiotics for pregnant women. .

Materials and Method

Collect and diagnose bacteria:

Period from Jan. 2019. Until Apr. 2019 Urine samples were collected from women with urinary tract infection at AlAziziyah, AlEssaouira, and Al Karama hospitals with about 205 samples. Following the method (6) all isolates were obtained using conventional tests and confirmed by using (Chrome-Agar™ Orientation / France) diagnostic for E. coli. (7).

Detection of virulence factors for E.coli:

Phenotypic detection for 90 E.coli isolates from urine was done to detect the ability of Hemolysin production, Hemagglutination method, and biofilm formation (8), Serum resistance by (9).

Preparation of the vaccine for virulent bacteria:

The most ferocious and positive local isolates were selected for all virulence factors using the main method for prepare vaccine which depends on (10).

Immunization schedule:

White mice weighing 25 grams aged 62 to 96 days were purchased from the University of Baghdad College of Science / Animal Branch and under microbial-free conditions and pressed in cages for Feeding for 5 days without giving them fat in food and then placed under control in cages and divided into three groups for the purpose of giving the vaccine prepared in advance

1- The first and the second group dose were 0.5 ml of colony 1×10^8 cfu/ml injects subcutaneously twice in two weeks.

2-The third group (control) was given the solution in the same manner and a dose of 0.5ml from PBS pH = 7.2±2

Where the serum was collected during the immunization period from 2 to 6 weeks at the end of each immunization time and stored at -18C° until used in the verification of the quantity of antibody (11).

Estimated LD50 and challenge test:

According to the following equation, the lethal dose 50 was estimated by counting dead and live mice in each

group for one month, which was injected subcutaneously with bacteria Choose most vicious local isolate E. coli. The live bacterium takes to make gradient dilution from 10^{-1} to 10^{-8} according to (12). Also, lethal dose 50 worked dependent on the method mention in (13). 48 normal animal separate to 8 cages, then groups injected by the subcutaneous method with use 0.5ml of diluents except one group the control that gives 0.5 ml from PBS pH=7.2±2 by the same method for challenge test, totally cages watch for one month to detect lethal and survival mice.

$$\% \text{ of Mortality} = \frac{\text{Total Dead}}{\text{Sum of (Total live + Total Dead)}}$$

Determination (IgG) quantification in mice serum during immunization:

From 2 to 6 weeks of administering the vaccine, then was used (Mouse IgG Elisa kit) to quantify of antibody, and to investigate humoral immune response in mice during immunization.

Data Analysis

Program IBM spss ver.22 Used to analysis data to obtained significant different between groups of mice

Results and Discussion

Isolation and Diagnosis:

In our examination from 1/1/2019 until 30/4/2019, an aggregate of 200 urine tests was gotten and refined. Out of 205 samples of urine, results demonstrated 140 (68.29 %) were positive culture and 45 (21.95 %) were negative culture while 20 (9.75%) were indicated contaminate urine culture Table (1). The conveyance of confined relies upon the age of (20 to 62) years old, for female patients, the age went from (20 to 29) was 40 (28.75%) and this is the most overwhelming ages contaminated with gram-negative microorganisms. The age were Showed in (Table 2)

Table 1. The Distribution percentage of isolated depends on age from (20 to 62) years old.

Age group (years)	No. of isolating	%
20 - 29	40	28.75
30 – 39	24	17.14
40 – 49	21	15
50 – 59	26	18.57
60 – 62	29	20.7
Total of isolate	140	100

Table 2. Results of the biochemical test and CHROM-agar.

Bacteria	Biochemical Test						
	%	Gram stain	Indole	Citrate	Urease	Motility	Color on Chrom-agar
E. coli	64.28	G-ve	+	—	—	+	Dark- violet
K. pneumonia	19.28	G-ve	—	+	+	—	Metallic- blue
P. mirabilis	9.28	G-ve	—	—	+	+	Brown

Results showed the percentages of all isolates taken from urine using biochemical tests and chrome agar was as follows: E. coli 64.28%, Klebsiella spp. 19.28%, and P. mirabilis 9.28%. In another study, the highest percentage of our study results was about 83.3% (14) in the (Table 3). Therefore, the results appeared E.coli dominates in infection of urine tract. Shown in (Fig.1) color of isolates on chrome- agar

Figure1. (A)E.coliDark- violet, (B)K. Pneumonia Metallic-blue ,and(C) P. mirabilisBrown.

Virulence factors:

The result of our study to detect Heamolysin produce by 21(23.33%) isolate ofE.coli from UTI that identical to outcome obtained by (15). α- hemolysis target erythrocyte of patient, also, cause an effect on it to lead inflaming, damage, and weak patient resist. Also provoke Release Superoxide, H2O2 and O2 consuming by cells renal, consist of sensitizing by immune cell (16).Out of the total 90 isolates we tested 37 isolate shows Mannose resistance hemagglutination as percent (41.11%) and mannose sensitive hemagglutination in percent (05.55%) this result very close to result of the study done in India (17). While inconsistent with another study included low percent in (MRHA) Mannose resistance hemagglutination (28.09%) and high percent in (MSHA) mannose sensitive hemagglutination (8.5%) (18). Hemagglutination is mediated by fimbriae. The ferocity is determined for UPEC type 1- fimbriae connection with mannose element including of receptor on host cell in a urinary tract, and play important role in first step of biofilm by attachment to the epithelial cell

of a host ⁽¹⁹⁾. In our study, a total of 90 isolates detected to biofilm formation, 64 isolates Strong biofilm produce was (71.11%), percent of moderate biofilm produce was 18 (20%), and weak biofilm produce was 8 (8.88%) that result agreement with study conducted in West Africa ⁽²⁰⁾. However, our results differ from the results of the study carried out by ⁽²¹⁾ that showed (45%) weak biofilm produce, (49%) moderate biofilm produce, (5%) strong

biofilm produce. The present study result about virulence factor Serum resistance showed 28 isolates of E.coli in percent (31.11%) positive that are in close with the results of the study achieved by ⁽²²⁾. As compared with another study ⁽²³⁾ the result was a higher (90%). Serum of human reluctance by E.coli is a critical ferocity factor. All outcomes showed in (Table3) with (Fig.2)..

Table 3. Percentage of ferocity agents for E.coli from urine.

V. Factor Result	Heamolysin	Biofilm	MRHA	MSHA	Serum resistance

LD50:

According to the dose used to calculate the lethal dose 50 (1X10¹⁰) as show in (Table 6) The experimental challenge test was performed for all groups in intraperitoneally injection 4 LD50 (4 X 10¹⁰) method for

the virulent E. coli. The results showed that the fortified mice showed mild signs within 2 days and return to normal within a week. The control group showed death within 3 days our result came very close to study (24), and In this search discover the prepared vaccine (whole-cell bacteria) protected animal (mice) against infection by the intraperitoneal route, In a above study showed incompatibility immunization was used in several ways where the mice were fortified by the intraperitoneally but did not survive when using the intranasal method. Where the survival rate of the protected mice was better than the control group, UPEC bacteria its first reason in infection of urine tract in a host. In our experiment, we tested the vaccine susceptibility to provide protection against severe isolates and explained that immunized mice are better to survive compared to the control group. Table (4).

Table 4. Calculation of the lethal dose 50 of E. coli in mice

Group	Dose	Live	Dead	Total live	Total dead	%
1	1x10 ¹³	0	6	0	21	100
2	1x10 ¹²	0	6	0	15	100
3	1x10 ¹¹	2	4	2	9	81
4	1x10 ¹⁰	3	3	5	5	50
5	1x10 ⁹	4	2	9	2	18
6	1x10 ⁸	6	0	15	0	0
7	1x10 ⁷	6	0	21	0	0
Control	PBS	6	-	-	-	0

Determine IgG quantity:

The results reported in a (Table5) to detect Antibody quantity with a mean was (192±11.2) at zero weeks from the injection. Then reaches to the middle value of mean (405.3 ±16.1) in 2 weeks .then reach to a high value at 4 weeks (749.1 ±20.4) The result of values showed a significant increase of IgG quantity at the p-value of least of (0.05 value) from 2 to 6 weeks when compared with the control group, In general, the UPEC strain contains several virulence factors, so the vaccine used from this local strain must capable of stimulating humoral immunity representing by antibody(IgG)antagonistic effect to virulent agents , which appear at varying phases of urine tract infection. So the local vaccine is promising and efficient to protect against virulence factor of UropathogenicE.coli and infection, as mentioned in a study ⁽²⁵⁾.

Table 5. Antibody (IgG) quantity in serum of mice by Elisa during 6 weeks

Treatment (weeks)	Immunized group with UPEC vaccine Mean ± SE	Control group Mean ± SE
0	192±11.2 A	195.9 ±8.3 A
2	405.3 ±16.1 A	202 ±12.3 B
4	749.1 ±20.4 A	188.9 ±11.9 B
6	660 ±22 A	190 ±10.9 B

Conclusion

After assessment virulence factors for all isolate then using fierce local isolation from 90 isolate which that gave protective immunity against virulence factors and infection of UPEC in immunized mice compared with control mice with use an important parameter is determined the quantity of antibodies (IgG) in the mice serum during immunization 6 weeks to monitor and investigate the vaccine activity to stimulate the humoral immune response, and immune system. .

Abstract

Jo-1, anti-Mi-2, anti-Ro52, anti-PM/Scl-100 and -75, anti-Ku, anti-SRP, anti-anti-PL-7, anti-PL-12, anti-EJ, and anti-OJ are associated with myositis and are also found in systemic lupus erythematosus. **Materials & methods:** We studied serum of 170 patients with systemic lupus erythematosus (97 females & 63 males) had definite or probable myositis according to physicians, the clinical status of patients was determined from their medical records and 20 adults' healthy controls. Sera were screened for anti-ANA IgG antibodies and Anti-dsDNA IgG antibodies by using ELISA kits obtained from AESKU Diagnostics. also 11 autoantibodies were detected by using IgG immunoblot kit were used (EUROLINE Myositis Profile3, Euroimmun AG, Germany). **Results:** The analysis revealed that Jo-1 were more frequencies were present in 76 patients with SE followed by Mi2 were present in 59 patients., Ku, SRP, PM-Scl75, PM-Scl100, Ro-52, PL-7, PL-12, EJ, and OJ were present in 46, 38, 34, 28, 28, 22, 19, 11 and 5 patients respectively. The immunoblot results showed the highest intensity of anti-Mi-2, anti-Ku, anti-PM/Scl-100, anti-SRP, anti-PL-12, anti-OJ in females more than males with rheumatoid arthritis diseases, while the anti-EJ, anti-PL-7, anti-Jo-1, and anti-PM-Scl75 showed lowest intensity was +/17, ++/48, ++/33, and ++/29 respectively in females. **Conclusion:** The level of these autoantibodies associated with myositis were detected in 170 patients with SLE. The present results indicate that it is clinically useful to determine the serum levels of myositis-associated autoantibodies in patients with SLE even when their underlying diseases are not myositis.

Key words: auto-antibodies, myositis, Systemic Lupus Erythematosus, Immunoblot

Introduction

The systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the presence of autoreactive B and T cells, responsible for the aberrant production of a broad and heterogeneous group of autoantibodies. Shereret al. in 2004 documented that more than a hundred sixteen different antibodies found in SLE patients¹. The Specific detection of autoantibodies in systemic autoimmune diseases same as the myositis, either systemic or organ specific, can have both diagnostic and prognostic importance. Some autoantibodies have a clear pathogenic role such as anti-Jo-1 in polymyositis². Among the myositis-specific autoantibodies reported to date, are directed against cytoplasmic antigens, such as

tRNAsynthetase (Jo-1 or PL-1, PL-7, PL-12, EJ, OJ, JS, and KS), signal-recognition particle (SRP), Mas, KJ, and Wa. Also antibodies to nuclear antigens include anti-Mi-2, anti-PMS (PMS1, and PMS2), PM-Scl, Ku, RNP (U1-RNP and U2-RNP, U4/U6-RNP, and U5-RNP), Ro 52 kDa and, more rarely, Ro 60 kDa³. Auto-antibodies in myositis are very different in antigen specificity and characteristics. thus, different in-house laboratory methods for their detection have been used to date. Recently, a single multi-analytic line blot assay has been developed representing a promising methodological approach for testing⁴.

Immunoblotting with positively sera of antibodies has been previously reported. So in this study, used

the diagnostic performance of a novel, commercially available immunoblot technician for the standardized detection of several autoantibodies was evaluated at reference laboratories using serum panels from clinically patients with SLE and various controls.

Materials and Method

Samples

A Total of 170 serum samples has been collected from SLE patients whom suffering from myositis as (97 females and 73 males) and 20 healthy controls, which were pay a visit and residence in hospitals from date of 15\9\2017 to 15\6\2019 and diagnosed by the treating physicians and confirm the diagnosis by specific tests for each one. Their ages are ranging from 9- 61 years.

Methods

Laboratory investigation for the detection of anti-dsDNA and anti- ANA IgG antibodies

Anti-dsDNA IgG antibodies and anti- ANA IgG antibodies were determined by using commercial ELISA kits obtained from AESKU Diagnostics. All test items were operated strictly in accordance with the manufacturer’s instructions.

Measurement of myositis-specific autoantibodies and myositis-associated autoantibodies

The recruited patients were evaluated for a myositis-associated autoantibody antibodies or myositis specific autoantibodies. For the detection, IgG immunoblot kit were used (EUROLINE Myositis Profile3, Euroimmun AG, Germany), this provides a qualitative in-vitro assay for human antibodies to 11 different myositis antigens includes: anti-Ro52, anti-PM/Scl-100 and -75, anti-Ku, anti-Mi-2, anti-SRP, anti-Jo-1(histidyl-), anti-PL-7 (threonyl-), anti-PL-12 (alanyl-), anti-EJ(glycol-), and antiOJ(isoleucyl-tRNA synthetase). The manufacturer’s instructions were followed while carrying out the assay. After the membrane strips were dried and automated evaluations of these strips for the analysis of different bands and examined with EUROLineScan system provided by the manufacturer, the reading was taken by keeping the strips on a flatbed scanner (Canon) which enables the EUROLineScan to recognizes the position of the strips, identify the bands and measure its intensity. The results were defined as positive when

the signal intensity was more than 11. The intensity of autoantibodies is graded according to the signal intensity into weakly 11–25 (+), moderately 26–50 (++) and strong more 50 (+++).

Findings

Among 170 onset SLE patients, 119 (70%) were ANA seropositive apportioned as 80 (67.22 %) at females and 39 (32.78%) at males. One hundred and sixty SLE patients (94.17%) showed a positivity for anti-dsDNA apportioned as 91(56.88%) and 69 (43.12%) at females and males respectively (Table 1).

Table(1): Percentage seropositive of ANA, anti-dsDNA and ANCA associated with SLE patients (n=170)

Genders Test	SLE patients		
	Females	Males	Total
	No. (%)		
ANA (n=119)	80 (67.22)	39 (32.78)	119 (100)
Anti-dsDNA (n=160)	91(56.88)	69 (43.12)	160(100)

ANA: Antinuclear antibody, Anti- dsDNA: Anti-double-stranded DNA

Univariate analysis (Table 2) showed that SLE patients with positive antibodies for ANA and anti-dsDNA according to age groups and gender. The results of ANA showed the highest percentage of ANA is in the females within the age group (31- 40) years followed by the patients within the age group (41- 50) years (24.37%, 17.65%) respectively, while the lowest percentage was shown in males within age group (10-20) years and females patients within the age group (> 50) years. Anti-dsDNA analysis showed the highest percentage of anti-dsDNA is in females within the age group (41- 50) years followed by the patients within the age group (21- 30) years (21.25%, 17.5%) respectively, whilst the anti-dsDNA result has lowest percentage in females (2.5 %). See (Table 2). The results of the statistical analysis showed significant differences $P \leq 0.05$.

Table (2): Percentage seropositive of ANA, anti-dsDNA and ANCA in relation to age groups and genders associated SLE

Genders Age group	SLE patients					
	ANA (n=119)			anti-dsDNA (n=160)		
	Females	Males	Total	Females	Males	Total
	No. (%)			No. (%)		
10 – 20	7(5.88)	4(3.36)	11(9.24)	7(4.37)	8(5.0)	15(9.37)
21 -30	18(15.13)	9(7.56)	27(22.69)	28(17.5)	12(7.5)	40(25.0)
31- 40	29(24.37)	12(10.09)	41(34.46)	18(11.25)	23(14.38)	41(25.63)
41 – 50	21(17.65)	8(6.72)	29(24.37)	34(21.25)	19(11.88)	53(33.13)
> 51	5(4.2)	6(5.04)	11(9.24)	4(2.5)	7(4.37)	11(6.87)
Total	80(67.23)	39(32.77)	119(100)	91(56.87)	69(43.13)	160(100)

ANA:Antinuclear antibody, Anti- dsDNA: Anti–double-stranded DNA,

Table 3 shows percentage of seropositive of myositis antigens in patients with systemic lupus erythematosus relation to age groups and genders. According to data in this study, the results of SLE patients showed the highest percentage of the diseases under study is in the females within the age group (31- 40) years followed by the patients within the age group (21 -30) years (17.65%, 15.30%) respectively, while the lowest percentage was showed within age group (10-20) years and males patients within the age group (> 50) years. See (Table 3). The results of the statistical analysis showed significant differences $P \leq 0.05$.

Table (3) Percentage seropositive of myositis antigens in relation to age groups and genders associated SLE

Genders Age groups (years)	SLE patients(n =170)		
	Females	Males	Total
	No. (%)		
10 – 20	9(5.29)	10(5.88)	19(11.17)
21 -30	26(15.30)	23(13.53)	49(28.83)
31- 40	30(17.65)	18(10.59)	48(28.24)
41 – 50	21(12.35)	13(7.65)	34(20.00)
<51	11(6.47)	9(5.29)	20(11.76)
Total	97(57.06)	73(42.94)	170(100)

In present study, the Jo-1 and Mi2 were observed more frequently in patients with SLE were present as 76, 59 respectively. Ku, SRP, PM-Scl75, PM-Scl100, PL-7 and PL-12 were present in patients as 46, 38, 34, 28, 22, 19 respectively while the lowest frequently were OJ which present in 5 patient. According to genders, the results showed that Jo-1 and Mi2 were recorded more frequently in females patients as 41, 38 respectively while the lowest frequently were OJ recorded in 1 female patient. Moreover, we did not observe patients with positivity to EJ in females with SLE (Table 4).

Table (4) Frequency of myositis-specific and myositis associated autoantibodies in patients with SLE

Markers Study groups		Mi2	Ku	PM-Scl100	PM-Scl75	Jo-1	SRP	PL-7	PL-12	EJ	OJ	Ro-52
	No. / 170											
SLE	Males	21/170	18/170	16/170	21/170	35/170	20/170	6/170	8/170	11/170	4/170	7/170
	Females	38/170	28/170	12/170	13/170	41/170	18/170	16/170	11/170	-/170	1/170	21/170
Total		59/170	46/170	28/170	34/170	76/170	38/170	22/170	19/170	11/170	5/170	28/170

The overall immunoblot results with the classical serological markers of anti-PM/Scl-100 and -75, anti-Ku, anti-Mi-2, anti-SRP, anti-Jo-1, anti-PL-7, anti-PL-12, anti-EJ, and anti-OJ showed the highest intensity of anti-Mi-2, anti-Ku, anti-SRP, anti-PL-12, anti-PM/Scl-100, and anti-OJ in females more than males in patients with SLE, while the Ro-52, PL-7, Jo-1, anti-PM/Scl -75 and anti-EJ showed lowest intensity in females than males were +++/53, ++/50, ++/47, ++/41 and +/21 respectively in SLE patients (Table 5).

Discussion

To our knowledge, this is the first report that evaluates the presence of various myositis autoantibodies in patients with Systemic Lupus Erythematosus in Mosul city. Anti-nuclear antibodies (ANA), a heterogeneous group of autoantibodies against nuclear antigens, are

often tested as a rapid screening tool in patients with suspected systemic lupus erythematosus (SLE) or other connective tissue diseases⁵. Multiple studies show ANA positivity to be highly prevalent in various patient populations. In this study, the prevalence of positive ANA in SLE patients was 70%, which was lower than previous reports (90-100%)⁶. A different genetic background could explain these differences. SLE is a multifactorial disease in which genetic and environmental factors interplay, determining disease development⁷. The genetic background could explain not only the disease susceptibility but also the autoantibodies production. On other hand, some of patients received much medication for treating their underlying diseases. Many drugs are reported to produce ANA and have been reviewed extensively such as Hydralazine, procainamide, chlorpromazine and quinidine⁸.

In the present study, we registered a frequency of anti-dsDNA greater than 90% that is similar to the data reported in the literature for SLE populations⁹. Antibodies to dsDNA are of great importance in SLE, It is known that anti-dsDNA antibodies are present in 70–90% of SLE patients and in less than 0.5% of the controls. The majority of SLE patients are found to have anti-dsDNA antibodies at some time during their illness. The presence of anti-dsDNA has been found to precede the onset of lupus symptoms by up to 5 years and have been correlated with SLE activity¹⁰. In discrete study, Chung and colleagues published that many previously identified SLE-associated genes are more strongly associated with the production of anti-dsDNA than with disease susceptibility¹¹. The authors demonstrated the association between polymorphisms (SNPs) located in the MHC, STAT4, IRF5, and ITGAM regions and the positivity for anti-dsDNA antibodies. Conversely, only SNPs in the MHC and IRF5 regions have been identified in negative patients¹¹.

We used in this study the Euroline blot immunoassay technique which is the diagnostic method, also seemed to detect a higher proportion of myositis autoantibodies among SLE patients compared to other studies. Our study showed that the systemic lupus erythematosus patients have a variety of autoantibodies which acceptable with previous studies have reported that were detected in patients with SLE^{12,13}. Also, in agreement with the data from the literature, we found a predominance of Anti-Ro52, Anti-Ku in SLE patients, compared to other of myositis autoantibodies¹⁴.

Previous studies reported that Anti-EJ antibody and anti-Jo-1 antibody were also detected frequently in SLE and another non-myositis CTD and as for other myositis-associated autoantibodies, anti-PM-Scl75 antibody was detected in 7 patients with SLE while anti-Ku antibody was demonstrated in 3 patients with PM/DM, 4 patients with SLE and 3 patients with MCTD¹⁵. However, our study revealed that anti Jo-1 is more common in females, with a approximately female-to-male ratio of 2:3 which confirmed with Cavagna et al. who documented in an international retrospective multicenter study that anti Jo-1 is more common in females¹⁶.

The role of anti-Ku in the pathophysiology of autoimmune diseases is not entirely understood. However, the present study showed the high incidence of Anti-Ku autoantibodies with SLE patients were 27.06% different with previous studies which revealed that Anti-Ku autoantibodies have been identified in 7-18% of the patients with overlap syndromes such as SLE¹⁷. Suggested that may be due to limitation in a cohort number of patients in this study.

The most important finding of previous studies has been reported the presence of anti-Ro52 antibodies in different systemic autoimmune rheumatic diseases¹⁸. Our findings are similar to those previously reported¹⁹ that showed the presence of anti-Ro52 in SLE patients were 16.47% and showed the high incidence in males more than females. However, In previous studies patients with SLE had higher frequency of anti-Ro52 in a prevalence between 36 and 64%²⁰. Ro52 is a member of the tripartite motif (TRIM) family of single-protein E3 ligases and is known to be a target for autoantibody production in systemic autoimmune rheumatic diseases. Ro52 function is still unknown²¹.

In summary, These results indicate that anti-Ro52, anti-PM/Scl-100 and -75, anti-Ku, anti-Mi-2, anti-SRP, anti-Jo-1 (histidyl-), anti-PL-7 (threonyl-), anti-PL-12 (alanyl-), anti-EJ (glycol-), and anti-OJ (isoleucyl-tRNA synthetase) autoantibodies are closely associated with myositis as well as Systemic Lupus Erythematosus were detected in our series of Iraqi patients. Also, The present results indicate that it is clinically useful to determine the serum levels of myositis-associated autoantibodies in patients with SLE even when their underlying diseases are not myositis. This study is the first report in Mosul/ Iraq that evaluates myositis autoantibodies among SLE patients, so further studies in a larger number of Iraq patients may be

warranted.

The Effects of HIV/AIDS Education on Knowledge, Attitude, and Satisfaction for AIDS Prevention Self Massage on College Students in Korea

Ji Min Lee¹, Sung Jung Hong², Eun Hee Kim³

¹Associate Professor, Semyung University, Department of Nursing, Korea, ²Assistant Professor, Andong National University, Department of Nursing, Korea, ³Associate Professor, Suseong College, Department of Nursing, Korea

Abstract

Background/Objectives: It is important to provide education for university students about HIV/AIDS. This study was to evaluate the effects of HIV/AIDS education program in knowledge, attitudes of HIV/AIDS, and satisfaction of education.

Methods/Statistical analysis: The research design was a nonequivalent control group pretest-posttest design. The participants were comprised of 102 students (experimental group=50, control group=52) in Korea. A self-questionnaire knowledge and attitudes about HIV/AIDS were administered before, and after 180 minutes of HIV/AIDS education. The collected data was analysed descriptive statistics, Chi-square test, and t-test.

Findings: There were significant differences in the mean scores of knowledge, and attitude of HIV/AIDS and were significant differences satisfaction of education between two groups.

Improvements/Applications: HIV/AIDS education including multimedia was found to be an effective method for increasing knowledge, and attitudes of AIDS/HIV. The results suggest that customized educational programs with methods and contents should be developed to improve knowledge, exciting and participation of the learners.

Keywords: HIV/AIDS, Education, Knowledge, Attitudes, Satisfaction

Introduction

HIV/AIDS is one of the most destructive diseases and has become an even more significant international health issue^[1]. Since the first case were reported 1980s in the U. S, the disease has spread to virtually every country. In 2017, UNAIDS estimated that 33.7 million people were infected with HIV/AIDS^[2] and 29 million people died HIV globally^[1]. The total number of Koreans diagnosed with HIV have been increased since 2000 in Korea^[3]. As of 2016, there have been 15,208 cumulative reported cases of HIV/AIDS^[4]. Of those, approximately half all HIV-infected people are age 15-29 years^[5]. Therefore, it

is necessary to provide education about HIV/AIDS for young people.

However, Koreans hold strong stigmatizing attitudes about HIV/AIDS and people living with HIV/AIDS. Because of the social discrimination and stigma attached to homosexuality in Korea, it is culturally reluctant to discuss these sexually topics. Furthermore, people living with HIV/AIDS are mostly away from their work, family and intimated persons, and even religious groups^[6-7]. Discussion on the subjects of homosexuality and HIV/ AIDS is thought sensitive and uncomfortable with the Korean culture. People who are infected HIV/AIDS chance on taboo, bias, and discrimination. This fact can sometimes be the negative effect of living with HIV/AIDS. Fear of this happening can lead to people being sensitive about telling others that they have HIV/AIDS or avoiding contact altogether with other people.

AIDS phobia, prejudice, and discrimination began with the introduction of HIV/AIDS to Korea because the mass media was reporting it as a contagious disease. Many people were under the wrong information that only contact with an HIV positive individual would cause HIV infection^[8]. Regrettably, information about HIV/AIDS in South Korea is not accurate even though many research have been studied and published within South Korea^[9]. People with HIV/AIDS may end up suffering in silence due to the social stigma put on by society and may not seek out for help or treatment that is needed. Therefore, it is important to ask a way for active treatment and live actively in society for people of infected with HIV/AIDS, they need to be supported physically and psychosocially as well as being accepted as a valuable member of the community. Previous studies have reported that knowledge of HIV/AIDS is important determinant for prevention of HIV and the pathways to changing attitudes of HIV. Furthermore, knowledge reduce the stigma against people with HIV/AIDS.

Newly, the results of many research found the results of effect of HIV/AIDS educational program on knowledge, attitudes, and stigma et al^[9-11]. However, many research were confined, their outlines were on easily providing or determining knowledge utilizing one way teaching method. Therefore, developing new tools to use students increase knowledge and attitudes have become an important part of education. The video learning methods is reported to improve learner attention, explanation, and memory^[12]. And the video learning method can add to images and sound stimuli more the using paper material or other method for education, multimedia allows students actively participate in their learning process, which resulted in higher knowledge gain, improve attitude, and decreased fear or phobias of persons with HIV/AIDS^[13]. Through this education method, students can be encouraged to practice infection prevention activities while actively engaging in social interactions with people with HIV/AIDS without prejudice towards those with it. The purpose of this study is to identify the effects of HIV/AIDS education on knowledge, attitude, and satisfaction for prevention in University students.

Method

This study was nonequivalent control group pretest-posttest design to evaluate the effects of HIV/AIDS education program on knowledge, attitude, and satisfaction for education in University students.

The participants for this study were senior university students who (a) volunteered to participate in the research and (b) were enrolled in the Health and Well-being course. Sample size was based on previous study examining the effect of educational interventions using multimedia^[14]. Using the statistical software G*Power V.3 at a statistical power of 0.80, effect size 0.27, and statistical significance 0.025, the estimated sample size required to perform 2 sample t tests was 92(46 students in the experimental group and 46 in the control group).

The study was conducted among university students at S university in Korea, who receive their health and well-being course. Participants were senior students who were enrolled in S University, in J city, South Korea, from September 1st to December 31st, 2016. Each participants signed a written consent from that specified the purpose of this study and the rights of the participants and voluntarily agreed to participate.

The instrument of this study were as follows. HIV-related knowledge was assessed using a 19-item questionnaire^[5-6]. The ranges of the scores are from score of zero (0) to score of 19 on the composite index, which means the higher the score, the higher knowledge level of HIV/AIDS. The Cronbach's α **α** was .78 in this study. To measure attitudes towards HIV/AIDS, 17 questions were taken from the tool developed by the Center for Disease Control and the department of academic research of the Korean Association for AIDS Prevention in 2013^[7]. Students' attitudes were measured using the 5-point Likert scale ranging from one (1): Strongly disagree to five (5): strongly agree. The Cronbach's α **α** of this tool was .81 in this study.

Satisfaction of the education was measured using the 5-point Likert scale ranging from 3 questions (1): strongly disagree to five (5): strongly agree. The results indicated that the higher the score, the higher the satisfaction with the education by the students.

The educational program was developed after reviewing literature, research articles, and video presentations. This program was reviewed by content experts in HIV/AIDS. This education program consisted of six sessions totaling 180 minutes that are required to run all six sessions. These educational sessions are (a) Understandings of AIDS, (b) Summary and understanding of AIDS, Definition of AIDS and natural death Characteristics of HIV infection, Diagnosis of

AIDS, Confirmation system of diagnostic examination, Sexually transmitted diseases, (c) Policy of AIDS and human rights, support services, AIDS-related laws and regulations, (d) Sexuality of human and sexual culture, Sexural counseling, Sexuality and understanding of sexual minority (e) Understanding of people living with HIV/AIDS, social understanding of people living with HIV/AIDS and disease, and follow up of people living with HIV/AIDS, and (f) Discussion on phobia toward AIDS and intent for AIDS prevention.

Statistical analyses were done utilizing SPSS, version 25.0 (IBM Corporation, USA). The homogeneity of subjects' characteristics and variables were used

to descriptive statistics, t-test, and chi-square. The differences in knowledge, attitudes, and satisfaction among two groups was used to t test.

Result and Discussion

1. General characteristics of the subjects

There were no significant difference between the two groups at baseline for general characteristics of the subjects [Table 1]. The mean age of 20.9 years was the experimental group and, and the mean age of 20.8 years was the control group. The majority of subjects were female (82.0% in the experimental group versus 86.5% in control group).

Table 1. Homogeneity of General Characteristics and Dependent Variables (N=102)

Characteristics	Exp. (n=50) n(%) or M±SD	Con. (n=52) n(%) or M±SD	t/χ ²	p
Age	20.9± 1.56	20.8±1.45	3.631	.481
Gender				
Male	9 (18.0)	7(13.5)	.397	.593
Female	41(82.0)	45(86.5)		
GPA	2.78±1.54	3.15±2.12	1.016	.312
AIDS Education experience				
Yes	12(24.0)	13(25.0)	.014	.907
No	38(76.0)	39(75.0)		
Knowledge	8.52±.87	8.72±.86	1.156	.251
Attitude	3.26±.53	3.35±.48	.890	.376

Exp: Experimental group

Con: Control group

GPA: Grade point average

There was demonstrated no statistically significant differences between the two groups on the total mean scores for knowledge ($p = .251$), and attitude ($p = .376$) at baseline. There was no statistically significant difference in demographic characteristics (gender, age, GPA, and education experience and independent variables (knowledge, and attitude of HIV/AIDS before education) between the experimental and control groups [Table 1].

2. Comparison knowledge, attitudes and education satisfaction between two groups after intervention

The mean score of knowledge before education (total score =19) in the experimental group was 8.52 ($\pm .87$), and this changed to 22.18 (± 0.76) after education.

In the control group, the mean baseline knowledge score was 8.72 ($\pm .86$), and this changed to 11.03 (± 1.21) after education. The mean score of attitudes before education in the experimental group was 3.26(.53), and this changed to 4.21 ($\pm .78$) after education. In the control group, the mean baseline attitudes score was 3.35 ($\pm .48$), and this changed to 3.87 ($\pm .90$) after education. There were found statistically significant better knowledge in the experimental groups after education ($p < .001$) and attitudes ($p < .05$). And there were statistically significant difference for knowledge ($p < .001$) and attitudes ($p < .001$) between the pretest and posttest in the two groups. There were statistically significant difference for satisfaction of education ($t=3.911, p < .001$) [Table 2].

Discussion

This study was conducted to evaluate the effects of HIV/AIDS education on knowledge, attitude, and satisfaction for education in university students. To establish the basis for applying education methods to improve the knowledge and attitudes to increase preventive behavior while reducing prejudice and fear towards individuals with HIV/AIDS. In this study, the educational program had a positive impact on increasing the knowledge level of university students and improving their attitudes toward HIV/AIDS. This findings were similar to studies of the previous research [1][13]. The results of these studies also stated that using discussion, audiovisual presentation, or quiz types of the educational methods allows students actively participate in their learning process, which resulted in higher knowledge gain, improve attitude, and decreased fear or phobias of persons with HIV/AIDS when compared to the traditional lecture. Like these studies, in this study, the educational programs provided with audiovisual aids had improved knowledge and attitudes more than other instructional methods, thereby enhancing preventive measures against the disease^[12] [15-16]. Literature supports that using the audiovisual improves students' concentration due to an audio/visual stimulus; the scenes are often self-explanatory, thus enhances longer retention of the knowledge^[17]. Therefore, HIV / AIDS education using audiovisual material is encouraged because it promotes a better understanding of health and motivates learners to participate in health promotion activities, which in the long run, results in better health outcomes. Previous studies suggested that combining PowerPoint slides, audiovisual materials, and question and answer sessions helped to change prejudice about HIV/AIDS and argued the need for ongoing small group discussion sessions to change the attitude toward people with HIV/AIDS. It is believed that the educational program used in this study allowed students the opportunity to freely express and share their thoughts and ideas with team members that positively influenced the attitude changes toward HIV/AIDS. Therefore, changing attitudes based on sociocultural values may require a special program as it is difficult by simple knowledge-based education^[18]. Including individual or small-group discussions in an educational program that allows students to share their ideas may be more effective in changing attitudes. The educational program used in this study included a lecture using audiovisual aids, and small group discussions provided in the experimental group while the control group received a traditional

lecture using only PowerPoint Slides. The results of compared to the control group, the experimental groups' learner satisfaction was significantly higher. Also, it is confirmed that students in the experimental group actively provided feedback on the educational program and made broad recommendations as well. It is believed that in addition to textbooks, a realistic educational program reflecting social and cultural realities heightened students awareness and lessened anxiety towards HIV/AIDS through discussions. The limitation of this study was that there was no group who received a single lecture as an educational program, and the long-term effects of the educational program used in this study were not confirmed.

Conclusion

The purpose of this study was to evaluate the effects of HIV/AIDS education on knowledge, attitude, and satisfaction for AIDS prevention in college students. In this study, a new multimodal HIV/AIDS education was provided to the college students to identify the effects of this educational program on the knowledge and attitude towards HIV/AIDS. The results of this study revealed that multimodal educational programs provided in this study were found to be helpful in improving college students knowledge and attitude toward HIV/AIDS. This study provided a foundation to develop effective HIV/AIDS educational programs. Based on the results of this study, it is necessary to develop a variety of customized educational programs with their methods and contents that are exciting and promotes the active participation of the learners. Further ongoing research is recommended to confirm the effects of the educational program used in this as well as its impact on students majoring in health sciences and non-health sciences in other universities in different geographical locations.

The Study on the Empathy of Nurses and the Quality of Nursing Provided to Hospitalized Children Perceived by Nursing Students

Bo-Yun Huh¹, Jae-Woo Oh¹, Mi-Ran Kim¹

¹Professor, Department of Nursing, Konyang University, South Korea

Abstract

Background/Objectives: This study was conducted for the nursing students with the experience of pediatric ward clinical practice to grasp the degree of the quality of children and families-centered nursing and further to provide the basic data which can improve the quality of nursing by evaluating the empathy of nurses and the content of the quality of children and families-centered nursing which was performed in the ward where children were hospitalized perceived. This study is a descriptive survey study for identifying the empathy of nurses and the degree of the quality of nursing provided to hospitalized children perceived by nursing students.

Methods/Statistical analysis: The subjects of this study were 119 nursing students in the 3rd and 4th grade with an experience of pediatric ward clinical practice among the students in nursing department of the university located at M city. Data was collected from Oct 15, 2017 to Oct 30, 2017. The SPSS 21.0 Program was used in data analysis.

Findings: As a Result, the difference in the empathy of nurses and the quality of nursing provided to hospitalized children according to the general characteristics of the subjects had a statistically significant difference in the empathy and clinical practice period of nurses($p=.009$), the performance in the quality of nursing, and clinical practice period($p=.042$).

Improvements/Applications: In conclusion, it is thought that it is necessary to review the clinical practice period.

Keywords: Empathy, Quality of Nursing, Hospitalized Children, Nursing Students, Clinical Practice

Introduction

Hospitalization of a child is a crisis situation which arouses ennui, boredom, anxiety and fear to a child patient, and does stress and burden about the disease process to a family which changes the structure and function of a family^[1]. A family is a main element which affects the growth, development and health of a child, and as it has health problem itself, the subjects of child care should include the family as well as the child^[2]. Therefore, it can be said that patients and a family-

centered nursing that the focus of nursing should be on children and a family, not a nurse, is a basic philosophy of child care^[3]. A nurse who takes care of a child should not only have the expertise and skills of a child care but also empathize, respect and give a sense of trust to children and their parents^[4], and child care should support the growth and development of children as well as be safe and comfortable to children emotionally^[5]. That is, for the successful child care, a nurse's competence is needed along with the creation of the atmosphere where a nurse, a patient and a family depend on each other^[6]. A nurse should possess the ability for communication, conflict management, and a professional attitude as well as the theoretical knowledge of child care and family dynamics, and proficient nursing skills^[7].

Corresponding author:

Jae-Woo Oh,

E-mail: ojw77@konyang.ac.kr

Above all, the empathy is an important factor that has an effect on forming, maintaining and developing the emotional bond with a healer with which a nurse can stand on the patient's side and look at the world from the patient's point of view^[8]. The empathy, a positive emotion, is the ability to understand the world that the other party understands. As the true value of empathy is not only to understand the physical demands of the patient but also to usefully work such as psychologically reacting to them, it can be said that it is very important to child nurses who should care in a special environment, and child nurses who care for children should continuously develop and utilize their internal resources^[9].

Professional nursing is a practical study which is applied to the nursing field based on the theoretical knowledge of nursing^[10], and nursing education is a process where nursing students acquire all the theoretical knowledge which is necessary to perform the role of nurses, explore how to apply the acquired knowledge to an actual nursing situation, and acquire practical skills through a clinical practice^[11]. Especially, clinical practice is an essential element in nursing education as well as theoretical education^[12], and through this clinical practice, nursing students experience various nursing fields and prepare to play a role which meets the social concerns and demands of health^[13]. That is, nursing students learn nursing skills, time management, and professional socialization through clinical practice education, reinforce learning with the behaviors of clinical field leaders during clinical practice education, and have an opportunity to acquire the role of nursing profession and socialization by discovering a role model from them^[14]. It is important to improve the clinical performance ability of nursing students through clinical practice education, and considering that clinical practice is important to nursing students in the process of becoming professional nurses, it is thought that nursing skills and knowledge of a child care which they experience through pediatric ward clinical practice can improve clinical performance ability as pediatric ward nurses when they become new nurses, and play an important role in having knowledge and attitude as pediatric ward nurses in the future.

Therefore, this study was conducted for the nursing students with the experience of pediatric ward clinical practice to grasp the degree of the quality of children

and families-centered nursing and further to provide the basic data which can improve the quality of nursing by evaluating the empathy of nurses and the content of the quality of children and families-centered nursing which was performed in the ward where children were hospitalized perceived.

Method

The subjects of this study were 119 nursing students in the 3rd and 4th grade with an experience of pediatric ward clinical practice among the students in nursing department of the university located at M city. The responses of 116 students except those of 3 ones who responded insufficiently were analyzed.

Data was collected from Oct 15, 2017 to Oct 30, 2017. As for the method of data collection, the researcher visited subjects, explained the purpose and method of the study, distributed a questionnaire to those who agreed to participate in the study, and explained precautions and how to respond. Before collecting data, the purpose of the study, personal confidentiality, and that it will not be used for purposes other than the research were explained to the subjects. Those who agreed on it participated in the survey.

With the collected data, using SPSS 21.0 Program, the general characteristics of the subjects were analyzed with real number and percentage, the empathy of nurses and the degree of the quality of nursing provided to hospitalized children perceived were done with mean and standard deviation, the relationship between the empathy of nurses and the quality of nursing provided to hospitalized children perceived was done with Pearson's correlation coefficient, the difference in the empathy of nurses and the quality of nursing perceived by nursing students according to the general characteristics of the subjects was done with T-test.

Discussion

The main results are discussed as follows. First, the empathy of nurses perceived by nursing students was average rating 3.60 points out of 5. As there are no preceding researches, the direct comparison with them is difficult, however, the result of this study was higher than that(2.99) of Lee Hyun Jeong^[15] for nurses. It is thought that this result appeared because the nursing intervention such as communication and explanation is done for protectors as clinical practice place is a pediatric ward and its subjects are children, and because the communication technique is differently applied to the children by their developmental stage even if it is possible to communicate with them. The importance in the quality of nursing provided to hospitalized children is average rating 3.34 points out of 4, and the performance in it was average rating 3.12 points out of 4. As there are no preceding researches which have measured the quality of nursing provided to hospitalized children, the direct comparison with them is difficult, however, in this study, the degree of the quality of nursing provided to hospitalized children perceived by nursing students was over average. It is thought that this result appeared because nursing students are well aware of the characteristics of child care that nurses should not only have the expertise and skills of child care but also empathize, respect and give confidence to children and their parents, and that child care should not only be safe and comfortable to children emotionally but also support the growth and development of children, and because they observed the nursing behaviors of pediatric ward nurses which reflected the characteristics of child care.

Second, the empathy perceived by nursing students had a positive correlation with dignity and respect($r=.282$, $p<.01$), explanation($r=.313$, $p<.01$), participation and cooperation($r=.214$, $p<.01$), and nursing activity($r=.344$, $p<.01$), which are the subregions of the importance in the quality of nursing provided to hospitalized children, and with the dignity and respect($r=.299$, $p<.01$), explanation($r=.321$, $p<.01$), participation and cooperation($r=.281$, $p<.01$), and nursing activity ($r=.426$, $p<.01$), which are the subregions of the performance in the quality of nursing.. As there are no preceding researches which have identified the relationship between empathy and the quality of nursing provided to hospitalized children, the direct comparison with them is difficult. It is thought that this result appeared because the empathy is an important factor that has an effect on forming, maintaining, and developing the emotional bond with a healer with which

a nurse can stand on the patient's side, and look at the world from the patient's point of view^[9], and because the empathy, a positive emotion, is an ability to understand the world that the other party understands, and the true value of empathy is not only to understand the physical demands of the patient but also to usefully work such as psychologically reacting to them.

Third, the difference in the empathy of nurses and the quality of nursing provided to hospitalized children according to the general characteristics of the subjects had a statistically significant difference in the empathy and clinical practice period of nurses($p=.009$), the performance in the quality of nursing, and clinical practice period($p=.042$), however, it had no statistically significant difference with the importance in the quality of nursing. It is thought that this result appeared because the more the clinical practice period increases, the more the opportunity to observe the empathy of nurses and the performance of nursing provided to hospitalized children perceived by nursing students increases. The hospitalization of children is a stressful event which causes the change in the role of family members and the function of a family as a crisis situation of a family^[16], and it is actually impossible for nurses alone to provide all nursing which patients need, and for quality nursing, it is efficient for the family to provide a care together^[17]. Nurses and parents should take care of children through interaction where they share the information and responsibility of child care based on clear communication on an equal footing(Lee, 2007), and nurses should provide patients and families with the information completely and unbiasedly, and help them understand it completely^[18]. For these processes, as the clinical practice period gets increased, the opportunity to experience can increase, so in order to observe the interaction of nurses, hospitalized children, and families and the performance of nursing which is provided, it is thought that it is necessary to consider the increase in the clinical practice period at a pediatric ward.

In conclusion, it is thought that it is necessary to review the clinical practice period, and further, and to develop the programs which can enhance the empathy for improving the smooth communication with children and families so that nursing students may understand the role as pediatric ward nurses during clinical practice period, and improve clinical performance ability.

Conclusion

As the suggestions based on the result of this study, it is thought that it is necessary to prepare the systematic plans in the educational process for improving the understanding of child and family care, and that based on the understanding of child and family care, it is necessary to expand the opportunity that nursing students can experience the child and family care during a clinical practice period. The suggestions for the follow-up studies are as follows: the results of this study have a limit to generalization, as this study was conducted only for nursing students in a city, so the comparison study and the systematic analysis study for nursing students with a variety of characteristics and local nursing students are necessary. Second, as it is thought that there will be difference according to the types of clinical practice institutions, the follow-up studies by the types of them are suggested.

Relationship between Attitudes to Child Nursing College Students Perceived Punishment, Child Abuse Awareness and Knowledge

So-Ja Jeon¹, Jae-Woo Oh²

¹Professor, Department of Nursing, Chungbuk Health & Science University, South Korea,

²Professor, Department of Nursing, Konyang University, South Korea

Abstract

Background/Objectives: This study was conducted to present the basic data for developing education programs for nursing students through correlation research between the awareness and knowledge of child abuse and the attitude toward child corporal punishment for nursing students, and to contribute to the development of customized education programs by grade.

Methods/Statistical analysis: The subjects of this study were 200 nursing students in first and second grade of a university located in D city. Data collection was conducted from Oct 1 to Oct 30, 2018. With the collected data, using SPSS Program.

Findings: As a result, the awareness of child abuse had a statistically significant difference in grade, completion of child abuse prevention education, and completion of education related to child abuse after entrance.

Improvements/Applications: In conclusion, in order to increase the awareness and knowledge of child abuse of nursing students and to cultivate their attitude toward child corporal punishment which is unallowable, it is thought that the indirect experience through the curriculum and non-curriculum of child nursing science of department of nursing will be helpful.

Keywords: *Child Abuse, Awareness, knowledge, Nursing Students, Child Corporal Punishment*

Introduction

Child abuse has often occurred at home under the name of discipline from long ago. Especially in Korea, as the tendency of thinking highly of the value of a family and parents is strong due to the influence of Confucian culture, corporal punishment has been widely found at home, and educational scenes with a permissive attitude as discipline. However, since child abuse negatively affects the physical, emotional, and social development and adaptation of children and adolescents, and can have a negative effect on the growth and development of them as a crime which can lead to various after-effects up to adulthood in the long run, the attention of people who

are around is necessary to find the abuse early^[1]. while the number of cases of child abuse increases and the severity of its symptoms has been revealed, the children who are victims don't protect themselves, and do not express the abused situation or ask for help because they don't have an ability to solve the problem by judging the situation on their own. On the other hand, perpetrators don't report their mistakes themselves, so child abuse is easily concealed if someone who is a third person doesn't inform the world of it with responsibility^[4]. Therefore, in order to find and treat the abused children as well as to prevent child abuse, it must be preceded to know what abuse is and to perceive its dangers^[5]. In the developed countries, nurses are legally designated as a mandated reporter to play an important role in selecting and preventing child abuse, and are requested to have a heavier sense of responsibility as experts^[6]. The reason why mandated reporters are designated by a law like

Corresponding author:

Jae-Woo Oh,

ojw77@konyang.ac.kr

this is that it is more important to find and report child abuse early than any other thing. However, in Korea, the number of child abuse reported by mandated reporters accounted for only 32%(8,288) of the total number of reported cases in 2016(25,878). It's a very low figure compared to the cases that child abuse is reported by non-mandated reporters(68% of all child abuse report rate)^[7]. It is reported that the disturbance factors that hinder the reports of child abuse are a lack of knowledge of the symptoms and signs of abuse, report procedure, and legal process^[2,3], the attitude that child abuse is not serious enough to report, and that it will not be helpful even to report^[4, 5], and a thought that the report may have a negative effect on parents and children, and that rearing can't be interfered as it is parents' right^[5,6]. A nurse is in a position to observe the interaction between children and parents, to provide child care, and to play an important role in reporting, mediating and preventing child abuse when finding child abuse. This early involvement of nurses may be the basis for providing information and support for child rearing to parents who have difficulty in forming the attachment to the child in a preventive way or to pregnant women who are relatively at risk of child abuse. Nursing students as well as nurses should be the subjects of systematic education of child abuse as well. Nursing students will be the first to encounter children in various environments such as hospitals and community health centers after graduating from the university, and perform a role which quickly finds and takes care of abused children. If nursing students who will perform these roles are to be educated and acquainted with the exact definition of child abuse, the selection of abused child and how to report it, it is thought that the sensitivity and knowledge of child abuse of nurses can be improved in the long run, which will be a future-oriented strategy for reducing the rate of child abuse occurrence. Thus, it is thought that it is important to establish a correct attitude by grasping the awareness and knowledge of child abuse of nursing students, and by identifying their attitude toward corporal punishment. However, it was investigated that nursing students didn't know much about the law though they had an interest in child abuse, and that they had very little experience in education or training^[8]. Therefore, this study was conducted to present the basic data for

developing education programs for nursing students through correlation research between the awareness and knowledge of child abuse and the attitude toward child corporal punishment for nursing students, the future caregivers or prospective mandated reporters, and to contribute to the development of customized education programs by grade.

Method

For this study, data from 200 nursing students at K university in Daejeon Metropolitan City was collected, and 193 questionnaires excluding 7 ones whose response was insufficient were finally analyzed.

Data was collected from Oct 1, 2018 to Oct 30, 2018. As for the method of data collection, the researcher visited subjects, explained the purpose and method of the study, distributed a questionnaire to those who agreed to participate in it, and after explaining precautions and how to respond, data collection was conducted. Before collecting data, according to research ethics, the purpose of the study, personal confidentiality, and that it will not be used for purposes other than research were explained to the subjects. Those who agreed on it participated in the survey.

With collected data, using SPSS Program, the general characteristics of the subjects were analyzed with real number and percentage, The knowledge and awareness of child abuse of nursing students and their attitude toward child corporal punishment were done with mean and standard deviation, the relationship between the knowledge and awareness of child abuse of nursing students and their attitude toward child corporal punishment was done with Pearson's correlation coefficient and the difference in the awareness and knowledge of child abuse of nursing students and their attitude toward child corporal punishment was done with ANOVA.

Results and Discussion

1. General Characteristics of Subjects

Characteristics of Subjects are shown in [Table 1].

Table 1. General Characteristics of Subjects N=200

Variables	Categories	No(%)
Gender	Male	27(13.5)
	Female	173(86.5)
Grade	1st grade	50(25.0)
	2nd grade	50(25.0)
	3rd grade	50(25.0)
	4th grade	50(25.0)
Completion of child abuse prevention education	Yes	90(45.0)
	No	110(55.0)
Completion of child abuse related education after entrance	Yes	149(74.5)
	No	51(25.5)

2. Degree of The Awareness and Knowledge of Child Abuse of Nursing Students and Their Attitude Toward Child Corporal Punishment

It was revealed that the awareness of child abuse of nursing students was average rating 3.04 points out of 4, the knowledge of child abuse was average rating 6.8 points out of 17, and the attitude toward child corporal punishment was average rating 2.37 points out of 6.

3. Relationship Between The Awareness and Knowledge of Child Abuse of Nursing Students

and Their Attitude Toward Child Corporal Punishment

The relationship between child abuse awareness, knowledge, and attitudes toward child punishment is shown in [Table 2].

Table 2. Relationship between variables

Variables	Awareness of Child Abuse	Knowledge of Child Abuse r(p)	Attitude Toward Child Corporal Punishment r(p)
Awareness of Child Abuse	1		
Knowledge of Child Abuse r(p)	.190**	1	
Attitude Toward Child Corporal Punishment	-.237**	-.161**	1

	No	2.78±0.44		0.40±0.23		2.49±0.76	

Discussion

Main results are discussed as follows.

First, the awareness of child abuse of nursing students was above average with average rating of 3.04 out of 4. It was similar to the result(3.02) of Jo Yu Hyang and Jeong Yeong Hae's study^[8] for nursing students. It can be said that the result of this study appeared because the subjects of nursing department of K university took lessons on child abuse through a subject of child nursing science due to the characteristics of department of nursing, and experienced the campaign activities for preventing child abuse through club activities. The knowledge of child abuse of nursing students was 6.8 out of 17. This result is difficult to make a direct comparison with the preceding studies, as there are none which have measured the knowledge of child abuse for nursing students. However, As nurses who act in all areas of clinic often encounter the children and adolescents who suffer from the physical, sexual abuse, they need to be more interested in it. Therefore, it can be said that it is very meaningful and important to educate them so that they may acquire the right knowledge of child abuse, maintain their interest in child abuse, and conduct prevention, discovery, and case management, The attitude toward child corporal punishment of nursing students was low(average rating of 2.37 points out of 6). It is thought that this result supports the result of study of Jo Kyeong Mi and Kim Un Ju^[10]. that nursing students had a low degree of tolerance for the corporal punishment, and that it is a positive result, as that the degree of tolerance for child corporal punishment is low can be a factor to increase the intention of report of child abuse. The scope of tolerance for the corporal punishment in the process of child rearing is different between nations and cultures, and Chinese students are less critical on the rough, authoritative behaviors, and physical punishment of parents^[11,12,13]. However, like the result of this study, in the study of Feng and Levine^[5], Taiwanese nurses showed a low degree of tolerance for child corporal punishment, which reveals that it is a cultural change within a young generation due to the introduction of western culture and the economic development. That is, considering the study that the professional education and the cultural difference have an important effect on the intention of report of child abuse more than the gender, age, and the socio-economic status of nurses^[14], that the tolerance for the corporal punishment gets lowered is a positive change in enhancing the intention of report of nurses.

Second, the awareness of child abuse of nursing students showed a positive correlation with the knowledge of child abuse, but a negative correlation with the attitude toward child corporal punishment. As there are no results of preceding researches, the results of this study are difficult to compare with them directly. Actually, only 35.3% of the respondents who had an experience of finding the child abuse reported it. The reporters had an attitude that they didn't allow it, had more knowledge of child abuse, and had more experience of having access to education and knowledge of child abuse^[15]. The report rate of child abuse of nurses is low, which reveals that it is an important nursing process to find and report child abuse cases, however, the level of knowledge of child abuse, preparation for it, and confidence in reporting methods and how to utilize available resource are very low^[16]. That is, it is thought that it is necessary to develop programs to cultivate the unacceptable attitude toward and right knowledge of the corporal punishment for nurses and preliminary nursing students.

Third, the awareness of child abuse had a statistically significant difference in grade, completion of child abuse prevention education, and completion of education related to child abuse after entrance. It can be said that this result appeared because the subjects of this study learned the concept of child abuse in child nursing science and had an indirect experience of child abuse prevention campaign activities through tasks. The knowledge of child abuse showed a statistically significant difference in gender, which is thought because the subjects of study are mainly composed of girl students as nursing students, and it is considered that more in-depth researches are necessary. The attitude toward child corporal punishment showed a statistically significant difference in grade and the completion of child abuse prevention education. In Korea, due to the influence of Confucian culture, corporal punishment has been widely done in a family, and educational scenes with an allowable attitude as discipline because the tendency of thinking highly of the value of a family and parents is strong, however, it is thought it is a result of the cultural change within a young generation due to the introduction of western culture and economic development, and that it is the influence of the process which is handled in child nursing science such as growth development and child abuse as nursing students go up in grade.

Conclusion

In order to increase the understanding and sensitivity of child abuse, not only have to raise the awareness of child abuse by systematically educating and promoting the standardized contents, but also through proper parenting attitude. Eradication of the abuse is urgent. In addition, the number of trainings as well as educational experiences related to child abuse can increase the reporting intention affecting abuse reporting behavior. There is a need to develop educational programs that reflect the educational needs of college students and to prevent child abuse education programs that apply various teaching methods.

Reorganization of Learning Objectives Using Ontology Technique

Myung Mi Shin¹, Su-Jin Han², Hye-Sook Choi³

¹Professor, Shingu College, Dept. of Dental Hygiene, Republic of Korea, ²Professor, College of Health Science, Gachon University, Dept. of Dental Hygiene, Republic of Korea, ³Professor, Kyungdong University, Dept. of Dental Hygiene, Republic of Korea

Abstract

Background/Objectives: This study, the linkages between the educational curriculum were investigated by applying the ontology method to the learning goal in the field of clinical dental support among the learning goals of the department of dental hygiene.

Methods/ Statistical Analysis: In this study, the ontology was applied to the learning goals for clinical dental support field. In the basic design, the opinions on the area setting, usage purpose, provided information, and user-friendly design included in the ontology were collected. The ontology construction was developed using ASP, a web-based program and database construction was composed with MS-ACCESS 2010 version.

Findings: We have composed the learning goals of dental clinical field in the department of dental hygiene.

The dental clinical field is made up of a total of 7 subjects and classified into parts, chapters, and sections. From the learning goals, the contents that must be learned consist of priority A and the contents that should be learned optionally learn consist of B. Users can determine whether or not they can select the priorities and whether or not include chapters and sections. They can search by entering a specific keyword for the learning goals. The learning goal priority was set to 'A' and the learning goals were searched including 'chapter' and 'section'. As a result, the relevant learning goals in oral and maxillofacial surgery, conservative dentistry and orthodontics could be confirmed.

Improvements/Applications: This program will be able to be used usefully to set educational purposes and design appropriate education for it through the linkage between subjects.

Keywords: Dental Field, Dental Hygienist, Learning goals, Learning Objectives System, Ontology, Reorganization of Learning

Introduction

Ontology is an explicit formalization to conceptualize certain interest area and it can be a way of establishing knowledge systematically [1]. The formalization through ontology helps to find exact information by clearly defining and describing in detail the concept of the subject. Also, it has the advantage of linking flexibly with existing knowledge in case that knowledge is shared and new knowledge is added [2].

In the present medical field, the studies on the shared decision support system development for treatment using ontology and domain-specific language have been reported [3-8]. In the field of dentistry, ontology is divided into data analysis and knowledge discovery, dental education and training, legal protection and compliance, evidence-based dentistry, information exchange and integration, and clinical decision support systems [9-13]. In terms of dental education and training, there has been the case that ontology has been used to produce augmented reality applications to educate students [2,14-15].

In South Korea, dental hygiene has been grown for approximately 50 years and has been looking for academic

change. American Dental Hygienists Association presents Standard of Applied Hygiene Practice, and is attempting to teach and nurture to progress systematic approach to dental hygiene knowledge and work and critical thinking, decision-making ability and problem-solving ability of dental hygienists. In South Korea, departments of dental hygiene have been established at 82 universities nationwide and about 5,000 hygienists have been graduated every year and education to produce highly competent dental hygienists has been devoted [16]. Furthermore, in order to train standardized dental hygienists who have dental hygienists' basic skills, learning goals have been set based on the core terminology draft for the development of national examination questions and learning goals [17] of the department of dental hygiene, and have been applied to the national examination of dental hygienists. The learning goals of the department of dental hygiene, as a guide about compulsory and optional contents in the curriculum of a wide range of academic subjects, are the first activities which should be performed at the beginning of education. Particularly, the collection of learning goals is used for various purposes such as suggesting directions for teaching design activities, inducing learners' motivation to be educated, determining criteria for teaching strategies, evaluating criteria for learners' achievement status, effective management of class time, and providing effective feedback, and moreover, it is used as the basis for the national examination criteria and examination questions development standards. In order to perform efficiently dental hygienists' jobs, the learning goals of the dental hygiene curriculum has in-depth relationships with the dental hygienists' jobs and the educational purposes should be set systematically, and the educational contents appropriate to them should be chosen and the organization and the evaluation method should be designed and provided [18,19].

Therefore, in this study, the linkages between the educational curriculum were investigated by applying the ontology method to the learning goal in the field of clinical dental support among the learning goals of the department of dental hygiene.

Method

The development of the ontology followed the ontology development methodology of previous studies

[20-22] which is known widely and easy to understand. In this study, the ontology was applied to the learning goals for clinical dental support field (conservative dentistry, dental prosthetics, pediatric dentistry, orthodontics, oral and maxillofacial surgery, periodontology, dental materials).

In the first step, the domain and scope of the ontology was determined. For this, the basic design was completed in a brainstorming way by consisting of 1 ontology development expert, 1 domain expert and 4 service users and by holding a total of 4 meetings for a week. In the basic design, the opinions on the area setting, usage purpose, provided information, and user-friendly design included in the ontology were collected. Considering the characteristics of end-users, the vocabulary selection of concept and the classification of concept were considered.

In the second step, the important items of the learning goals used in the ontology were listed and main sentences were also listed. The chapters and sections of the learning goals were listed and the relationships between the learning goals were elicited.

The third step is to define the class, class hierarchy, and establish the class relationships.

In the fourth step, the concept was expressed by defining the class from the list of main items created in the third step and defining the relationship between the defined class hierarchy and classes.

The fifth step was to build the actual instance according to the ontology schema. It was checked and revised whether or not the necessary concepts were not left out and the concepts were not defined imprecisely.

In the final screen configuration, the learning goals were enabled to search for the learning goals including the chapters and sections and enabled to use the priority A and B items of the learning goals separately. The ontology construction was developed using ASP, a web-based program and database construction was composed with MS-ACCESS 2010 version. The data flow diagram is shown in Figure 1.

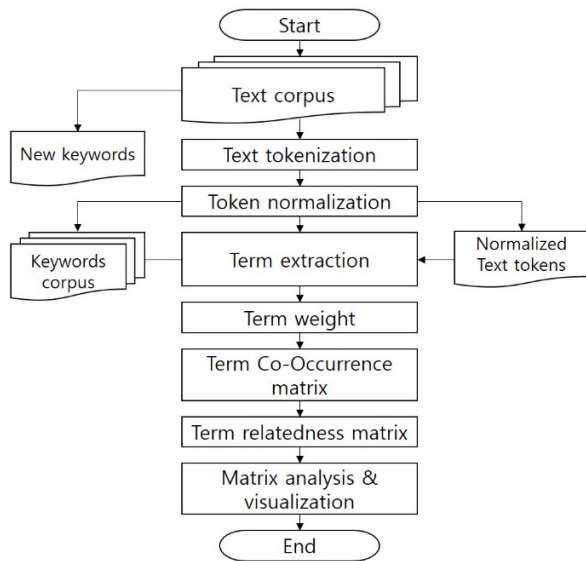

Figure 1. The data flow diagram

Result and Discussion

The composition of the learning goals of dental clinical field in the department of dental hygiene is shown in table 1. The dental clinical field is made up of a total of 7 subjects and classified into parts, chapters, and sections. From the learning goals, the contents that must be learned consist of priority A and the contents that should be learned optionally learn consist of B.

Conservative dentistry consists of 14 chapters. Priority was 69 for A and 64 for B. Dental prosthetics consists of 6 chapters in 2 chapters. Priority was 79 for A and 72 for B. Pediatric dentistry consists of 23 sections in 9 chapters. Priority was 61 for A and 76 for B. Orthodontics consists 51 sections in 11 chapters. Priority was 75 for A and 126 for B. Oral and maxillofacial surgery consists of 37 sections and 9 chapters in 4 parts. Priority was 63 for A and 90 for B.

Periodontology consists of 32 sections in 10 chapters. Priority was 67 for A and 72 for B. Dental materials consist of 30 sections in 15 chapters. Priority was 61 for A and 104 for B.

Table 1. The composition of the learning goals of dental clinical field in the department of dental hygiene

Subject	Parts	Chapters	Sections	Priority	
				A	B
Conservative dentistry	-	14	-	69	64
Dental prosthetics	2	6	18	79	72
Pediatric dentistry	-	9	23	61	76
Orthodontics	-	11	51	75	126
Oral and maxillofacial surgery	4	9	37	63	90
Periodontology	-	10	32	67	72
Dental materials		15	30	61	104

User screen is shown in Figure 2. Users can determine whether or not they can select the priorities and whether or not include chapters and sections. They can search by entering a specific keyword for the learning goals.

Figure 2. Oral and Maxillofacial Surgery Screen Configuration

The result screen of user search is shown in Figure 3. This is a screen configuration that shows the whole learning goals of oral and maxillofacial surgery.

Subject	Part	Title	Chapter	Title	Section	Title	learning goal	Priority
Oral and maxillofacial surgery	Part 1	Overview of Oral and maxillofacial surgery	Chapter 1	Dental hygiene in Oral and maxillofacial surgery	Section 1	Overview of Oral and maxillofacial surgery	We can define the Oral and maxillofacial surgery.	B
Oral and maxillofacial surgery	Part 1	Overview of Oral and maxillofacial surgery	Chapter 1	Dental hygiene in Oral and maxillofacial surgery	Section 2	Overview of Oral and maxillofacial surgery	We can list the major diseases of the Oral and maxillofacial surgery.	B
Oral and maxillofacial surgery	Part 1	Overview of Oral and maxillofacial surgery	Chapter 1	Dental hygiene in Oral and maxillofacial surgery	Section 3	Overview of Oral and maxillofacial surgery	We can explain the principles of treatment for major diseases in Oral and maxillofacial surgery.	B
Oral and maxillofacial surgery	Part 1	Overview of Oral and maxillofacial surgery	Chapter 1	Dental hygiene in Oral and maxillofacial surgery	Section 4	Overview of Oral and maxillofacial surgery	We can manage post-op patients.	B

Figure 3. whole learning goals of oral and maxillofacial surgery

Figure 4 shows searching for learning goals with the term ‘Diagnosis’ and shows the results of searching for learning goals with the term ‘Diagnosis’. The learning goal priority was set to ‘A’ and the learning goals were searched including ‘chapter’ and ‘section’. As a result, the relevant learning goals in oral and maxillofacial surgery, conservative dentistry and orthodontics could be confirmed.

In figure 5, the results obtained by applying the term ‘diagnosis’ to the ontology were expressed in an algorithm.

This program was designed to set educational purposes through the relationship between subjects and to use to design education suitable for it. The ontology was applied to help to find more accurate information by defining clearly and describing in detail the main concept of the learning goals of the national examination through the linkage between knowledge of the learning goals of the national examination of dental hygienists, in addition, it was applied to be used as basic data for defining the relationship between the learning goals and linking flexibly with existing learning goals in the creation of new learning goals. The linkage of learning goals with the term ‘Diagnosis’ was investigated after constructing the ontology and as a result, the relevant learning goals could be confirmed in oral and maxillofacial surgery and conservative dentistry. It has the advantage of obtaining easily knowledge that is difficult to find in case that it is composed of a collection of learning goals, also it helps to identify the linkage between learning goals at a glance. This helps to find more accurate information by defining clearly and describing in detail the concept

of resources when analyzing between concepts through ontology, and additionally, this is a result that reflects the advantage of ontology that it is possible to share knowledge and infer new knowledge by clarifying the relationship between terms [10].

Priority Total A B Chapter Y Section Y

Subject	Part	Title	Chapter	Title	Section	Title	learning goal	Priority
Oral and maxillofacial surgery	Part 2	Practice of Oral and maxillofacial surgery	Chapter 1	examination and diagnosis	Section 2	Meaning and Observation of Life-Symptoms	We can measure breathing.	A
Oral and maxillofacial surgery	Part 2	Practice of Oral and maxillofacial surgery	Chapter 1	examination and diagnosis	Section 2	Meaning and Observation of Life-Symptoms	We can measure body temperature.	A
Oral and maxillofacial surgery	Part 2	Practice of Oral and maxillofacial surgery	Chapter 1	examination and diagnosis	Section 2	Meaning and Observation of Life-Symptoms	We can measure the pulse.	A
Oral and maxillofacial surgery	Part 2	Practice of Oral and maxillofacial surgery	Chapter 1	examination and diagnosis	Section 2	Meaning and Observation of Life-Symptoms	We can measure blood pressure.	A

Figure 4. the results of searching for learning goals with the term ‘diagnosis’

Discussion

Specifically, in oral and maxillofacial surgery, 6 learning goals related to vital signs, systemic diseases, and dental treatment were presented. In conservative dentistry, 2 learning goals for the diagnosis of dental

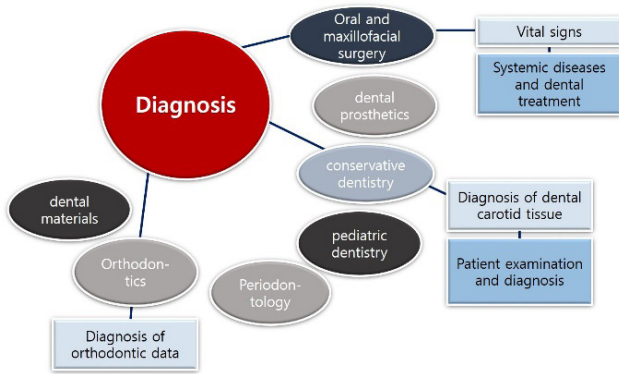

Figure 5. The results obtained by applying the term ‘diagnosis’ to the ontology

hard tissue and examination were suggested and in orthodontics, 1 learning goal for calibration diagnosis data was proposed. It presents a guide to prepare for learning by identifying the linkage of learning goals between subjects.

Moreover, the result of applying the ontology showed empty data values in some subjects. The empty data values were the values corresponded to ‘part’ and ‘section’, and the subjects were conservative dentistry, pediatric and adolescent dentistry, orthodontics, periodontology, dental materials, and practice. As a result of analyzing a collection of the learning goals to tackle this kind of problem, in oral and maxillofacial surgery and dental prosthetics, learning goals were presented by consisting of ‘part’, ‘chapter’ and ‘section’, and furthermore, in pediatric adolescent dentistry, orthodontics, periodontology, dental materials, and practice courses, they were presented by composing of ‘chapter’ and ‘section’. Lastly, in conservative dentistry, the learning goal was presented as ‘chapter’. Therefore, as learning goals were not composed in the same environment, there was a difference when the learning goals were described. It is considered that it will be necessary to be discussed to clarify the criteria that compose the learning goals when they are revised in the future.

Conclusion

The first thing to be done in the process of the preparation of learning is to select learning goals.

Learner’s prior knowledge should be identified, the depth of learning should be defined, and learning goals should be chosen, organized and evaluated in consideration of the linkage with subsequent studies. In that point, this program will be able to be used usefully to set educational purposes and design appropriate education for it through the linkage between subjects. Also, it helps to find more exact information by defining clearly and describing in detail the main concept of the learning goals of the national examination through the linkage between knowledge of the learning goals of the national examination of dental hygienists, and additionally, it will be able to be used as a basic data to define the relationship between the learning goals and to link flexibly with existing learning goals when new learning goals are created.

It is considered that differences in the expression of terminology which is the problem derived from the result of the study, in other words, the part in which the same concept is described in different terms, should be fully discussed when the learning goals are revised. In the future, if the system of overall learning goals is established by extending and applying this program to whole learning goals, it is believed that this program will serve as an opportunity to prepare guidelines for defining concepts between learning goals and designing lessons.

Abstract

Background/Objectives: This study intended to examine the needs of oral care and to provide the basic data required to develop related products through the trend analysis on the relation between the chronic disease and the oral health according to the diabetes treatment.

Methods/Statistical analysis: 458,301 research subjects older than 45 years were selected by requesting the raw data of 2015, 2016 and 2017 local community health survey. For the data analysis, the statistical software R program was used, and the significant level was less than 0.05.

Findings: In case of having diabetes, it was shown that the hypertension, arthritis, depression etc. were significantly high out of the chronic disease and the subjective health level was also poor ($p < 0.001$). In the oral health, in case of having diabetes, as the subjective oral health level was poor such as subjective periodontal tissue health level was poor and the mastication was inconvenient and the subjective oral health level was poor.

Improvements/Applications: For the patient with diabetes, diverse measures for the management of complications of the chronic disease and oral health care should be prepared at national level for the systematic oral health care.

Keywords: Diabetes, Oral health, Chronic diseases, Trend analysis, Local community health survey.

Introduction

Diabetes is the metabolic disease having characteristics of high blood sugar and occurs by the lack of the insulin resistance and the insufficient insulin secretion [1]. Diabetes occurs in about 9 million people around the world every year and as a result, it is estimated that 80% of the patients die [2]. Diabetes causes the chronic complications such as atherosclerosis, stroke, renal diseases, retinopathy, oral diseases, etc. As the chronic disease such as diabetes, hypertension, cardiovascular disease, etc. occurs in the adult, the

research on the relation with periodontal disease is being increased [3, 4]. The preceding researches reported that the periodontal disease has relation with cardiovascular disease and osteoporosis [5], and the blood pressure is high when having periodontal diseases than when does not having periodontal disease [6]. In addition, it was reported that the prevalence of the periodontal disease was higher in the people having diabetes [7], and the people having chronic diseases have poor periodontal condition compared to the normal people [8]. Through diverse epidemiological researches, it is known that the longer the diabetes is the possibility of the periodontal disease occurrence is high and the destruction of periodontal tissue is severe in the patient with diabetes after 30 years of age [9]. The inflammation by the diabetes accelerates the damage to the tissues

Corresponding Author :

Kyung-hee Kang,

dhkhkang@konyang.ac.kr

in the surrounding area of tooth [10] and the high blood sugar increases the inflammation of periodontal tissue by changing the capillaries in the whole body and the gingiva [11]. As recently, the chronic diseases such as diabetes, metabolic syndrome, cardiovascular disease, hypertension, etc. which occur commonly in the adults of middle age and old age, are increased, the research on the relation with periodontal disease is being increased but the research at the national level is not sufficient. Therefore, this study intended to examine the needs of oral care and to provide the basic data required to develop related products through the trend analysis on the relation between the chronic disease and the oral health according to the diabetes treatment.

Method

458,301 research subjects older than 45 years were selected by requesting the raw data of 2015, 2016 and 2017 local community health survey. For the data analysis, the statistical software R program was used, and the significant level was less than 0.05. For the general characteristics of the research subjects, chi-square test was performed for the age, education level,

marital status and the income according to the gender and the trend analysis by year was analyzed with linear by linear association. The logistic regression analysis for the chronic disease and oral health was performed by taking the diabetes treatment as dependent variable.

Result and Discussion

1. General Characteristics

In the results of analyzing the general characteristics by gender, for the age, the male was 121,281 persons (60.1%) occupying the highest proportion (p<0.001). In the education level, the male graduated the college or higher was 128190 persons (41.7%) occupying the highest proportion (p<0.001). In the marital status, the male having spouse was 171,709 persons (85.4%) the most and the female having spouse, divorced, widow and separate woman in order were shown significantly (p<0.001). In the household income, the male and female from 1 million won to 3 million won were 75,178 persons (37.6%) and 88,178 persons (34.6%), the most, followed by the female and the male with less than 1 million and the male from 3 million won to 5 million won, in order (p<0.001) [Table 1].

2. Chronic Disease according to Diabetes

The case that does not have hypertension in the group without diabetes was 273,487 persons (69.2%), showing significantly high and the case having hypertension in the group having diabetes was 38,887 persons (61.9%) showing significantly high. For the arthritis, the subject having arthritis in the group without having diabetes was 348,725 persons (88.2%) showing significantly high and the subject having arthritis in the group having diabetes was 10,921 persons (17.3%) (p<0.001). For the depression, the case that does not have depression in

the group without having diabetes was 348,725 persons (88.2%) showing significantly high and the subject who receives the psychological counseling in the group having diabetes was 1,015 persons (1.6%) (p<0.001). For the stress psychological counseling, the subject who does not have diabetes and does not receive the psychological counseling was 388,000 persons (98.3%) showing significantly high and the subject who is receiving the psychological counseling without having diabetes was 6,714 persons (1.7%) the lowest (p<0.001) [Table 2].

3. Oral Health and Oral Health Practice Trend of Person having Diabetes by Year

In the subjective oral health level, the proportion of the subject having diabetes who answered “Poor” was high but showed the decreasing trend (p<0.001). For the experience of mastication inconvenience, the proportion of “Inconvenient” was shown decreasing trend (p<0.001). For the form of using prosthesis, the proportion “I have both upper and lower prosthesis” showed the decreasing trend (p<0.001). toothbrushing showed the decreasing trend (p<0.001). In the tooth brushing after breakfast, the trend not having breakfast was increased and toothbrushing showed the decreasing trend (p<0.001). The toothbrushing after lunch showed the increasing trend (p<0.001). Toothbrushing after dinner and before sleep showed the increasing trend

(p<0.001) [Table 3].

4. Annual Trend of Reason Not Receiving Annual Oral Examination and Required Dental Treatment of Person having Diabetes

For the annual oral examination, the subject without having diabetes who did not receive examination was 317,425 persons (80.3%) the most (p<0.001). For the reason not receiving required dental examination excluding the case of not avoiding the examination, the subject having diabetes who did not receive examination by the economical reason was 5,110 persons (8.1%) showing significantly high (p<0.001). In the trend by year, the proportion of the subject who does not receive the examination while having diabetes showed the significantly increasing trend (p<0.001). Although the

reason of not receiving required dental treatment was economical but it showed the decreasing trend ($p < 0.001$) [Table 4].

Conclusion

This study analyzed the 2015, 2016 and 2017 local community health survey results of 458,301 persons having 45 years or more to verify the oral care needs of the patients with diabetes and to provide the basic data required for development of related products through the trend analysis on the relation between the chronic disease and the oral health according to the diabetes treatment. In the analysis results, in case of having diabetes, it was shown that the hypertension, arthritis, depression etc. were significantly high out of the chronic disease and the subjective health level was also poor ($p < 0.001$). In the oral health, in case of having diabetes, as the subjective oral health level was poor such as subjective periodontal tissue health level was poor and the mastication was inconvenient and the subjective oral health level was poor, it was observed that there is problem in oral health case. In the degree of oral health practice, it was shown that the people do not receive the annual oral examination well and particularly, the toothbrushing, which is the basic for oral health care, is not performed well when mastication is inconvenient, after the dinner and before sleep ($p < 0.001$). In conclusion, for the patient with diabetes, diverse measures for the management of complications of the chronic disease and oral health care should be prepared at national level for the systematic oral health care.

Abstract

Background/Objectives: This study is an experimental study to investigate the effect of Dialectical Behavior Therapy (DBT) skills training on depression and abstinence self-efficacy of people with alcohol use disorder.

Methods/Statistical analysis: The study was conducted on patients with alcohol use disorder diagnosed in one mental health department hospital, and 10 subjects were included in the control group receiving medication and 10 subjects were in the experimental group receiving additional dialectical behavior therapy skills training. Data collection was conducted from July 17, 2017 to September 4, 2017, once a week for a total of 8 sessions. The collected data were analyzed by Mann-Whitney U test, Friedman and repeated measure ANOVA.

Findings: The results showed that there was a significant effect on the viewpoint and interaction of the experimental group and the control group on depression, and the abstinence self-efficacy showed a significant difference in the pre-post-follow up period.

Improvements/Applications: It is expected that this program will continue to be used in education for the treatment and rehabilitation of patients with alcohol use disorders.

Keywords: Alcohol, Abstinent, self-efficacy, Alcohol Use disorder, Depression, Dialectical Behavioral Therapy(DBT)

Introduction

According to the results of the mental illness survey by the Ministry of Health and Welfare in 2016, the annual prevalence of alcohol use disorder was estimated to be 3.5% (1.39 million) of the 18-64 year old population, followed by anxiety disorder (5.9%), and the lifetime prevalence was 12.2%, which was the highest among mental disorders^[1]. In addition, alcohol use disorder has a high recurrence rate, with more than half recurrence within 1 year after treatment and show highest recurrence

risk within the first 3 months after discharge^[2].

Depression is a common emotional condition in people with alcohol use disorder, especially in that it induces negative patterns of communication and causes negative emotions and behaviors to manifest dysfunctional interactions with family members^[3]. Depression promotes recurrence of people with alcohol use disorder^[4-5], and promotes irritability, sleep disturbances, loss of appetite, and indigestion, all of which lead to ineffective symptoms in general life, which diminishes the quality of life^[6].¹

Corresponding Author :

Se-jin Ju,

lovepdd@nsu.ac.kr

Since alcohol is a central nervous system inhibitor, it increases the mood at first, but higher intake leads to

higher depression, and depression increases even after sobering up^[7].

Abstinence self-efficacy acts as an important psychological factor in maintaining abstinence and recovery^[8]. When faced with internal and external high risk situations related to drinking, those with high self-efficacy tend to actively abstain with strong belief in skills and abilities that they can overcome themselves, but those with low self-efficacy is more likely to give up or avoid work with focus in his or her inability in the same situation^[9-10]. In the intervention program related to abstinence, the study of depression as a variable^[11-13] and the study of abstinence self-efficacy as a variable^[13-14] have already proved effective in many studies in Korea. However, while dialectical behavior therapy skills training has been intervening in a variety of subjects outside the country, it has not seen the light in Korea. Dialectical Behavior Therapy skills training has been shown to be beneficial to people who are experiencing problems with substance use, anger control, depression, and anxiety as well as emotional problems such as an urgent response to intense emotions^[15].

Dialectical behavior therapy reduces the avoidance behavior by stopping the evaluation or judgment of oneself replacing the meaning of true life with material through the mindfulness technique and having an attitude accepting unpleasant and painful experiences as it is^[16]. It also improves the ability to continuously pursue goals through Mindfulness and improves behavioral outcomes such as automatic drinking habits^[17].

The purpose of this study was to determine whether dialectical behavior therapy skills training is effective in depression, which is an important variable in the prevention of recurrence and recovery of people with alcohol use disorders and to examine whether there is a change in abstinence self-efficacy^[18], which is an important psychological factor in improving the quality of life^[3] of people with alcohol use disorders. Research problems to achieve this objective are as follows.

Method

Research design

This study is an experimental study to investigate the effect of Dialectical Behavior Therapy (DBT) skills training on depression and abstinence self-efficacy of people with alcohol use disorder.

Research subject

This study was conducted on adult patients who were diagnosed with alcohol use disorder according to DSM-IV or DSM-5 criteria and were admitted to hospital in one mental health medicine hospital. 2 patients who had been absent for more than 2 times, and 3 patients who were discharged during the program were excluded from the study, and then 10 control subjects and 10 experimental subjects were selected as final subjects.

Research tool

Beck Depression Inventory: BDI

For the degree of depression, the Beck^[19] depression index (BDI) was used. A total of 21 items were composed of 3 sub-factors including negative attitude, difficulty in performance, and difficulty in physical condition.

Alcohol Abstinence Self-efficacy Scale: AASE)

For abstinence self-efficacy, abstinence self-efficacy scale^[20] was used. The 4 sub-domains were negative emotions, social pressure, physical pain, withdrawal and craving, consisting of 20 items, with 5 items in each domain.

Research process

Dialectical behavior therapy skills training in this study was reconstructed based on the dialectical behavior therapy guide of Linehan^[21], and the dialectical behavior therapy guide by Marra^[15].

The dialectical behavior therapy skills training process of this study was conducted for a total of 8 sessions once a week for 120 minutes each time, and after 4 weeks after the program termination, post examination was performed.

Data analysis method

To verify the effectiveness of the program, the data obtained from the pre- and post-test were analyzed using SPSS 23.0 program as follows. The collected data were analyzed by Mann-Whitney U test, Friedman and repeated measure ANOVA.

Result

1. Verification of homogeneity between experimental group and control group

[Table 1] There was no significant difference

between the two groups as a result of verifying differences between groups.

Table 1. Homogeneity test Between Experimental Group and Control Group

Variable	Group	M	SD	z
Depression	Exp.	24.00	5.08	-.23
	Cont.	24.00	6.62	
Alcohol Abstinence Self-Efficacy	Exp.	44.00	8.54	-.46
	Cont.	44.60	9.56	

2. Differences in pre-post-follow up tests of depression and abstinence efficacy

[Table 2] Participants in the experimental group showed that the negative attitude ($\chi^2 = 6.4, p < .05$) and difficulty in physical condition ($\chi^2 = 7.2, p < .05$), which are subordinate factors of depression, were significantly lower in the post-test and follow-up test scores than in the pre-test scores.

[Table 2] In the sub-scales of abstinence self-efficacy, the scores of post and follow-up test were significantly higher than pre-test scores in all sub-factors such as withdrawal and drinking impulse ($\chi^2 = 15.3, p < .001$), bodily and other anxiety ($\chi^2 = 11.2, p < .01$), negative emotions ($\chi^2 = 12.8, p < .01$), and social pressure ($\chi^2 = 7.4, p < .05$), showing significant difference between the tests.

3. Changes in pre-post-follow up tests of depression and abstinence self-efficacy

[Table 3] Shows changes in pre-post-follow up tests of group depression and abstinence self-efficacy. Depression showed a significant difference between the two groups in the pre-post-follow up tests scores between the two groups ($F = 7.12, p < .001$), and there was significant difference according to time ($F=82.05, p < .001$). Abstinence self-efficacy by group did not show a significant difference between the two groups in pre-post-follow up tests, and there were significant differences according to time ($F=86.74, p < .001$).

Table 3. Repeated measures ANOVA of Depression and Alcohol Abstinence Self-Efficacy

Variable	Source	Type III Sum of Squares	degree of freedom	Mean Squares	F

Discussion

This study examined the effects of dialectical behavior therapy skills training on depression and abstinence self-efficacy of people with alcohol use disorder and examined whether the effects persisted after program termination.

First, the experimental group participating in the dialectical behavior therapy skills training showed a significant decrease in the negative attitude and the physical difficulty among sub-factors of depression after the program, and similar level was maintained in the follow-up test. This is a significant result that dialectical behavior therapy skills training affects depression in the experimental group and continues to be effective. These results are consistent with previous studies on middle school students with depression tendencies^[22], elderly depression patients^[23], and inpatient female patients^[24], showing that dialectical behavior therapy skills training is a useful means of intervention for people with alcohol use disorder. In the results of the pre-post-follow-up test scores of the depression between the experimental group and the control group, the experimental group showed a significant effect on the group interaction according to time in all the sub-factors, but no significant change was observed in the control group. This means that dialectical behavior therapy skills training affects the depression of the experimental group and the effect is sustained. In addition, results of this study was supported by the results of a study on middle school students with depression tendencies^[22] and a previous study on elderly depression patients^[23].

Depression is a negative emotion commonly experienced by people with alcohol use disorders, which is uncomfortable and overwhelmingly prone to cause thought and action in suicide, requiring thorough management. The technique of imagination takes advantage of the power of the mind to produce a positive emotion, which is a simple way to visualize a relaxed scene in great detail^[25], and the contents of the program seemed to reduce the depression of the experimental group as a result of re-supplying the power to accommodate the strong and overwhelming emotional distress, causing the participants of the experimental group to experience physical and psychological relaxation.

Second, the experimental group participating in dialectical behavior therapy skills training showed a significant increase in all sub-factors in the pre-post-follow up tests of abstinence self-efficacy after the

program, and the score was also maintained in the follow-up test. In addition, through the change of the pre-post-follow up tests, the experimental group improved in all the sub-factors during the program implementation and remained until the follow-up examination period, while the control group remained almost unchanged. This is a result demonstrating that dialectical behavior therapy skills training is effective in promoting abstinence self-efficacy of people with alcohol use disorder. The result of the study is supported by a study of a 2-year clinical trial of patients with borderline personality disorder, the group that performed DBT reported that the number of days of substance use was significantly reduced, and that some have stopped using substances^[26], and a DBT program study on patients with methamphetamine abuse where abstinence was maintained in the 6-month and 1-year follow-up results^[27].

Based on these results and effects, the significance and implications of this study are as follows. For the first time in Korea, the study applied dialectical behavior therapy skills training to people with alcohol use disorder and the results showed that depression decreased and abstinence self-efficacy showed a significant change, thus providing a framework for self-regulation of abstinence and recovery of people with alcohol use disorders. In addition, the significance can be seen in that, based on the results of this study, there is potential to apply dialectical behavior therapy training at the hospital or in the community.

Conclusion

There are limitations of this study and suggestions for follow-up studies. The subjects who participated in this study were a few people with alcohol use disorder who were admitted to a single mental health medicine hospital, and there is a limit to the environmental and sociological characteristics of the subjects, making it difficult to generalize them to people with alcohol use disorder. In future studies, there is a need to study people with alcohol use disorders according to various demographic and sociological characteristics. In addition, it is proposed to study various effects of dialectical behavior therapy skills training by adding various variables such as anxiety, depression and abstinence self-efficacy.

The Effect of Parenting Attitudes and Major Satisfaction on Career Decision Making Self-Efficacy in undergraduate Students

Kyung Sook Kim

Professor, Dept. of Nursing, Namseoul University, South Korea

Abstract

Background/Objectives: The purpose of this study was to examine the effect of parental attitude and major satisfaction on the career decision making self-efficacy.

Methods/Statistical analysis: The subjects were students from N university. The instruments were used structured questionnaires for major satisfaction, parental attitude, and career decision making self-efficacy. Data were analyzed using descriptive statistics, and hierarchical regression.

Findings: The mean scores of career decision making self-efficacy, major satisfaction were 2.82 ± 0.43 , 3.03 ± 0.52 points respectively. As a results of regression analysis, age and major satisfaction were statistically significant factors. Of the variables added in Model 3, only the achievement oriented was a significant factor affecting career decision making efficacy.

Improvements/Applications: Based on the results of this study, achievement-oriented parenting attitudes are needed at home to enhance career decision-making self-efficacy of college students, and career counseling should be done considering major satisfaction.

Keywords: *Career decision making self-efficacy, Parenting attitude, Major satisfaction, undergraduate students*

Introduction

Many people are highly interested in job position which is very prospective in future society. However, it is still unclear that which occupation will be more promising job due to drastic technology development, change of industrial system, and aging phenomenon. As society become more complex and uncertainty of job career increase, adolescents are susceptible to getting high stress to decide proper occupation^[1]. Especially, majority of Korean students have little time to search their aptitudes or decide their future career path during adolescence because of education system, which is mainly focused on university entrance exam and excessive burden of educational stress. Major selection without adequate consideration makes students hard to

adapt well in the university life. Searching and selecting various careers is one of the most important tasks among the college students^[2]. Undergraduate students finally decide their own career path through considerate preparation with searching about their abilities, personal interests, characteristics, and values. Through this process, they can encounter many psychological and social difficulties; insecurity future, employment anxiety, pressure for success. College students are struggling to deal with such problems by getting useful advices from their parent, teachers, and mentors^[3]. In recent years, there have been many successful cases that college students deal with career problems by easily getting useful information using online media such as internet. In practice, college students much prefer to collect information about prospective and high-income jobs using various online networks than getting advices from their alumni or professors. Besides, they can share job information by forming relationship in social networks to manage career problems in case

Corresponding Author:

Kyung Sook Kim,

kgs4321@nsu.ac.kr

they couldn't get adequate help from online searching. Various factors; career attitude maturity, career decision making, career adaptability, career preparation skills are actively studied between researchers^[4], and these factors have close correlation with job satisfactory, life satisfactory, and subjective stability^[5].

Family is the smallest unit of society which human first encounter and form one's own lifestyle and life values. Children are strongly effected from their caregivers, and the effects are not just confined to childhood but remain until adulthood^[6]. Moreover, parenting attitudes perceived by children have strong influence on achievement goals, self-esteem, self-efficacy, self-control, materialism values^[6,7]. Additionally, active interaction with parents have effects on emotional, cognitive, and social development of children and is a factor to experience socialization and develop personal skills^[8]. As Basow & Howe claimed^[9], parents have the most powerful impacts on their children for career decision and their main responsibility is that help children to make proper career decision and regard oneself as a competent and prospective person. Adolescents who were employed in jobs that do not match their majors were reported to have lower wages^[10], have lower job satisfaction^[11] and higher turnover rates^[12].

Thus, this study has conducted to provide basic materials for program development which assist career decision and improvements of college students.

Method

The subjects were 122 students from N university. Career Decision-Making Self-Efficacy Scale-Short Form(CDMSES-SF)^[13] was used as the questionnaires. This tool was translated into Korean by Lee and Lee^[14]. The higher the score, the higher the career decision-making self-efficacy. Parenting attitude is the instrument developed by Oh & Lee^[15]. This tool is divided into four areas of affection-hostility, autonomy-control, achievement-non achievement, rationality and irrationality. Each item has a five-point Likert

scale, which means that the higher the score, the more affectionate, autonomous, accomplished, and reasonable.

For the major satisfaction, 12 items of 5 points Likert scale were used, including 5 items of curriculum satisfaction and 7 items of general satisfaction among 34 items developed by Ha^[16]. Data were analyzed using descriptive statistics, Pearson's correlation and hierarchical regression by SPSS 23. To begin the study, All students completed the informed consent form and agreed to participate prior to administering the study. Participants also received information on this study including research aims, potential risks, and benefits of this study.

Result

1. General characteristics of the subjects

The sample data consisted of 122 students, 33 males (26.8%), and 90 females (73.2%). The mean age of the subjects was 21.8 years. Of the 122 students, 28 students (22.8%) were freshmen; 59 (48.0%) were sophomores, 18 (14.6%) were juniors and 18 (14.6%) were seniors. Parents were mostly concerned about their children's employment and 74 parents (60.1%) were very interested in getting a job. Career decision making self-efficacy was significant difference between the two groups in terms of the major of the subjects

2. Descriptive statistics and correlations

Descriptive statistics for main variables are shown in Table 2. The mean scores of career decision making self-efficacy, major satisfaction were 2.82 ± 0.43 , 3.03 ± 0.52 point, respectively. The average scores of affection orientation, autonomy orientation, achievement orientation, and rational orientation in the subscale of parental attitude were 2.96 ± 0.46 , 2.73 ± 0.30 , 2.96 ± 0.39 , 2.95 ± 0.49 , respectively. Career decision making self-efficacy was significantly positively related to major satisfaction ($r = .626$, $p < .001$), affection-oriented ($r = .240$, $p = .008$), and achievement-oriented ($r = .472$, $p < .001$).

3. Factors influencing the burnout of the nurses

The hierarchical regression analysis was conducted to examine the factors affecting career decision making self-efficacy (see Table 4). The analysis was used to control the effects of personal characteristics and major satisfaction, subdomain of parental attitude. Model 1 included age and major. Model 2 added major satisfaction to Model 1, and Model 3 added 4 subdomain of parental attitude to Model 2. Multicollinearity was found to be acceptable through tolerances and VIF.

Model 1 was statistically significant in age and major. In Model 2, major satisfaction and age were found to be factors significantly associated with career decision making self-efficacy. Of the variables added in Model 3, only the achievement oriented was a significant factor affecting career decision making efficacy. Age and major satisfaction were also statistically significant factors affecting career decision making self-efficacy. The adjusted explanatory power was 79.0% and increased by 2.7% over Model 2.

Table 4: Factors affecting career decision making self-efficacy

Variables	Model 1		Model 2		Model 3

Discussion

Recently, the occupational groups have become more complex and diversified, and undergraduate students have been worried about their career after graduation. Parenting attitudes play a decisive role in the cognitive, emotional and behavioral development of children^[17]. and parents have the greatest influence on their career decisions^[18]. Also, the university students work to develop competencies to establish their careers,

and to grow as capable professionals.

The results of this study are summarized as follows.

First, there was a significant correlation between major satisfaction and career decision-making self-efficacy, and affective, autonomous, achievement-oriented, and rational-oriented attitudes among sub-variables of parenting attitude had a significant positive correlation with career decision-making self-efficacy.

In a previous study of middle school students[19], the parental attitudes perceived by the children, the more affectionate, autonomous, achievement, and rational oriented, the higher the children's self-efficacy and also, the higher the career maturity. Therefore, parental affectionate, autonomous, achievement-oriented and rational-oriented parenting attitude is considered to have a positive result in choosing and deciding the career of the child.

Second, among general characteristics, age and major characteristics were factors of career decision-making self-efficacy in model 1, and age was also a significant factor in models 2 and 3. The effect of age is believed to have contributed to confidence in career decision-making due to a great deal of interest and effort as we grow older. Additionally, major satisfaction is considered to be more important in career decision-making than major characteristics. Satisfaction in one's major increases self-efficacy in career decision-making, which is also linked to future job adjustment.

Third, in the hierarchical regression analysis, major satisfaction was the most important factor affecting career decision self-efficacy. Career decision making self-efficacy increased with increasing major satisfaction. This was similar to the research of Lee and Kim^[20], whose major satisfaction had a significant relationship with career decision efficacy^[21].

When job matching coincides with the major, job satisfaction is high and turnover intention is lowered^[22]. Therefore, career education or counseling of university should be focused on students who are not satisfied with their major. The findings of this study suggest that universities need to provide programs to support career exploration and career decision-making for students who are not satisfied with their majors.

Fourth, only achievement-oriented parenting attitude influenced career decision-making self-efficacy. Many career education researchers have reported the effects of parenting attitudes on career decisions^[18,23]. Father's achievement-oriented parenting attitude influenced the career attitude maturity of elementary school children^[23]. The current study also suggest that parents' achievement-oriented attitudes may influence how children choose and decide on their careers. Parents' achievement-centered attitudes seems to have led them to design their career plans more systematically and concretely with confidence in their careers.

If adolescences have a career that suits their aptitude through their career plans, they will be well-adapted to work and have high job satisfaction. Parents need to have a nurturing attitude that emphasizes the preparation for self-realization and the competence of the social needs. Additionally, as the degree of autonomy of parents was related to career decision-making, the more they supported autonomy, the more positive the adolescents were in the tasks necessary for career decision-making^[24]. In this study, there was a positive correlation between career decision-making self-efficacy and autonomous orientation, but it was not an influence factor. By the way, according to Kim et al, father and mother's autonomous parenting attitude was an influencing factor undergraduate students' career calling positively^[25]. Ivengar and Lepper^[26] say that in Western cultures, the positive effects of autonomous parenting attitudes are emphasized, whereas in Asian cultures, the consequences of controlled parenting attitudes are not negative. Sovet and Metz^[27] pointed out that the influence of autonomy on parenting attitudes could vary according to culture and Korean adolescents showed a positive relationship with their parents' strict and controlled behaviors and career decision-making self-efficacy. Therefore, further studies are needed because the sub-variables of rearing attitude are limited in explaining the effect on career decision-making self-efficacy.

In conclusion, in order to enhance the career decision-making self-efficacy, it is necessary to confirm the satisfaction with the major and to provide career counseling for students with low major satisfaction. In addition, Parents need to support their children to have the competencies required by future jobs.

Conclusion

This study was attempted to identify the factors that affect the career decision making self-efficacy of undergraduate students. The main results of this study are as follows. Career decision making self-efficacy was significant difference between the two groups in terms of the major of the subjects. Hierarchical regression analysis showed that of the variables added in Model 3, only the achievement oriented was a significant factor affecting career decision making efficacy. Age and major satisfaction were also statistically significant factors affecting career decision making self-efficacy. Based on the results of this study, achievement-oriented parenting attitudes are needed at home to enhance career

decision-making self-efficacy of college students, and career counseling should be done considering major satisfaction.

Changes in Chemical Structure of Iopamidol Contrast Agents According to Radiation and Environmental Conditions

Beom-Hee Han¹, Cheong-Hwan Lim², Sung-Hun Jeong³

¹Doctoral Student, Dept. of Health Care, Hanseo University, Rep. of KOREA, ²Professor, Dept. of Health Care, Hanseo University, Rep. of KOREA, ³Doctor, Dept. of Radiology, Seosan Jungang General Hospital, Rep. of Korea

Abstract

Background: To prevent contrast agent's side effects, it is important to provide accurate information about the contrast agent and fulfill the duty of explaining the medication, experience of side effects, and medical history. However, the incidence of safety accidents associated with contrast agents is continuously increasing. Therefore, the objective of this study was to prepare an improvement plan for problems derived by analyzing changes in chemical structure of contrast medium according to radiation and external environment.

Method: The chemical structure of the standard sample was analyzed using Nuclear Magnetic Resonance Spectroscopy (NMR) in P contrast agent of Iopamidol preparations used in Korean medical institutions. Samples were obtained by irradiation under 3Gy and 5Gy conditions according to the Photon 10MV, Electron 20MeV condition and the radiation dose according to the radiation and environmental conditions. Contrast agent samples after opening and sealed but expired samples were also obtained. These samples were analyzed and chemical shift values in the ¹H-NMR spectrum using NMR analysis were compared.

Findings: ¹H-NMR analysis results of P contrast medium irradiated with Photon 10MV and 5Gy and sealed but expired P contrast medium samples showed no change in chemical shift. However, there were changes in chemical shift value in P standard sample, showing triple peaks in 1.1-1.2ppm range. In addition, the sample irradiated by Electron 20MeV and 3Gy showed double peaks. The sample irradiated by Electron 20MeV and 3Gy condition showed a single peak in the 3.0-3.5ppm region, demonstrating a change in chemical shift value. In the 1.0-1.4ppm region, P contrast medium standard samples showed triple peaks and opened contrast medium samples showed double peaks in the middle peak among the triplet, demonstrating changes in chemical shift value.

Improvements: Changes in chemical structure of contrast agent were observed in contrast medium after electron irradiation and in contrast medium after opening. In this regard, guidelines for the administration of contrast medium should be prepared as soon as possible so that consumers could have accurate information and their right of choice.

Introduction

X-ray was discovered by a German physicist, Professor Roentgen, in 1895. It has revolutionized medical imaging. Internal structures of the human body can be revealed depending on relative densities of

adjacent tissues. By energy absorbing or transmitting X-rays, medical image could be convert into a black and white ratio. However, for some biological tissues, it is difficult to use X-ray absorption to distinguish between absorption and the neighboring tissue. In the case of barium sulfate and vascular and biliary. To overcome this problem, in the early days, clinical application of iodinated benzoate was started by filling the tube or body cavity with a substance of sufficient density for X-ray absorption^[1-2].

Corresponding Author:

Cheong-Hwan Lim,
lch116@hanseo.ac.kr

The iodinated material not only provides contours of the invisible tissue in traditional X-rays, but also provides physiological data as it penetrates into the tissue where disease is expected and exits through blood vessels. In addition, various iodide microparticles have been developed to show the outline of the reticular endothelial tissue in a very limited range. Such substances were developed in the early 19th century to nicely complement the existing X-ray technology^[3-4].

Contrast agent technology has advanced dramatically since then. The development of non-ionic contrast agents has removed charges, reduced osmotic pressure, and reduced overall toxicity tremendously^[5].

With these remarkable advances in CT, MRI, and ultrasound, the clinical application of contrast agents has completely changed the existing concept, enabling the clarification of difference in density of adjacent tissues that could not be distinguished by X-rays in the past. Most importantly, new possibilities for tissue growth have been developed. By changing the magnetic moment or reaction state of the tissue, it plays an important role in magnetic resonance and ultrasound imaging. Expression of target tissues by this concept and selective enhancement have provided the basis for more exciting developments in the evolution of contrast agents^[6].

However, the occurrence of safety accidents ranging from mild side effects such as rash after injection of contrast agent to death in serious cases due to increase in contrast agent use continues to increase. Recently, harm cases of contrast agents received by the Consumer Injury Surveillance System (CISS) have been steadily received and side effects related to contrast agents have increased more than eight times over five years from 1,688 cases in 2009 to 14,572 cases in 2014. In order to prevent contrast agent's side effects, it is important to provide accurate information about the contrast agent drug and fulfill the duty of explaining the medication, experience of side effects, and medical history^[7-8].

Thus, the objective of this study was to grasp safety status of contrast agents used by hospitals and prepare improvement measures for problems derived by analyzing chemical structure changes according to the change of external environment. Results of this study will help us secure consumer safety.

Method

The most useful method for determining the

structure of matter is the study of spectroscopy. Among many spectroscopy methods known to date, the best is the NMR spectroscopy method which can analyze even a small amount of sample. This method has recently been extended to all fields dealing with materials, not only in the structure of chemicals, but also in fields of metabonomics for quantitative analysis, drug development, and drug design. P contrast agents of Iopamidol formulations were also analyzed using NMR to identify chemical structural changes.

1. Research Materials

The water-soluble iodine contrast agent has a basic structure of tri-iodinated benzene, in which three iodine atoms are bonded to positions 2, 4, and 6 of the benzene ring^[9-10].

Since tri-iodinated benzene itself is not soluble in water, water-soluble iodine contrast agent is made by combining substituents with side chains (R1, R2, R3) corresponding to positions other than iodine bonds to provide water solubility^[11-12]. Therefore, the difference between various iodine contrast agent is the difference in the structure of the substitution material. By changing this structure, the water-soluble iodine contrast agent is improved^[13].

Non-ionic monomers that are widely used at present have many (5-6EA) -OH bonds on three side chains, including a carboxyl group. Hydroxyl groups have a very high affinity for water, making the entire compound water-soluble. Since non-ionic monomers are not ions, dissociation does not occur in aqueous solution or blood. They exist in one molecule. Therefore, low osmotic pressure can greatly reduce the risk of side effects. In addition, the number of iodine in non-ionic monomeric contrast medium determines the contrast of radiographic images^[14-16].

Non-ionic monomer contrast agents currently used by hospitals mainly have six types: Iopamidol, Iopromide, Iohexol, Iobitridol, Ioversol, Iomeprol [Table 1]. Among which, P contrast agent of Iopamidol formulation accounts for more than 60% of the Korean medical market. P contrast agent features Iopamidol formulation with the lowest viscosity among the first contrast agents developed in Korea. It has a molecular formula of $C_{17}H_{22}I_3N_3O_8$ [Figure 1]. As an additive, a mixture of tromethamine, sodium calcium edetate, hydrochloric acid, and water for injection shows effect for peripheral vein and cerebral artery angiography^[17].

Table 1. Types of Non-ionic Monomer Contrast Agent

Formulation	Product Name
Iopamidol	Iopmiro, Pamiray
Iopromide	Ultravist
Iohexol	Omnipaque, Omnipure, Iobrix, iMAX, Hexosure, Ashexol, Bonorex, Everay
Iobitridol	Xenetix
Ioversol	Optiray, Tomoray
Iomeprol	Imeron

IOPAMIDOL

Figure 1. Chemical Structure of P Contrast Agent (Iopamidol)

2. Experiment Equipment

NMR spectra enable structural analysis of compounds based on locations of resonance peaks. For most organic compounds, analysis with ^1H and ^{13}C is commonly used. The principle of NMR can usually be described in three steps: 1) alignment of magnetic nuclear rotation in the applied constant magnetic field; 2) perturbation caused by the oscillating magnetic field in which the alignment of the nuclear spindle is weak, which is generally called high frequency pulse; and 3) the NMR signal is detected after RF or pulse with the voltage that is induced in the detection coil by preceding surrounding nuclear spin.

The distribution of electrons in the molecule changes the resonance frequency. Thus, even the same kind of nucleus might have different NMR resonance frequencies. In NMR, instead of directly indicating the

resonance frequency, the difference from the resonance frequency of the reference material is converted into a chemical shift and displayed. In addition, spectral peaks can be cracked through spin-spin coupling with other nuclei with the same molecular spin.

In ^1H -NMR, the resonance signal is recorded by how much it is shifted from resonance signals of 12 equivalent hydrogens among TMS (Tetra Methyl Silane). In ^{13}C -NMR spectrum, the resonance signal is recorded by how far it is from resonance signals of four equivalent carbons among TMS. The position of the resonance peak is called a chemical shift expressed as δ in ppm (part per million) (Equation 1).

$$\delta = \frac{\nu_{\text{sample}} - \nu_{\text{reference}}}{\nu_{\text{reference}}} \times 10^6 \quad (\text{Equation 1})$$

The chemical shift value of ^1H appears over the range of 0-10ppm. ^{13}C chemical shift value is distributed over the range of 0-220ppm, wider than ^1H [18].

3. Research Methods

This study aims to understand changes in safety and environment of the contrast medium for P contrast agent which has the highest share among the 6 non-ionic monomer contrast agents used in Korean hospitals by analyzing its chemical composition using NMR in accordance with changes of radiation dose, radiation energy, and time.

First, NMR was used to accurately identify the chemical structure of the standard sample of P contrast medium. Next, the P contrast agent stimulated by a change in radiation energy, dose, or time under the following conditions was collected:

- (1) Radiation energy: Photon 10MV, Electron 20MeV;
- (2) Radiation dose: 3Gy, 5Gy;
- (3) Changes in time were analyzed for sealed and expired P contrast media;
- (4) External exposure: analysis after opening.

The structure of the material was derived from data of chemical structure analysis using NMR. Elements of material structure were estimated and analyzed by using chemical shift values.

Result

1. $^1\text{H-NMR}$ analysis of standard samples of P contrast agent

Analysis of the standard sample of P contrast agent was well shown in the $^1\text{H-NMR}$ spectrum. Broad peaks appeared in the 8.968ppm region of the $^1\text{H-NMR}$ spectrum. Double lines appeared around 4.5ppm. Single lines appear in 4.159ppm and 3.849ppm regions. The triplet that appeared around 3.6ppm was tromethamine. The doublet that appeared around 1.5ppm and the triplet that appeared around 1.2ppm were impurities. The highest peak in the 4.8ppm region was predicted to be water[Figure 2].

Figure 2. $^1\text{H-NMR}$ analysis of standard samples of P contrast agent

2. $^1\text{H-NMR}$ comparison analysis of specimens irradiated with standard P contrast agent and photon 10MV at 5Gy

According to $^1\text{H-NMR}$ analysis, the standard sample of P contrast medium and the P contrast medium irradiated by photon 10MV and 5Gy showed no change in chemical shift.

3. $^1\text{H-NMR}$ comparison analysis of specimens irradiated with standard P contrast agent and electron beam 20MeV at 3Gy

Analysis of $^1\text{H-NMR}$ analysis for the reference sample of P contrast medium and P contrast medium irradiated by electron 20MeV at 5Gy showed that the P reference sample had peaks in triplet at 1.1-1.2ppm region, but had double line peaks in the condition of electron beam energy 20MeV and dose 3Gy, demonstrating a change in chemical shift value[Figure 3]. In the 3.0-3.5ppm region, the P standard sample did not show a peak. However, it showed a single line peak in the condition of electron beam energy of 20MeV at 3Gy, providing evidence that the chemical shift value was changed[Figure 4].

Figure 3. $^1\text{H-NMR}$ comparison analysis of specimens irradiated with standard P contrast agent and electron beam 20MeV at 3Gy (1.1-1.2ppm area)

Figure 4. $^1\text{H-NMR}$ comparison analysis of specimens irradiated with standard P contrast agent and electron beam 20MeV at 3Gy (3.0-3.5ppm Area)

4. $^1\text{H-NMR}$ comparison analysis of standard P contrast agent and after fixed period of time sealed P contrast agent

$^1\text{H-NMR}$ analysis of the standard sample of P contrast agent and the sealed but expired P contrast agent showed no change in chemical shift value.

5. $^1\text{H-NMR}$ comparison analysis of P contrast agent standard samples and after opening

According to $^1\text{H-NMR}$ analysis of P standard sample and opened P contrast medium sample, the P standard sample clearly showed triple peaks in the 1.0-1.4ppm region. The opened contrast medium sample showed double peaks in the middle among the triplet, demonstrating changes in chemical shift value[Figure 5].

Figure 5. $^1\text{H-NMR}$ comparison analysis of P contrast agent standard samples and after opening

Conclusion

In this study, chemical structure change was analyzed by NMR for P contrast agent of Iopamidol preparation among non-ionic monomer contrast agents according to changes in radiation dose, radiation energy, and time. As a result, ¹H-NMR analysis of P contrast medium irradiated with photon 10MV at 5Gy and sealed but expired P contrast medium showed no change in chemical shift. However, there was a change in chemical shift value in contrast agent after irradiated electron beam and in opened contrast agent sample. In this regard, government guidelines for the administration of contrast medium should be prepared as soon as possible. Accurate information on the contrast agent should be provided to consumers for their right of choice.

Factors affecting the Post-Anesthetic Recovery Score and Length of Stay in the Recovery Room in Elderly Patients with Hypertension

Sunmi Kim¹, Myoungjin Kwon²

¹Nurse, Chungnam National University Hospital, South Korea, ²Assistant Professor, Daejeon University, Dept. of Nursing, South Korea

Abstract

Background/Objectives: As the elderly experience a decline in physical and mental function, their memory decreases, their dependence increases, and their adaptability is reduced, resulting in a reduction in their ability to adapt to surgical operations. To improve the elderly patients' resilience to surgery and anesthesia, it is necessary to identify factors that affected them.

Methods/Statistical analysis: The subjects of this study were 104 elderly patients with hypertension, who underwent elective surgery under general anesthesia, understood the purpose of this study, and voluntarily agreed to participate in the study. In this study, data on the general characteristics of patients, disease-related factors, and related postoperative factors were collected. Data collected were analyzed using IBM SPSS 25.0 program. The significance level was set to .05.

Findings: The factors significantly affecting the post-anesthetic recovery score included education level, experience of surgical operation, anesthesia length, operative site, GCS, body temperature, and cerebrovascular complications, and their explanatory power was 68.9% ($p < .001$). The factors significantly affecting the length of stay in the recovery room included the frequency of surgical operations, cardiac disease, operative site, pain, body temperature, airway obstruction, and the amount of bleeding, and their explanatory power was 54.9% ($p < .001$).

Improvements/Applications: To increase the post-anesthetic recovery score and reduce the length of stay in the recovery room in elderly surgical patients, it is necessary to identify the influencing factors and provide appropriate interventions. We suggest that further studies be conducted in the future to investigate factors related to surgical operations and anesthesia in the elderly.

Keywords: Hypertension, Elderly, Post-anesthetic recovery, Length of stay, psychotic factors

Introduction

In South Korea, the elderly population aged 65 or over was approximately 7.4 million in 2018, accounting for 14.3% of the total population of 51 million^[1]. In 2016, South Korea's life expectancy was 82.36 years old; however, its healthy life expectancy was 64.9 years old, and the duration of disease or injury in individuals is approximately 17 years^[2].

Of the elderly in South Korea, 98.5% have one or more chronic diseases, and 73.0% are patients with multi morbidity, that is, they have two or more chronic diseases. To control disease, the elderly constantly make use of medical institutions, of which 77.4% of the elderly have used health centers in the past one month, and the average number of their visits to medical institutions was 2.4 times^[3]. In addition, out of the total 491,926 operations in 2015 in South Korea, 346,811 were performed on elderly patients aged 65 or older, accounting for 70.5%^[4]. However, the perioperative mortality rate for elderly patients is 3-5 times higher than for non-elderly patients, and much attention is,

Corresponding Author :
Myoungjin Kwon
E-mail: mjkwon@dju.kr

thus, required from anesthesia induction to recovery in elderly patients^[5].

The prevalence of hypertension, which is the most prevalent among chronic diseases, is over 60.0% in individuals over the age of 65, and it increases with age, causes various diseases, and worsens symptoms^[6].

In particular, the risk of surgical operation for the elderly with hypertension increases, and such patients may often face difficulty in recovering from anesthesia^[7,8]. Therefore, surgical operations and anesthesia for elderly patients with hypertension require a careful approach, considering related influencing factors.

The post-anesthesia recovery score is used to assess the extent of recovery of patients in the recovery room, and provides reasonable information in determining discharge from the recovery room by assessing reflexes, breathing, consciousness, circulation, and skin color in patients^[9]. As elderly patients have a high prevalence of various diseases, more attention is needed for appropriate recovery management and post-anesthetic recovery management in the recovery room.

The recovery room is a place where postoperative intensive care takes place, and it has the greatest impact on patients' recovery, and is also the place where nursing care for maintaining the patients' respiratory functions, cardiopulmonary functions, and electrolyte levels is provided^[10].

The length of stay in the recovery room reflects a patient's condition, and an extended length of stay in this room indicates that a patient's recovery is poor^[11]. Therefore, a lot of effort has been made to reduce the length of stay in the recovery room. The results of previous studies have shown that factors affecting the length of stay in the recovery room among elderly patients included age, number of diseases, albumin level, chills, pain, arrhythmia amount of bleeding, cardiovascular side effects, hypertension, delirium, and anesthetic drugs^[11-12]. Regarding nursing care for elderly patients in the recovery room, there is a need for ongoing attention and techniques for effective nursing interventions that take into account the patients' physical and psychological factors.

This study attempted to determine the factors affecting the post-anesthetic recovery score and length of stay in the recovery room in elderly patients with

hypertension.

Method

The subjects of this study were 104 elderly patients with hypertension, who underwent elective surgery under general anesthesia, understood the purpose of this study, and voluntarily agreed to participate in the study.

Data collection was conducted at a university hospital from January 2, 2016 for 6 months using face-to-face questions, which were asked 10 minutes prior to the beginning of surgery after individual patients had entered the operating room area, patient charts, anesthesia records, recovery room records, and direct recording in the instruments of observations in the operating and recovery rooms

The general characteristics of the subjects included gender, age, marital status, education level, drinking status, smoking status, the experience and frequency of surgical operations, the presence or absence of past general anesthesia, and body mass index (BMI).

Disease-related factors included lung disease, thyroid disease, kidney disease, metabolic disease, cardiac disease, diabetes, cerebral disease, cancer, depression, arrhythmia, osteoporosis, dementia, and ASA class.

Postoperative factors included pain, Glasgow Coma Scale (GCS), body temperature, shivering, cardiovascular, pulmonary, and cerebrovascular complications, delirium, endotracheal extubation, airway obstruction, amount of bleeding, nausea and vomiting, the post-anesthetic recovery score, length of stay in the recovery room.

Data collected were analyzed using IBM SPSS 25.0 program:t-test or ANOVA, Scheffe test, Pearson's correlation coefficients, Stepwise multiple regression analysis.

Results

1. Differences in the post-anesthetic recovery score and length of stay in the recovery room according to the general characteristics of the subjects

As shown Table 1, among the subjects, 44 (42.3%) were female, the number of those aged 65-70 years old was 56 (53.8%), and the number of those living with

their spouse was 56 (53.8%). In terms of education level, 44 (42.3%) were elementary school graduates or below, and middle school graduates. There were 68 (65.4%) non-drinkers and 88 (84.6%) non-smokers. The number of those who had experienced surgical operations was 84 (80.8%), the number of those undergoing one operation was 56 (53.8%), and the number of those with experience of general anesthesia was 80 (76.9%). The number of

those with a BMI of 22.9kg/m² was high at 52 (50.0%).

The post-anesthetic recovery score differed according to age, education level, drinking and smoking status, the experience and frequency of surgical operations, and BMI $p < .05$. The length of stay in the recovery room differed according to education level, the experience of surgical operations, and the frequency of operation $p < .05$.

2. Differences in the post-anesthetic recovery score and length of stay in the recovery room according to disease-related factors

As shown Table 2, in terms of disease-related characteristics, there were 16 subjects (15.4%) with kidney disease, 16 (15.4%) with metabolic disease, 16 (15.4%) with cardiac disease, 28 (26.9%) with diabetes, 24 (23.1%) with cancer, and 28 (26.9%) with dementia.

The post-anesthetic recovery score differed according to the presence or absence of cerebral disease and dementia ($p < .05$). The length of stay in the recovery room differed according to the presence or absence of kidney disease, cardiac disease, and arrhythmia ($p < .05$).

3. Factors affecting the post-anesthetic recovery score and length of stay in the recovery room

As shown Table 3, the factors significantly affecting the post-anesthetic recovery score included education level, experience of surgical operation, anesthesia length, operative site, GCS, body temperature, and cerebrovascular complications, and their explanatory power was 68.9% ($F = 13.55, p < .001$).

The factors significantly affecting the length of stay in the recovery room included education level, kidney disease, metabolic disease, diabetes, depression, operative site, cerebrovascular complication, delirium, and airway obstruction, and their explanatory power was 84.4% ($F = 44.01, p < .001$).

Discussion

There were differences in the post-anesthetic recovery score depending on age, education level, drinking and smoking status, the experience and frequency of surgical operations, and BMI among the general characteristics of the subjects. In particular, drinking, smoking, and BMI, which are risk factors for hypertension, had similar effects with the results of this study involving elderly patients with hypertension.

There was a difference in the anesthesia recovery score depending on cerebrovascular disease and dementia among disease-related factors. The post-anesthetic recovery score was lower in those with cerebrovascular disease than in those without this disease, and was lower in those with dementia than in those without dementia. There was a difference in the length of stay in the recovery room depending on the presence or absence of kidney disease, cardiac disease, and arrhythmia, and the length of stay in the recovery room was longer in those with diseases than in those without any disease, which is consistent with the results of a previous study^[13] regarding the length of stay in the recovery room according to the past history of disease in elderly patients. Therefore, these results could confirm that the elderly patients with hypertension also suffer from other chronic diseases.

The results of the multiple regression analysis to determine the factors affecting the post-anesthetic recovery score and length of stay in the recovery room revealed that GCS is the most influential factor in the post-anesthetic score, cardiac disease for the length of stay in the recovery room. In the case of general anesthesia, its main target of action is the central nervous system, and neurologic assessments such as GCS are, thus, needed for patients during awakening from anesthesia^[14]. As neurological injury can affect recovery from anesthesia, related careful nursing care is needed^[15].

According to the results of a study by Kim et al.^[16], cardiac disease was a factor significantly affecting the length of stay in the recovery room, and its impact was greater in elderly patients with chronic diseases such as hypertension. In the case of the increasing elderly surgical patients, the severity of the operation is high and the patients' resilience is often reduced. Therefore, adequate nursing care for elderly patients in the recovery room is, thus, important in reducing complications and mortality^[16-18]. Adequate post-anesthesia care for elderly patients is required, accordingly.

Conclusion

This study was conducted to investigate the factors affecting the post-anesthetic recovery score and length of stay in the recovery room. The results of this study established that the post-anesthetic recovery score was higher in those with higher GCS scores, the length of stay in the recovery room was longer in those with cardiac disease.

To increase the post-anesthetic recovery score and reduce the length of stay in the recovery room in elderly surgical patients, it is necessary to identify the influencing factors and provide appropriate interventions. We suggest that further studies be conducted in the future to investigate factors related to surgical operations and anesthesia in the elderly.

Influencing Factors on Happiness of Nurses in General Hospitals

Sung-Yun Ahn¹, Myoung-Jin Kwon²

¹Associate Professor, Pai Chai University, Dept. of Nursing, South Korea,

²Assistant Professor, Daejeon University, Dept. of Nursing, South Korea

Abstract

Background/Objectives: This study was conducted to verify the effects of quality of life and stress on the happiness of nurses in general hospitals.

Methods/Statistical analysis: The participants were 173 general hospital nurses. Data were collected from November 1 to 15, 2018, and analyzed using SPSS 25.0 program. The significance level was set at .05.

Findings: The results showed a significant difference in happiness ($p < .05$) depending on the general characteristics of age, marital status, number of beds of the hospital, number of nurses of the hospital, job satisfaction level, colleague relationship satisfaction level, employment status, and subjective health. Further, stress and happiness displayed a significant negative correlation ($r = -.27, p < .001$). Job satisfaction level and subjective health were identified as significant influencing factors on happiness.

Improvements/Applications: The implementation of a happiness promotion program that considers the influencing factors is needed to promote the happiness of nurses in general hospitals.

Keywords: Nurse, Happiness, Stress, Quality of life, Influencing factors

Introduction

Every human being seeks happiness. Although people now live in an era of material prosperity, their interest in the pursuit of a happy life is only growing. Happiness is defined by subjective emotions toward and evaluation of one's overall life^[1]. In positive psychology, it is defined as a fun, actively engaging, and meaningful life^[2]. The Republic of Korea (hereafter, Korea) ranks among the lowest, at 29th, among 35 member countries of the Organization for Economic Cooperation and Development in terms of the Happiness Index; other indices, such as environmental quality, health condition, and social connections, are evaluated to be low as well^[3].

Measuring the Happiness Index of nurses at the nursing site in general hospitals is important. As happiness reduces stress and is a factor with a positive

effect on one's environment, happiness at the workplace is critical^[1]. Most importantly, nursing involves the provision of a sense of reliability and stability to patients and emotional interaction with

Corresponding Author: Myoungjin Kwon, Dept. of Nursing, mjkwon@dju.kr

them, so nurses' happiness is directly related to the happiness of patients^[4]. Although nursing is a stable profession that supports people in need and contributes to society, working as a nurse in a clinical environment is considered a difficult job. Therefore, in reality, many nurses in general hospitals prefer other clinical workplaces with better working conditions^[5].

Nurses in general hospitals tend to experience decreasing quality of life deriving from an irregular life style owing to shift work; they undergo much stress. Meanwhile, happiness and joy at the workplace are emphasized as factors that lower the intention of leaving the job for nurses^[6]. If nurses in general hospitals can lead a happy work life, their stress in the work

Corresponding author:
Myoungjin Kwon,
E-mail: mjkwon@dju.kr

environment can be reduced, which, in turn, will allow them to perform their duty, ultimately improving the quality of nursing.

Studies have been conducted on happiness in clinical nurses. Kim^[7] reported that self-respect and work engagement show a positive correlation, whereas depression shows a negative correlation. Nam et al.^[8] showed that higher sense of calling and autonomy and a lower degree of turnover relate to happiness. In Ju et al.^[4], a positive correlation was found with the nursing work environment and a negative correlation with emotional labor. Park^[9] identified a negative correlation with stress and physical symptoms. The happiness of nurses has mostly been associated with variables linked to the nursing work environment. Despite the fact that happiness is an important component for improving quality of life^[10], studies on the relation between happiness and quality of life are few, as are those on the relation between stress and happiness.

In this context, this study aimed to verify the effects of quality of life and stress on the happiness of nurses in general hospitals and to identify relevant factors for their happiness. It is expected that the results can provide useful base data for the promotion of happiness in nurses in general hospitals and clinical environments.

Method

This descriptive correlative study was conducted to verify the effects of quality of life and stress on the happiness of nurses.

The participants of this study were 173 nurses who understood the purpose of the study and voluntarily gave consent to participate in the study. The number of participants was estimated using G*Power ver. 3.1.9.2. Based on a multiple regressive analysis with medium effect size .15, significance level .05, statistical power .95, and 10 variables, the required minimum sample size was 172 nurses.

For the measurement of happiness, the Subjective Happiness Scale developed by Lyubomirsky and Lepper^[11] was used. The tool consists of four questions based on a seven-point Likert scale; higher points indicate greater subjective happiness. Cronbach's α was .78 in this study.

For the measurement of stress, the simplified work stress measurement tool developed by Jang et al.^[12] was

used. The tool consists of 24 questions in total based on a four-point Likert scale; higher points indicate higher work stress. Cronbach's α at the time the tool was developed was .79 and was .80 in this study.

For the measurement of quality of life, the official Korean version of the Professional Quality of Life Scale: Compassion Satisfaction and Fatigue Version 5, developed by Stamm^[13], was used. The tool has 30 questions based on a five-point Likert scale, with 10 items under empathy and satisfaction in a positive section and 20 items under empathy and fatigue in a negative section. Higher points indicate higher empathy and satisfaction, and vice versa. Cronbach's α was .75–.88 at the time the tool was developed, and was .70–.88 in this study.

The survey was conducted from November 1 to 15, 2018. The study purpose, process, participant anonymity, and confidentiality were explained to the participants. The research team pledged to the participants that the collected data would be used only for the study purposes of the study and that they could be withdrawn at any point without any consequence to the participants.

The collected data were analyzed using IBM SPSS 25.0. The analysis proceeded as follows:

- 1) The general characteristics of participants were analyzed based on frequency, percentage, average, and standard deviation.
- 2) Differences in the level of happiness in accordance with the general characteristics were analyzed through a t-test or ANOVA, and a post hoc analysis was conducted by a Scheffe's test.
- 3) Correlations between happiness, stress, and quality of life were studied using Pearson's correlation coefficients.
- 4) A hierarchical multiple regression analysis was conducted on the factors influencing participants' happiness.

Results

1. Differences in happiness according to the general characteristics of participants

As shown in Table 1, the participants were, on average, 31.18 years old, female, and single. In terms of religion, 123 participants (71.1%) were non-religious,

accounting for the highest number. The number of beds of the hospitals where they work was 37.16 on average, with most under 30. The number of nurses of the hospitals where they work was 13.39 on average, with most between 10 and 18. The duration of clinical experience was 87.39 months on average. A total of 103 participants (59.5%) had no experience of turnover, accounting for the highest number. The highest number of responses in terms of work satisfaction was “average,” “satisfactory” for colleague satisfaction, and “average” for subjective health (94 people, 54.3%).

The difference in the level of happiness in relation to age indicated that participants aged 40 years or older had the highest happiness index, and more so when married than when single. Further, the happiness index was higher for the participants working in a hospital with a lower number of beds and nurses, and with higher work and colleague satisfaction. In addition, participants who perceived their health condition to be subjectively healthy showed a higher happiness index ($p < .05$). No significant difference was found in other characteristics.

2. Correlation of happiness, stress, and quality of life

Table 1: General Characteristics and Differences in Happiness According to the General Characteristics of Participants (n = 173)

Characteristics	Categories	n(%)	M(SD)	Happiness	
				M±SD	t/F(p)/Scheffe’s
Age (years)	≤ 29	86(49.7)	31.18(7.53)	17.04(6.54)	6.87(.001)
	30–39	50(28.9)		18.63(3.49)	
	≥ 40	37(21.4)		19.36(3.12)	
Sex	Male	16(9.2)		18.43(3.63)	0.53(.593)
	Female	157(90.8)		17.93(3.55)	
Marital status	Married	57(32.9)		19.25(3.27)	-3.31(.001)
	Others	116(67.1)		17.37(3.54)	
Religion	No	123(71.1)		17.66(3.49)	-1.80(.073)
	Yes	50(28.9)		18.74(3.63)	
Number of beds	≤ 30	90(52.0)	37.16(23.96)	18.60(3.39)	3.27(.040)
	31–58	46(26.6)		17.58(3.93)	
	≥ 59	37(21.4)		16.94(3.19)	

As shown in Table 2, happiness had a significant negative correlation with stress ($r = -.27, p < .001$).

3. Influencing factors of happiness

To verify the explanatory power of influencing factors on happiness, happiness was set as a dependent variable, whereas the variables that showed difference among the general characteristics, such as age, marital status, number of beds and nurses, work satisfaction, colleague satisfaction, work pattern, and subjective health, were set as the primary independent variables. Quality of life and stress were set as the secondary independent variables to conduct a multiple regression analysis. The results of validation of the regressive formula showed that the Durbin–Watson statistic level was 1.86, indicating no issue in auto-correlation. The tolerance limits were .509–.951 and .505–.950, all above 0.1. The levels of variance inflation factors were 1.052–1.965 and 1.053–1.982, all at 10 or below, indicating no issue in multicollinearity.

As shown in Table 3, work satisfaction and subjective

Discussion

This study was conducted to investigate the effects of stress and quality of life on the happiness of nurses. In terms of the general characteristics of the participants, the happiness index was the highest among those aged 40 years or above, and married were happier than unmarried participants. These findings support earlier reports on nurses stating that job satisfaction level as a nurse^[14] and happiness index^[4] are higher as nurses grow older. These also support the fact that nurses tend to find greater happiness in their 40s than in their 20s by helping others^[15]. In terms of employment status, full-time workers had a higher happiness index compared with two- and three-shift workers. This result supports the result of preceding studies^[4,8] that full-time workers are more satisfied than part-time workers and that nurses are less satisfied with their job owing to stress from a three-shift routine. These results show the need for the development of a full-time employment system and environmental support for nurses to accumulate long-term clinical experience, ultimately to promote happiness in nurses.

In this study, the happiness index was high in participants working at hospitals with a higher number of beds and those with higher work satisfaction and higher colleague satisfaction. In addition, we found a statistically significant negative correlation between happiness and stress. Therefore, the reasons for the high happiness index in the abovementioned participants can be understood from this study and previous research results^[10,16] that showed a negative correlation between work stress and happiness. Moreover, a previous study^[4] showed that an increase in happiness occurs when nurses perceive their work environment in a positive way. In other words, if the number of beds, work satisfaction,

and colleague satisfaction are high, the nurse recognizes the working environment as positive and experiences a decrease in stress, which leads to greater happiness.

In this study, work satisfaction and subjective health accounted for 23.8% of happiness. Work satisfaction is an influencing factor according to previous studies that showed that happiness increases when a nurse perceives their work environment positively^[4] and that a high level of autonomy, which affects work satisfaction, promotes happiness^[8]. Considering the earlier results^[17] that the happiness of people working in nursing colleges is affected by organizational factors, such as professional advancement, job characteristics, work environment, and welfare, rather than personal factors, happiness is particularly important for the nursing profession. Therefore, work satisfaction through improving the work environment needs to be considered as a priority in promoting the happiness of nurses.

In this study, the happiness index was high among those who perceived themselves to be subjectively healthy; subjective health alone accounted for 24.6% of happiness. This result supports a previous finding^[18] that awareness of health has a statistically significant positive correlation with happiness. Therefore, improvement in subjective health is highly important in promoting the happiness of nurses.

Conclusion

This study was conducted to verify the effects of quality of life and stress factors on the happiness of nurses in general hospitals and thereby provide basic data for the development of a detailed interventional program designed to promote the happiness of general hospital nurses.

Happiness is the ultimate goal of every human being; all strive to lead a happier life. Happiness is also characterized by its contagious nature, where one human being's happiness is spread to others. The happiness of nurses can trigger positive emotions in patients and can be effective in the treatment of the latter. Therefore, there is a need to invest much effort in promoting the happiness of nurses.

This work recommends a follow up study on various influencing factors on the happiness of nurses. We also suggest the development and application of a happiness promotion program to which such factors are applied.

Cancer Screening Findings in Korean People with Disabilities: 2016-2017

Soo-Kyung Bok¹, Youngshin Song², Ga-Won Seo³, Yeon-Yong, Kim⁴, Seongjun Ha⁴

¹Professor, Chungnam National University College of Medicine, Department of Rehabilitation, Republic of Korea, ²Professor, Chungnam National University College of Nursing, Department of Nursing, Republic of Korea, ³Associate Professor, Joongbu University, Department of Nursing, Republic of Korea, ⁴Researchers, National Health Insurance Service, Big Data Department, Republic of Korea

Abstract

Background/Objectives: Cancer screening programs are effective in the early detection of several cancers. This study aimed to identify the findings of cancer screenings that were conducted in 2016 and 2017.

Methods/Statistical analysis: Sample were obtained from the National Health Insurance Service, and the cancer screening findings among both people with disabilities and those without were compared. Gastric, breast, colon, liver, and cervical cancer were analyze the findings of the screening programs. The findings were categorized as benign, suspicious of malignancy, or other categories (depending on type of cancer). Descriptive statistics and the X2-test were used to analyze the findings among the groups.

Findings: The findings were as follows: For gastric cancer screenings, 0.30% in 2016 and 0.35% in 2017 of those screened who had brain injury were found to have gastric cancer, whereas 0.16% in 2016 and 0.15% in 2017 of those screened who were non-disabled where found to have gastric cancer ($p<.001$). For breast cancer screenings, 0.90% in 2016 and 0.54% in 2017 of those screened who had brain injury had findings that were suspicious of malignancy. For colon cancer screenings, 4.48% in 2016 of those screened who had brain injury were found to have colon cancer, whereas 3.70% in 2016 of those who were non-disabled were found to have colon cancer ($p<.001$). For liver cancer screenings, people with brain injury had the most findings that were suspicious of liver cancer in 2016 ($p<.001$), whereas people with physical impairment had the most findings that were suspicious of liver cancer in 2017 ($p<.001$). The non-disabled group had the highest incidence of carcinoma in situ among groups in 2016 ($p<.001$) and 2017 ($p<.001$).

Improvements/Applications: Rigorous cancer screening programs should be implemented and expanded to include brain injury and physical impairment disabilities for the early detection of gastric, breast, colon, and liver cancer.

Keywords: Disability, Cancer, Screening, Brain injury, Physical impairment

Introduction

Cancer is a major health problem in Korea. Though the incidence and mortality rate of cancer are growing, the 5-year relative survival rate for cancer patients has improved in Korea. For example, in 2016, the cancer incidence rate was 269.0 per 100,000 individuals, but

the 5-year relative survival rate for patients with cancer increased from 41.2% (1993-1995) to 70.6% (2012-2016) [1]. Cancer screening programs may contribute to early detection and the improvement in the 5-year survival rate for cancer patients [2,3].²

In Korea, the National Health Insurance Service's screening programs focus on five types of cancer: gastric, breast, colon, liver, and cervical cancer. Gastric and breast cancer screenings are applied to people over 40 years old, colon cancer in people over 50, cervical

cancer in women over 30, and liver cancer in people over 40 [4]. The frequency of screenings are every 2 years for gastric, breast, and cervical cancer, and once every year for colon and liver cancer [4]. Disabilities is one of venerable state in terms of healthcare. The World Health Organization’s “Global Disability Action Plan 2014-2021” states that “Disability is a global public health issue because people with disability, throughout the life course, face widespread barriers in accessing health and related services, such as rehabilitation, and have worse health outcomes than people without disability” (P.1) [5]. Increases in the number of people with disabilities are related to increases in chronic conditions such as cancer [5]. However, due to physical and socio-cultural limitations, many people with disabilities face barriers to regular access to health services [6,7]. For example, women with disabilities encounter barriers in accessing transportation, buildings, rooms, assistance, equipment, and procedures when seeking cervical cancer (pap smear and human papillomavirus testing) and breast cancer screening (mammography) [8,9].

Cancer incidence rates, survival rates, prevalence, and mortality are annually reported by the Korean government [2,10], but there is limited information regarding studies for comparing the findings of cancer screening among people with different types of disabilities and people with no disabilities. The purpose of this study was to compare the findings of five types of cancer (gastric, breast, colon, liver, and cervical cancer) screenings among both people with and without disabilities in 2016 and 2017.

Method

The study sample was obtained from 2016 and 2017 data from the National Health Insurance Service (NHIS).

In this study, 14,479,357 screenings conducted in 2016 (42,470 in those with brain injury, 448,775 in those with physical impairment, 730,712 in those with any form of disability, and 13,257,400 in those who were non-disabled) and 14,721,500 screenings conducted in 2017 (41,792 in those with brain injury, 440,912 in those with physical impairment, 731,063 in those with any form of disability, and 13,507,733 in those who were non-disabled) were analyzed.

Cancer screenings are available through the National Health Insurance Service for five types of cancers: gastric cancer, breast cancer, colon cancer, liver cancer, and cervical cancer. Findings are classified into different

categories depending on the type. The findings for gastric, breast, and colon cancer are as follows: cancer, suspicious of malignancy, benign, and undefined. The findings for liver cancer are as follows: need more follow-up diagnosis, suspicious of malignancy, and others. The findings from cervical cancer are as follows: infectious disease, carcinoma in situ, suspicious of malignancy, and others.

Frequencies and percentages for cancer screening findings were analyzed using Microsoft Excel (Redmond, Washington, USA) and SAS software (Carey, NC, USA). Descriptive statistics and the X2-test were used to calculate significance.

This secondary analysis study was approved by the Joongbu University Institutional Review Board (JIRB-2019070801-01-190710). After institutional review board approval was obtained, the NHIS approved the extraction of the sample (NHIS-2019-1-457).

Results

1. Gastric cancer screening

For the gastric cancer screenings, 0.30% in 2016 and 0.35% in 2017 of those screened who had brain injuries were found to have gastric cancer, whereas 0.16% in 2016 and 0.15% in 2017 of those screened who were non-disabled were found to have gastric cancer (p<.001). In both 2016 and 2017, the highest gastric cancer diagnosis group was the brain injury group (p<.001). [Figure 1] summarizes the findings from gastric cancer screenings conducted in 2016 and 2017.

Figure 1. The findings from gastric cancer screenings conducted in 2016 and 2017

2. Breast cancer screening

For the breast cancer screenings, 0.90% in 2016 and 0.54% in 2017 of those screened who had brain injury had findings that were suspicious of malignancy, whereas 0.58% in 2016 and 0.64% in 2017 of those

screened who had physical impairment had findings that were suspicious of malignancy. In 2016, the group with the most findings that were suspicious of malignancy was the brain injury group, whereas the group including all individuals with disabilities (the disabilities group) had the most findings that were suspicious of malignancy in 2017 ($p<.001$). [Figure 2] summarizes the findings from breast cancer screenings conducted in 2016 and 2017.

Figure 2. The findings from breast cancer screenings conducted in 2016 and 2017.

3. Colon cancer screening

For the colon cancer screenings, 4.48% in 2016 and 6.56% in 2017 of those screened who had brain injury were found to have colon cancer, whereas 3.70% in 2016 and 3.56% in 2017 of those screened who were non-disabled were found to have colon cancer ($p<.001$). In 2016, 3.75% of those screened who had physical impairment were found to have colon cancer, whereas in 2017, 3.41% of those screened who had physical impairment were found to have colon cancer. In both 2016 and 2017, the brain injury group was the highest colon cancer diagnosed group among the four groups (brain injury, those with physical disabilities, those without physical disability, and the non-disabled) ($p<.001$). [Figure 3] summarizes the findings from colon cancer screenings conducted in 2016 and 2017.

Figure 3. The findings from colon cancer screenings conducted in 2016 and 2017

4. Liver cancer screening

In 2016, 1.17% of those screened who had brain injury had findings that were suspicious of liver cancer, whereas in 2017, 0.65% of those screened who had brain injury had findings that were suspicious of liver cancer ($p<.001$). People with brain injury had the most findings that were suspicious of liver cancer in 2016 ($p<.001$), whereas in 2017 people with physical impairment had the most findings that were suspicious of liver cancer in 2017 ($p<.001$). [Figure 4] summarizes the findings from liver cancer screenings conducted in 2016 and 2017.

Figure 4. The findings from liver cancer screenings conducted in 2016 and 2017

5. Cervical cancer screening

For the cervical cancer screenings, the non-disabled group had the highest incidence of carcinoma in situ among the four groups in 2016 ($p<.001$) and 2017 ($p<.001$). These findings were different from findings for gastric, breast, colon, and liver cancer [Figure 5].

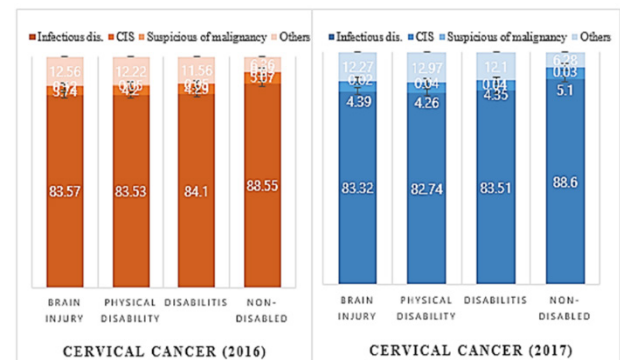

Figure 5. The findings from cervical cancer screenings conducted in 2016 and 2017

(CIS: carcinoma in situ)

Discussion

The results showed that cancer screening findings were different according to presence of disabilities and types of disability in this investigation. Particularly,

the number of suspicious of malignancy findings from gastric, breast, colon, and liver cancer screenings in disabilities caused by brain injury and physical disability were significantly higher than those without disabilities. Cancer is more common in people with disabilities than in people without disabilities because people with disabilities are less likely to be screened at optimal times.

The Korea cancer statistics showed that gastric, colorectal, prostate, thyroid, and liver cancer were highly prevalent in men, whereas women were more prone to thyroid cancer, followed by breast, colorectal, gastric, and cervix uteri cancer [1]. However, only five types of cancer screenings (gastric, breast, colon, liver, and cervical cancer) are offered by the Korean government. Cancer screening not only in those without disabilities but also in those with disabilities can reduce the incidence of late-stage cancer [11].

The gastric, colon, liver cancer are the most common cancer in Korea regardless of being disabilities [10]. Those who have disabilities are more likely to expose a cancer risk factors because there is a limit to fully utilizing physical function contrary to one's will. Particularly, person with disabilities caused by brain injury and physical impairment are not easy to take their regular health screening. [8]

Therefore, based on these findings, more effective cancer screening policies in terms of effective resources, facilities, timing and types of cancers screened should be developed and continuously implemented.

Conclusion

Cancer screening programs are designed for the early detection of cancer. The findings from this study showed that people with disabilities such as brain injury and physical impairment were more likely to be diagnosed with gastric, breast, colon, and liver cancer than non-disabled people in 2016 and 2017. Based on these results, continuous monitoring of cancer screening findings should be performed for disabilities, and various cancer screening programs, such as lung cancer screening programs, should be applied to disabilities.

National Health Screening Program Non-Participation Rates Among Koreans with Brain Injury-Based Disabilities: 2016–2017

Youngshin Song¹, Miyoung Lee², Soo-Kyung Bok³, Ancho-Lim⁴, Yeon-Yong Kim⁵, Seongjun Ha⁵

¹Professor, Chungnam National University College of Nursing, Department of Nursing, Republic of Korea, ²Associate Professor, Eulji University College of Nursing, Department of Nursing, Republic of Korea, ³Professor, Chungnam National University College of Medicine, Department of Rehabilitation, Republic of Korea, ⁴Doctoral Student, Chungnam National University College of Nursing, Department of Nursing, Republic of Korea, ⁵Researchers, National Health Insurance Service, Big Data Department, Republic of Korea

Abstract

Background/Objectives: The National Health Screening Program is currently performed in Korea. This study compared the non-participation rates between disabilities caused by brain injury and those without disability in 2016 and 2017.

Methods/Statistical Analysis: Data were extracted from the National Health Insurance database. Among the data, chest X-ray, blood pressure, blood sugar, body mass index (BMI), auditory and visual functions, Hepatitis B virus, hemoglobin, liver function, bone mineral density, lower extremity function test, balance test, depression, and cognitive function test results were compared between the disability from brain injury and non-disability groups. Descriptive statistics were used to analyse the non-participation rates between these groups.

Findings: About 0.3% (n=42,457) of individuals had disabilities due to brain injury. In 2016, the non-participation rates for chest X-ray and urine cholesterol among those with disability due to brain injury were 3.8%, and 4.1%, respectively. However, the non-participation rates among those without disabilities were only 0.9% and 0.4%, respectively. The non-participation rates among disabilities due to brain injury were also significantly higher than that in those without disability population in other examination programs. In 2017, 3.3% of individuals with disabilities due to brain injury did not participate in chest X-rays, compared to 0.8% of individuals without disabilities. Similarly, the non-participation rates for urine protein test were 4.1% and 0.4%, respectively. The non-participation rate for all examination programs for health screening was higher among those with disabilities due to brain injury than that in those without disabilities. The average non-participation rates for the group of individuals with disabilities due to brain injury were 5.0% in 2016 and 4.4% in 2017, compared to 1.6% and 1.4%, respectively, for the group without disabilities.

Improvements/Applications: The National Health Screening program should be applied to all citizens regardless of disability. Policies are needed to increase participation in health screening programs among individuals with disabilities.

Keywords: Disability, Brain injury, Health, Examination, Program

Introduction

National health screening programs are effective methods that allow timely detection and evidence-based treatment to reduce morbidity and mortality [1]. However, the World Health Organization (WHO) has

Corresponding Author:

Miyoung Lee

Email: mylee3730@eulji.ac.kr

reported that people with disabilities worldwide have difficulty accessing health care and disability-related services [1,2].

In Korea, the government collects information from the National Health Insurance Service Health Screening Database (NHISD) containing the results of health screening programs for its citizens [3]. While many citizens have participated in the National Health Screening program to monitor their health and detect health changes since 1999, some individuals with health conditions such as disabilities cannot easily access the healthcare system to use the National Health Screening program due to limited physical activity and social resources. The purpose of the health screening program is to improve the long-term health outcomes such as hypertension and diabetes by providing opportunities for the insured to change their lifestyles through regular health check-up [4]. From infants to older adults, all life stages can be involved in their health status by school or government screening every one or two years [4]. The health screening program consists of two stages. The primary screening items include anthropometry, tuberculosis testing, chest disease evaluation, and breast radiation, urine protein measurement, anemia assessment, diabetes testing, blood sugar measurement, kidney ailment evaluation, nephritis assessment, liver ailment evaluation, and oral examinations, while cognitive impairment, health education, health risk assessment, blood pressure, and blood sugar are monitored based on the results of primary health screening [4].

According to a national survey of persons with disabilities in 2017, approximately 5.4% of Koreans have physical disability, disability caused by brain injury, etc. Within this population, approximately 10% of disabled individuals have disabilities caused by brain injury. Previous data showed that only 57.2% of people with disabilities caused by brain injury participated in the national health screening program, whereas 80% of people with physical disabilities received government health screening [5]. Although overall non-participation rates were reported for people with disabilities, limited detailed information was available regarding health

screening items.

Therefore, the present study investigated the national health screening non-participated rates among people with disabilities caused by brain injury and compared them to the rates among non-disabled Korean people in 2017 and 2018 using data derived from the NHISD.

METHOD

[Table 1] presents the demographics of the sample.

The study sample was derived from the NHISD, which is provided through the NHIS. The NHIS provides the National Health Insurance Data Sharing Service. Before obtaining tailored data, approval was obtained from the NHIS (NHIS-2019-1-457).

Among 13,289,870 and 13,549,525 insurant registered in 2016 and 2017, respectively, the non-participation rates for each item in the primary health screening people were compared between individuals with disabilities caused by brain injury (n=42,470 in 2016, n=41,792 in 2017) and those without disabilities (n=13,247,400 in 2016, n=15,507,733 in 2017). The majority of non-participants with disabilities caused by brain injury in 2016 and 2017 were male (61.2% in 2016 and 62.8% in 2017). The mean ages among those with disability due to brain injury were approximately 63 years in 2016 and 2017, compared to 48 years in 2016 and 49 years in 2017 among those without disability. Among people with disabilities caused by brain injury, 23% had self-employed insurance in 2016 and 2017, compared to 16% in the non-disability group.

The severity of disability among those with disabilities caused by brain injury is described in Table 1, in which lower grades indicate higher severity. In other words, grade 1 is the highest disability severity level. In the present study, 23.8% of the disabled individuals had grade 3, or moderate, disability, while the prevalence of the other grades ranged from 10–17%.

Table 1. Demographics of sample (N=13,289,870 in 2016; N= 13,549,525 in 2017)

Characteristics	Classification	Disability due to brain injury, n (%)		Non-disabilities, n (%)	
		2016 (n=42,470)	2017 (n=41,792)	2016 (n=13,247,400)	2017 (n=13,507,733)
Sex	Male	26,853 (61.2)	26,262 (62.8)	7,010,648 (52.9)	7,106,969 (52.6)
	Female	15,617 (38.8)	15,530 (37.2)	6,246,752 (47.1)	6,400,764 (47.4)
Age, years	Mean (± SD)	63.35 (±12.40)	63.42(±12.47)	48.77 (±14.02)	49.06(±14.05)
Types of insurance	Self-employed	10,046 (23.7)	9,766 (23.4)	2,237,122 (16.9)	2,263,961 (16.8)
	Employed	27,515 (64.8)	27,146 (64.9)	10,927,476 (82.4)	11,155,556 (82.6)
	Medical aids	4,909 (11.5)	4,880 (11.7)	92,802 (0.7)	16512 (0.6)
The severity of disabilities	Grade 1	4,559 (10.7)	4,549 (10.9)		
	Grade 2	7,057 (16.6)	6,768 (16.2)		
	Grade 3	10,090 (23.8)	9,663 (23.1)		
	Grade 4	6,516 (15.3)	6,328 (15.1)		
	Grade 5	6,770 (15.9)	7,052 (16.9)		
	Grade 6	7,478 (17.6)	7,432 (17.8)		

The data in this study was extracted from NHID in 2016 and 2017.

The primary health screening includes anthropometry (obesity, blood pressure, eyesight, and hearing test), tuberculosis, chest disease, breast radiation, uroscopy (protein in urine), blood (anemia, diabetes, blood sugar, kidney ailments, nephritis, and liver ailment), and oral (dental caries, periodontal disease, and missing tooth) examinations, as well as consultation (diagnosis of past medical history, lifestyle, and general status) and notification of primary health screening results and health risk assessment [4].

Among these screenings, we compared the non-participant rates of chest X-ray for tuberculosis and chest disease, blood pressure, blood sugar, body mass index (BMI), auditory and visual functions, hemoglobin, aspartate aminotransferase/alanine aminotransferase (AST/ALT), low-density lipoprotein (LDL) cholesterol, hepatitis B virus, bone mineral density test (BMD),

physical function test for elderly (low extremity function, balance test), depression, and cognitive function test between people with disabilities caused by brain injury and non-disability. Depression was screened using Patients Health Questionnaire 9-item (PHQ-9) [6] and cognitive function was measured using the Korean Dementia Screening Questionnaire C (KDSQ-C) [7].

Descriptive statistics were performed to analyze the frequencies, percentages, and means of the sample characteristics. The non-participants rates of chest X-ray for tuberculosis and chest disease, LDL cholesterol, hepatitis B, BMD test, physical function test for elderly (low extremity function, balance test), depression, and cognitive function test were calculated based on frequencies and percentages in Excel.

As this study was secondary data analysis, the Joongbu University Institutional Review Board approved a review exemption (JIRB-2019070801-01-190710).

Result

1. Non-participation rates for the National Health Screening program in 2016

[Table 2] shows the National Health Screening program non-participation rates in 2016. The non-participation rates for each health screening item among people with disabilities caused by brain injury and those without disabilities people in 2016 were investigated.

The results showed that people with disability caused by brain injury did not participate in many of the screening items, with 3.8% not receiving chest X-rays to identify tuberculosis and chest disease, compared to 0.9% of those without disabilities. The non-participation rates for blood pressure monitoring, BMI check, and auditory and visual function assessments were also higher in individuals with disability due to brain injury than in those without disabilities.

2. Non-participation rates in the National Health Screening program in 2017

[Table 3] shows the National Health Screening program non-participation rates in 2017.

Among 13,549,626 insured individuals in 2017, 41,772 had disabilities due to brain injury. Among those with disability caused by brain injury, 3.3% did not receive chest X-ray examinations for tuberculosis and chest disease, compared to 0.8% of individuals without disabilities.

Among those with disabilities caused by brain injury, 0.3% did not participate in blood pressure monitoring; in addition, 1.0% of disabled people did not monitor their

BMI. Auditory and visual functions were not assessed in 0.6%, and 0.8% of people with disability caused by brain injury, respectively. In contrast, 0.1% of non-disabled people did not take participate in blood pressure, blood sugar, BMI, auditory and visual functions, anaemia, and liver ailment assessments.

However, similar to 2016 data, there was no difference in 2017 in the percentages of non-disabled people and people with disability caused by brain injury who did not undergo hepatitis B virus antigen and antibody testing. People with disability caused by brain injury also less often received BMD and physical function assessments compared to the rates in those without disabilities.

Table 3. Non-participation rate of national health screening program of disability due to brain injury and non-disabilities in 2017

Health screening items	Target disease	Disability due to brain injury		Non-disabilities	
		Target n	n (%)	Target n	n (%)
Chest X-ray	Tuberculosis and chest disease	41,772	1,380 (3.3)	13,507,854	103,464 (0.8)
Blood Pressure	Hypertension	41,772	117 (0.3)	13,507,854	1,572 (0.1)

Discussion

The purpose of general health screening is the early detection and prevention of cardiovascular and cerebrovascular disease, hypertension, diabetes, and other chronic disease [2,4]. In Korea, the screening targets insured individuals aged 40 years and older, who undergo screening once every two years. Almost all costs are covered by the government. However, persons with disabilities are a venerable population as a health screening.

Previous studies reported that people with disabilities have limited use of medical benefits due to their physical, emotional, and socio-cultural difficulties [8-12]. That is, people with disabilities have restrictions on their use of the healthcare system for screening during their regular health check-ups, thus increasing the prevalence of chronic disease [9]. Hwang et al. reported that 25.3% more individuals with brain impairment had experienced unmet healthcare needs than those without impairments [9]. The lack of money and inaccessible transportation were the main reasons for unmet healthcare needs [9, 11].

The results of this study showed that people with disabilities caused by brain injury did not participate in many of the screening items. Kim et al. reported that only 29.8% of 1,073 people with disabilities participated in the health screening program [5]. Assessment of the non-participants within this population according to demographic factors showed that people of lower age, lower education levels, and severe disability grades tended to have lower health screening participation [5].

Comparison of the health screening non-participation rates in 2016 and 2017 among people with disabilities caused by brain injury showed lower rates of non-participation overall. However, we did not identify the reasons for the lack of participation in health screening.

As such, this study has several limitations. First, statistical significance was not confirmed between individuals with disabilities caused by brain injury and individuals without disabilities. Second, as noted above, information was not available regarding the reasons for non-participation in health screening. Third, although it is meaningful to analyse entire data using national data, future studies should assess non-participation rates according to demographic characteristics. Despite these limitations, the determination of non-participation rates by analysis of 2 years of health screening data from an entire population is an important contribution of this

study.

Conclusion

This study investigated and compared health screening non-participation rates between people with disabilities caused by brain injury and those without disabilities. The results showed that individuals with disabilities due to brain injury received fewer health screenings as part of the program as compared to individuals without disabilities. The participation rates were particularly low for chest X-ray examinations, BMD, and physical function test among individuals with disabilities caused by brain injury compared to those in individuals without disabilities. Based on these findings, further follow-up studies on the non-participation rates of health screening and analysis of their causes are required. Moreover, policies are needed to increase health screening participation rates among individuals with disabilities.

Comparison of Ventilation Volume and Airway Pressure of an Advanced Airways in Virtual Reality Ambulance Simulation

Sang-Gyun Roh¹, Jee-Hee Kim²

¹Professor, Sunmoon University, Department of Emergency Medical Services, 70, Sunmoon-ro, 221 beon-gil, Tangjeong-myeon, Asan-si, Chungcheongnam-do, 31460, Korea, ²Professor, Kangwon National University, Department of Emergency Medical services, 346, Hwangjo-gil, Dogye-eup, Samcheok, Gangwon-do, 25949, Korea

Abstract

Background/Objectives: It is convenient to apply C-E technique during ventilation using bag-valve mask in the moving ambulance. Purpose of the study is to investigate the effective ventilation volume and airway pressure.

Methods/Statistical analysis: The National Fire Service Academy conducted Virtual Reality (“VR”) based ambulance simulations from April 17, 2018 to April 28, 2018. The mean and standard deviations of mean ventilation and airway pressure were analyzed using descriptive statistics and ANOVA and SPSS software 12.0 (SPSS Ins., Chicago, IL, USA) program.

Findings: When VR-based intubation was performed, the ventilation volumes were 375 ml (± 30.71), 225 ml (± 8.48), 324 ml (± 6.56), 244 ml (± 7.79), and 427 ml (± 10.42) when using bag-valve mask, laryngeal mask, laryngeal tube, I-gel, and intubation, respectively. Airway pressure was 17.48 cmH₂O (± 0.28) from endotracheal intubation, 14.79 cmH₂O (± 1.51) from bag-valve mask, 13.49 cmH₂O (± 0.78) from laryngeal tube, 8.66 cmH₂O (± 0.80) from I-gel, 6.73 cmH₂O (± 0.53) from laryngeal mask showed airway pressure.

Improvements/Applications: The present study has significance in that basic data for the method of using a professional airway are provided by adequate ventilation for each professional airway in transit.

Introduction

Since free airway and assisted respiration before the admission affect the patient’s life directly, successful airway management is an essential emergency treatment. For the patients with heart failure, they require onsite professional cardiopulmonary resuscitation (CPR) depending on the situations such as disease status, existence of witness, witness’ CPR, and so on. However, for those who are difficult to perform professional CPR at the site and who do not recover with CPR, professional CPR should be performed during the transportation. It is difficult to perform proper chest compression and

artificial respiration during the transportation due to multiple elements of obstacles.

Artificial respiration is very critical emergency treatment for the patients not only with heart failure but also with apnea. Airway should be secured, and efficient ventilation should be provided at the site applying good airway management. Generally, ventilation is provided by bag-valve mask when CPR is performed at the heart failure state before the admission.

In the ventilation of bag-valve mask, airway management, close contact between mask and face, 1/3 bag compression, prevention of hyperventilation, bag compression during chest compression, and so on may affect the ventilation, which may be worsened during the transportation. In addition, efficient delivery of ventilation may be difficult during the transportation by

Corresponding Author:

Jee-Hee Kim,

E-mail: kjh1962@kangwon.ac.kr

movement of ambulance and unstable posture. According to the recent guideline, efficient ventilation at the heart failure state is recommended to deliver 500 ~ 600 ml ($6 \sim 7 \text{ ml/kg}$)^[1], because the seat of ambulance crew in the ambulance is located beside the patient, it is not convenient to apply C-E technique in case of ventilation using bag-valve mask and also efficient ventilation is difficult due to obstacles despite intubation. Even in case of intubation, it can be pushed out of the mouth during chest compression, hence, it is not easy to deliver ventilation during the transportation.

Many previous studies^[2-4] were conducted related to the delivery of one-time respiration while no study was done related to the ventilation during the transportation. This study was conducted with the subjects of manikins to compare the ventilation volume and airway pressure using bag-valve mask between the situation of basic airway management and the situations of laryngeal mask, I-gel, laryngeal tube, and intubation to the bronchus in the VR-based ambulance. Also, it aimed to compare the results of VR-based study with the previous studies performed in the fixed situation and to apply this to the sites so as to suggest the fundamental data for the efficient delivery of ventilation during the transportation.

Materials and Method

1. Research design and data collection

This is a comparative study to measure the ventilation volume of bag-valve mask with RespiTrainer® Advance in the situation applying special ventilator in the VR-mock ambulance. To do so, VR-based simulation ambulance was used in National Fire Service Academy and “urban beltway scenario” was applied among developed scenarios. Transportation time was for 6 minutes maintaining 60 to 80 km/hour. In the test, 150 times of ventilation volume were compared between the case only using bag-valve mask and the cases using bag-valve mask in the states of intubation, laryngeal tube, I-gel, and laryngeal mask. For the data, ventilation volume to be delivered to the lung and airway pressure were collected using RespiTrainer® software.

2. VR based simulation ambulance

The VR based ambulance designed to enable the education and training of emergency services in various road environments was developed as a fire research and development (R&D) project. VR based simulation ambulance implemented VR by applying Ambulance

Driving Simulation S/W to computer controlled moving platform design [Figure 1]. Six scenarios have been developed to suit the surrounding environment, such as rural, urban and suburban environments, and are designed so that the rescuer can drive while monitoring scenarios set up outside the ambulance.

Figure 1. VR-based simulation ambulance

2. RespiTrainer® Advance

RespiTrainer® Advance (version 1.1, Ingmar, Pittsburgh, USA) is the equipment that is optimized for a wide range of special air intubation training and skills, and has realistic materials and anatomical structures. High-performance test lungs (QuickLung®) can achieve realistic lung capacity in adults, and software can be used to verify data such as ventilation and airway pressure. Airway resistance and compliance were set at $5 \text{ cmH}_2\text{O/L/s}$ and $50 \text{ ml/cmH}_2\text{O}$, which are the mean values of healthy persons without lung disease [Figure 2].

Figure 2. RespiTrainer® Advance

3. Advanced Airway

For BVM, storage sac was attached to Laerdal® Silicone Resuscitator, and volume of bag was used with 1,600 ml. #4 of I-gel® was used after closing opened end

for reducing pressure of stomach. King LTS-D™ #4 was used for laryngeal tube, injecting 80 ml of air to the cuff after closing upper esophageal opening for reducing pressure of stomach. With respect to the tube for intubation, Mallinckrodt® I.D. 7.5 was used fixing 22 cm of intubation depth. Cuff was fixed by Thomas® Tube Holder not to be moved or pulled out after injecting 10 ml of air [Figure 3].

Figure 3. Advanced Airway. Endotracheal intubation(A), I-gel(B), Laryngeal mask airway(C), Bag-valve mask (D), Laryngeal tube (E)

All experiments were conducted within a VR-based simulation ambulance and were conducted at the National Fire Service Academy from April 17, 2018 to April 28, 2018. All data were collected using RespiTrainer® software (version 1.1, Ingmar, Pittsburgh, USA) to collect ventilation and airway pressure. The collected data were analyzed using SPSS software 12.0 (SPSS Inc., Chicago, IL, USA). The mean and standard deviation of ventilation and airway pressure were analyzed using descriptive statistics and ANOVA.

Result

1. Ventilation volume

Ventilation volumes delivered to the lung were compared between the case using VR-based bag-valve mask and the cases using bag-valve mask in the states of intubation. Ventilation volumes were 375 ml (± 30.71), 225 ml (± 8.48), 324 ml (± 6.56), 244 ml (± 7.79), and 427 ml (± 10.42) when using bag-valve mask, laryngeal mask, laryngeal tube, I-gel, and intubation, respectively [Table 1].

Table 1. Comparison of delivered volume

	Mean (ml)	Min	Max	SD	F	p	Scheff'e

2. Airway pressure Ventilation volume

Table 2 shows the results of airway pressure analysis with VR-based endotracheal intubation. The endotracheal tube showed an average airway pressure of $17.48 \pm .28$ cmH₂O, with a minimum airway pressure of 16.70 cmH₂O and a maximum airway pressure of 18.30 cmH₂O. The bag-valve mask showed an average airway pressure of $14.79 \pm .151$ cmH₂O, with a minimum airway pressure of 4.60 cmH₂O and a maximum airway pressure of 17.40 cmH₂O. Laryngeal tube showed an average airway pressure of $13.49 \pm .78$ cmH₂O, with a minimum airway pressure of 11.40 cmH₂O and a maximum airway pressure of 15.40 cmH₂O. I-gel showed an average airway pressure of $8.66 \pm .80$ cmH₂O, with a minimum airway pressure of 6.70 cmH₂O and a maximum airway pressure of 12.10 cmH₂O. Laryngeal mask airway showed an average airway pressure of $6.73 \pm .53$ cmH₂O, with a minimum airway pressure of 5.70 cmH₂O and a maximum airway pressure of 8.10 cmH₂O [Table 2].

DISCUSSION

Airway management is very important for emergency patients. If breathing of a patient is erratic or a patient does not breath, assisted respiration should be provided. The optimization of ventilation during CPR is a broad of research^[5]. A bag-valve mask is used being connected with intubation or with a laryngeal tube, I-gel, laryngeal mask, and so on also in a state it is intubated during positive pressure ventilation^[6,7]. The present study comparatively analyzed ventilation volume delivered to the lung when air was ventilated using a bag-valve mask after a professional airway was intubated in a moving ambulance.

Ventilation volumes were found to be in the order of intubation, bag-valve mask, laryngeal tube, I-gel, and laryngeal mask, showing values of 427 ml, 375 ml, 324 ml, 244 ml, and 225 ml, respectively ($p = .000$). In previous studies, ventilation volumes of intubation, bag-valve mask, laryngeal tube, and laryngeal mask were found to be 497 ml, 386-421 ml, 365 ml, and 351 ml, respectively^[8,9]. However, these studies were conducted in a stationary situation. The surest method to secure an airway is to insert a tube into the airway. While intubation is the method most widely used in hospitals to maintain an airway^[10,11], successful intubation is not easy in a pre-hospital situation. It is possible only when the performer has sufficient experience and is prepared at all times. Thus, intubation is not much performed in a pre-hospital situation in practice^[12,13]. For such a reason, supraglottic airway devices (laryngeal tube, I-gel, and laryngeal mask) are recommended in a pre-hospital situation because they make intubation relatively easy. However, while intubation of a supraglottic airway device is easy, the ventilation state may be poor as it is difficult to achieve adhesion in a moving site and it can be pushed superior and it is difficult to prevent inhalation of stomach contents^[8].

It is also difficult to continuously deliver air required for ventilation volume in a moving ambulance. When the maximum volume and the minimum volume were compared, these values were shown to be in the order of intubation (min. 399 ml, max. 463 ml), bag-valve mask (min. 168 ml, max, 436 ml), laryngeal tube

(min. 305 ml, max. 346 ml), I-gel (min. 229 ml, max. 270 ml), and laryngeal mask (min. 205 ml, max. 252 ml) with the exception of the minimum of bag-valve mask. Differences between minimums and maximums of intubation, bag-valve mask, laryngeal tube, I-gel, and laryngeal mask were shown to be 64 ml, 268 ml, 41 ml, 26 ml, and 47 ml, respectively. All ventilation methods excluding intubation showed low respirations [Figure 4].

Figure 4. Ventilation volume in a VR-based moving ambulance. Minimum and maximum volumes of the ventilation method for which only a bag-valve mask was used continued to be in an unstable state

If the pressure inside the airway exceeds 20 to 25 cmH₂O, it might cause lung damage with reflux and aspiration complication^[13-15]. In previous studies, intubation, laryngeal tube, laryngeal mask, I-gel, and bag-valve mask showed values of 8 to 11 cmH₂O, 8 to 10 cmH₂O, 7.86 cmH₂O, 10 cmH₂O, and 8 to 10 cmH₂O, respectively [8, 16, 17]. In the present study, intubation, bag-valve mask, laryngeal tube, I-gel, and laryngeal mask showed pressure values of 17.48 cmH₂O (±.28), 14.79 cmH₂O (±1.51), 13.49 cmH₂O (±.78), 8.66 cmH₂O (±.80), and 6.73 cmH₂O (±.53), respectively ($p=.000$). It was difficult to continuously deliver airway pressure in a moving ambulance. The minimum and maximum pressures were shown to be in the order of intubation (min. 16 cmH₂O, max. 18 cmH₂O), bag-valve mask (min. 4 cmH₂O, max. 17 cmH₂O), laryngeal tube (min. 11 cmH₂O, max. 15 cmH₂O), I-gel (min. 6 cmH₂O, max. 12 cmH₂O), and laryngeal mask (min. 5 cmH₂O, max. 8 cmH₂O) with the exception of the minimum pressure of bag-valve mask [Figure 5].

Figure 5. Airway pressure in a VR-based moving ambulance. In the case of the ventilation method for which only a supraglottic airway device and a bag-valve mask were used, the minimum and maximum pressures continued to be in an unstable state.

It is convenient to apply C-E technique during ventilation using bag-valve mask in the moving ambulance. Upon the results of VR-based simulation ambulance study, ventilation was high in the order of intubation, bag-valve mask, laryngeal tube, I-gel, and laryngeal mask while laryngeal mask and I-gel had less efficient ventilation.

As not an actual patient but an experimental lung was used, the present study had limitations in that airway resistance or anatomical difference could not be taken into account; VR-based urban outer road scenario failed to sufficiently reflect the field road situation; and it was not clear whether VR-based computer-controlled moving platform design sufficiently reflected the suspension of an ambulance actually driven. However, the present study has significance in that basic data for the method of using a professional airway are provided by analyzing adequate ventilation for each professional airway in transit.

Conclusion

Bag-valve mask is a device to be able to provide the patients who require assisted ventilation with positive pressure ventilation. In case of assisted respiration, 500-600 ml (6-7 ml/kg) is recommended and it is hard to provide proper ventilation volume during the transportation. This is a study performed in the subjects with manikins showing the highest ventilation volume in case of intubation followed by bag-valve mask,

laryngeal tube, I-gel, and laryngeal mask in VR-based ambulance. Compared to the previous studied conducted in the fixed state, ventilation volumes showed lower by 69 ml, 19 ml, and 125 ml in intubation, laryngeal tube, and laryngeal mask, respectively; and minimum and maximum ventilation volumes showed the differences by 168 - 436 ml, 205 - 252 ml, 305 - 346 ml, 229-270 ml, and 399 - 463 ml, in bag-valve mask, laryngeal mask, laryngeal tube, I-gel, and intubation, respectively; demonstrating difficulty in delivering constant amount of respiration in the transportation. Among supraglottic airway devices, laryngeal tube and I-gel showed with 225 ml and 244 ml, demonstrating difficulty in close contact with airway.

Effects of Social Support and Life Stress of Women in Climacterium on Meaning of Life

Ji-Woo Han

Associate Professor, Kyungdong University, Nursing of Department, Korea

Abstract

Background/Objectives: This study is intended to provide basic data on the development of nursing intervention programs to solve the stress of life, the social support, life stress and meaning of life for Climacterium women.

Methods/Statistical analysis: The study was conducted by Climacterium women in W city in Gangwon province, collecting data from February 11 to February 22, 2019, and a total of 173 people.

Findings: The study found that Climacterium women's social support was significant in age, education, marriage, occupation, and monthly income, and that life stress was significant in age, education, marriage, and monthly income. The meaning of life was significantly higher in education, marriage, occupation, and monthly income. Social support for Climacterium women showed a negative correlation with life stress, and a significant static correlation with the meaning of life. Economic problems, which are a lower factor of life stress of Climacterium women, have been a factor that has a significant negative impact on the meaning of life.

Improvements/Applications: Since Climacterium women play a pivotal role in family life, it is necessary to develop a support program that can measure the level of life and fully play a pivotal role in society as a whole.

Keywords: *Climacterium women, Social support, Life stress, Meaning of life, Gangwondo*

Introduction

The climacteric period of women brings about substantially physical, psychological and social changes in terms of developmental steps. Since the blood concentration of estrogens reduce due to the decline of ovarian function, physical and mental symptoms appear in this period^[1]. In addition to physical and mental symptoms, they experience life crisis due to life stress within family life if they do not adapt to it as children grow up, land jobs or go independent for marriage in terms of society^[2]. When faced with stress, social support not only cope with positive stress, but help the environment change to be able to cope with

individual crisis through interaction within the social system of life of women in climacterium. This life stress can affect their whole life and bring about a diverse range of maladaptive symptoms, which consequently could influence on the meaning of life. The meaning of life is cited to serve as a positive factor that grants welfare even in case of stressful situations or accidents that trigger extreme level of stress^[3-4]. The loss of life meaning that could lead to climacteric crisis is one of critical issues for regaining their physical, emotional and psychological conditions since most of them have devoted to family life and child-rearing and centered the meaning of life in family rather than themselves after they got married^[5]. Therefore, research is needed to be carried out to prepare for methods to regain climacterium that affects the meaning of life in a positive way and to remove their life stress and enjoy healthy life.

The present study is thus intended to lay foundations to explore entire life stresses and enhance the meaning

of life they experience by examining variables that social support and life stress affect the meaning of life they feel.

Method

The present study is narrative research to identify the association among social support, life stress and meaning of life of women in climacterium. It presumed that their social support and life stress affect the meaning of life. We set a study model as shown in Figure 1 based on this premise.

Figure 1. Research Model

Subjects in this study were women in climacterium who reside in W city, Gangwon-do. We collected data from February 11 to February 22, 2019. We explained the purpose and reason of our research to women who consented to participate in our study by visiting home, business and educational centers where subjects remain. We needed 166 subjects to determine the number of samples by using G*power 3.1 program^[6] needed for regression analysis shown as effect size=.15, level of significance $\alpha=.05$, and power=.095. Questionnaires were administered to 180 subjects and eventually analyzed data from 173 subjects except for seven non-responded or ineligible questionnaires among collected papers.

For data analysis, we used SPSS v.23 program. ANOVA was employed to analyze the mean difference among demographic features, social support, life stress and life meaning of study subjects. Scheffé test was conducted for post analysis. Pearson's correlation coefficient was adopted to see the association among social support, life stress and life meaning of study subjects according to demographic features. We employed multiple regression and analyzed outcomes to identify the effects of their social support on life stress and life meaning.

Instrument

1. Social support

We used an instrument applied by^[7]. This instrument consists of 13 questions as scales to measure social support of women in climacterium. Questions include seven regarding family support and six on subscales. Each question consisted of five-point Likert scale ranging from 1 point "never" to 5 point "highly." As scores are higher, they are likely to receive more social supports from family, friends, neighbors and groups. Reliability coefficient shown in^[7]'s research turned out Cronbach's $\alpha=.943$ and the coefficient in this study presented Cronbach's $\alpha=.953$. For sub-sectors, family support was Cronbach's $\alpha=.926$ and support from other people showed Cronbach's $\alpha=.938$, respectively.

2. Life stress

Questionnaire through which 20 items were extracted and arranged from instrument on life stress of women in climacterium developed by^[8] was used in the present study. Questions were 20 questions regarding four sections encompassing five questions on family relationship, five questions on economy, five questions on health and other five questions on role. Individual question consisted of five-point Likert scale ranging from 1 point "never serious" to 5 point "very serious" depending on life stress experiences. As scores are higher, it indicated higher level of life stress put on women in climacterium. Reliability coefficient shown in^[7]'s research exhibited Cronbach's $\alpha=.914$ and the coefficient in this study was Cronbach's $\alpha=.955$. For sub-sectors, family support was Cronbach's $\alpha=.944$, economy was $\alpha=.954$, health was Cronbach's $\alpha=.918$ and role presented Cronbach's $\alpha=.895$, respectively.

3. Meaning of life

An instrument on the meaning of life was developed by^[9] and the meaning of life scale (MLQ: Meaning in Life Questionnaire) used by^[10] was restructured. Questions consisted of five-point Likert scale ranging from 1 point "never" to 5 point "highly yes." As scores are higher, it refers to stronger motivation for pursuing the meaning of life, grants and perceives more meanings to subjective life. Reliability coefficient shown in [10]'s research exhibited Cronbach's $\alpha=.880$ and the coefficient in this study was Cronbach's $\alpha=.923$

Results

1. Frequency analysis on demographic features of study subjects

Results of analyzing the frequency of demographic features among 173 participants regarding age revealed that 85 participants in 46 to 50-year-old primarily accounted for 49.3%, whereas 12 people in 40 to 45-year-old were least. For academic background, 81 participants were graduates accounted for 46.6%, while nine under elementary school accounted for 5.5%. For marriage year, 11-15 years accounted for 32.9% (57), while 16-20 years accounted for 8.2% least (14). Part-time job or temporary work accounted for 37% (64), followed by regular job (23.3%, 40), housewife (19.2%, 33), professional (12.3%, 21) and self-employment (8.2%, 14) among entire respondents regarding occupation. Less than four million won accounted for 27.4% (47) regarding monthly income, while less than a million won accounted for 12.7% least (22). Regular menstruation or climacterium primarily accounted for 35.6% (62) regarding menstruation status.

2. Difference among social support, life stress and meaning of life according to demographic features

Distribution analysis was conducted and Scheffé test was later performed as post-analysis to examine the difference of each variable. The mean difference of age revealed that social support (F=8.68, p<.001) and life stress (F=3.40, p<.05) were statistically different. Post-analysis showed that social support was the highest in a group ranging 40-year to 45-year-old compared to other groups. The 40-year to 45-year-old group showed higher life stress than a 51-year to 55-year-old group.

The mean difference of academic background revealed that social support (F=7.66, p<.001), life stress (F=15.53, p<.001) and meaning of life (F=2.95, p<.05) were statistically significant. Post analysis suggested that a “graduated from more than graduate school” group showed higher social support than other groups. In contrast, a “graduated from elementary school” group showed the highest level of life stress compared to a “graduated from high school” group and “graduated from university” group.

Meanwhile, the mean difference of marriage year presented results that social support (F=9.01, p<.001), life stress (F=4.11, p<.01) and meaning of life (F=2.85, p<.05) were statistically significant. Post analysis

suggested that a “16-20 years” group showed higher marriage years than other groups. On the other hand, a “single” group showed higher marriage years than a “less than five-year” group.

The mean difference of occupation revealed that social support (F=6.72, p<.001) and meaning of life (F=2.82, p<.05) were statistically significant. Post analysis showed that a “self-employment” group presented higher social support than other groups.

The mean difference of monthly income suggested that social support (F=4.41, p<.01), life stress (F=3.77, p<.01) and meaning of life (F=5.79, p<.001) were statistically significant. Post-analysis specifically revealed that a “less than three million won” group showed higher social support than a “less than two million group” and a “more than four million won” group. A “less than two million group” showed higher level of life stress than a “less than three million group.” A “more than four million won” group showed higher meaning of life than a “less than three million won” group and a “less than two million group.”

3. First hypothesis

‘Social support of study subjects will give negative effects on life stress.’

As shown in Table 1, the influence over life stress of control variables were statistically significant (F=11.617, p<.001). It indicates lower life stress as their academic background and social support are higher and the first hypothesis is supported.

4. Second hypothesis

‘Social support of study subjects will affect the meaning of life positively.’

Family support and supports from other people as subfactors of social support did not affect the meaning of life significant. Therefore, the second hypothesis was rejected.

5. Third hypothesis

‘Life stress of study subjects will affect the meaning of life negatively.’

As shown in Table 2, The independent variable explains the independent variable as 56.1%, which was statistically significant (F=7.926, p<.001). Monthly income (p<.01) showed positive impacts on the meaning of life. Stress from economic problems (p<.01) gave negative effects on the meaning of life. This implies that higher monthly incomes means higher meaning of life. As life stress is higher due to economic problems, it can be said that the meaning of life is low. Thus, the third hypothesis was adopted.

Conclusion and Proposal

This study is intended to examine the effects of social support and life stress of women in climacterium on the meaning of life.

First, the difference among social support, life stress and meaning of life according to demographic features of women in climacterium revealed that social support was statistically significant different in terms of age(p<.001), academic background(p<.001), marriage year(p<.001), occupation(p<.001) and monthly income(p<.01). Life stress was statistically significant different in terms of age (p<.01), academic background (p<.001), marriage year (p<.01) and monthly income (p<.01). Meaning of life was statistically significant different in terms of academic background (p<.05), marriage year (p<.05), occupation (p<.05) and monthly income (p<.001).

Second, the correlation among social support, life stress and life meaning of women in climacterium suggested that social support and life stress showed negative correlations, while social support and meaning of life showed significantly positive correlations.

Third, regression analysis of their social support, life stress and meaning of life exhibited that social support gave negative effects on life stress, while no effect on meaning of life.

Fourth, higher level of stress from economic problems as a subfactors of their life stress functioned as a variable that significantly affects the meaning of life adversely.

In short, we would like to propose as follows based on the above findings.

First, subject scope needs to be expanded to generalize and apply results as the present study tested women in climacterium who reside in some small and medium-sized cities in Gangwon-do. In addition, a

continuous follow-up study is proposed to reduce life stress and enhance the meaning of life among ordinary middle-aged women in family and society.

Second, specific and verifiable evidence should be prepared by studying medium variables that their social support and life stress can affect the meaning of life and by establishing local governance.

Third, women in climacterium play pivotal roles in family life such as education in family and drive to boost energy in the society. Thus, support program to play pivotal roles in the society needs to be developed and national policy should be established to estimate the level of life and construct social support system for efficient handle.

The Effect of Adult Attachment Types, Gender Role Attitude on the Heterosexual Relationship Satisfaction in University Students

Hee Jeong Kim

Professor, Namseoul University, Department of Nursing, Korea

Abstract

Background/Objectives: The purpose of this study was to examine adult attachment types, gender role attitudes and heterosexual relationship satisfaction of college students and to examine how they affect satisfaction with heterosexual relationships.

Methods/Statistical analysis: This study is a descriptive correlation study to investigate the degree of adult attachment type, gender role attitude, and heterosexual relationship satisfaction of college students. The data were collected by 183 college students located in S, G and C province who agreed to participate in this study. The collected data were analyzed by frequency and percentage, mean and standard deviation, Pearson correlation and multiple regression.

Findings: The results of this study were as followings: Male 29.8% female 70.2%, mean age 24.8 years. There was a statistically significant negative correlation ($r = -0.622$, $p < .01$) in satisfaction with heterosexual relationship and adult attachment, and significant positive correlation ($r = 0.236$, $p < .01$) between heterosexual satisfaction and gender role attitude. The worse the attachment anxiety, the worse the heterosexual relationship satisfaction ($B = -.528$, $p < .001$), the worse the attachment avoidance, the lower the Heterosexual relationship satisfaction ($B = -.632$, $p < .001$). On the other hand, the more classical the gender role attitude, the more likely the Heterosexual relationship satisfaction is fall ($B = -.412$, $p = .001$).

Improvements/Applications: Therefore, it is necessary for a university student to develop a program that can identify his or her attachment type and actively cope with this relationship.

Keywords: *adult, attachment, college, heterosexual relationship, Gender role.*

Introduction

Erikson suggested building close relationships with people as a fulfillment task to accomplish in early adulthood. Humans live through many development tasks throughout their lives, and the early adulthood is a time of building a mature interpersonal relationship by building a close relationship through their interpersonal relationships with others [1]. College students at this time experience difficulties or conflicts in forming a broader interpersonal relationship [2], and seem to be fully exercising their functions as adults, but they are not completely separated from their parents, causing anxiety about full independence with the psychological burden on the role demanded by society.

Attachment refers to an intimate, strong emotional bond that one feels about someone close to him that is formed through interaction with a primary parent in the early part of one's life [3]. Adult attachment is the result of the transition to friends and lovers who are not primary carers [4]. Unstable adult attachment is a variable that foretells the personality characteristics of an individual and has a significant effect on the quality of the relationship and the satisfaction of the relationship. Unstable adult attachment is divided into two dimensions: anxiety attachment and avoidance attachment; anxiety attachment means a dimension that is too preoccupied with relationships or afraid of being rejected or abandoned by others; and avoidance attachment means a dimension that makes it uncomfortable to be intimate with others [5]. In addition, the attachment target of university students

in the suddenly expanded relationship is diverse and the attachment pattern is complicated, so the attachment is different from the initial stage of development [6]. Many attachment theorists argue that in order to understand adult interpersonal patterns, it is more appropriate to understand the overall level and pattern of attachment to current opposite sex friends or intimate others than to identify the type of attachment to parents formed in the early stages of development [7]. Adult attachment is also consistently studied in a wide range of fields as well as developmental psychology and is known as a significant variable to heterosexuality satisfaction [8,9]. A university student's experience in heterosexuality is closer than other interpersonal relationships, including family and friends, and the formation of intimate heterosexuality in early adulthood has a positive effect on individuals, such as helping them in mental health and improving the quality of life throughout their lives [10]. In particular, heterosexuality is an important concern for college students and a key interpersonal and developmental task. In fact, among the issues that university students appeal to counseling centers [11], they reported that the most influential person is their opposite sex [12].

Compared to the innate biological concept of sex (sex), the gender role is an expected behavioral characteristic of men or women in the affected society and culture based on biological gender [13]. In general, the masculinity of gender roles represented an independent, competitive and achievement-oriented character, and femininity had been known to represent a warm, sensitive and friendly character, and acting according to gender roles was considered very natural and desirable for men and women [14]. According to the study, such gender roles also affect relationships between men and women, women who value the quality of relationships in resolving conflicts between lovers try to resolve conflicts more actively than men, while men who value the status of relationships tend to avoid conflicts [15]. Cheng (2010)'s study also found that women are socialized and educated to solve problems more relationship-oriented in conflict situations, while men tend to avoid them by being socialized and educated as achievement or task-oriented [16]. However, since the study by Lee and Park [17] did not distinguish between men and women, and Kim and Lee [18] conducted the study only on women, it was not clear how gender roles actually affect heterosexual satisfaction, so it was thought that it would be necessary to repeat the study. Since the previous research was reviewed that there

were many references to adult attachment and gender role as variables that affect the heterosexual relationship satisfaction in college students, this study tries to re-examine the effect of adult attachment type and gender role on the satisfaction of the opposite sex in university students. Therefore, I want to find out the relationship between adult attachment style, sex role attitude and heterosexual relationship of college students, what variables are influencing them, and try to contribute to the mature heterosexual relationship satisfaction of college students.

Method

This study was conducted for about three months from August to October 2018. The survey was conducted on 183 college students attending N University in C city, C Province. All data used was collected according to the approved guidelines and screening procedures of "N University". A total of 190 questionnaires were collected and 183 of them were used in the study, excluding seven insufficient ones.

Adult attachment type

In this study, we found that students in college had to measure adult adhesion patterns in their bodies. Kim [19] modified and validated the ECR-R (Experience of Close Relation Ship-R) of Frey, Waller and Brennan [20]. The scale of attachment-anxiety is 18 questions and the sub-scale of attachment-avoidance is 18 questions, consisting of 36 questions, five-point Likert scale, and Kim's study [19] showed that Cronbach's α was .89 and .85, respectively. In this study, Cronbach's α of attachment-anxiety was .85, an attachment-avoidance was .92.

Gender role attitude

Developed by Osmond and Martin [21], it was measured by the Sex Role Attitude Measurement Tool (SRA), which was translated into Korean by Moon's study [22]. The gender-role attitude consisted of performance-force perception (12 items) and gender-role recognition (5 items), and a total of 17 items were measured on a 5-point Likert scale (1=not at all, 5=very much). The total score is 17 to 85 points, meaning the higher the score, the more modern gender roles they have. In a study by Moon's [22] Cronbach's α was .82. In this study, the total questionnaires Cronbach's α was .83.

Heterosexual relationship satisfaction

The Marital Satisfaction Inventory (MSI) developed by Snyder [23] was revised by Kwon and Chae [24] to a phrase that You [25] considers suitable for dating in Korea, and used the sentence analyzed by Lee [26]. Overall dissatisfaction, emotional communication problems, problem-solving communication, and shared time conflict are composed of 41 questions and are a true measure of response with ‘Yes’ or ‘No’. The higher the score on the scale, the more satisfied the relationship is. In a study by Lee [26], the Cronbach’s α was overall dissatisfaction .90; emotional communication problems .85, problem-solving communication .74, and shared time .74, with a total of .91. In this study, the Cronbach’s α was found to be overall dissatisfaction .83, unsatisfactory emotional.85, unsatisfactory problem-

solving communication .83, shared time .84, and overall as .88

Result and Discussion

The general characteristics of the subjects in this study are as shown in Table 1. The average age of the subjects was 20.80±1.80. There were 53 (29.0%) men and 130 (70.1%) women, while 124 (67.8%) were currently dating. When asked about the number of heterosexual relationship, 97 respondents (53.3 %) answered “two times,” When asked, “How long was the dating period?” 54 respondents (29.0 %), 32 respondents (17.5 %) answered “between six months and one month,” 49 respondents (26.8 %) said they had dating for more than three years, and 10 respondents (5.5 %) answered that they had been dating for more than three years.

Table 1. General characteristics (N=183)

Characteristics	Categories	n(%) or M±SD
Age		20.80±1.80
Gender	Male Female	53(29.0) 130(70.1)
Now, Heterosexual relationship	Yes	124(67.8)
Number of heterosexual relationship	1-2 times	97(53.0)
	3-5 times	57(31.1)
	More than 5 times	29(15.8)
The period of heterosexual relationship	Less than 3 month	38(20.8)
	3-5months	54(29.5)
	6months-1year	32(17.5)
	1year-3yesar More than 3 years	49(26.8) 10(5.5)

Table 2 shows the correlation between each variable.

Table 2. Correlations among adult attachment type, gender role attitude and heterosexual relationship satisfaction.

Variables	1	2	3	4	5	6	7

1. attachment- anxiety, 2.attachment-avoidance, 3. Gender-role attitude, 4. Dissatisfaction overall, 5. Emotional communication problems, 6. Problem-solving communication, 7.Shared time conflict. * p<.05, ** p< .01, *** p< .001

The results of multi-regression analysis on how each variable affects the Heterosexual relationship satisfaction are as shown in Table 3. The worse the attachment anxiety, the worse the heterosexual relationship satisfaction (B= -.528, p<.001), the worse the attachment avoidance, the lower the Heterosexual relationship satisfaction (B= -.632, p<.001). On the other hand, the more classical the gender role attitude, the more likely the heterosexual relationship satisfaction is fall (B= -.412, p=.001).

Discussion

This study is a descriptive relationship study to identify factors that affect the satisfaction of the heterosexual partner in college students. Based on the results of the previous research, I would like to discuss some. In the correlation between the variables in this study, the two sub parameters of attachment types, attachment

Table 3. Multiple regression of adult attachment type, gender role attitude and heterosexual relationship satisfaction

Predictors	Heterosexual relationship satisfaction						
	B	SE	β	t	p	tolerance	VIF
Constant	5.598	6.908		13.598	<.001		
Attachment anxiety	-.528	.089	-.416	9.244	<.001	.980	1.017
Attachment avoidance	-.632	.078	-.378	-8.437	<.001	.989	1.014
Gender role attitude	-.412	.165	-.378	4.132	.001	.991	1.015

Anxiety and attachment avoidance, both showed a statistically significant negative correlation with the heterosexual relationship satisfaction. In the Attachment Anxiety case, the results were the same as in the preceding study, in which people with attached anxiety tend to be immersed in interpersonal relationships and reduce their satisfaction with the opposite sex if they feel

afraid of being abandoned and rejected in a relationship they feel close to [8,27].

In a study by Lee and Yang [27], people who tend to attachment avoidance themselves to high self-esteem but avoid close relationships, excessively belittling reliance on others, and believing in themselves, they are more likely to be isolated alone. That result was similar to this

report because it could be thought that the heterosexual relationship satisfaction would be reduced. In addition, according to Erickson's theory of psychological and social development [1], the primary developmental task in early adulthood is to gain intimacy through relationships between peers and lovers. This suggests that active intervention is necessary in satisfying the opposite sex of university students, which is early in adulthood. The results of this study showed that gender role attitudes had a statistically significant negative correlation with heterosexual relationship satisfaction, and that the higher the posture of traditional, or classical gender roles, the lower the rational relationship satisfaction level. In the study by Choi and Yang, who studied the relationship between adult women's love-relationship satisfaction and the gender stereotype, there was no significant statistical difference between gender stereotypes and heterosexual relationships [29], and there was a significant relationship in the study by Sanchez et al [30]. It is believed that the reason for this is that Choi and Yang conducted research with a gender stereotype tool with strong sociocultural concepts [29], rather than a tool for gender roles with strong biological gender concepts.

Conclusion

This study investigated the effect of adult attachment type and gender role attitude on heterosexual relationship satisfaction, and the result was to induce interpersonal satisfaction through healthy heterosexual relationship of university students and to form more mature interpersonal relationship after employment. It is meaningful that the basic data is presented. As a result, it is expected that this basic data will give students the opportunity to re-experience the attachment and gender roles of college students, thereby forming a positive heterosexual relationship, and also to be the basis for positive interpersonal relationships. However, it is difficult to expand the results of this study because the study was conducted only by a small number of early adult students. In addition, it is necessary to be careful because it cannot convey the characteristics of the socio-cultural perspective in the gender role attitude because it can convey the biased knowledge. In addition, since the results of research on various sub concepts were not reported in the satisfaction of heterosexual relations, it is suggested to conduct research on these sub concepts later.

The Effects of Economic Stress, Career maturity and Major Satisfaction on the Job Stress in Third and Fourth Grade Students of University

Hee Jeong Kim

Professor, Namseoul University, Department of Nursing, Korea

Abstract

Background/Objectives: As most college students go older, more stress about getting a job. This study was to investigate the effects of economic stress, career maturity and major satisfaction on college students' job stress..

Methods/Statistical analysis: Data collection was conducted from November, 2017 to June, 2018 in 200 students who understood the purpose of the study and agreed to participate in the study. The collected data were analyzed by frequency, mean, standard deviation, Pearson correlation, and multiple regression analysis.

Findings: The subjects were 78 (38.4%) male and 122 (60.1%) female. The mean age was 21.9 (± 1.47). Employment stress was statistically significant positive correlated with economic stress ($r = .567, p < .001$), significant negative correlated with majors' satisfaction ($r = -.426, p < .001$) and career maturity ($r = -.585, p < .001$). Also Major satisfaction was statistically significant positive correlated with career maturity ($r = .329, p < .001$). According to the results of a multi-regression analysis to find out the impact of economic stress, career maturity, and major satisfaction on the job stress. The higher job economic stress ($\beta = .384$), job stress was higher. Also the lower career maturity ($\beta = -.398$), the higher the job stress, and the lower the major satisfaction ($\beta = -.278$), the e job stress was higher.

Improvements/Applications: Various youth career education and career development nursing programs will be required to lower the employment rate of college students, so the results of this study will be basic data.

Keywords: *Job, economy, stress, career maturity, major, satisfaction, college student*

Introduction

At the stage of development, college students who are in early adulthood in late adolescence experience various stresses because they have to expand their social activities from admission to college, adapt to new environment and study, worry about tuition fees, and the recent rise in the youth unemployment rate [1]. In addition, this period cannot be independent from the parents psychologically, and the stress can be higher than any time due to the high dependency. In particular, the financial burden of college tuition, living expenses, and the possibility of employment in the future of college students caused economic stress, and the economic stress was the highest in college life [2]. For college students living in modern society, employment is a

very important factor in determining their overall life. As most college students go to higher grades, they are more likely to be stressed with regard to employment. This is not a problem confined to specific departments, but is experienced by all university students in Korea [3]. However, as youth unemployment has been increasing due to the economic downturn at home and abroad, it has recently been shown that the youth unemployment rate in our 20s is 10.7 percent, higher than the overall unemployment rate of 5.2 percent. [4], the nation's youth (ages between 15 and 29) has been rising continuously since 2012, but the unemployment rate recorded 9.8 percent in 2017 and 10.0 percent in the first quarter of 2018, far above the total unemployment rate. The employment assistance index for young people, which indicates the unemployment rate, stands at 23 percent

and the number of unemployed young people, including potential job seekers, stands at about 1.13 million, with one in five young people known to be unemployed [5]. There are many reasons like this that college students will experience a great deal of stress in finding a job. Job stress is a stress that occurs during the process of college students determining career paths or preparing for employment, which increases physical or psychological instability and increases awareness and tension related to employment [6]. Career is more important than simply choosing a job, because it depends on all aspects of life, including occupation and social status, depending on the career we choose [7]. Therefore, the choice of majors comes first in choosing a career, which is a very important choice in a college student's life that is related to a career. Thus, mature students in choosing their careers will be able to live happy lives, satisfied with the jobs they choose. Crites [8] said that the degree of relative job preparation that appears when compared to students of the same age group. In Kang's study, he explained that there is a need to devise ways to enhance the career maturity of college students, describing them as a variable that has a greater impact on career-setting levels [9]. There were also studies that looked at the relationship between job stress and job insecurity and career maturity in relation to employment. In particular, since many department selection opportunities are given before entering university, and each university's admission selection methods are becoming more diverse, the educational environment surrounding universities is rapidly changing due to the changes, so students choose their own grades and geography, or departments their parents wish to pursue rather than choose their own favorite and desired I think this problem is becoming more of a job stress. What is closely related to the careers of college students depends on what they preach their major. A high level of satisfaction with one's major makes one's thoughts on career clear and leads to a state of peace with one's decision. The degree of satisfaction in the major will be high if the departments in which you belong now match the standards for your career path or career set by an individual [10]. College students' satisfaction with their majors is a positive factor in determining their jobs and having a positive impact on their confidence in their job-related task performance, and as a result, students with high degree of professional satisfaction showed high levels of career maturity [10, 11]. The results of a preceding study to find out the relationship between major satisfaction and job stress report that the higher the degree of major satisfaction, the lower the

job stress and the lower the degree of major satisfaction, the higher the job stress [12]. Therefore, career maturity is very necessary for university students. The degree of satisfaction with the majors is a clear indication of students own idea of career and a comfortable state of students's decision [8]. Major satisfaction is the product of judging the course or career set by an individual, and if the current department is consistent with the ideal of his / her life or future career or occupation, the major satisfaction will be high [9]. This study is to find out how the economic stress, seniority, and satisfaction level of majors affect the job stress of university students, and to present basic data on the preparation of nursing intervention measures to reduce the employment stress of college students

Method

The questionnaire data was collected using the questionnaire printed for about 8 months from the beginning of November, 2017. The study was conducted on 260 third and fourth grades attending university in C Province who agreed to the study. All data used was collected according to the approved guidelines and screening procedures of "N University".

Economic stress

In this study, to measure economic stress, Kang [13]'s tools were used to modify and supplement the Economic Hardship Questionnaire (EHQ) developed by Lempres [14] to suit college students. A total of 12 questions are the five-point Likert scale, and the higher the score, the more economic difficulties they have experienced. In Kang's study [13], the Cronbach's α was .88 and in this study it was .89

Carrier maturity

To measure the maturity of a career, Kim [15] modified the Career Maturity Inventory (CMI) developed by Crites [8]. CMI consists of two sub-domain areas: attitude scale and capability scale, and in this study, attitude measure was used. The higher the score the better the carrier maturity. The Cronbach's α in this study was .86.

Major satisfaction

In order to measure the major satisfaction of those studied, the Program Evaluation Survey [16] developed by Illinois University was modified by Kim and Ha [17]. A total of 18 questions are included, and the higher the score on the 5-point marker scale, the higher the

professional satisfaction level. In the study by Kim and Ha [17], tool reliability, Cronbach's α was .92, and .88 in this study

Job stress

Based on the Cornell Medical Index (CMI) of Cornell University's Shepherd et al [18] to measure the employment stress of university students and modified by Kang [19] were used. 21 questions in total. It consist on the 5-point Likert scale, the higher the score means higher economic stress. In Kang's study [20], Cronbach's α was .703 and it was .731 in this study.

Result and Discussion

1. General characteristics of the subjects

The general characteristics of the participants are shown in Table 1. The mean age of the subjects was 21.96± 1.44 years. The study participants included 78 males (38.4%) and 122 females (60.1%). By grade, 59.1% of third grade students. The students' majors was the health and medical science (53.2%) is the most.

Table1. General characteristics (N=200)

Characteristics	Categories	n(%) or M±SD
Age		21.96±1.44
Gender	Male Female	78(38.4) 122(60.1)
Grade	Third year	120(59.1)
	Forth year	80(39.4)
Average grade (The highest rating is 4.5)	Below 2.0	5(2.5)
	2.01~3.0	34(16.7)
	3.01~4.0	142(70.0)
	Above 4.01	19(9.4)
Major	Science	8(6.1)
	Engineering	26(19.7)
	Line of humanities	38(18.7)
	Health and medical science	108(53.2)
	Arts and physical science	10(4.9)

2. Correlations among economic stress, career maturity, major satisfaction and job stress

Table2 shows the results of Pearson's correlation coefficients to confirm the correlation between economic stress, career maturity, major satisfaction, and employment stress.

Table 2. Correlations among economic stress, career maturity, major satisfaction and job stress (N=200)

Variables	Economic stress	Career maturity	Major satisfaction	Employment stress
Economic stress	1	-.328***	-.286***	.567***
Career maturity		1	.329***	-.585***
Major satisfaction			1	-.426***
Job stress				1
* p<.05, ** p< .01, *** p< .001				

Table 3 shows the results of multiple regression. The higher the economic stress ($\beta=.384$), job stress was higher. Also the lower career maturity ($\beta=-.398$), the higher the job stress. And the lower the major satisfaction ($\beta=-.278$), the job stress was higher.

Table 3. Multiple regression of job stress, economic stress, career

Predictors	Job stress						
	B	SE	β	t	p	tolerance	VIF
Constant	4.625	7.908		11.510	<.001		
Economic stress	.428	.012	.384	7.244	<.001	.981	1.014
Career maturity	-.632	.089	-.398	-7.407	<.001	.986	1.016
Major satisfaction	.090	.079	-.278	2.135	.001	.983	1.015

Discussion

In this study, the career maturity was 3.48 out of 5. Although not a study using the same tools as this study, Han's study of nursing students [20] found that the career maturity status was 3.91 points, slightly higher than this study subjects. The reason is that nursing students get a job even before they graduate, and the employment rate is better than those of other majors. It is believed that nursing students are more mature in their career maturity than other college students. As shown in this study, career maturity and major satisfaction have shown a statistically significant positive correlation, which can be thought that higher major satisfaction will result in a mature attitude in determining course. As a result of the above, Han's research [20] supported this study. In this study, there was a statically significant negative correlation between the career maturity and the job stress, multiple regression analysis also showed that the lower the maturity of career, the higher the employment stress. A study by Kim and Choi [21], who studied college students' depression, employment stress and career maturity, also showed a significant negative correlation between employment stress and career maturity, and found that the lower their career maturity, the higher the employment stress, the same as the result of this study. I think getting a good job for third and fourth graders is a very important crisis in life. Therefore, the stress they have to suffer is thought to be very high. Therefore, I think stress management and arbitration are very important interventions in early adult nursing.

In this study, there was a statistically significant correlation between major satisfaction and career maturity. Also, the higher the satisfaction of the major, the lower the job stress. In the preceding study,

satisfaction with the major chosen when going to college is a major factor in the formation of career consciousness, and satisfaction with the major of university students is a factor that has a positive effect on job determination and confidence in job-related task performance. As a result, students with high degree of satisfaction in major studies reported high levels of seniority [11, 21], so preceding studies supported the results of this study. Through the above discussion, it can be seen that economic stress, career maturity, and major satisfaction are important variables that affect job stress. If the students prepare the educational environment at the university level to reduce economic stress and increase the degree of student's professional satisfaction, I think it can help the job stress of college students decrease if the degree is increased by various efforts of the department itself.

Conclusion

The results of this study could be used as a basic data for developing pro-program for career counseling and guidance to reduce employment stress for college students in the future. In the development of a program to enhance the cadence of college students, the government should consider the above findings and apply such methods as improving the teaching method and granting them a chance to succeed in making decisions about their academic performance so that they can contribute to enhancing their professional satisfaction and further enhancing their career maturity. However, since this study targeted university students from some local material universities, there are limitations to the wider interpretation of the research results. We believe that there is a need for continuous exploration of variables that can attempt repeated research for college students in more diverse departments and that can mediate or

control job stress.

Major Factors Having Influence on the Subjective Happiness of Korean Youth; From the 13th KAHBOS Data

Weon-Hee Moon¹, Myoungjin Kwon²

¹Associate Professor, Pai Chai University, Dept. of Nursing, South Korea, ²Assistant Professor, Daejeon University, Dept. of Nursing, South Korea

Abstract

Background/Objectives: As a study of secondary analysis that analyzed the 13th (2017) Korean Adolescents' Health Behavior Online Survey data second time, this is a descriptive study performed for the purpose of identifying the major factors having influence on the subjective happiness perceived by the youth.

Methods/Statistical analysis: The subjects of the 13th (2017) survey were 64,991 students from total 800 schools and out of them, 62,276 students from 799 schools participated showing 95.8% of participation rate. For the general, physical and psychological factors, the complex sample frequency analysis and for the major factors having influence on the subjective happiness, the complex sample regression analysis were used.

Findings: The age, grade, economic level, frequency of having breakfast per week, experience of receiving treatment by the violence, frequency of physical activities more than 60 minutes per week, fatigue recovery with the sleep, weight control effort, BMI, smoking, stress, subjective cognition of body type, subjective health, suicidal ideation and the agony counselor were drawn as the major factors having statistically significant influence on the subjective happiness received by Korean youths.

Improvements/Applications: To enhance the happiness of the youth, the happiness enhancement program about breakfast management prevention of violence, physical activities more 60 minutes per week, sleep and fatigue recovery, weight control, smoking, stress management, suicidal ideation, counseling with the family as counselor, etc. is need to be activated.

Keywords: Youth, Happiness, Health Behavior, KAHBOS, Affecting factors

Introduction

Adolescence is the period that the rapid changes are experienced in the physical, mental and spiritual aspect and particularly, the growth and the development in this period influence on the adult period, too, and ultimately, the adolescence is considered as important phase to determine the quality of life of a man. Happiness refers to the subjective state that one experiences the positive emotion or satisfaction in one's life through the control and commitment exerting the strengths and the potentials of an individual^[1]. In the research of Diener^[2] that

investigated the happiness from 7,204 college students in 42 countries, most people consider the satisfaction in life and the happiness very important and only 6% of the respondents answered that the money is more important than the happiness and 69% answered that the happiness is one of the most important scales^[3].

The research results that studied the Korean adolescents are as follows. National Youth Policy Institute reported that in the results of analyzing the first and third graders of middle school and the second graders of high school using NYPI Panel Survey data, it was shown reverse V shape that the happiness is high in the third graders of middle school that the first graders of middle school and the second graders of high school. Another research explored the factors having influence on the subjective happiness of youth by analyzing the

Corresponding Author:

Myoungjin Kwon,

Dept. of Nursing, mjkwon@dju.kr

10th Adolescents' Health Behavior Online Survey in 2014^[4], and its results showed that the happiness was higher in the middle school students than the high school students.

The subjective happiness index of the Korean youth published by 2016 8th International

Comparison of Youth and Children Happiness Index, the subjective happiness index of Korean youth was 82 points showing the lowest among the 22 OECD countries. This result explains that as shown in various data that reported the seriousness of the cognition of stress and depression and the suicidal ideation in the adolescence, the happiness and the satisfaction in life perceived by Korean youth is significantly low compared with the other countries^[5].

The subjective happiness is the evaluation method of recognition on overall subjective well-being and one evaluates subjectively what degree he/she feels the happiness^[6]. The happiness in the adolescence has influence on the quality of life after one became adult, which will become major evaluation factor in the area of mental health in the national level. That is, the emotional aspect is the most essential factor for sound growth of youth influencing through entire life. Therefore, this study is attempted to identify the current status for the sound growth in the emotional level related to the happiness of the youth and to contribute to establishing the direction for the purpose of identifying the major factors having influence on the happiness perceived subjectively by Korean youths.

Method

The 13th (2017) survey was conducted with 64,991 students from total 800 schools, 400 middle schools and 400 high schools, but 62,276 students from 799 schools participated showing 95.8% of participation rate based on the number of students.

For the general characteristics, the questionnaire items asking the gender, age, academic achievement, economic condition, residential type, number of breakfast taken per week, hour of using smartphone, experience of receiving the treatment by the violence were used.

For the physical factor, the questionnaire items asking the physical activities, degree of fatigue recovery with sleep, weight control effort, BMI, drinking,

smoking.

For the psychological factor, the questionnaire items asking stress, subjective body image, subjective health, subjective happiness, suicidal ideation, the agony counselor were used.

The data were analyzed after generating complex sample plan file by giving weight using the IBM SPSS 25.0 program, and the analysis was conducted by setting the significance level to 0.05. For the degree of general, physical and psychological factors of the subject, the complex sample frequency analysis was used. For the major factor having influence on the subjective happiness perceived by the subject, the complex sample regression analysis was used.

Results

1. General, physical and psychological factors

Out of the general factors, in the gender, the male was 31,624 students (52.1%), showing highest proportion, the age was 12-15 (54.1%), in the academic achievement, 47,624 (76.4%) students answered that their academic achievement is medium and in the economic condition, 53,970 (86.5%) students were medium showing highest proportion.

Out of the physical factors, in the number of days performing physical activities more than 60 minutes a week, '2 days or less' was high (68.1%), and 46,128 students (74.9%) answered that 'fatigue is not recovered with sleep'.

Out of the psychological factors, in the stress, 23,259 students (37.2%) answered that they feel 'very much' and 23,564 students (39.0%) answered 'happy'.

2. Factors having influence on subjective happiness

To identify the factors having influence on the subjective happiness of Korean youth, the complex sample regression analysis was performed taking the subjective happiness as dependent variable and the rest of variables as independent variable.

The significant difference was shown in the age, academic achievement, frequency of having breakfast a week, treatment experience by the violence, frequency of physical activities more than 60 minutes a week, fatigue recovery with sleep, weight control effort,

BMI, smoking, stress, subjective cognition of body type, subjective health, suicidal ideation and the agony counselor. its explanatory power was 34.1% ($F = 653.55$, $p < .001$)

Discussion

This study was conducted to identify the major factors having influence on the subjective happiness of Korean youth. In the results of this study, the happiness in the students of 12~15years old was lower than the student whose age is 16 ~ 18 years old, which is as same as results of the research by Lee and Known^[7] and as the happiness in the youth can be enhanced by the commitment to the peer group and the reinforcement of fellowship, which is reinforced when the school age is higher^[8], it is deemed to be shown lower in the students

of 12-15 years old, which is relatively younger age. In this study, the higher the academic achievement, the lower the happiness. Since in the results of research by Park and Seong^[9] the better the academic achievement, the higher the happiness in the youth and in the results of research by Han and Han^[10], the higher that economic level, the higher the happiness in the youth, they showed the different results from this research. Considering the fact that the fervor of academic achievement in the Korean youth is shown high than the youth of any society^[11] and that the stress is severe by that, the relation between them needs to be researched repeatedly. In addition, as the psychological factors, family relationship, the peer relationship, etc. may have more influence than the income level of household^[12], it need to understand the happiness in the youth considering these factors more.

	Others	1.0		

In the results of this study, the quality of life was represented high in the students having 3 breakfasts a week than those who having 4 breakfast a week, which is same as the results of research by Lee and Kwon^[7]. In addition, those who do not have treatment experience by the violence perceived happier than those who have it, which is similar to the results of research by Park, Hong and Han^[13]. The high stress in the youth may influence on the acts of violence, which becomes the cause of low happiness^[13]. Therefore, to prevent the acts of violence by the youth, it needs to enhance the happiness. In the results of research by Kim and Yeom^[14], there was difference according to the gender but the subjective happiness was represented high when the physical activities per week by the youth is more than 0 ~2days. However, this study showed the difference as the happiness was low when it was 3 days or more, for which the additional research is needed considering the detailed setting on the type and the scope of the physical activities and other characteristics of the youth. In the results of this study, the happiness was low when the students do not recover from fatigue with sleep compared to when they do not, which is as same as the result of research by Lee^[15] and proves the importance of physical factors in the happiness. Therefore, to enhance the happiness of the youth, the sleep enough to recover from the fatigue is needed. In the results of this study, the happiness was high when the students do not control the weight and when the BMI is less than 25kg/m², which is as same as the results of research by Sim^[16]. The adolescent who satisfies with his/her own appearance is high feels happy but if the satisfaction is low, as the high interest is not satisfied, the happiness is lowered as he/she shrinks psychologically^[16]. Therefore, to enhance the happiness of the youth, it is necessary to make them to have correct perception on the appearance. In the results of this study, the happiness was high when perceiving less stress. This result is as same as the results of research by Suh^[17] and since the stress in the youth may cause the anxiety and frustration of the youth resulting in emotional problem^[18], the active intervention to relieve the stress is required.

In the results of this study, the students who do not think of suicide feel higher happiness compared to those who think of it, which is as same as the results of research by Park and Lee^[19]. The depression, which is being increased continuously, can be led to suicidal impulse, which may hinder the satisfaction with life and exert negative influence on the happiness^[20, 21].

Therefore, the emotional approach to reduce the stress and the depression is required.

In this study, higher happiness was shown in case of counseling the agony with other than family than the case of counseling the agony with the family. However, the open communication can become a factor to enhance the happiness of the youth^[22], it is necessary to maintain not only the positive relationship with the peer group but also the efficient communication with the family.

Conclusion

The youth can grow up as a matured adult as long as they adapt to lots of changes experiencing the emotionally. The emotion is the important factor to stabilize the life and among them, the happiness is the important factor having influence on the quality of life. Therefore, to enhance the happiness of the youth, effort to activate the intervention program around the breakfast, prevention of violence, physical activities more than 60 minutes per week, sleep and fatigue recovery, weight control, non-smoking, stress management, suicidal ideation, counseling with the agony counselor, etc. is required. And the follow-up research considering the diverse factors having influence should be made and the happiness enhancement program should be developed.

Effects of Intervention on Home-Based Environmental Counselling for Children with Severe Allergic Diseases

Chae-Bong Kim¹, In-Soon Kang², Hyo-Sun LEE³

¹Researcher, Department of Public Health, Korea University, South Korea, ²Researcher, Environmental Health Center for Asthma, Korea University, South Korea, ³Professor, Department of health science & 3D printing, Dongnam Health University, South Korea

Abstract

Background/Objectives: Home-based environmental management is the key to managing allergic diseases. This study identified the effects of environmental counseling intervention in children with atopic dermatitis and respiratory diseases.

Methods/Statistical analysis: The participants were 198 children with allergic diseases who participated in the study in 2016. In 2017, 66 children with severe allergic diseases in a follow-up study were selected. We ultimately analyzed the effect of environmental counseling in 26 children. To assess the effect of the intervention, the research team conducted a pre-test (baseline) and post-test (follow-up) twice. Trans-epidermal water loss (TEWL) and scoring atopic dermatitis (SCORAD) index were used to assess atopic dermatitis (AD) and forced expiratory volume in 1 second (FEV₁), forced vital capacity (FVC), immunoglobulin E (IgE), and eosinophil counts were used to assess respiratory diseases.

Findings: In children with AD, the baseline and follow-up SCORAD index values were 40.33 and 31.15 points, respectively. In children with respiratory diseases, the baseline and follow-up FEV₁ values were 77.77 and 87.53 points, respectively; baseline and follow-up FVC values were 81.38 and 95.54 points, respectively; baseline and follow-up IgE values were 520.86 and 481.37 points, respectively; and baseline and follow-up eosinophil values were 4.97 and 4.42 points, respectively. Thus, home-based environmental counseling decreased FEV₁ and FVC values.

Improvements/Applications: Patients with respiratory diseases treated with home-based environmental counseling exhibited positive changes in FEV₁ and FVC values. Home-based indoor environmental counseling is regularly needed to manage respiratory diseases. The parents of children with respiratory diseases must try to minimize their exposure to harmful substances indoors.

Keywords: respiratory diseases, counseling, children, home-based, indoor environmental

Introduction

Allergies are known chronic diseases with a high prevalence in infants and children^[1]. A literature review of studies published between 1995 and 2013 reported that allergic disease symptoms have decreased or stopped in children and adolescents^[2]. However, allergic diseases are increasing as lifestyles become Westernized and the environment becomes more

polluted^[3]. This evidence suggests that environmental management is very important in allergic diseases. Although the Asthma Control Guideline emphasized the need for environmental control^[4], insufficient studies have examined the effects of disease improvement due to environmental control. A study reported in *The New England Journal of Medicine* found that environmental intervention in allergen sensitization and environmental risk factors improved asthma conditions^[5]. Children with allergies are generally sensitive to many indoor allergen factors, but counseling or education on comprehensive indoor allergens is commonly lacking. Preventive education and teaching interventions for

Corresponding Author :

Hyo-Sun Lee,

E-mail: rosalee0228@naver.com

asthma patients reportedly improved symptoms^[7-8] One study showed the effects of asthma by environmental interventions in the home^[5], but this study focused on the effects of atopic dermatitis and respiratory diseases in socioeconomically disadvantaged children. Among the reported Korean studies, there was insufficient evidence of the environmental risk factors and allergic diseases for socioeconomically disadvantaged groups^[6]. Previous studies focused on reducing exposure to only one allergy-causing substance found indoors rather than trying to improve the indoor environment as a whole^[5,9-10]. Therefore, here we aimed to assess the effectiveness of a home-based comprehensive environmental counseling intervention in children with allergic diseases to provide evidence of the ability of voluntary management of the indoor home environment through environmental counseling to help improve allergic diseases.

Method

1. Study Design

This study was conducted in 2016 as part of the Korea Environmental Industry & Technology Institute (KEITI) for the Environmental Diseases Prevention Project (EDPP) for socioeconomically disadvantaged people. The purpose of the EDPP is to identify indoor hazardous environment factors for home based the living space and provide socioeconomically disadvantaged children the environmental management service through counseling. This study aimed to identify changes in the symptoms of children with atopic dermatitis and respiratory diseases before and after intervention using environmental counseling.

2.2. Study Sample

We obtained the EDPP data from the KEITI between 2016 and 2017. The EDPP participation criteria were chosen by low-income households as children with allergic diseases. The study target were 198 children with allergic diseases who participated in the study in 2016. We excluded those who did not meet our inclusion criteria as shown in Figure 1. Of the 198 children with allergic diseases who participated in the EDPP in 2016, 66 with severe allergic diseases were screened. The inclusion criteria were as follows: 1) age over 6 months, 2) sensitivity to food allergens, 3) sensitivity to inhalant allergens, 4) positive for skin test findings, and 5) agreement to participate in the study. The final sample included 26 children with severe allergic diseases; 21 who participated in the EDPP in 2017 but did not participate

in the clinical intervention trials were omitted. Among the final 26 patients, 13 had atopic dermatitis, while the other 13 had respiratory diseases[Figure 1].

Figure 1. Selection process for study participants

3. Outcome Measures

To check the intervention effect of the environmental counseling at the Environmental Health Center for Childhood Asthma, Korea University conducted the same clinical tests two times. Demographic characteristics, disease duration, and diagnosis were investigated. Outcome measurements included skin, blood, and pulmonary function tests. The effects of the intervention in patients with atopic dermatitis were tested using the trans-epidermal water loss (TEWL) test and SCORing Atopic Dermatitis (SCORAD) index. Patients with respiratory diseases were subjected to tests of immunoglobulin E (IgE), eosinophils, forced expiratory volume in 1 second (FEV₁), and forced vital capacity (FVC). We measured TEWL using a “Tewameter” TM300 (Courage and Khazaka Electronics, Cologne, Germany). The SCORAD index was evaluated for overall surface and visually distinct symptoms and two subjective variables^[11]. The IgE concentration was measured by Coat-A-Count Total IgE IRMA (Diagnostic Products Co., Los Angeles, CA, USA)^[12]. The pulmonary function test was measured in accordance with the guidelines of the American Association for Respiratory Care^[13]. The FEV₁ and FVC

tests were conducted in accordance with the guidelines of American Thoracic Society and European Respiratory Society^[14]. We selected the highest of three FEV₁ and FVC values collected using the pulmonary function test instrument (1022 digital spirometer; VIASYS, Palm Springs, CA, USA). In addition, food and inhalation allergen sensitization was confirmed using the multiple allergen simultaneous test (MAST).

2.4. Intervention and follow up

The intervention provided counseling for environment management for patients through home visits by an environmental counselor. Environmental counselors are trained professionals who completed professional training on the Eco-Mom-Korea. One family's counseling time (for parents and patients) was a total of 6 hours. The environmental counselors visited the home three times and called the family by mobile phone 10 times. The first home visit included indoor environmental monitoring and a pre-survey, the second visit included home indoor environment management, and the third visit included health behavior management counseling and other topics. Children with severe allergic diseases visited the hospital twice before and after the intervention. The first test (baseline) was administered on November 9, 2017, while the second (follow-up) was administered on November 30, 2017. No participant dropped out from the study.

2.5. Statistical Analysis

The statistical analysis was performed with basic statistics and a paired sample t-test. The probability of significance was interpreted as being statistically significant when less than 0.05.

Result and Discussion

The average age was 10.69 years; 53.8% (n = 14) of the participants were girls. Those with a family history comprised 84.6% (n = 22) of the sample, while those delivered by cesarean section comprised 46.2% (n = 12). Those who had been breastfed accounted for 65.4% (n = 17), while those with secondhand smoke exposure accounted for 57.7% (n = 15). The prevalence over 6.73 years of age was 50.0% (n = 13) for atopic dermatitis and 50.0% (n = 13) for respiratory diseases. In baseline atopic dermatitis function, mean TEWL was 36.33 (range, 18.80–76.90), while mean SCORAD index was 40.33 (range, 20.00–76.00). Regarding baseline respiratory disease function, mean FEV₁ was 77.77% (range, 60.00–114.00%), mean FVC was 81.38% (range, 60.00–113.00%), mean IgE was 520.86 IU/mL (10.00–1131.00 IU/mL), and mean eosinophil proportion was 4.97% (range, 1.30–10.10%). Regarding environmental exposure, secondhand smoke affected a mean 57.70% (n = 15) of patients. The allergen sensitization prevalence was 30.8% (n = 8) for food and 80.8% (n = 80.8) for inhalants [Table 1].

Table 1. Baseline characteristics of the 26 children

Characteristic	n/N	% or 95% CI
Demographic Characteristic		
Girls (%)	14/26	53.8
Age (yr)	10.69	2.93 (5.00-16.00)
Family history (%)	22/26	84.6
Cesarean section (%)	12/26	46.2
Breastfeeding (%)	17/26	65.4
Duration of allergic diseases (yr)	6.73	3.21 (2.00-15.00)
Allergy symptoms within 1 week before (%)		
Atopic dermatitis	13/26	50.0

Cont... Table 1. Baseline characteristics of the 26 children

Respiratory diseases	13/26	50.0
Baseline atopic dermatitis function (% of predicted value)		
Trans-epidermal water loss (n = 10)	36.33	19.58 (18.80-76.90)
Scoring atopic dermatitis (n = 12)	40.33	15.23 (20.00-76.00)
Baseline respiratory diseases function (% of predicted value or IU/mL)		
Forced expiratory volume in one second (n = 13)	77.77	14.54 (60.00 – 114.00)
Force vital capacity (n = 13)	81.38	15.38 (60.00 – 113.00)
Immunoglobulin E (n = 13)	520.86	439.88 (10.00 – 1131.00)
Eosinophil (n = 13)	4.97	3.07 (1.30 – 10.10)
Environmental exposure (%)		
Secondhand smoke exposure	15/26	57.7
Allergen (%)		
Food allergen	8/26	30.8
Inhalant allergen	21/26	80.8

The final 26 children selected had a 30.8% food allergen sensitization prevalence in 2016 that increased to 46.2% in 2017, while the inhalation allergen sensitization prevalence was 80.8% in 2016 and decreased slightly to 76.9% in 2017 for inhalants [Table 1-2].

Table 2. Changes in food allergen and inhalant allergen sensitization rate

Examination item	Baseline (n, %)	Follow-up (n, %)	Difference*
Food allergen	8 (30.8)	12 (46.2)	-8(-15.4)
Inhalant allergen	21(80.8)	20(76.9)	1(3.9)

*Differences were used to determine the difference between 2016 and 2017

In children with atopic dermatitis, the baseline TEWL index was 36.33 (range, 18.80–76.90), while the follow-up TEWL was 48.64 (range, 17.60–101.50), an increase of 12.31. The baseline SCORAD index was 40.33 (range, 20.00–76.00), while the follow-up SCORAD was 31.15 (range, 13.00–71.00), a decrease of 9.18. In children with respiratory diseases, the baseline FEV₁ was 77.77% (range, 60.00–114.00) and the follow-up FEV₁ was 87.53% (range, 73.00–122.00%), an increase of 9.76% (p = 0.023). In addition, the baseline

FVC was 81.38% (range, 60.00–113.00%), while the follow-up FVC was 95.54% (range, 85.00–123.00%), an increase of 14.16% (p = 0.004). Also, the baseline IgE was 520.86 IU/mL (range, 10.00–1131.00 IU/mL), while the follow-up IgE was 481.37 IU/mL (range, 14.30–1253.00 IU/mL), a decrease of 39.49 IU/mL. The baseline eosinophil proportion was 4.97% (range, 1.30–10.10%), while the follow-up eosinophil proportion was 4.42% (range, 1.00–8.20%), a decrease of 0.55% for inhalants [Table 3].

Table 3. Allergy symptom changes after intervention

	Examination items	Baseline (M, 95% CI)	Follow-up (M, 95% CI)	Difference*	t(p)**
Atopic dermatitis	TEWL n = 10	36.33 (18.80-76.90)	48.64 (17.60-101.50)	-12.31	-4.816 (0.001)
	SCORAD n = 12	40.33 (20.00-76.00)	31.15 (13.00-71.00)	9.18	1.584 (0.142)
Respiratory diseases	FEV1 (%) n = 13	77.77 (60.00-114.00)	87.53 (73.00-122.00)	-9.76	-2.604 (0.023)
	FVC (%) n = 13	81.38 (60.00-113.00)	95.54 (85.00-123.00)	-14.16	-3.498 (0.004)
	IgE (IU/mL) n = 13	520.86 (10.00-1131.00)	481.37 (14.30-1253.00)	39.49	0.562 (0.584)
	Eosinophil (%) n = 13	4.97 (1.30-10.10)	4.42 (1.00-8.20)	0.55	1.254 (0.234)

abbreviation: M, mean; CI, confidence interval; TEWL, trans-epidermal water loss; SCORAD, scoring atopic dermatitis; FEV1, forced expiratory volume in one second; FVC, forced vital capacity; IgE, immunoglobulin E: *Difference values were used to determine the difference between 1 week (baseline) and 3 weeks; **P values were determined using the paired sample t-test.

The symptoms of allergy-stricken children can be decreased even slightly with focus on environmental management at home. Environmental counseling aims to continuously manage the home indoor environment by identifying allergens and linking them to health behaviors to reduce allergies. One study reported the importance of developing self-care plans, patient education and counseling, and regular checkups to effectively manage asthma[15]. Therefore, the families of severely allergic children require much attention and practice. In previous studies, the effects of home-based environmental intervention were assessed for children with asthma, but in our study, health changes for home-based environmental counseling intervention were evaluated for children with atopic dermatitis and respiratory diseases. In this study, the levels of FEV1 and FVC were lower after the intervention. While not significant, IgE and eosinophil levels decreased. Since we did not investigate the participants' medication use or disease treatment during the intervention period, environmental counseling had limited ability to explain the reduction in these factors. That is why our findings may have been accidental. However, it is clear that reducing exposure to allergens in the home can decrease children's respiratory and allergy symptoms.

We provided information on bedding management, ventilation (air circulation), and vacuum cleaner use, cleaning water dusters, and maintaining proper temperature and humidity through three home visits and 10 telephone consultations. In particular, a recent meta-analysis[16] study reported that air filtration improved asthma symptoms. While previous studies showed no change in waste capacity in a home-based environmental intervention[5], our study showed the opposite result. Seo et al. suggested that long-term and systematic environmental monitoring is necessary since socioeconomically disadvantaged children are exposed to indoor environmental risk factors[6]. Therefore, environmental management education through continuous counseling will be needed, as more frequent environmental counseling may effectively reduce the symptoms of atopic dermatitis and respiratory disease.

We confirmed that ongoing counseling by environmental counselors is effective at preventing allergies. However, subsequent studies are needed since our study intervention methods were not sophisticated, the methods of arbitration were not evaluated, and few samples were obtained. Having a particularly small sample was the largest study limitation.

Conclusion

In summary, TEWL in atopic dermatitis patients was not improved through this intervention of environmental counseling. However, The symptoms of FEV₁ and FVC in children with respiratory diseases were improved after the intervention. Therefore, environmental counseling in the home positive affected respiratory disease symptoms. The parents of children of respiratory diseases will need to try to reduce their exposure to harmful substances indoors and clean up the in-home environment.

Abstract

Background/Objectives: As the field activity of the fire fighter is increased increasing the exposure to the traumatic event, the development of effective program to reduce the job stress is needed.

Methods/Statistical analysis: The present study investigated levels of emotional intelligence, self-efficacy, and job stress by personal characteristics, working environment of ambulance workers, and grasped their correlations. A survey of ambulance workers in service at fire stations in the northern Gyeonggi province was conducted from Feb. 22 to Mar. 31, 2019 and 160 questionnaires were analyzed. Collected data were subjected to frequency analysis, t-test, and ANOVA using SPSS software 12.0 program.

Findings: Emotional intelligence showed a score of 63 out of 80 points. Emotional intelligence of females was higher than that of males. That of workers not younger than 35 years was higher than that of workers younger than 30 years. That of fire engineers or fire lieutenants was shown to be higher than that of firefighters. Job stress of females was higher than that of males. That of EMT level 2 qualification holders or workers who took the training course was shown to be higher than that of EMT level 1 qualification holders. That when less than three workers were mobilized was shown to be higher than that when three workers and more were mobilized. Self-efficacy showed a positive correlation with emotional intelligence but a negative correlation with job stress. Emotional intelligence showed a negative correlation with job stress. The higher the emotional intelligence, the higher the self-efficacy. The higher the emotional intelligence and self-efficacy, the lower the job stress.

Improvements/Applications: To reduce the job stress, the health should be improved and the field response capability should be enhanced by establishing the strategy to enhance the emotional intelligence.

Keywords: Emotional Intelligence, Self-effectiveness, Job Stress, Health Promotion, Health Condition

Introduction

The fire fighter encounters many direct traumatic events in various accident sites that he/she is in fear of physical injury or life. Since the accident such as industrial accident, building collapse, natural disaster,

etc. is rapidly increased by the diversification of social environment, the disaster management system is needed. As of 2018, the activity of 119 Rescue Center was 2,788,101 cases and occupies more than 68% out of 4,066,201 mobilization cases of fire fighting. Fire-fighting officer carries out the job hard to bear physically and mentally and belongs to stress high risk group due to frequent exposure to the traumatic event, irregular shift and standby for mobilization, health risk and physical

hazard, insufficient manpower, tragic accident, etc.

Emotional intelligence^[1] is the positive emotional propensity and understands the feeling of not only himself (herself) but also other surrounding people exactly and is the ability to utilize and regulate his/her own feelings^[2]. According to Shin^[3], the emotional intelligence regulates the self-expression based on the recognition of one's own emotion, is the ability to establish relationship with others effectively and positively, and the changes of the emotional intelligence has effect on the self-efficacy.

Han^[4] said that as the individual having high positive emotional propensity has relatively excellent positive problem solving ability and makes effort to solve the problem actively, the stress level was very low.

Self-efficacy means the conviction that one can do a certain work. It can be defined as judgment on one's own ability to organize and perform a series of behavioral processes required to achieve the job assigned to the person^[5]. Gist and Mitchell^[6] have stated that persons with a high level of self-efficacy can effectively perform their jobs and make continuous efforts for the goals without giving up. Job stress can be said to be the level at which one personally perceives psychological and physical adverse effects caused by business ability and environment of an organization member due to requirements of individuals and difference in opinions depending on the job. It means psychological and emotional tension level of perceiving the imbalance in the relation between an individual and the job environment^[7].

The factors having effect on the job stress are personal characteristics, social support, job characteristics, personal health condition, working environment and organization characteristics and there are lots of researches for them but the research on the mental health of fire fighter has been made mainly on the post-traumatic stress disorder.

The purpose of this study is to provide the basic data for effective job stress reduction by identifying the effect of the emotional intelligent perceived by the fire fighter on the self-efficacy and job stress and the mediating effect of self-efficacy.

Materials and Method

1. Experimental tools

1) Emotional Intelligence

For emotional intelligence, WLEIS (Wong and Law Emotional Intelligence Scale) was used. WLEIS is a tool developed by Wong and Law^[2] and adapted by Lim^[8]. The tool is comprised of 16 questions belonging to four sub-categories: four questions related to one's own emotional understanding, four questions related to other's emotional understanding, four questions related to utilization of emotion, and four questions related to adjustment of emotion. Its total score ranges from 16 to 80 and, with higher score indicating higher level of emotional intelligence.

2) Self-Efficacy

Self-efficacy means the conviction that one can successfully perform a particular behavior in a particular situation^[5]. Personal Efficacy Beliefs Scale developed by Riggs and Knight^[9] was used after translation. It is made up of 20 questions related to perception of one's own emotion, perception of other's emotion, adjustment of one's own emotion, and utilization of emotion. The higher the score, the higher the self-efficacy.

3) Job Stress

To measure job stress, Job Content Questionnaire (JCQ) prepared by adapting job stress tool developed by Karasek et al^[10] to fit the Korean environment of which the validity was verified was used. This tool has a total of 14 questions: five questions for job requirements, three questions related to the authority to make decisions and job autonomy, and six questions related to availability of skill. Its score ranges from 0 to 42, with higher score indicating higher job stress.

2. Data Collection and Analysis

A survey of ambulance workers in service at the fire stations in the northern Gyeonggi province was conducted from Feb. 22 to Mar. 31, 2019. A total of 160 questionnaires were analyzed. Collected data were subjected to frequency analysis, t-test, and ANOVA using SPSS software 12.0 program.

Results and Discussion

Demographic characteristics of study subjects are summarized in Table 1. Regarding gender, there were 115 (71.9 %) males and 45 (28.1 %) females. As for age, the number of workers not younger than 30 years was 109 (68.1 %) and the number of workers younger than

30 years was 51 (31.9 %). Regarding education level, the number of graduates from a 4-year college or higher level was 88 (55 %) and the number of graduates from a 2-year college was 68 (42.5). Regarding qualification levels, the number of EMT (emergency medical technician) level 1 qualification holders was 96 (60.0 %), the number of nurses was 37 (23.1 %), and the number of EMT level 2 qualification holders was 24 (15 %). Regarding service career, the number of workers with service career between 1 and 3 years was 52 (32.5 %) and the number of workers with service career between

3 and 5 years was 43 (26.9 %). For salary, 103 (64.4 %) workers were receiving a monthly payment between 3 and 4 million won. As for rank, 140 (87.5 %) workers were fire engineers or firefighters. For marriage status, 87 (54.4 %) workers were unmarried. Regarding the number of workers mobilized, 138 (72.8 %) workers were mobilized in a group of four workers or more. Regarding exercise and hobbies, 146 (76.4 %) workers were found to exercise regularly and 139 workers (72.8 %) were enjoying hobbies [Table 1].

Table 1. General characteristics of the subjects(N=160)

Variables	Categories	n	%
Gender	Male	115	71.9
	Female	45	28.1
Age	24 ~ 29a	51	31.9
	30 ~ 34b	69	43.1
	>35c	40	25.0
Education level	High school	4	2.5
	College	68	42.5
	University	83	51.9
	Over graduate school	5	3.2
Certification	EMT level 1a	96	60.0
	EMT level 2b	24	15.0
	Nurse c	37	23.1
	Education d	3	1.9
Work period (year)	<1a	17	10.6
	1 ~ <3b	52	32.5
	3 ~ <5c	43	26.9
	5 ~ <8d	33	20.6
	≥8f	15	9.4
Monthly income (Korean won)	<3,000,000	23	14.4
	3,000,000 ~ <3,500,000	62	38.8
	3,500,000 ~ <4,000,000	41	25.6
	≥4,000,000	34	21.2
Class	Fire fighter a	67	41.9
	Senior fire fighter b	73	45.6
	Fire sergeant	16	10.0
	Fire lieutenant	4	2.5
Marital status	Married	73	45.6
	Single	87	54.4
Number of people	<3a	16	8.3
	3-4b	37	19.4
	>4c	138	72.3
Regular exercise	Yes.	45	23.6
	No.	146	76.4
Hobby	Yes.	139	72.8
	No.	52	27.2

Regarding emotional intelligence by gender, females showed higher values than males ($p = .043$). For job stress, females had higher job stress than males ($p = .045$). Although self-efficacy and job stress of females were higher than those of males, differences between the two were not statistically significant. Emotional intelligence of workers not younger than 35 years was found to be higher than that of workers younger than 30 years ($p = .041$). Job stress of workers younger than 30 years was higher than that of workers not younger than 35 years ($p = .047$). However, self-efficacy did not show any statistically significant difference among age groups. According to education level, self-efficacy of graduates from a college or a graduate school was higher than that of high school graduates ($p = .049$).

By qualification level, job stress of EMT level 1 qualification holders was found to be lower than that of EMT level 2 qualification holders and those who took the training course ($p=.007$). By service period, self-efficacy of workers with service career between 5 and 8 years was higher than that of workers with a service career of 8 years or longer ($p = .045$). Emotional intelligence was higher when service career was longer. Job stress of workers with service career shorter than 3 years was shown to be higher ($p = .028$).

Regarding emotional intelligence of workers of each rank, the emotional intelligence of fire engineers was found to be higher than that of fire lieutenants or fire captains ($p = .050$). Self-efficacy of fire engineers and fire lieutenants was found to be higher than that of firefighters ($p = .048$). Job stress was shown to be higher when less than three workers were mobilized than that when three or more workers were mobilized ($p = .033$). Emotional intelligence had a score of 63 out of 80 points. Self-efficacy had a score of 57 out of 100 points and job stress had a score of 38 out of 42 points [Table 2].

We intended to look into traumatic events caused by repeated exposure to diverse rescue sites^[10], including psychological stress where dangerous situation should be immediately coped with and psychological difference felt in a working environment different from general working circumstances.

The overall job stress level of subjects had a score of 38 points, similar to the result of Yoon et al^[11]. Although the result by gender was shown to be similar to that of preceding studies^[12,13], some studies have reported different results.

Table 2. Emotional intelligence, self-efficacy, and job stress of the subjects according to general characteristics(N=160)

Variables	Categories	Self-efficacy		Emotional intelligence		Job stress

Yoon et al^[10] have also reported that the younger the worker, the lower the specialty education level, the shorter the service period, and when the rank of the worker is firefighter and the worker is unmarried, the higher the job stress. However, some studies have also shown that the longer the service period, the higher the job stress^[15-17].

Emotional intelligence of females was higher than that of male. That of workers not younger than 35 years was higher than that of workers younger than 30 years.

Self-efficacy showed a positive correlation with emotional intelligence ($r = 0.462, p = .000$). supporting previous result showing that the higher the emotional intelligence, the higher the self-efficacy^[18, 19]. Self-efficacy and job stress showed a negative correlation ($r = -0.119, p = .042$). Emotional intelligence showed a negative correlation with job stress ($r = -0.173, p = .018$) [Table 3].

Table 3. Correlation coefficients between related variables(N=160)

Variable	Self-efficacy	Emotional intelligence	Job stress
Self-efficacy	1	.462(0.000)	-.119(.042)
Emotional intelligence	.462(0.000)	1	-.173(.018)
Job stress	-.119(.042)	-.173(.018)	1

Based on the above study result, emotional intelligence and self-efficacy were confirmed to have an effect on job stress. Accordingly, a program that increases emotional intelligence and self-efficacy should be developed. Physical and mental health of ambulance workers should be improved by establishing a strategy to enhance emotional intelligence and self-efficacy to

reduce job stress.

Conclusion

Emotional intelligence of females was higher than that of males.

Self-efficacy showed a positive correlation with emotional intelligence but a negative correlation with job stress. Emotional intelligence showed a negative correlation with job stress. The higher the emotional intelligence, the higher the self-efficacy. The higher the emotional intelligence and self-efficacy, the lower the job stress.

Based on above mentioned results, the emotional intelligence has effect on the job stress. Therefore, to reduce the job stress, the health should be improved and the field response capability should be enhanced by establishing the strategy to enhance the emotional intelligence.

Abstract

Background/Objectives: This study was performed to investigate the effects of job satisfaction and burnout on nursing service quality in long-term care hospital.

Methods/Statistical analysis: Participants were 120 nurses working at 10 long-term care hospitals. Data were collected from August to September, 2017. The collected data were analyzed using SPSS 22.0

Findings: Job satisfaction was different according to total clinical experience, career in present hospital, and monthly income. Burnout was different according to age, marital status, total clinical experience, monthly income, and pattern of shift. Nursing service quality was different according to monthly income, and pattern of shift. There were significant correlations among job satisfaction, burnout and nursing service quality. Factor influencing nursing service quality was burnout and explanatory power was 33.6%.

Improvements/Applications: In order to improve the nursing service quality, it is important to create an environment where nurses can work long-term and reduce burnout.

Keywords: Job satisfaction, Burnout, Exhaust, Nursing service quality, Long-term care hospital

Introduction

In the medical service sector, the nursing workforce is involved in most medical service areas at the point of contact with the patient. Therefore, both nurse- and patient-related factors can have significant influence on nursing service quality. Because nursing service is a strategic factor determining the productivity and competitiveness of nursing units at hospitals and is also a factor affecting the perception of nursing care by its consumers, it is essential to improve nursing service [1]. However, many previous studies have shown that nurses suffer from burnout due to accumulated fatigue and stress due to such factors as excessive workload and interpersonal conflict, and that such job burnout reduces work efficiency and organizational productivity, resulting in reduced nursing service quality [2]. In addition, burnout can have other negative consequences

such as lowered job satisfaction. Job satisfaction drives nurses to have pleasant and positive attitudes toward their work, which affects the quality of nursing care for patients [3]. Reduced job satisfaction can not only affect nursing service quality but also results in turnover, which can be extended to the problem of supply and demand of the nursing workforce and human resource management. 4

Most domestic studies on nursing service quality conducted up to now have focused on the assessment of nursing service quality from the consumer's perspective, such as nursing care customer satisfaction, revisit intention, and perception gap in nursing service between customers and providers, and on the assessment of the economic profits of hospitals [1,4]. However, studies on factors affecting nursing service quality from the perspective of nursing providers have not been widely conducted. For quality management in nursing services from the perspectives of nursing providers, this study aimed to investigate the effects of job satisfaction and burnout on nursing service quality, and to provide basic

data for nursing human resource management.

Method

1. Study design

The present study was a descriptive correlational study designed to examine the relationship between job satisfaction, burnout, and the nursing service quality among nurses in long-term care hospital.

2. Participants

Participants in this study were 126 nurses from 10 long-term care hospitals. The study was conducted between August and September of 2017. The sample size was calculated using G*Power 3.1.9.2. Based on linear multiple regressions with the effect size .15, significance level of .05, and power of test of .95, the sample size calculated was larger than the recommended size of 74; thus, it satisfied the requirement. One hundred twenty (95.2%) questionnaires were used for final data analysis, excluding six that was considered inadequate.

3. Instruments

3.1. General characteristics

General characteristics were age, career in present hospital, total clinical experience, marital status, educational background, monthly income, and pattern of shift.

3.2. Job satisfaction

Job Satisfaction was measured using the Minnesota Satisfaction Questionnaire^[5] developed by Minnesota Industrial Research Institute, translated by Lee and Park^[6] and supplemented by Choi^[7]. A total of 15 items were rated on a 5-point Likert scale, ranging from “very unsatisfied” (1 point) to “very satisfied” (5 points). A higher score indicates higher job satisfaction. The reliability of this tool was calculated to be .69 in a study^[7] and .827 in the present study.

3.3. Burnout

Burnout was measured using Maslach Burnout Inventory developed by Maslach and Jackson^[8], and translated by Choi and Chung^[9]. This tool consists of a total of 22 items, and each item is rated on a 7-point Likert scale, ranging from “never” (0 points) to “every day” (6 points). A higher score indicates higher burnout. The reliability of this tool was calculated to be .84 in a

study^[9] and .906 in the present study.

3.4. Nursing service quality

A nursing service quality was developed by Joo^[10] to measure the quality of Korean nursing services based on the SERVPERF model developed by Cronin and Taylor^[11], and the tool that was modified and supplemented by Lee^[12]. This tool consists of a total of 20 items, and each items is rated on a 5-point scale, ranging from “strongly disagree” (1 point) to “strongly agree” (5 points). A higher score indicates higher quality of service. The reliability of this tool was calculated to be .97 in a study^[12] and .938 in the present study.

4. Analysis

Data were analyzed using SPSS version 20.0 software according to the following analyses:

1) The differences in job satisfaction, burnout, and nursing service quality according to the general characteristics of the participants were analyzed using t-test and analysis of variance, and the post-hoc test was performed using the Scheffé test.

2) Pearson’s correlation coefficients were calculated to examine the correlations between job satisfaction, burnout, and nursing service quality.

3) The factors that affect nursing service quality were analyzed using multiple regression analysis.

Result

1. General characteristics

The participants of this study were 120 nurses, the majority (n=68 [56.7%]) of which were aged 40 to 50 years as shown in table1. The majority of the participants (n=104 [86.7%]) were married. In terms of education level, the majority (n=72 [62%]) were junior college graduates. The proportion of those with more than 15 years of total clinical experience was the highest (41.7%). In terms of years at the current long-term care hospital, 40 (33.3%) had worked at the hospital for less than 5 years, 42 (35%) had worked at the hospital for 2-5 years, and 38 (31.7%) had worked at the hospital for more than 5 years. The majority of the participants (n=87 [72.5%]) had an average monthly income of 2-2.5 million South Korean won (KRW). In terms of shift pattern, the number of those with 3-shift work was 58 (48.3%).

Table 1: General characteristics (N=120)

Characteristics	Categories	n(%)
Age(year)	< 40	28(23.3)
	40 - < 50	68(56.7)
	≥ 50	24(20.0)
Marital status	Unmarried	16(13.3)
	Married	104(86.7)
Educational background	Diploma	72(60.0)
	Bachelor	38(31.7)
	Higher than a master's degree	10(8.3)
Total clinical experience(year)	< 7	36(30.0)
	7 - < 15	34(28.3)
	≥ 15	50(41.7)
Career in present hospital(year)	< 2	40(33.3)
	2 - < 5	42(35.0)
	≥ 5	38(31.7)
Monthly income (Won)	< 200	18(15.0)
	201 - < 250	87(72.5)
	≥ 250	15(12.5)
Pattern of shift	3 shift work	58(48.3)
	2 shift work	12(10.0)
	Fixed	50(41.7)

2. Differences in variables by general characteristics

Table 2 shows the differences in job satisfaction, burnout, and nursing service quality according to the general characteristics of the participants. A significant difference was observed in job satisfaction according to total clinical experience ($F=9.786$, $p<.001$), number of years at the current hospital ($F=3.966$, $p<.001$), and average monthly income ($F=9.203$, $p<.001$). The results of the post-hoc test revealed that the score for job satisfaction was higher in those with more than 15 years of total clinical experience compared with those with less than 7 years of total clinical experience, in those who had been at the current hospital for more than 5 years compared with those who had been at the current hospital for less than 2-5 years, and in those with an average monthly income of more than 2.5 million KRW compared with those with an average monthly income of less than 2 million KRW.

A significant difference was observed in burnout according to age ($F=7.664$, $p=.001$), marital status ($t=2.100$, $p=.037$), total clinical experience ($F=7.935$, $p=.001$), average monthly income ($F=4.493$, $p=.013$) and shift pattern ($F=3.721$, $p=.027$). The results of the post-hoc test revealed that the score for burnout was higher in those under the age of 40 than in those over the age of 50, in those who were unmarried than in those who were married, in those with less than 7 years of total clinical experience than in those with more than 15 years, in those with an average monthly income less than 2 million KRW than in those with an average monthly income of more than 2.5 million KRW, and in those with 3-shift work than in those with fixed shift work.

A significant difference was observed in nursing service quality according to average monthly income ($F=4.445$, $p\leq.014$) and shift pattern ($F=6.988$, $p=.001$). The results of the post-hoc test revealed that the score for nursing service quality was higher in those with an average monthly income of more than 2.5 million KRW than in those with an average monthly income of 2-2.5 million KRW and in those with fixed shift work than in those with 3-shift work.

unit: cm, *: p<0.05, **: p<0.01, ***: p<0.001

3. Degree and correlation among variables

The mean scores for job satisfaction, burnout, and nursing service quality among the participants was 3.25, 2.09, and 3.76 points, respectively as shown in table 3. The nursing service quality is significantly correlated with job satisfaction ($r = .397, p < .001$), with burnout ($r = -.579, p < .001$).

Table 3: Degree and correlations among variables (N=120)

	M±SD	Range	Job satisfaction	Burnout
			r	r
Job satisfaction	3.25±0.58	1-5	-	-.526***
Burnout	2.09±0.88	0-6	-.526***	-

unit: cm, *: $p < 0.05$, **: $p < 0.01$, ***: $p < 0.001$

4. Factors influencing nursing service quality

To identify the explanatory power of factors related to the quality of nursing service, a linear regression analysis was conducted with nursing service quality as the dependent variable, an with job satisfaction and burnout as the independent variables. Burnout ($\beta = -.512, p < .001$) had a significant influence on the nursing service quality, with an explanatory power of 33.6% in table 4.

Table 4: Factors influencing nursing service quality (N=120)

Discussion

This study found that there were significant differences in job satisfaction according to number of

years of clinical experience, number of years at the current hospital, and average monthly income. These results are consistent with the results of a study [13] showing a significant difference in job satisfaction according to clinical experience among nurses in tertiary hospitals, and the results of a study [14] showing a significant difference in job satisfaction according to clinical experience and wages among general hospital nurses. Therefore, in order to enhance job satisfaction in nurses, it is essential to provide economic satisfaction by guaranteeing adequate wages, and to provide conditions for nurses to build their career until they become skilled at the job.

The results of this study also found that there was a significant difference in nursing service quality according to average monthly income and shift pattern. In other words, nursing service quality was found to be significantly higher in those with fixed shift work, which is consistent with the results of a previous study [13] showing that nursing service quality was significantly higher in general hospital nurses who did not work at night. In addition, these results are similar to the results of a study [14] indicating that nursing performance in general hospital nurses differed according to wage levels. Therefore, in order to improve nursing service quality, it is necessary to reduce night shifts, increase fixed shift work, and offer appropriate wages to nurses.

The results of this study showed that nursing service quality was significantly positively correlated with job satisfaction, and that burnout was a variable with a 33.6% influence on nursing service quality. These results are consistent with the results of a previous study involving public health nurses [16] and another previous study involving general hospital nurses [13] showing that job satisfaction was positively correlated with nursing service quality, although there was a difference in the subjects between the studies. The results of this study are also supported by those of a previous study [15] that found that burnout was positively correlated with nursing service quality among nurses in comprehensive nursing care wards.

Physical and emotional exhaustion can lower nursing service quality. Therefore, in order to improve nursing service quality in long-term care hospitals, it is necessary to manage nursing human resources through increasing regular shift work, providing proper conditions for career building, and, thus, proactively reducing burnout among nurses.

Conclusion

Job satisfaction was found to be significantly higher and burnout was lower in those with significantly more clinical experience. Therefore, inducing nurses to work long-term and enhancing their nursing job satisfaction are ways to improve nursing service quality.

Antimicrobial Effect of Cinnamon Oil Against Oral Microorganisms

Yeo-Jin Jeong¹, Jun-Seon Choi²

¹MSc. Student, Graduate School of Gachon University, Department of Dental Hygiene, Republic of Korea,

²Professor, Gachon University, Department of dental hygiene, Republic of Korea

Abstract

Background/Objectives: There has been a growing interest in the antimicrobial activity of natural extracts that inhibit the growth of microorganisms without side effects. Therefore, we evaluated the antibacterial effects of cinnamon oil against *oral microorganisms* existing in dental plaque.

Methods/Statistical analysis: Dental plaque was formed on bovine specimens using a growth medium for 6 days, followed by treatment with either 2.5% cinnamon oil, 0.12% chlorhexidine gluconate, or 10% dimethyl sulfoxide for 5 min, twice per day. On day 7, each specimen was imaged using quantitative light-induced fluorescence–digital to assess microbial activity of dental plaque. A one-way analysis of variance and the Scheffe *post hoc* test were performed to analyze the differences in red/green ratio (R/G values) of dental plaque between the three treatment groups.

Findings: The average R/G values of dental plaque was the lowest in the 2.5% cinnamon oil group (1.180 ± 0.010), and these values were significantly different from those of the chlorhexidine gluconate group (1.249 ± 0.008) ($p < 0.001$). Furthermore, the changes in the mean R/G values of each specimen showed statistically significant differences over time ($p < 0.05$). Thus, we suggest that cinnamon oil is an effective antimicrobial agent that inhibits the proliferation of anaerobic bacteria in dental plaque.

Improvements/Applications: Further studies should compare and analyze the antimicrobial activity of cinnamon oil against *oral microorganisms* at different concentrations.

Keywords: Antimicrobial agent, Antimicrobial effect, Cinnamon oil, Oral microorganisms, Oral diseases

Introduction

According to the 2018 Statistics Korea report, dental caries and periodontal disease are among the top 10 outpatient diseases for which Koreans visit medical institution^[1], and these easily preventable conditions are costly to both patients and the national healthcare system. Therefore, the government and dental professionals should work to develop a variety of intervention strategies to effectively prevent these diseases.

Dental caries and periodontal diseases are the main diseases that lead to tooth extraction, and their main

cause is dental plaque, which contains more than 700 microbial species^[2]. Dental plaque is a complex mass of microorganisms with high viscosity created when various oral bacteria get attached to salivary glycoproteins thinly attached to the tooth surface^[3]. If dental plaque is not removed periodically, new bacteria will keep attaching to its surface, which makes the dental plaque more mature^[4]. Eventually, mature dental plaque becomes the cause of demineralization of the tooth or inflammation of periodontal tissue^[4]. Therefore, for the prevention of oral diseases, dental plaque accumulated on tooth surfaces should be thoroughly removed periodically.

The methods of controlling dental plaque are divided into mechanical methods such as tooth-brushing and chemical methods such as oral rinsing^[5]. Although tooth-brushing is the most basic method to control dental plaque, many people do not use proper tooth-brushing

Corresponding Author:

Jun-Seon Choi,

E-mail: junseon@gachon.ac.kr

technique and fail to effectively remove dental plaque^[5]. Chemical methods are effective for removing interdental plaque that cannot be removed by tooth-brushing^[6]. Hence, chemical methods are necessary for effective control of dental plaque.

Unfortunately, however, chlorhexidine gluconate, the most commonly used antimicrobial agent, can have side effects such as extrinsic dental staining or oral dryness, despite its effectiveness at inhibiting dental plaque formation^[7,8]. In addition, when used constantly, its ability to inhibit dental plaque formation can diminish due to antibiotic resistance^[9].

Recently, there has been increasing interest in essential oils extracted from herbs such as sweet basil as an alternative to chlorhexidine gluconate^[10]. In particular, several studies have found that cinnamon oil has antibacterial effects on various bacteria, including *Staphylococcus aureus*^[10,11]. Therefore, in this study, we analyze the antibacterial effects of cinnamon oil against *oral microorganisms* present in dental plaque using quantitative light-induced fluorescence–digital (QLF-D).

Method

This study was approved by the Ethics Committee of Gachon University (No. 1044396–201904-HR-057–01). An *in vitro* study was performed to evaluate the antimicrobial effects of cinnamon oil against *oral microorganisms*. All experimental processes in this study are based on previous studies^[12–14].

First, cinnamon oil extracted from *Cinnamomum zeylanicum* via steam distillation was purchased from doTERRA (USA). Based on the results of a preliminary solubility test, the concentration of cinnamon oil to be used in the study was 2.5%. Tooth specimens (6 mm in diameter × 5 mm in thickness) were made using bovine incisors without cracks or white spots. Human stimulated saliva was collected from one healthy individual who had no active oral diseases and who had not used any antibiotics within the prior 3 months. The collected saliva was inoculated into each specimen, placed on a 24-well plate, and then incubated for 4 h (10% CO₂, 37°C). Then the saliva was aspirated from the wells, and a pre-made growth medium (0.5% sucrose and basal medium mucin) was added to the plate^[12]. The plates were incubated for 6 days (10% CO₂, 37°C), with the growth medium replaced at the same time each day. During the 6 days, each specimen was treated with

either 2.5% cinnamon oil (experimental group), 0.12% chlorhexidine gluconate (positive control group), or 10% dimethyl sulfoxide (negative control group) for 5 min, twice per day.

On day 7 of incubation, each specimen was photographed using QLF-D to assess microbial activity of dental plaque. QLF-D detects porphyrins produced by oral bacteria using 405 nm blue light. The blue light conditions were set as follows: shutter speed 1/30 s, aperture 5.0, and ISO 1,600^[15]. The average red/green ratio (R/G values) of the images was calculated using ImageJ (NIH, MD, USA)^[13]. A higher R/G values indicate high anaerobic bacterial activity.

A one-way analysis of variance (ANOVA) and the Scheffé *post hoc* test were performed to analyze differences in R/G values of dental plaque between the three treatment groups. A repeated measures ANOVA was conducted to compare the changes in the mean R/G values of dental plaque of each treatment group over time. A p-value < 0.05 was chosen to indicate a significant difference between groups.

Result and Discussion

R/G values were the lowest in the 2.5% cinnamon oil group (1.180 ± 0.010), and there was a significant difference between this group and the chlorhexidine gluconate group (1.249 ± 0.008), with the values of the 10% dimethyl sulfoxide group being highest (1.461 ± 0.003; p < 0.001) [Table 1]. The red fluorescence of each specimen is shown in Figure 1. A higher red fluorescence intensity indicates heightened activity of anaerobic bacteria. As a result of the repeated measures ANOVA, the changes in the mean R/G values of each specimen showed statistically significant differences over time (p < 0.05) [Figure 2]. In particular, the R/G change was the smallest in the specimen which was treated with 2.5% cinnamon oil.

We used cinnamon oil extracted by steam distillation, because this method extracts the highest concentration of antimicrobial components^[16], and the 2.5% cinnamon oil was found to have a greater antimicrobial effect against *oral microorganisms* than 0.12% chlorhexidine gluconate and 10% dimethyl sulfoxide. Our results suggest that cinnamon oil can be used to inhibit the formation of the pathogenic bacteria that cause dental diseases as effectively as chlorhexidine gluconate, which is commonly used in clinical practice.

As an increasing number of studies have confirmed the antimicrobial effects of cinnamon oil, in-depth research to amplify the antimicrobial activity of the oil has begun. One study reported that cinnamon oil's antimicrobial effect increases when combined with other essential oils, such as thyme oil^[17]. Another recent study proposed the combination of cinnamon and antibiotics as an alternative therapeutic application that not only decreases the side effects of antibiotics but also enhances their curative effects on infectious diseases^[18]. Although the antimicrobial effects of cinnamon oil against various microorganisms such as *S. aureus* have come to light, the mechanism behind them have not been fully elucidated. A few studies have suggested that cinnamaldehyde, a major component of cinnamon oil, causes microleakage of bacterial cell membranes^[19,20]. Moreover, a study found that not only cinnamaldehyde but also eugenol, another component of cinnamon oil, has antibacterial activity^[21]. Our study revealed, using QLF-D, that cinnamon oil inhibits the proliferation of anaerobic bacteria in dental plaque. Further research is needed to clarify the antimicrobial mechanism of cinnamon oil against pathogenic *oral microorganisms*. Furthermore, future studies should analyze and compare the antimicrobial activity of cinnamon oil against *oral microorganisms* according to concentration. Finally, it is necessary to search for other surfactants with high biocompatibility aside from dimethyl sulfoxide that can be used as a chemical solvent for cinnamon oil.

Table 1: R/G values according to treatment group (at 7 day)

Treatment group	R/G values	
	Mean ± SD	F(p)
2.5% Cinnamon oil	1.180 ± 0.010 ^a	621.277 (<0.001)
0.12% Chlorhexidine gluconate	1.249 ± 0.008 ^b	
10% Dimethyl sulfoxide	1.461 ± 0.003 ^c	

^{a,b,c}The different characters are significant by Scheffe's multiple comparison at $\alpha=0.05$.

A: 2.5% cinnamon oil, B: 0.12% chlorhexidine gluconate, C: 10% dimethyl sulfoxide

Figure 1. Red fluorescence of each specimen (at 7day)

Figure 2. Changes in the mean R/G values of each specimen over time

Conclusion

Cinnamon oil is a natural substance that has a strong antibacterial effect against *oral microorganisms* without the side effects associated with chlorhexidine gluconate. This finding suggests that cinnamon oil has the potential to be developed as a preventive agent to prevent oral diseases. Further studies should analyze the antimicrobial effect of cinnamon oil against *oral microorganisms* at different concentrations. Furthermore, it is necessary to search for other surfactants with high biocompatibility aside from DMSO that can be used as a chemical solvent for cinnamon oil.

Study on Admission Motivation and Institution Selection Intention of Elderly Residing in Long-Term Care Institutions

Yun-Jeong Kim¹, Boo Hwan Ahn², Kyong Ja Im²

¹Professor, Department of Health, Counseling and Welfare, Hanseo University, Republic of Korea,

²Doctor Course, Department of Elderly Welfare, Hanseo University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to investigate the significant factors related to admission motivation and institution selection, in elderly residing in long-term elderly care institutions.

Methods/Statistical analysis: The study analyzed the data of 381 resident elderly among the data of ‘validation of long-term care institutions (institution salary) evaluation’ by Kim et al. The frequency analysis, t-test, oneway ANOVA, and multiple regression analysis were applied using SPSS21.0.

Findings: First, main determinants of institution admission were to review the children, including the son/daughter-in-law and daughter/son-in-law, rather than the individual or spouse, and the institution was determined taking into account the level and accessibility of the services as available for the elderly person requiring those services for care. Second, for institution admission motivation, it was found that the higher the ‘institution preference,’ the higher the institution recommendation intention and institution reselection intention. In other words, institution admission motivation was high in ‘family relations,’ but it was found that the present institution should have the ‘preference for institution’ as noted for the current institution, if it is to be recommended to another elderly person or is to be readmitted.

Improvements/Applications: The most important consideration of the service quality of the caregiver is the core of the operation of long-term elderly care institutions rather than the size, credibility and location of the institution.

Keywords: Long-term care institutions, Admission motivation, Institution recommendation intention, Institution reselection intention, Institution preference, Service quality

Introduction

As the elderly long-term care insurance system in Korea has been implemented for more than 10 years, the social endeavors to support the surge of elderly residing in long-term care institutions, the expansion of the day-care institution and the short-term care institution for deinstitutionization, and the rapid increase in community care are all different variables to be considered as these issues are being repeated.

In Korean culture, it is known that many elderly people prefer to live at home until death. This is because the meaning of ‘home’ for the elderly is its own domain, and it refers to the identity of the person ^[1] as a place to communicate with friends and neighbors. Therefore, the advent of institution admission due to the movement of the place of residence does not only mean the movement of the settlement, but also the interpersonal relationship which has been lived in the past, and also the separation with life. For this reason, there is still a negative perception of institution admission for an elderly person in society^[1]. Although socially long-term elderly care institutions are spreading, for the elderly, institution admission is a shame, and therefore resistance is high ^[2-5]. Above all, the elderly individuals are more likely to experience negative life circumstances

Corresponding Author:

Boo Hwan Ahn,

E-mail: daebart@daum.net

regarding their ability to care for themselves before institution admission. Migration from home to long-term elderly care institutions can be the most negative event experienced by the elderly [6-8].

Therefore, the purpose of the study is to analyze the minute details on why and who decided on the admission to which institution, the intentions to recommend the current institution to other elderly individuals who may require similar types of care, and the reasons for readmission if one had left and returned, even with the negative perception of elderly residence movement. The purpose of this study was to investigate factors related to admission motivation and institution selection in elderly residing in long-term elderly care institutions.

Method

1. Data

The data of resident elderly among the data of 'verification of effectiveness of long-term care institutions evaluation' by Kim et al., [9] was analyzed. In this case, after being recommended the elderly who can be surveyed from the institution, when the elderly allowed the questionnaire, the study conducted face-to-face questionnaires. Finally, the resulting data of 385 subjects were used for analysis.

2. Measurement Tools

Admission motivation : The admission motivation consisted of 8 items with reference to previous studies related to institution admission motivation. It was used in analysis through 3 sub-variables including family relations, need of care, and institution preference.

Institution selection intention and related factors : Institution selection intention was divided into institution recommendation intention and institution reselection intention. It was composed of a 3 point Likert scale with the 2 questions.

3. Characteristics of Subjects

In this study, the participants were noted that 71.7% were females and 28.3% were males, and the average age was 79.54 years old with most participants being 80 or older. There were generally no spouses (79.8% no spouses), 70.3% attended school, and 29.7% did not attend school.

4. Data Analysis Method

In this case, the frequency analysis, t-test, oneway ANOVA, and multiple regression analysis were applied using SPSS win 21.0.

Results

1.General Tendency of Variables

First, the institution admission determiner was found to be primarily determined as the responsibility of the son/daughter-in-law. When choosing an institution, they considered the level of service and the accessibility of the institution. In this instance, the service level was noted at 35.2%, and the institution accessibility was 35.0%. In the case of admission costs, it is unlikely that these factors will be taken into consideration, since the rates for long-term care institutions nationwide are similar in scope.

In these cases, according to institution use experience, 64.1% of people were in the first institution, and when transferred, they were transferred mainly from other nursing homes. Generally speaking, the reasons for the transfer seemed to be a preference for the new institution rather than the inconvenience of service or accessibility, and institution selection was somewhat different from the consideration.

In addition, 75.5% of the respondents answered that they would like to recommend admission to other elderly people, and that this is positive, and the reason is because the service is considered to be of good quality. Also, 76.2% of the respondents answered that there is an intention to return to the current institution and choose again, because the service is of good quality.

Next, the institution admission motivation was 4.209 for 'family relations', 3.220 for 'need for care,' and 3.437 for 'institution preference,' and it was found they chose the current institution as family members were close to where the institution was or through family recommendation.

2. Difference of Admission Motivation and Institution Selection Intention

Among the admission motivations, 'family relations' was significantly different according to age, marital status, and economic status of the elderly. That being said, the elderly in their 70s were choosing an institution for 'family relations' compared to elderly in their 60s,

and elderly people who were married rather than those who had divorced, widowed, or parted ways with their spouses, who were in general households selected institution because of ‘family relations.’ ‘Institution preference’ was significantly different according to gender and economic status of the elderly. In other words, elderly women compared to elderly men, and the elderly in the general household were more likely to adhere to the institution than a person considered to be in the category of welfare household elderly. However, the specific ‘need for care’ according to sociodemographic characteristics of resident elderly was not significant [Table 1].

In the case of institution recommendation intention in the selection of the institution, the difference according to the education level and economic condition of the elderly was considered to be shown as significant. The

institution recommendation intention of the elderly with education was higher than the institution recommendation intention of the elderly with no education, and for this reason the institution recommendation intention of the elderly in general households was higher than that of the elderly in welfare households. By way of explanation, the institution reselection intention in the selection of institution was significantly different according to the marital status and education level of the elderly. Taking this result into account, the institution reselection intention of the elderly with no spouse was higher than the institution reselection intention of the elderly with spouse, and the institution reselection intention of the elderly with education was higher than the institution reselection intention of the elderly without education [Table 2].

2. The Effects of Institution Admission Motivation of Resident Elderly on Institution Selection Intention

Particularly important in order to investigate the effect of resident elderly’s institutional admission motivation on institution recommendation intention and institution reselection intention, the study conducted a hierarchical regression analysis of institution recommendation intention and institution reselection intention using independent variables for stage 1 control variables (sociodemographic characteristics) and stage 2 admission motivation [Table 3, Table 4].

[Table 3] shows the results of the hierarchical regression with the dependent variable as the institution recommendation intention. In effect, the Model II was significant, but Model I with only control variables was shown to not be significant. The Durbin-Watson value was 1.639 and the independence of the residuals was secured. It is important to realize that the control variables accounted for 4.1% of institution recommendation intentions and admission motivation accounted for 12.1% of institution recommendation intentions, and a

total of 8 variables accounted for 16.2% of institution recommendation intentions of resident elderly. Of the 8 variables, only the influence of institution preference was considered to be significant, and institution recommendation intention was higher when admission was preferred.

[Table 4] shows the results of the hierarchical regression, with the dependent variable being the institution reselection intention. As a result, Model II was significant, but model I with only control variables was not significant. The Durbin-Watson value was 1.844 and the independence of the residuals was secured. However, to sum up the results, the control variables accounted for 4.5% of the institution recommendation intention, and admission motivation explained 4.9% of the institution recommendation intention, and a total of eight variables accounted for 9.4% of resident elderly’s institution reselection intention, and the model’s explanatory power seems to be low. Of the 8 variables, only the influence of institution preference was shown to be significant, and institution reselection intention was higher when admission was preferred.

Discussion

Results First, the main determinants of institution admission were children, including the son/daughter-in-law and daughter/son-in-law, rather than from the individual or spouse, and the institution was determined taking into account the level and accessibility of the services for the elderly person requiring care. Most of the elderly are shown to be living in the institution that they currently reside in, and recommending the institution that they are living in to other elderly people has high intention and high intention to reselect. This implies that the satisfaction of the elderly residing in the institution is high, but on the other hand, it can be predicted that there is no alternative but to live in care facilities or formal elderly care institutions. In other words, if the admission determinant was ‘self’ rather than ‘children, daughter-in-law, and relative’s, it was shown that the adaptation was higher^[8], and if admission was made by the recommendation of a child or relatives, skepticism and self-esteem about life were low and psychological depression and anxiety was high^[10]. Considering this, the main determinants of institution admission are as determined from the elderly’s ‘children,’ and it is difficult to interpret the answer only positively that the elderly will recommend and reselect the institution in which they live. Therefore, active policies are needed

to improve the quality of life of elderly people who are going to live the rest of their days in an institution.

Second, in institution admission motivation, it was found that the higher the ‘institution preference,’ the higher the institution recommendation intention and institution reselection intention was measured in these cases. In other words, institution admission motivation is noted as being high in ‘family relations,’ but if the institution in which the resident is present recommends it to other elderly people, or if these individuals leave for some reason and then return, the ‘preference for institution’ for the current institution needs to be present. In addition, it is necessary to integrate the fact that perceptions related to service was the reason for institution selection, reason for institution recommendation intention, and noted as the reason for institution reselection intention in the previous analysis. The suitability between the type of service and the needs of the elderly will lead to institution preference, and will also be reselected and recommended to elderly people in similar situations.

Conclusion

Consequently, the most important consideration of the service quality of the caregiver is the core of the

operation of long-term elderly care institutions rather than the size, credibility and location of the institution. Under these circumstances, it is important to improve the quality of life of elderly people by improving the service quality, which is an important issue in the elderly welfare policy. At present, the core staff of the available service provision for the elderly patients is the care worker. In these cases, support for care workers may be one of the ways that can be reviewed to find new initiatives to improve service quality, and such support may include increasing the number of care workers per elderly person, and an effort to consider managing the improvement of labor conditions of care workers.

The Effect of New Nurse's Peer Satisfaction and Educational Satisfaction on Clinical Performance

Myoungjin Kwon¹, Sun Ae Kim²

¹Professor, Daejeon University, Dept. of Nursing, Republic of Korea, ²Professor, Korea National University of Transportation, Dept. of Nursing, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to analysis the effects of peer satisfaction and educational satisfaction to nurses' clinical performance.

Methods/Statistical analysis: The subjects of this study were 162 nurses who understood the purpose of the study and agreed to voluntarily participate in the study. The collected data were analyzed using Pearson's correlation coefficients and hierarchical multiple regression analysis using the IBM SPSS 25.0 program.

Findings: The results showed that peer satisfaction and education satisfaction were significant factors, and their explanatory power was 27.5% ($F = 6.08, p < .001$).

Improvements/Applications: In order to improve the clinical performance of new nurses, education programs considering the impact factors are needed. This study can be used as the evidence.

Keywords: *clinical performance, peer satisfaction, educational satisfaction, nurse, regression*

Introduction

Nursing is becoming more complex and the severity of patients is increasing with the increase in the elderly population. As a result, nurses are required to have a high level of abilities required for patient care. The acquisition of new nurses' fast and stable clinical performances ensures the safety of patient care, increases satisfaction, and lowers turnover to stabilize the organization^[1]. However, some nurses, particularly new nurses, were reported lack of clinical performance^[2]. New nurses have a difficult time not only because they need to improve their clinical performance, but also because they have to adapt to their organizations. Critical thinking^[3,4], working conditions^[5], and experience as a nursing college student^[6] were found to be factors affecting a nurse's clinical performance in previous studies. Nurses' critical thinking skills enable them to pinpoint the patient's problem and provide nursing care for the problem. The physical and human environment

of the nurse's organization affects the nurse's work efficiency. Moreover, number of studies described factors that influence new nurses' clinical performance. In previous studies, social support^[7], interpersonal relationship^[8], problem solving ability^[9] were found to be an influencing factors, considering similar variables related to this study.

Social support, in particular, plays an important role in fostering professionals who can function independently and support nursing in their different roles and ultimately increase the organizational adaptability of new nurses. As with social support, new nurses learn about interpersonal skills in the clinical setting and try to form natural relationships. Problem solving skills are the ability to identify and solve problems that patients have in common with critical thinking.

The clinical performance of graduated new nurses depends not only on academic skills at school, but also on education and preparation for job skills in the field^[10]. And in Korea, the nursing education certification evaluation is used to confirm the overall evaluation of nursing education and the degree of achievement of learning outcomes. The aim of this course is to ensure

Corresponding Author:

Sun Ae Kim

E-mail: sakim@ut.ac.kr

that they are able to play a role as new nurses for the 4th grade students who are about to graduate.

Through many years of continuous evaluation, it is expected that the quality of nursing education and the basic ability of new nurses will be improved. However, the evaluation of the difference between these results and the new nurse's ability in actual clinical practice is still somewhat insufficient. Therefore, there are evaluation difficulties in the part of how these training programs can actually help care for patients. It can be a reasonable evaluation method to verify how helpful the training content has been to patient care through the satisfaction assessment of trained nurses. The relationship with peers is also important because nursing performs patient care while interacting with other professions. As well as communicating with colleagues, support from colleagues is relevant to the performance of nurses^[11].

In addition, after graduating, he becomes a new nurse and acquires knowledge and practical skills that are more suitable for the field through training conducted at the clinical site. However, little has been done about how satisfied new nurses are in the various levels and contents of education provided. For this reason, satisfaction with education can be relatively neglected because new nurses place the highest priority on acquiring knowledge and acquiring practical skills. However, educational satisfaction is likely to influence how much more educated people can focus on the content of education, which may affect the future image of education. Nurses are professions with high demands for continuous education in clinical settings, regardless of position. We must continue to learn new nursing techniques that change from evidence to relatively simple ability to learn new diagnoses and equipment. Therefore, in professional nurses, education is a very important element of capacity building and satisfaction with such education is related to the effectiveness of education and should not be overlooked.

Yet, not enough is known about how peer satisfaction and educational satisfaction impacts clinical performance. Therefore, although few of the existing studies have been found, we want to identify the impact of education satisfaction and peer satisfaction on clinical performance, which is considered to be important factors in the clinical performance of nurses.

Thus, the purpose of this study was to describe the influencing factor to clinical performance in hospital staff new registered nurses.

Method

This study is a descriptive correlation study to identify the effect of new nurses' peer satisfaction and educational satisfaction on clinical performance.

The subjects of this study were 162 nurses who understood the purpose of the study and agreed to voluntarily participate in the study. The number of subjects in this study is calculated by $G * Power$ ver. 3.1.9.2. Program. As a result of multiple regression analysis, the minimum number of samples required was 153 with a mean effect size of .15, significance level .05, power of .95, and 7 variables.

The tools used in the study were clinical performance, peer satisfaction, and educational satisfaction measurement tools.

The clinical performance measurement tool was modified and supplemented by Kim^[12], which was developed by the Korea Nursing Evaluation Institute^[13]. With a four-point Likert scale of 21 total questions, the range of scores is 21-84, and the higher the score, the better the nursing performance. At the time of tool development, the Cronbach's α was .91, and in this study it was .94.

Peer satisfaction was measured using a three-point scale in paragraph 1 consisting of satisfied, average, dissatisfied.

The education satisfaction level measured the tools developed by Lowery^[14] and translated by Lee^[15]. As a five-point Likert scale with a total of 14 questions, the higher the score, the higher the degree of satisfaction with the exercise leader and overall practice. At the time of tool development, the Cronbach's α was .96, and in this study it was .96.

Data were collected about participants' age, gender, Work Department, Working Period, Working department Training Period, Hope Department, Hospital Practice Experience, Residence, Work Satisfaction, Peer Satisfaction, Hospital Satisfaction, Department Movement Experience, matching nurse's image, subjective health awareness.

Weights were assigned through the IBM SPSS 25.0 program to generate a composite sample plan file and analyzed. The significance level was set to .05.

The subjects’ characteristics and the factors were calculated using actual numbers and weighted percentages, and χ^2 -test was used to compare groups. Pearson’s correlation coefficients and hierarchical multiple regression were used to determine the factors that influence to clinical performance.

Results

1. General characteristics of the subjects

Clinical performance was significantly different according to gender ($p = .018$) and job satisfaction ($p < .001$), Peer satisfaction ($p < .001$), hospital satisfaction ($p < .001$), nurse image compliance ($p < .001$), subjective health ($p = .001$) (Table 1).

2. Correlation between peer satisfaction, educational satisfaction, and clinical performance

The results of analyses show that correlations between clinical performance and educational satisfaction are significant positive correlation ($r = .23$, $p = .011$), between clinical performance and peer satisfaction are significant negative correlation ($r = -.30$, $p < .001$) (Table 2).

3.3 Influencing factors of clinical performance

Multiple regression analysis was performed using clinical performance as a dependent variable to identify the explanation ability of factors affecting clinical performance.

In order to confirm the explanatory power of factors affecting clinical performance, the clinical performance was used as a dependent variable, and the primary independent variables of gender, job satisfaction, hospital satisfaction, matching nurse image, and subjective health awareness, which showed differences in general characteristics of subjects. As a variable, secondary regression analysis was performed by additionally inputting peer satisfaction and education satisfaction. The regression showed that the Durbin-Watson statistic was 1.62, indicating no autocorrelation. Tolerance limits of .620-.935 and .558-.921 were all 0.1 or higher, and the dispersion expansion factors of 1.069-1.640 and 1.085-1.793 were all below 10, indicating no multicollinearity.

In the first analysis, as shown in Table 3, work satisfaction was a significant factor and the explanatory power was 22.2% $F = 6.10$, $p < .001$. The second analysis also showed that work satisfaction and education satisfaction were significant factors, and their explanatory power was 27.5% ($F = 6.08$, $p < .001$).

Discussion

This study produced new knowledge that general characteristics, peer satisfaction, and education satisfaction influencing on the clinical performance of new nurses in the following sections, we discuss our findings compared with previous research findings. And we identify limitations.

As expected, the positive correlation between clinical performance and education satisfaction was supported.

Training for new nurses is an essential part of reducing the turnover of new nurses^[16], increasing satisfaction and increasing the productivity of nursing organizations^[17].

In the previous study, the more educated and experienced nurses had fewer drug failures, and the less patient fall down accident^[18]. These findings provide a practical evidence that goes beyond the vague expectations or expectations that nurses' education improves the quality of patient care. In other words, the actual number of medication errors and the number of patients fall of the subjects were examined and objectively showed that the more education, the less these mistakes were made and the quality of patient care improved.

Previous studies have shown that differences in satisfaction with education and willingness to participate have an impact on the effectiveness of education. However, it is pointed out that if such educational satisfaction is high, the effect of education is high and the factors that increase the educational satisfaction are highly related to race, grade, and

individual's disposition^[19]. However, as mentioned above, educational satisfaction is influenced by various factors such as personal disposition and race. How this subjective judgment can be objectively assessed is very important to secure the basis for understanding the exact phenomenon in the future. The tools used in this study were also reliable, which can be seen as a result of confirming the relationship between satisfaction and clinical performance.

In addition, in the same context as this study, if the organization's career development support, including education, is satisfactory, the turnover rate of nurses will be lowered, and the nurse's capacity will be strengthened as time goes by, and clinical performance will be improved. However, satisfaction is subjective judgment, which may lead to inaccurate interpretation. Therefore, there is a need for repeated research by using different satisfaction evaluation tools.

In this study, researchers found that clinical performance and education satisfaction were correlated and clinical performance and peer satisfaction were negatively correlated. ($r = -.30$, $p < .001$) However, previous studies have reported that the higher the peer support of new nurses, the higher the clinical performance^[20]. In addition, high peer support influences job satisfaction, thus increasing job satisfaction^[21]. The support of colleagues and supervisors is important factor to help new nurses adapt to the clinical field, and since clinical adaptation is directly related to their job ability, the support improves the new nurse's ability. Existing studies have shown that active support from co-workers and supervisors is a factor that helps new nurses cope with the situation and work well^[22]. Since new nurses

may feel uncertainty and loneliness, it is important to reliably adapt to the hospital system in order to work effectively in hospitals^[23]. Peer support and support can enhance clinical performance and eliminate isolation^[24]. The negative correlation between peer satisfaction and clinical performance in this study is different from previous studies. It seems that the research tool showed a difference in that it was a three-point scale of a single question. In addition, this study was aimed at new nurses in a hospital, and the diversity of organizational culture was excluded. In addition, it is necessary to confirm the difference between peer support used in previous studies and peer satisfaction in this study. It may be necessary to confirm this part as not all support may lead to satisfaction. Therefore, further research is needed because the findings that peer support is associated with peer satisfaction could not be found.

Conclusion

There was a significant correlation between peer satisfaction and educational satisfaction with clinical performance. And explanatory power was also significant. Based on the results, it has been found that there is a need to increase peer satisfaction and educational satisfaction in order to enhance the clinical performance of nurses, which should be considered in the development of strategies and interventions.

Diagnostic Performance of Multiparametric MR Imaging According to the Location of Prostate Cancer

Jihae An¹, Keum Won Kim¹, Jae Young Seo¹, Young Joog Kim¹, Min Jae Yoon¹, Dong Hyun Oh¹

¹Medical doctor, Department of Radiology, Konyang University Hospital, College of Medicine, Daejeon, South Korea

Abstract

Background/Objectives: Most prostate cancers occur in the peripheral zone (PZ) of prostate and a few in the transition zone (TZ). We compared MRI findings and clinicobiologic findings among PZ, TZ and PZ+TZ prostate cancers to determine if cancer location is independently associated with outcomes.

Methods/Statistical analysis: A retrospective study was performed of 70 men who underwent multiparametric-MRI prior to radical prostatectomy from 2014.03~2018.02. Fifty-two prostate cancers were included in this study. We investigated the comparison serum-PSA, tumor size, prostate weight, Gleason score, presence of extracapsular extension, ADC value on DWI, PIRADS category and pathologic tumor stage, according to the location of prostate cancer (PZ, TZ, and PZ+TZ prostate cancers), using statistical methods.

Findings: 30/52(58%) were PZ in location, 14/52(27%) were in TZ, and 8/52(15%) were with PZ+TZ prostate cancer. Patients with PZ+TZ cancer presented with large total cancer size ($\geq 1.5\text{cm}$), MRI evidence of presence of extracapsular invasion ($p < 0.001$), seminal vesicle invasion ($p = 0.026$) and lymph node invasion ($p < 0.001$). The mean ADC value was significantly lower in the PZ+TZ cancer (mean ADC 0.455 – 0.83 (median 0.643)) than in PZ (0.4555 – 1.342 (median 0.90)) and TZ cancer (0.579 – 1.211 (median 0.895)) ($p=0.005$). There was no significant difference related to serum PSA (p value 0.065), Gleason score (p value 0.235) between PZ, TZ and PZ+TZ lesion.

Improvements/Applications: PZ+TZ prostate cancer is associated with tumor, ECE, seminal vesicle invasion and low ADC value. So, tumor location should be taken into account in the process of evaluation, and mp-MRI can be a good tool to staging prostate cancer.

Keywords: Prostate gland, Prostate cancer, Prostate MRI, Diffusion weighted imaging, Transition zone, Seminal vesicle

Introduction

Prostate MRI is an important diagnostic method for detecting, locating and staging prostate cancer. Prostate MRI and reporting and data system for prostate cancer have evolved. Among them, multiparametric MRI (MP-MRI) and the PI-RADS classification are the most commonly used and the most accurate diagnosis of prostate cancer these days. MP-MRI is a combination of T2-weighted imaging (T2WI), diffusion weighted

imaging (DWI) and dynamic contrast-enhanced (DCE) MRI and is an accurate imaging modality in the detection, localization and stage of prostate cancer, providing both functional tissue information and anatomical information [1,2,3]. About 80% of prostate cancers occur in the peripheral zone (PZ) and 20% of prostate cancers occur in the transition zone (TZ). Most benign prostatic hyperplasia occurs in the TZ. At peripheral zone, tumor usually show smaller volume but Gleason score has higher than transition zone, so it appears more aggressive features [4]. And tumor extent, extracapsular extension of prostate cancer is associated with poor prognostic factors. And it contribute to positive surgical margins during

Corresponding Author :

surgery [5,6]. The presence of extracapsular extension (ECE) of prostate cancer after radical prostatectomy is one of the poor prognostic factors associated with cancer recurrence, cancer progression, and cancer-related mortality [7,8]. ECE is also associated with an increase in prostate-specific antigen (PSA) among prognostic factors, and a surgical margin after prostatectomy [9]. MRI findings of ECE in prostate cancer include bulging contours, irregular lines or spindles protruding out of the capsule, and tumor-capsule contact length greater than 1 cm [10]. Our purpose of this study is to evaluate MP-MRI and kinetic features among cancer location and cancer extent, and correlate with clinicopathologic findings for investigate for diagnostic accuracy of preoperative imaging.

Method

This retrospective study was performed with Institutional Review Board approval and the requirement for obtaining informed patient consent was waived. A total of 74 patients diagnosed with prostate cancer, based on MP-MRI prior to radical prostatectomy at our institution between March 2014 and February 2018 (mean age, 72 years; range, 60 – 87 years), were retrospectively analyzed. Clinical, MRI, and pathologic features were obtained. But 22 men were excluded due to whose MR imaging was low-quality with artifact, or incomplete clinicopathologic factors, or underwent neoadjuvant chemotherapy, or underwent robot-assisted prostatectomy. Of all 74 patients, 22 patients were excluded from this study. Fifty-two patients' data was analyzed. One genitourinary radiologist and 3 pathologists reviewed each case and matched each MRI region one more time after surgery was done. First, by clinicopathologic factors, age, preoperative serum PSA, total cancer size and Gleason score was investigated. The 2nd, MR finding included extracapsular extension, like bulging contour, capsular irregular spindle, neurovascular bundle asymmetry, breach capsule tumor extension and tumor capsule contact length. In addition, lymph node invasion, seminal vesicle invasion and ADC value was investigated.

Philips Intera Achieva 3 T MRI system (Philips Medical Systems, Best, Netherlands) was used. Axial, sagittal and coronal views of T2-weighted MRI images of prostate were obtained, using turbo spin echo (TSE) technique. The parameters were TR/TE/FA = 2500/100/90, FOV = 180 × 180 mm, matrix size = 312 × 306, 1.0 NEX, section thickness = 3 mm, and

intersection gap = 0. For T1-weighted MRI images, the axial T1-weighted 3D dynamic gradient-echo fat-suppressed sequence (e-THRIVE GD) technique was used to obtain one pre-contrast image, along with ten early and delayed contrast-enhanced images, each at a one-minute interval. The parameters were TR/TE/FA = 3.3/1.6/10, FOV = 200 × 200 mm, matrix size = 200 × 199, 1.0 NEX, section thickness = 3.5 mm, intersection gap = 0. DWI-Sense of prostate were obtained. In single shot echo-planar imaging with sense encoding, a b-value of 1000 mm²/s was used. The parameters were TR/TE/FA = 3260/65/90, FOV = 180 × 180 mm, matrix size = 72 × 72, 6.0 NEX, section thickness = 3 mm, and intersection gap = 0. For calculation of ADCs, a region of interest smaller than the lesion was selected, without including necrosis or liquids.

For statistical analysis, Statistical Package for the Social Sciences (SPSS), version 25.0 (SPSS Inc., Chicago, IL, USA) was used. Chi-squared analysis, Mann-Whitney and Kruskal-Wallis tests were respectively used to evaluate differences in clinicopathologic outcomes (age, tumor size, serum PSA, Gleason scores, extracapsular invasion, seminal vesicle invasion, lymph node metastasis) between PZ, TZ and PZ+TZ prostate cancers.

Result and Discussion

A total of 52 patients with prostate cancer consisted of eligible study groups. Table 1 showed 30/52(58%) were PZ in location, 14/52(27%) were in TZ, and 8/52(15%) were with PZ+TZ prostate cancer. Patients with PZ+TZ cancer presented with larger total cancer size (≥ 1.5 cm) than PZ cancer or TZ cancer (p value = 0.008). MR finding included extracapsular extension, like bulging contour, capsular irregular spindle, neurovascular bundle asymmetry, breach capsule tumor extension and tumor capsule contact length greater than 10mm. Patients with TZ cancer were less likely to have extracapsular extension (35% [TZ cancer], 40% [PZ cancer] versus 100% [PZ+TZ cancer], p = 0.006). Patient with TZ cancer were less likely to have seminal vesicle invasion (7% [TZ cancer], 13% [PZ cancer] versus 50% [PZ+TZ cancer], p = 0.026). Patients with PZ+TZ cancer were more likely to MRI evidence of presence of extracapsular invasion (p value = 0.006), seminal vesicle invasion (p = 0.026) and lymph node invasion (p < 0.001) than PZ cancer and TZ cancer. The mean ADC value was significantly lower in the PZ+TZ cancer (mean ADC 0.455 – 0.83 (median 0.643)) than in PZ (0.4555

– 1.342 (median 0.90)) and TZ cancer (0.579 – 1.211 (median 0.895)) (p=0.005). There was no significant difference related to serum PSA (p value = 0.065) and Gleason score (p value = 0.235) between PZ, TZ and PZ+TZ lesion. Figure 1 case was 73-years-old man with transition zone prostate cancer with extracapsular extension. Serum PSA was measured 33.84ng/ml. T2 weighted image showed enlarged transition zone and low signal intensity mass lesion on T2 weighted image, similar to benign prostatic hyperplasia. But, diffusion weighted image showed moderate water restriction and low ADC at transition zone than normal-appearing tissue, suggestive of transition zone prostate cancer. Also, T2 weighted image showed irregular bulging contour, capsular irregular spindle, showing positive extracapsular extension. Gross pathology showed transition zone prostate cancer with extracapsular

extension (Gleason score 8). Figure 2 case was 66-years-old man with left peripheral zone prostate cancer, organ confined cancer. Diffusion weighted image shows focal ovoid water restriction lesion at left peripheral zone and T2 weighted image showed no extracapsular extension. Figure 3 case was 73-years-old man with both peripheral zone and transition zone prostate cancer with extracapsular extension. Serum PSA was measured 48.7ng/ml. The diffusion weighted image (b=1000mm²/s) shows heterogeneously high signal intensity at both peripheral zone and transition zone and water restriction. The ADC value of the lesion was 0.455 x 10⁻³ mm²/s. T2 weighted image shows marked bulging contour, capsular irregular spindle, showing extracapsular extension. Gross pathology shows both peripheral zone and transition zone prostate cancer with extracapsular extension (Gleason score 9).

Table 1. Comparison of MRI radiologic findings according to location of prostate cancer

Characteristics	PZ	TZ	PZ + TZ	P value
Number of patients	30	14	8	
Age in years at surgery (median)	58-81 (69.5)	62-79 (70.5)	66-78 (72)	0.656

2	13 (35.1%)	3 (8.1%)	1 (2.7%)	0.151
3	9 (24.3%)	8 (21.6%)	3 (8.1%)	

* ADC value: ADC values (mean ADC value) (x 10⁻³ mm²/s)

ADC value 1: number of patients with less than mean ADC values

ADC value 2: number of patients with more than mean ADC values

Figure 1. Prostate cancer of transition zone in 74-years old man

(Serum PSA 33.84ng/ml, ADC 0.639, Gleason score 8)

A. The diffusion weighted image (b=1000mm²/s) shows high signal intensity at transition zone.

B. On the ADC map shows water restriction and low ADC than normal-appearing tissue at transition zone, the ADC value of the lesion was 0.639 x 10⁻³ mm²/s .

C. The axial T2 weighted image shows bulging contour, capsular irregular spindle and tumor capsular contact lengths longer than 1cm, positive extracapsular extension.

D. The axial dynamic contrast enhanced image shows heterogeneously enhancing mass with extracapsular extension at transition zone.

E. Gross pathology of specimen shows adenocarcinoma, extracapsular extension at transition zone.

Figure 2. Prostate cancer with left peripheral zone in 66-years-old Ma

(Serum PSA 26.4ng/ml, ADC 0.552, Gleason score 8)

A. The diffusion weighted image (b=1000mm²/s) shows focal high signal intensity at left peripheral zone.

B. On the ADC map shows mild water restriction and low ADC than normal-appearing tissue at left peripheral zone, the ADC value of the lesion was 0.552 x 10⁻³ mm²/s .

C. The axial T2 weighted image shows focal low signal intensity nodule in left peripheral zone without extracapsular extension.

D. The axial dynamic contrast enhanced image shows heterogeneously enhancing nodule without extracapsular extension at transition zone.

E. Histopathology of specimen shows adenocarcinoma, organ confined tumor at left peripheral zone (H & E stain, x 200).

Figure 3. Prostate cancer with peripheral zone and transition zone in 73-years-old Man

(Serum PSA 48.7ng/ml, ADC 0.455, Gleason score 9)

- A. The diffusion weighted image ($b=1000\text{mm}^2/\text{s}$) shows heterogeneously high signal intensity at both peripheral zone and transition zone.
- B. On the ADC map shows water restriction and low ADC than normal-appearing tissue at both transition zone and peripheral zone, the ADC value of the lesion was $0.455 \times 10^{-3} \text{mm}^2/\text{s}$.
- C. The axial T2 weighted image shows marked bulging contour, capsular irregular spindle and tumor capsular contact length was longer than 1cm, positive extracapsular extension.
- D. The axial dynamic contrast enhanced image shows irregular heterogeneously enhancing mass with extracapsular extension at both transition zone and peripheral zones.
- E. Gross pathology of specimen shows adenocarcinoma, extracapsular extension at both peripheral and transition zone.

Conclusion

The transition zone of the prostate is mainly caused by benign prostate hyperplasia, and the incidence of prostate cancer is lower than the peripheral zone. Transition zone prostate cancer is difficult to diagnose even by core needle

prostate biopsy, and it is difficult to differentiate between prostate hyperplasia and prostate cancer of transition zone by transrectal prostate ultrasound or previous conventional prostate MRI. However, MP-MRI scans allowed precise differential diagnosis. The diffusion weighted images would correlate with the pathological moderate and prostate cancer stages of prostate cancer, thus increasing the role of MP-MRI. So, our conclusion is, PZ+TZ prostate cancer is associated with aggressive pathologic features, extracapsular extension, seminal vesicle invasion and low ADC value and can lead to worse outcomes. In the process of predicting patient risk and assessing the patient's prognosis before prostatectomy, it is necessary to take into account the location of the tumor and the stage of the prostate cancer. MP-MRI can be a good diagnostic tool for detection and staging of prostate cancer. MP-MRI is a beneficial preoperative assessment tool for determining location and extent of prostate cancer.

A Study on the Awareness of Community Public Health Project among the Employees in The Public Health Center

Bo-Woo Lee

Professor, Dept. of Radiological Technology Gimcheon University, Republic of Korea

Abstract

Background/Objectives: This study aims to select the priority projects for the community inhabitants considered by the employees of the public health center and to enhance the inhabitants' health and their satisfaction level on the usage of public health center.

Methods/Statistical analysis: The questionnaire survey of 152 employees working at G health center in Gyeongsangbuk-do conducted a survey on projects that should be conducted as a priority level among residents' public health center for local residents. The survey items were composed of 4 - point Likert scale for health care project, health promotion project, and health care for the elderly.

Findings: Chronic disease control (3.40 ± 0.97) was rated as the most needed project with respect to the questionnaire on the priority of public health service projects for the elderly, followed by operation of the center for the elderly with dementia (3.34 ± 0.91) and visiting health control (3.21 ± 0.88). Medical rounding for silver center (2.82 ± 0.92) and bathing project for the disabled elderly (2.93 ± 0.88) were rated as the least needed.

Improvements/Applications: This study was conducted to utilize it as a basic data to prepare improvement plans for improving the health of local residents and activating the functions of public health center.

Keywords: *Public health center, Public health project, Health control, Health enhancement, Chronic disease*

Introduction

Public health center try to improve the quality of public health services and to enhance the health of the inhabitants by establishing the public health service projects to meet the community requirements and developing community public health service plans to cope with the needs of the inhabitants^[1-4]. According to Article 3 of Community Public Health Act, it was determined that the heads of local governments should establish and prepare the plans of community public health services to submit to the Minister of Health and Welfare so as to contribute the disease diagnosis and health enhancement of the inhabitants^[5,6].

Rapid increase of the elderly population, chronic and degenerative-centric changes of diseases, and initiation of local government era affected the significant changes of public health environments^[7-9]. Upon the changes of public health environments, demands of public health services from the community inhabitants have been expressed variously and actively. However, priority setting among community public health services in the communities and overall establishments of public health service projects independently are needed to meet the dynamic needs of public health services from the inhabitants within the limited scope of public health service resources such as human resources, facilities, budget and so on, in the communities^[10-13].

Plans of community public health services should be prepared not only by the persons in charge in the public health center but also by the related institutions such as local governments, local councils, and so on, as well as inhabitants upon their participations in the planning in multiple ways^[14-16]. When planning the community public health services, participations of multiple stakeholders and

Corresponding Author :

Bo-Woo Lee,

E-mail: moobbo@hanmail.net

harmonious communication will enhance the reliability of the plans upon applications of various opinions to the plans^[17,18]. Securing the balance by adjusting interests of different parties, it is expected to enhance the feasibility of the projects and to raise the inhabitants' interests and participations in the public health service institutions^[19,20]. Although it is important to prepare the plans of community public health services, the interest level in the planning process and implementation of the plans has been raised, which requires the suggestions of objective guidelines to apply these interests^[21,22]. Therefore, it is very critical process to establish both mid-to-long-term plans and annual short-term plans and to evaluate their outcomes so as to maximize the utilization effects of the project plans^[23,24].

Accordingly, the research purposes are as follows;

Priority setting among community public health services in the communities and overall establishments of public health service projects independently are needed to meet the dynamic needs of public health services from the inhabitants within the limited scope of public health service resources such as human resources, facilities, budget and so on, in the communities. This study aims to select the priority projects for the community inhabitants considered by the employees of the public health center and to enhance the inhabitants' health and their satisfaction level on the usage of public health center.

Method

The questionnaire survey of 152 employees working at G health center in Gyeongsangbuk-do conducted a survey on projects that should be conducted as a priority level among residents' public health center for local residents.

The questionnaire was distributed and the method of writing was explained. The survey items were composed of 4 - point Likert scale for health care project, health promotion project, and health care for the elderly as seen in [Figure 1]. The statistical program of SPSS version 18.0 was used for data analysis.

Result

1. General characteristics of the subjects

With respect to the functions of 152 study subjects, technical functions were 38.2%, nursing and medical service were 35.5%, and public health administration was 26.3%. For the gender of the subjects, 24.7% were males and 75.3% were females. As for the age groups, 32.9% were 50s or older, 31.6% were 30s, 23.7% were 40s, and 11.8% were 20s. In terms of education level, 40.1% were university graduates, 39.5% were college graduates, 10.5% were graduate school graduates, and 9.9% were high school graduates as seen in [Table 1].

2. Necessity in health care business

In the question about health care business for public health center employees, Care of dementia patients(3.52±0.85) was the highest priority. And care of hypertension patients (3.46±0.91), and care of diabetes patients (3.32±1.02). Care of thyroid disease(2.87±0.93) appeared to be the lowest business ranking as seen in [Table 2].

3. Necessity in health care business

In the question of health promotion projects for public health center employees, smoking cessation(3.47±0.77) was the most important. And it appeared as the priority business necessary in order of obesity(3.36±0.93) and

exercise(3.28±1.12). The project for stress (3.12±1.15) was ranked lowest as seen in [Table 3].

4. Needs of public health service projects for the elderly

Chronic disease control (3.40±0.97) was rated as the most needed project with respect to the questionnaire on the priority of public health service projects for the elderly, followed by operation of the center for the elderly with dementia (3.34±0.91) and visiting health control (3.21±0.88). Medical rounding for silver centers (2.82±0.92) and bathing project for the disabled elderly (2.93±0.88) were rated as the least needed ones as seen in [Table 4].

Table 2. Questions about necessity in health care business**Unit: person (%)**

Contents	Very Necessary	Necessary	Unnecessary	Very Unnecessary	Mean ± S.D.
Care of Hypertension patients	46(30.3)	99(65.1)	3(2.0)	1(0.7)	3.26±0.91
Care of Diabetic patients	51(33.6)	94(61.8)	4(2.6)	0(0)	3.30±1.02
Care of Mental patient	44(28.9)	81(53.5)	22(14.5)	2(1.3)	3.16±0.93
Care of Physically disabled patients	26(17.1)	94(61.8)	24(15.8)	2(1.3)	3.12±0.89
Care of Cerebrovascular disease patient	40(26.3)	91(59.9)	17(11.2)	0(0)	3.21±0.94
Care of Dementia patient	59(38.3)	73(48.0)	19(12.5)	0(0)	3.23±0.85
Care of Osteoporosis	20(13.2)	94(61.8)	28(8.4)	6(3.9)	3.05±1.04
Care of thyroid disease	10(6.6)	79(52.0)	54(35.5)	5(3.3)	2.97±0.93

Table 3. Questions about necessity of health promotion business**Unit: person (%)**

Contents	Very Necessary	Necessary	Unnecessary	Very Unnecessary	Mean ± S.D.
No smoking	71(46.7)	71(46.7)	95(9)	0(0)	3.42±0.77
Exercise	55(36.2)	81(53.3)	14(9.2)	0(0)	3.25±1.12
Moderation in drinking	51(33.6)	81(53.3)	14(9.2)	1(0.7)	3.22±0.86
Nutrition	49(32.2)	81(53.3)	15(9.9)	0(0)	3.20±0.95
Obesity	60(39.5)	80(52.6)	9(5.9)	1(0.7)	3.31±0.93
Stress	51(33.6)	81(53.3)	11(7.2)	4(2.6)	3.16±1.15

Table 4. Questionnaires on the priorities of public health service projects for the elderly**Unit: person (%)**

Contents	Very Necessary	Necessary	Unnecessary	Very Unnecessary	Mean ± S.D.
Operation of the center for the elderly with dementia	53(34.9)	66(43.4)	27(17.8)	1(0.7)	3.34±0.91
Health checkup for the elderly	36(23.7)	77(50.7)	35(23.0)	1(0.7)	3.04±0.94
Operation of physical therapy rooms	30(19.7)	85(55.9)	32(1.1)	3(2.0)	3.01±1.05
Medical rounding for silver centers	21(13.8)	84(55.3)	36(23.7)	9(5.9)	2.82±0.92
Bathing project for the disabled elderly	38(25.0)	60(39.5)	44(28.9)	8(5.3)	2.93±0.88

Visiting health control	35(23.0)	93(61.2)	22(14.5)	1(0.7)	3.21±0.88
Managements of cancer patients	23(15.1)	84(55.3)	40(26.3)	3(2.0)	3.01±1.02
National health checkup	33(21.7)	78(51.3)	33(21.7)	6(3.9)	3.14±0.94

Discussion

In Korea, the public health environment has been remarkably changed since the complete amendment of the Act of Community Public Health in 1995, and the position and roles of community public health services perceived passively have been expanded more and more.

With the establishment of local public health service planning, the works of public health center were activated and the collaborative system with local governments and healthcare professionals was established. In addition, collaborative relationships with private groups within the community were developed to perform the effective community public health project and they were utilized

as the useful data to establish the national public health service projects. Hence, the importance of preparation and utilization was empathized for the practical community public health service projects, and they tried to enhance the quality of medical services and health of the community inhabitants based on this.

The rapid increase of the elderly population and the change of disease pattern mainly focusing on chronic degenerative diseases are changing the health care environment in Korea. In addition, the opening of the era of full-scale local autonomy has a leading effect on the change of the health care environment. On the other hand, according to the change of the health care environment, the health care needs of residents are diversified and actively expressed. In order to meet the diverse health care needs of the community residents within the scope of health care resources such as limited manpower, facilities and budgets of the public health center, it is necessary to select the priority of community health care problems. Therefore, through this study, we will select priority projects for local residents that public health center employees think, and through this, we will increase the health promotion of local residents and the satisfaction of using public health center.

According to the results of the study, Among the health care projects for adults, the priority projects for the care of dementia patients(3.52±0.85), hypertension patients(3.46±0.91), and diabetes patients(3.32±1.02) were answered as the most necessary, and the demand for the smoking cessation(3.47±0.77) and obesity projects(3.36±0.93) was high in the health promotion projects(3.28±1.12). Chronic disease control (3.40±0.97) was rated as the most needed project with respect to the questionnaire on the priority of public health service projects for the elderly, followed by operation of the center for the elderly with dementia (3.34±0.91) and visiting health control (3.21±0.88). Therefore, we will carry out priority projects selected by public health center employees and select and manage the blood pressure recognition rate, blood sugar recognition rate, smoking rate, walking practice rate, and dementia test rate of local residents as performance indicators of public health center.

In order to successfully perform the health project, the competence and consciousness of the employees of the public health center are largely dependent on the results of the survey, so it is necessary to select the priority projects of the public health center for the local

residents and to improve the performance indicators for the project.

Conclusion

This study was conducted by dividing priority projects for health promotion of local residents into health management projects, health promotion projects, and welfare projects for the elderly. Through this, this study was conducted to utilize it as a basic data to prepare improvement plans for improving the health of local residents and activating the functions of public health center. The results of the study are as follows. First, the health care project for local residents is carried out by care of dementia patients, care of hypertension patients, and care of diabetic patients. The performance index is improved by selecting blood pressure recognition rate, blood sugar recognition rate and dementia test rate. Second, the health promotion project for local residents is carried out with smoking cessation business and obesity business, and the performance index is managed by selecting the smoking rate and walking practice rate.

The Health Care Needs of Local Residents in Korea

Misoon Jeon

Professor, Baekseok University, Dept. of Nursing, Republic of Korea

Abstract

Background/Objectives: This study is to utilize the health services of N- citizens as a basic data for establishing the 7th Regional Health Plan (2018 ~ 2022) respectively.

Methods/Statistical analysis: Tools for measuring the health care needs of the subjects were revised and supplemented by the tools of the Community Health Survey. Data was collected through a questionnaire from August 1 to August 21, 2018. Although 447 questionnaires were collected, 403 questionnaires were used for data analysis, except for 44 which were not clear or missing. The collected data were analyzed with the SPSS 18.0 program.

Findings: The result showed that the overall health service level was 2.90 out of 4.0, and the kindness of staff in the sub - area was the highest with 3.32 points, followed by medical service level 2.86, modernization of facilities 2.77, and excellence in equipment 2.69 points. The total health care needs of the subjects were 3.38 out of 4.0, health care services and health promotion services were 3.41 points higher respectively. As a result of analyzing the difference between total health care need, health care service, health promotion service, elderly health service, maternal & child health service by general characteristics, only gender and total health care demand showed statistically significant differences($t=-2.095$, $p=.037$). The result showed that there was positive correlation of the total health care need, health care service($r=.862$, $p<.01$), health promotion service($r=.849$, $p<.01$), elderly health service($r=.868$, $p<.01$), maternal & child health service($r=.856$, $p<.01$) in citizens of N city.

Improvements/Applications: Development of a health promotion program is needed to improve the population's health potential and the ability to overcome the risk factors of the disease.

Keywords: Health care, Health service, Need, Health care service, Resident

Introduction

In the meantime, the healthcare environment is changing, such as changes in disease patterns, an increase in the elderly population, a decrease in fertility, and an increase in the demand for health and welfare services. In order to implement the division of medicine and promote health promotion projects, the need for basic data for establishing health plans and developing health promotion programs is increasing.

The challenge facing health centers as health administrative agencies is to carry out the broader primary health care needs of local residents. It also develops and expands basic health care services such as new approaches for the health management of the residents, such as disease prevention and poor health promotion projects [1]. In addition, it is urgently needed

to redefine the function and role of the public health center to proactively cope with new health care demands as well as the primary health care functions for local residents [2].

The Local Health Law stipulates that the head of local autonomous governments should set up a local health care plan every four years and establish an annual plan every year [3, 4]. In addition, in the 「National Health Promotion Act」, The plan for establishing and implementing a detailed plan for the promotion of public health is stipulated, and the importance of the local health care plan is increasing [5].

In addition, the World Health Organization (WHO) encourages the regular calculation of health policy indicators, health-related socio-economic indicators, health care management indicators, and health status

indicators necessary for evaluating the performance of health policy [6, 7].

Korea has been conducting national health indicator surveys every three years since 1983. However, this survey is a sample survey for establishing a national health plan at the central level, but local governments with different conditions use the result in health care planning, but there are limitations [3].

To establish a health care plan, comprehensive data on community health issues as well as health-related health indicators are needed [4]. The results of this survey will serve as an index not only for evaluating the performance of the health projects that have been promoted but also for establishing the health center plan of the public health center that meets the needs of the citizens.

In order to effectively promote health projects, it is necessary to set goals and develop strategies for health promotion projects based on information on the health level of citizens, the use of health institutions, and the health consciousness behavior of local residents. In addition, measures should be taken to maximize the utilization of available health resources in the community by inducing community involvement.

Therefore, in order to effectively promote the health and health promotion projects for citizens of N city, the health service for the 7th regional health plan (2019 ~ 2022) was established by conducting a survey on the health center service level and the health service needs of the residents. It will be used as basic data and as a data for developing health projects and health promotion programs.

Method

1. Research Design

This study is a descriptive study to utilize the health services of N- citizens as a basic data for establishing the 7th Regional Health Plan (2018 ~ 2022) respectively. It will be used as basic data and as a data for developing health projects and health promotion programs.

2. Data Collection

The subjects of this study were 447 people from N city by random sampling method. They explained that the purpose of the study and the data collected were not used for anything other than the study, and

the anonymity and confidentiality of the subjects were guaranteed. In addition, the subjects were explained to the subjects that they have the right to participate or refuse the study at any stage of the study. Afterwards, the survey was conducted after receiving written consent for the research subjects who voluntarily participated. Data was collected through a questionnaire from August 1 to August 21, 2018. Although 447 questionnaires were collected, 403 questionnaires were used for data analysis, except for 44 which were not clear or missing.

3. Instruments

Health service level

The tools for measuring the level of health services have been modified and supplemented in the tools of the community health survey [8]. The tool was developed in four categories and was evaluated on a four-point scale, with four points representing 'very good' and one point representing 'very bad'. Higher scores indicate higher levels of health service, and Cronbach's α is 0.816.

Health care needs

A tool for measuring the level of health services was developed by modifying and supplementing the tools in the Community Health Survey [8]. The tool is divided into four categories and evaluated on a 4-point scale: 4 points for 'very necessary', 3 points for 'need', 2 points for 'not needed', and 1 point for 'not required at all'. Higher scores indicate higher levels of health care needs, and Cronbach's α is 0.961. The Cronbach's α value for health care needs was 0.961.

4. Data Analysis

The collected data were analyzed with the SPSS 18.0 program:

- The frequencies and percentages of the general characteristics of the subjects were calculated.

- To analyze the differences in the health care needs by general characteristics of the subjects, t-test and ANOVA were done. A Scheffé test was done as a post hoc test.

- The correlation between the health care need, health care service, health promotion service, elderly health service and maternal & child health service was analyzed with the Pearson's correlation coefficient.

Result

1. General characteristics

[Table 1] presents the general characteristics of the subjects. 28.3% of males and 71.7% of females had the highest age of 20 ~ 49, 58.5% of the total. The highest educational level was 45.4% for college graduates and 35.0% for high school graduates. The married status was the highest with 59.3% and the unmarried was 28.0%.

Table 1. General characteristics n=403

Characteristics	Categories	n	%
Gender	Male	114	28.3
	Female	289	71.7
Age(years)	10~19	71	17.6
	20~29	84	20.8
	30~39	84	20.8
	40~49	68	16.9
	50~59	39	9.7
	60~69	49	12.2
	70 over	8	2.0
	Education	Over college	183
High school		141	35.0
Middle school		38	9.4
Elementary school		41	10.2
Married status	Alone	113	28.0
	Spouse	239	59.3
	Bereavement	36	8.9
	Separation	8	2.0
	Divorce	7	1.7

2. Level of health service

The results of analyzing the health service level of the subjects are shown in Table 2. The overall health service level was 2.90 out of 4.0, and the kindness of staff in the sub - area was the highest with 3.32 points, followed by medical service level 2.86, modernization of facilities 2.77, and excellence in equipment 2.69 points.

Table 2. Level of health service

Division	Min.	Max.	M±SD
Health service level	1.50	4.00	2.90±.57
Kindness of Staff	1.00	4.00	3.32±.56
Modernization of facilities	2.00	4.00	2.77±.80
Excellence in equipment	1.00	4.00	2.69±.79
Medical Services	1.00	4.00	2.86±.67

3. Health care need

The total health care needs of the subjects were 3.38 out of 4.0, and the details are shown in Table 3. Among the sub-domains, health care services and health promotion services were 3.41 points higher respectively, followed by maternal and child health services 3.36 and elderly health services 3.34.

Table 3. Health care need

Division	Min.	Max.	M±SD
Total health care need	1.23	4.00	3.38±.48
Health care service	1.50	4.00	3.41±.53
Health promotion service	1.00	4.00	3.41±.54
Geriatric health service	1.00	4.00	3.34±.56
Maternal & child health service	1.00	4.00	3.36±.57

4. Differences in the health care needs by the general characteristics

[Table 4] shows the analyzed difference in the health care needs according to the general characteristics of the subjects.

As a result of analyzing the difference between total health care need, health care service, health promotion service, elderly health service, maternal & child health service by general characteristics, only gender and total health care demand showed statistically significant differences($t=-2.095$, $p=.037$). In other words, total health care need was higher for female than for male.

The sub-regional health care service showed no statistical difference by general characteristics.

Table 4. Difference in health care needs by general characteristics

5. Correlation between the health care need, health care service, health promotion service, elderly health service and maternal & child health service

As shown in table 5, the result showed that there was positive correlation of the total health care need, health care service(r=.862, p<.01), health promotion

service(r=.849, p<.01), elderly health service(r=.868, p<.01), maternal & child health service(r=.856, p<.01) in citizens of N city. This means that higher the total health care need in the citizens increase to more the level of health care service, health promotion service, elderly health service and maternal & child health service.

Table 5. Correlation between the health care need, health care service, health promotion service, elderly health service and maternal & child health service

Division	Total health care need	Health care service	Health promotion service	Elderly health service	Maternal & child health service
Total health care need	1				
Health care service	.862**	1			
Health promotion service	.849**	.713**	1		
Elderly health service	.868**	.696**	.647**	1	
Maternal & child health service	.856**	.634**	.642**	.713**	1

Discussion

This study attempted to provide basic data for establishing and evaluating local health policies that actively cope with changing social environment, regional environmental characteristics, and local health care environment through health survey of citizens in N city. In order to promote the health of local residents and to provide high quality health care services, the organization began by recognizing the need for new challenges and countermeasures by strengthening the medical capacity of localization by linking the organizations and functions of public health centers and public health centers.

The results of analyzing the health service level of the subjects showed that the kindness of staff had the highest score of 3.32 points out of 4.0, followed by medical service level of 2.86 points. This was similar to the results of the Lee ^[9] study, which found that 60.3% were satisfied with the professionalism of health center doctors. Park, et al ^[10] suggested a way to improve the satisfaction level based on the opinions of public health service users. To this end, the public health center should devise ways to increase its utilization by reinforcing active publicity activities. In addition, health centers are not public private institutions, but public health institutions for residents, so they should be able to provide visiting services.

The total health service needs of the subjects were 3.38 out of 4.0, with health care service and health promotion service being 3.41, respectively. The results were similar to the results of the survey on local residents in C city ^[11]. The results were 3.30 out of 4 in health care services, including health clinics, health program support, national health examination, etc. The results showed a high score, and the health promotion services such as smoking cessation clinic and oral health were higher than 3.10. In this way, it is necessary to identify services that have high demands of local residents and to devise plans to efficiently provide public health services based on the contents of the services.

The health business at the health center was primarily responsible for maternal and child health care, prevention, family planning and acute infectious disease management and some public health care. Most medical services rely heavily on the private sector, so preventive health services and health care services are managed separately ^[3]. However, due to the implementation of the national health insurance system and rapid changes

in disease patterns, a system of health service provision should be established and the functioning of the public service sector should be strengthened ^[12, 13].

In order to effectively and proactively cope with health problems, active health policy is required rather than passive methods that rely on treatment after sickness. Therefore, it is necessary for N citizens to improve their health potential and to cope with disease risks by providing their own health practice and providing health programs at various public health centers. As a result, it is thought that local residents can improve their quality of life and improve health promotion by improving their proper functioning level by practicing their own health care.

Based on the level and needs of the public health services of the residents identified in this study, the development of high quality services and the effect verification study should be conducted. In addition, measures should be in place to expand the scope of service use so that residents can use and receive various public health services.

Conclusion

This study will provide basic data for establishing and evaluating the local health policy actively coping with changing social environment, regional environmental characteristics and local health care environment through N-citizen health care surveys. In order to effectively and actively respond to healthcare problems, aggressive healthcare policies are required instead of passive methods that rely on treatment after the disease develops. Therefore, by improving the self-health management ability of N-citizens, it is thought that the health promotion and quality of life of the subjects can be improved.

Health Care Needs According to the Life-Cycle of Community Residents

Misoon Jeon

Professor, Baekseok University, Dept. of Nursing, Republic of Korea

Abstract

Background/Objectives: The purpose of this study analyzes health care needs by life cycle and provides basic data for developing health care programs accordingly.

Methods/Statistical analysis: Tools for measuring the health care needs of the subjects were revised and supplemented by the tools of the Community Health Survey. Data was collected through a questionnaire from August 1 to August 21, 2018. Although 897 questionnaires were collected, 843 questionnaires were used for data analysis, except for 54 which were not clear or missing. The collected data were analyzed with the SPSS 18.0 program.

Findings: The analysis of health care needs by life cycle was the highest in adolescents with 3.41 out of 4.0, followed by 3.40 in childhood, 3.39 in elderly, 3.35 in adulthood, and 3.31 in pregnancy. The difference in the health care needs by life cycle according to the general characteristics is as follows: in the difference analysis of health needs by gender and life cycle, there was a statistically significant difference in adolescents ($t=-2.770$, $p=.006$) and adulthood ($t=-1.970$, $p=.049$). There was also a statistically significant difference in health needs in adolescence ($F=2.225$, $p=.039$) and adulthood ($F=2.449$, $p=.024$). The difference between marital status and health demand was statistically significant in adolescence ($F=4.570$, $p=.001$) and adulthood ($F=3.715$, $p=.005$).

Improvements/Applications: Therefore, in order to improve the health potential of the residents, it is necessary to develop a health care program according to the life cycle.

Keywords: Health care, Need, Life-cycle, Community, Residents

Introduction

Recently, with the aging of the population and the extension of life expectancy, there is a need for a customized healthcare approach to optimize and use an approach that is optimized for healthcare targets [1, 2]. In other words, health care has different levels and influencing factors according to age, and a differentiated approach strategy is needed.

The task of the public health center as a front line for the health administration is to broadly fulfill the primary health care needs of the local residents and at

the same time to provide a new approach to the health management of the residents [3]. In other words, by developing and expanding basic health services such as disease prevention and health promotion projects [4, 5], it is urgently required to re-establish functions and roles so as to actively cope with primary health care and new healthcare demand for local residents

In particular, local health care plans should improve the efficiency of health care projects by coordinating plans to meet the health care environment and national health care policy, and provide comprehensive, high quality health care services to the locals. It is desirable to establish a local health care plan focusing on opinions of users of public health centers in order to continuously carry out preventive activities such as health promotion and health education that meet the needs of local residents and systematically promote the contents of

various businesses [6, 7].

The basic approach to lifelong health care programs assumes that the factors that threaten the maintenance and promotion of health during an individual's lifetime are different. Therefore, the program provided to each individual depends on the overall life cycle characteristics and individual characteristics [8].

The life cycle is the process of changing a person's life through certain stages at the individual or family level, i.e., according to the stages of human development, infancy, childhood, adolescence, adulthood, middle age, and old age.

In the case of operating health projects by life cycle, there is an advantage in that each program can be specified. However, since the current national health projects are operated by business units, life cycle health projects are distracting in terms of setting the direction of the project and there are many limitations in connection with the current health programs [8].

Therefore, this study divided the life cycle into pregnancy, childhood, adolescents, adulthood, and elderly, and analyzed health care needs of each life cycle considering current on - going health care business, we tried to provide basic data for setting the program.

Method

1. Research Design

This study is a descriptive study to analyze health care needs by life cycle and provides basic data for developing health care programs accordingly. The life cycle was divided into pregnancy, childhood, adolescent, adulthood and elderly.

2. Data Collection

The subjects of this study were 897 people from N and C city by random sampling method. They explained that the purpose of the study and the data collected were not used for anything other than the study, and the anonymity and confidentiality of the subjects were guaranteed. In addition, the subjects were explained to the subjects that they have the right to participate or refuse the study at any stage of the study. Afterwards,

the survey was conducted after receiving written consent for the research subjects who voluntarily participated. Data was collected through a questionnaire from August 1 to August 21, 2018. Although 897 questionnaires were collected, 843 questionnaires were used for data analysis, except for 54 which were not clear or missing.

3. Instruments

Health care needs

A tool for measuring the level of health services was developed by modifying and supplementing the tools in the Community Health Survey [9]. The tool is divided into four categories and evaluated on a 4-point scale: 4 points for 'very necessary', 3 points for 'need', 2 points for 'not needed', and 1 point for 'not required at all'. Higher scores indicate higher levels of health care needs. The Cronbach's α value for health care needs was 0.959.

4. Data Analysis

The collected data were analyzed with the SPSS 18.0 program:

- The frequencies and percentages of the general characteristics of the subjects were calculated.

- To analyze the health care needs by life cycle according to general characteristics of the subjects, t-test and ANOVA were done. A Scheffe test was done as a post hoc test.

- The correlation between the maternal health care, childhood health care, adolescent health care, adult health care & elderly health care was analyzed with the Pearson's correlation coefficient.

Result

1. General characteristics

[Table 1] presents the general characteristics of the subjects. 35.6% of males and 64.4% of females had the highest age of 20 ~ 49, 63.8% of the total. The highest educational level was 53.6% for college graduates and 32.0% for high school graduates. The marital status was the highest with 57.8% and the unmarried was 32.9%.

Table 1. General characteristics**n=843**

Characteristics	Categories	n	%
Gender	Male	300	35.6
	Female	543	64.4
Age(years)	10~19	172	20.4
	20~29	219	26.0
	30~39	172	20.4
	40~49	147	17.4
	50~59	60	7.1
	60~69	61	7.2
	70 over	12	1.4
Education	Over college	452	53.6
	High school	270	32.0
	Middle school	61	7.2
	Elementary school	60	7.1
Married status	Unmarried	277	32.9
	Spouse	487	57.8
	Bereavement	54	6.4
	Separation	13	1.5
	Divorce	12	1.4

2. Level of health care needs according to life-cycle

[Table 2] shows the results of the analysis of the health care needs of the life cycle, pregnancy, childhood, adolescents, adulthood and the elderly. The highest in adolescence was 4.0 to 3.41, followed by 3.40 in childhood, 3.39 in elderly, 3.35 in adulthood, and 3.31 in gestational age.

Table 2. Level of health care needs according to life-cycle

Division	Min.	Max.	M±SD
Pregnancy	1.00	4.00	3.31±.76
Childhood	1.00	4.00	3.40±.72
Adolescents	1.00	4.00	3.41±.62
Adulthood	1.00	4.00	3.35±.60
Elderly	1.00	4.00	3.39±.58

3. Difference in the health care needs by life cycle according to general characteristics

[Table 3] shows the analyzed the difference in the health care needs by life cycle according to the general characteristics of the subjects.

In the difference analysis of health needs by gender and life cycle, there was a statistically significant difference in adolescents ($t=-2.770$, $p=.006$) and adulthood ($t=-1.970$, $p=.049$). In both adolescents and adulthood, health needs were higher for women than for men. There was also a statistically significant difference in health needs in adolescence ($F=2.225$, $p=.039$) and adulthood ($F=2.449$, $p=.024$). Adolescence did not differ statistically by group. And in adulthood, the health needs of those in their 60s and over 70s were higher than those

in their 10s, 20s, 30s and 40s. There was no statistically significant difference in health care needs by life cycle in educational background. The difference between marital status and health demand was statistically significant in adolescence ($F=4.570$, $p=.001$) and adulthood ($F=3.715$, $p=.005$). The health needs of adolescents were higher in divorced persons than in separated persons and in adulthood, the health needs of divorced people were higher than those of unmarried, spouse and separated persons.

Discussion

This study identified health care needs according to the life cycle of local residents through the survey on health care of citizens in N and C cities. Based on the research results, we attempted to develop a health care program according to the life cycle. In addition, in order to promote the health of local residents and provide high-quality health care services, it was started with the recognition that the organization needs to reinforce medical capacity and new challenges and responses by linking the organizations and functions of public health centers and public health centers [10].

As a result of this study, health care needs were the highest at 3.41 out of 4.0 in adolescents and 3.40 in childhood. Therefore, it is necessary to focus on health care in childhood and adolescence.

Various health problems occur in each life cycle, and in order to solve these problems, health care services should be provided in consideration of physical and health characteristics. Adolescence is a process of growing up into adulthood and establishing a healthy lifestyle that affects health in adulthood [8]. Therefore, it is considered that what is required in adolescence is the development of a health care program to establish a healthy lifestyle and to build a self-image of health. In childhood, it is a continuation of the growth process of infancy, in which positive self-image and healthy life habits are formed through physical, mental and social growth. Therefore, in this period, it is necessary to develop health care programs such as health education and counseling to form health lifestyles.

Adulthood is the most active period of exerting physical, mental and social potential, and forms various social positions and relationships. It is also the time

to begin to be affected by health risks, depending on the health habits formed in the previous stages of the life cycle. In particular, since the forties, the disease of chronic degenerative diseases such as cancer and cerebrovascular diseases will increase rapidly. Therefore, the early detection of diseases is the most important time because the health lifestyle and the management of disease risk factors in this period are to determine the health of the old age. In old age, the incidence of disease continues to increase and mortality is high, and the causes of death are cerebrovascular diseases and cancer. This period is relatively weak in relation to individual health risk factors and diseases [11].

Lifelong health programs should include vaccinations, regular health check-ups, counseling and health education, and development of life cycle programs that take into account age-specific health care needs. Summarizing the characteristics of the life cycle programs included in a lifelong health care program, infants and toddlers should be monitored for vaccination and physical and mental development. In childhood, it is important to strengthen health education and counseling to establish healthy lifestyles. From adolescence onwards, health checkups should be strengthened periodically for early detection of chronic diseases. Of course, clinical tests and training content should be appropriately modified according to the risk factors identified individually [10, 12].

In addition, public health centers should provide appropriate services according to life cycles and encourage the participation of community members in social activities. And they need constant efforts, such as strengthening health infrastructures and developing health programs, to create a supportive environment for local residents and to manage their chronic diseases

efficiently.

Conclusion

Each life cycle leads to a variety of health problems. To solve these problems, it is necessary to provide health care services, taking into account their physical and health characteristics. Lifelong health programs also include vaccinations, routine screenings, counseling, and health education, but health care programs should be developed to take into account the characteristics of health care by life cycle.

Patients and Guardians' Perception on Comprehensive Nursing Care Services

Kyung-Sook Kim¹, Gaeyoung Kim², Hye-gyeong Cha³

¹Associate professor, Namseoul University, Dept. of Nursing, Korea, ²Instructor, Namseoul University, Dept. of Nursing, Korea, ³Assistant professor, Namseoul University, Dept. of Nursing, Korea

Abstract

Background/Objectives: This study is an exploratory study applying the Q-method to identify the characteristics and types of patients and guardians' perception on the comprehensive nursing care services.

Methods/Statistical analysis: A total of 430 Q-populations were extracted and the final 39 Q-samples were selected through processes such as deduplication and removal and integration of similar statements. The P-sample was selected for 32 people visiting a general hospital in which Comprehensive nursing care services were implemented. Data collection for P-samples was conducted in the consultation room of the hospital, and Data analysis was performed using the PC-QUANL program.

Findings: As a results, patients and guardians' perceptions on comprehensive nursing care services were identified as 'Expectation type for high quality inpatient care service and reduced care burden', 'Skepticism type for the establishment of comprehensive nursing care service system', and 'Indifferent type of comprehensive nursing care services system'. **Improvements/Applications:** This study can be used as a basic data for the establishment and development of comprehensive nursing care services system by identifying patients and guardians' understanding and needs for it.

Keywords: *Q-methodology, Comprehensive nursing care services, patients and guardians' perception*

Introduction

The comprehensive nursing care services system is a nursing service centered on nurses and other nursing staffs in the ward, without a guardian or private caregiver. It is a new inpatient care model developed to reduce the burden of nursing care expenses and improve the quality of infection control and hospitalization services in the hospital^[1,5], and it is a new nursing delivery system under the concept of guardians-free ward, providing nursing and care with nurses and other nursing personnel.

In Korea, caring of inpatients has traditionally been recognized as the responsibility of families (mainly women), but upon entering the modern society, family conflicts and financial burdens for caring and

nursing by families were increased due to changes in social conditions and lifestyles, including reduction of family functions due to nuclear family, increased opportunities for women to participate in society, aging population, and increasing number of people with chronic diseases^[2,3]. In order to address the economic and social burden of hospitalization and the degradation problems of quality of nursing inpatients, Korea first conducted a comprehensive nursing service system with public medical institutions in 2013, and as a result, it was confirmed that satisfaction among patients and guardians using comprehensive nursing care services increased, as the vulnerability of hospital infections was revealed during the MERS outbreak in 2015, and the demand for improvement of the culture of caregivers and visitors became higher^[1]. As a result, the National Health Insurance Service changed the name to "the comprehensive nursing care services" in accordance with the partial revision of the Medical Law by applying health insurance costs from 2015. As a result, the nation's

Corresponding Author:

Hye-gyeong Cha,
hgcha@nsu.ac.kr

hospital-centered nursing service delivery system has brought about a drastic change, with the inclusion of caring services, the service has been expanded from 107 institutions/7000 beds in 2015 to 495 institutions/37,000 beds nationwide as of the end of December 2018^[5] and plans to expand the number of beds by 100,000 by 2020^[6].

However, there are no studies on the perception of comprehensive nursing care services of patients and guardians at the present time, which is being expanded gradually to establish this system. Through this study, their types of perception of this system are identified and their characteristics are explored to understand the meanings of it.

The purpose of this study was to explore ways to improve the comprehensive nursing care service and to provide evidence and basic data for the stable spread of this system in Korea.

Method

A total of 430 Q-populations were extracted and the final 39 Q-samples were selected through processes such as deduplication and removal and integration of similar statements. The P-sample was selected for 33 people visiting a general hospital in which Comprehensive nursing care services were implemented. Data collection for P-samples was conducted in the consultation room of the hospital, and Data analysis was performed using the PC-QUANL program. Q-sorting is a process of modeling the perceptions and thoughts of patients and guardians about these services using a method of forcibly distributing 39 questions to the Distribution Chart for Q-sample, close to the normal distribution [Figure 1].

Figure 1. Distribution of Q sorting

Result and Discussion

3.1. Composition of Q-factors

In this study, various factors were designated and statistically processed, and the results were compared and reviewed, and three types were found. It was found that there were 17 people for Type 1 and 10 for Type 2 and 5 for Type 3. These three types accounted for 47.3% of the total variance and the explanatory power of each type is shown in Table 1.

Table 1. Eigen value and correlation between types

	Type 1 (N=17)	Type 2 (N=10)	Type 3 (N=5)
Eigen value	8.3631	5.1742	2.0841
Variance	.2534	.1568	.0632
Cumulative	.2534	.4102	.4734
Type 1	1.000		
Type 2	.090	1.000	
Type 3	.053	.444	1.000

3.2. Analysis of Characteristics by each type

Type1 were well aware of the positive aspects of these services and were named ‘Expectation type for high quality inpatient care service and reduced care burden’ because the system allows patients to receive professional care services more than before, and the caregiver considers it a good system to reduce the time and cost of nursing care.

Type 2 recognized that it would be unreasonable to implement these services with the current nursing human resources system, rather, there is a high risk of falling due to the absence of guardians, the role of nurses, nurse assistants, private caregivers, and guardians becomes ambiguous, and as they perceived it as a system that would make it harder for nurses to add the role of caregivers, this type was named ‘Skepticism type for the Establishment of Comprehensive Nursing Care Service System’.

Type 3 was named ‘Indifferent type of comprehensive nursing care services system’ because the average age was 33 years, belonging to relatively young people who had never played the role of guardian compared to other types,

did not know much about the contents and scope of this service, and did not show much interest in the system itself [Table 2] [Table 3].

Table 2. Statement of Z-score by type $\geq | 1 |$

Q31	Professional nurses provide quality service in three shifts per day.			

Discussion

Type 1 expected high quality inpatient nursing services and reduced burden on guardians for comprehensive nursing services. In Korea, private caring costs currently cost about 100,000 won a day, while the comprehensive nursing services are paid with health insurance benefits, allowing nursing services to be provided at the level of 20,000 won of their own charge^[15], thus reducing the financial burden of nursing, as well as ensuring quality of care for patients and guardians. In addition to the caring costs, the satisfaction level of patients increased with the service satisfaction level and the resulting willingness to reuse after the nursing care integration service implementation^[12,13], and patient safety indicators such as pressure ulcer, fall, infection, etc. were also improved^[17,18]. And according to^[1], satisfaction level is over 10% higher than non-test units of comprehensive nursing service, and more than 85% of patients are willing to use them again^[8]. In order to achieve the same effect as Type 1 thinks and anticipates positively, institutional support is required for the continuous expansion of the application of nursing and caring cost by disease and medical department within the current this system, and for accurate evaluation criteria of the patient's nursing needs and application of the project based on it.

Type 2 recognized that this system is currently unreasonable in the nursing human resources system, but the risks of falling due to the absence of guardians and the roles classification of nurses, nurse aids, private caregivers, and guardians is ambiguous, and the nurse can be even more difficult to take on the role of caregivers. The first problem that has been raised from the early stage of pilot operation to the current nursing care integrated service system is the nursing staff supply and demand problem and the placement criteria of nurses which do not reflect the nursing requirements^[2,8]. If this service is implemented without a clear standard for the expansion of nursing staff and job-specific work, the burden on nurses will increase, however, quality inpatient nursing services for patients cannot be expected, and many problems may arise due to the absence of caregivers. Therefore, it is believed that in order for the comprehensive nursing care service to be well established, it is necessary to analyze the workload by the nursing staff first, and to supplement the system such as the criteria for placement of nurses and proper task delegation by nursing profession.

Type 3 did not have much interest in these services, and showed a tendency not to know the difference between long-term care hospitals and these services, health insurance application status, and the scope and contents of comprehensive nursing care services. This system provide patients with high quality inpatient nursing services as well

as a guardian's burden reduction, also is necessary for the management of hospital infections, and is considered to be a system that shows positive performance, in the case of indifferent type who do not know the information about the purpose of implementation of this system, the difference between general wards or long-term care hospitals, and the scope of comprehensive nursing care services, like type 3, it is thought that this perception was shown due to a relatively young generation with no experience as guardians or poor exposure to information on this system. In order for this system to be successfully settled in Korea, public relations strategies are needed so that the general public as well as the few patients and guardians who can experience this service directly in some wards of some hospitals can learn about the system.

Conclusion

This study was designed to identify subjective perception of patients and guardians who experienced nursing care integration service by applying Q-methodology and to provide basic data for policy development research so that the comprehensive nursing care service system in Korea can be expanded in a more advanced direction by analyzing the characteristics of each type according to recognition.

Study on the Subjectivity of Medical Professionals Towards Pet Robots

Sunyoung Jang

Associate Professor, Hanseo Univ., 46 Hanseol Ro, Haemi-myun, Seosan-si, Chungcheongnam-do, Dept. Nursing, South Korea

Abstract

Background/Objectives: The objective of this study is to understand the subjectivity of medical professionals in their perception of pet robots, describe the characteristics of each subjectivity type and understand the categorization of pet robots.

Methods/Statistical analysis: The Q methodology was applied. Twenty medical professionals (doctors or nurses) currently employed in a clinical setting were asked to categorize 56 statements on pet robots. The collected data were analyzed using QUANL PC Program.

Findings: In this study, there were six people with a factor weight of 1.0 or higher in Type 1, six such people in Type 2 and eight people in Type 3. An analysis of subjectivity towards robot pets using the PC QUANL program revealed three factors, with an explanatory power of 77.61%. The explanatory power was 65.65% for factor 1, 6.42% for factor 2, and 5.53% for factor 3. As such, factor 1 can be seen as explaining robot pets the most. The study results show that the perception towards pet robots were categorized along three factors. The subjectivity types were ‘those who support the emotional advantages’, ‘those who emphasize the ease of pet management’ and ‘those who emphasize the convenience from technological development’.

Improvements/Applications: This study provided data for the use of pet robots in clinical settings and education of medical professionals.

Keywords: *Pet robot, Medical professional, Subjectivity, Q methodology, Nurses*

Introduction

Simple intervention where animals are used as a tool to form a trusting relationship between the patient and the medical professional and to start communication strengthens the treatment environment, makes patients happy, increases their responsiveness and helps them stay in contact with reality. In addition, their sense of self-respect is also promoted and leads them to have more positive interactions with others, which increases sociability^[1]. Animal-assisted therapy conducted with the anticipation of positive aspects of intervention where animals are used is a part of a comprehensive treatment process that was designed to promote the physical,

social, emotional and cognitive functions of human beings. In general, animal-assisted therapy brings physical benefits such as lowered cardiac disorders or blood pressure, brings social benefits such as joy and harmony, as well as bringing emotional benefits such as decreasing loneliness. It also has a psychological benefit of increasing social activities. In particular, animal-assisted therapy for the elderly was found to reduce loneliness^[2].

But using live animals poses the issue of individual preference, risk of infection or allergies and trauma caused by animals. As such, they can be a threat to health to those with a weakened immune system such as children or the elderly. This has led to limited cases of application. If the patient is living alone, there may be difficulties of taking care of the animal^[3]. To address these issues, countries in Europe or Japan are developing robot pets. Intervention programs using robot pets

can ensure a safe environment while maintaining or promoting the physical, mental and social health of the patient.

Medical professionals take up the largest share of work in a medical environment and are key personnel who have the most frequent contact with patients. As such, they need to provide safe and quality medical services within a limited time and in a fast-changing medical environment^[4]. The subjectivity of their perception towards patients in a nursing environment affect their nursing. Therefore, it is important to understand the perception of nurses or would-be nurses.

There is a lack of studies using robot pets on medical professionals. Q methodology starts from the perspective of the actor rather than the hypothesis of the researcher, and allows for understanding the characteristics of each type according to the structure of human subjectivity^[5]. Since the perception of medical professionals towards robot pets is a subjective and unique experience, Q methodology appeared to be appropriate in verifying the types of perception.

As such, this study seeks to provide basic data for the development of a differentiated education program, by understanding the structure of subjectivity towards robot pets from the perspective of medical professionals. The data will contribute to the development of an application program for robot pets in clinical settings and a Korean robot pet by medical professionals in the future.

Method

1. Selection of Q Population and Q Sample

Q The parent group was selected with a focus on students of nursing studies. To extract comprehensive statements on the effects of robot pets, review of literature from home and abroad, open-ended questionnaires and in-depth interviews were used. Through this process, 3 areas and approximately 200 Q parent groups were concluded. By bringing together the literature collected through literature review, a total of 100 Q parent groups were extracted. The Q sample extracted in this study was reviewed and revised to select highly distinctive 56 samples.

2. Q-sort and Data Analysis Method

The Q categorization takes the statements of the Q sample and asks the subjects selected through the P sample to normally distribute them, so that each

individual autonomously define robot pets^[6]. A Q card was used on 25 medical professionals to collect data. It took mostly 20-30 minutes for one subject to complete the Q categorization. The distribution of the Q sample categorized the statements selected through the Q sample from very strong agreement to very strong disagreement according to the importance. Statements on robot pets were categorized on a 14 point scale. Then an interview was conducted with the subject on the statements on the polar ends. For Q factor analysis, Principle Component Factor Analysis, varimax method was used. With a reference point of an Eigen value of 1.0, various number of factors were entered to get results and total explanation variance. The collected data had scores allocated from the Q sample distribution table. The converted scores were then used. The converted scores were coded in the order of Q sample numbers and processed with the main factor analysis by QUANL PC Program. Data analysis was done with the QUANL pc program.

3. Ethical consideration on research objects

The plan for this study was submitted to the Public Institutional Review Board designated by the Ministry of Health and Welfare before starting for ethical considerations related to subjects and received approval (P01-201812-23-007). Study subjects were described the objectives of the study and were guaranteed anonymity and confidentiality. They were also told that if they do not wish to share their personal information, it was not required. Contact information was given in case that they wanted to withdraw from the study at any time after completing the questionnaire. Questions unrelated to the study were also sincerely answered for ethical considerations.

It was also explained that subjects could withdraw from the study at any time after voluntary consent had been given. To uphold the rights of subjects and guarantee privacy, all collected data were anonymized and coded through Q sorting

Result and Discussion

1. Characteristics of each type towards robot pets

An analysis of subjectivity towards robot pets using the PC QUANL program revealed three factors, with an explanatory power of 77.61%. The explanatory power was 65.65% for factor 1, 6.42% for factor 2, and 5.53% for factor 3. As such, factor 1 can be seen as explaining

robot pets the most [Table 1]. Individuals corresponding to each factor are a group of people who have a similar response to robot pets.

Table 1: Eigen Value, Variance, and Cumulative Percentage

	Type I	Type II	Type III
Eigen Value	13.1308	1.2847	1.1059
Variance(%)	0.6565	0.0642	0.0553
Cumulative	0.6565	0.7208	0.7761

2. Analysis of each type

- Those who support the emotional advantages: There were a total of 6 people in Type 1. Those in Type 1 most strongly agreed with the statement, ‘I feel comfortable because interaction is done through sensors. (Z=2.39)’, ‘Responsibility is reduced.(Z=2.34)’, and ‘I don’t need to walk it.(Z=2.12)’. The statement that received the strongest disagreement were ‘I wish there would be a growth stage like a pet’, ‘I feel skeptical as a single button can erase all memories of the owner’, and ‘Even those who do not like pets can easily access it.(Z=-0.76)’.

The characteristics of Type 1 concern the emotional support received from robot pets that is similar to what can be received from live pets. They stated that there would not be any emotional lack because it’s a robot, and that when the robot pet is lost they would experience a similar feeling to the death of a pet dog. But they also said that robot pets can be seen as consumables in a society when even live pets are abandoned. They think that robot pets can be used for emotional support in a clinical setting, and that would be of help to the treatment of patients. This led to Type 1 being named ‘those who support the emotional advantages’.

- Those who emphasize the ease of pet management: There were a total of 6 subjects in Type 2. Statements that received the strongest agreement by Type 2 people were ‘My family likes it’ (Z=2.61)’, ‘It is convenient not to clean after them.(Z=2.48)’, and ‘With commercialization of robots, science and technology will further develop.(Z=2.40)’. The statements that received the strongest disagreement by those in Type 2 were ‘Even those who do not like pets can easily access it’, ‘I feel skeptical since all memories of the owner can

be erased with a single button’ and ‘It can remember the owner throughout its life.(Z=-0.75)’.

Type 2 individuals saw the advantages of pets in robot pets and are satisfied with the convenience in management as it saves the efforts, time or money required for raising pets. As such, they stated that it would be easier to apply robot pets in a clinical setting. Type 2 was named ‘those who emphasize the ease of pet management’.

- Those who emphasize the convenience from technological development: There were a total of 8 people in Type 3. The statements that received the strongest agreement by those in Type 3 were ‘I don’t have to worry about feeding the pet when traveling.(Z=2.42)’, ‘It costs a lot more when it is broken.(Z=2.25)’, and ‘No grooming is required.(Z=2.24)’. Statements that received the strongest disagreement by Type 3 people were ‘People who don’t like pets can easily access it’, ‘I wish it had a growth stage like pet animals’ and ‘I feel skeptical as all memories about the owner can be erased with a single button.(Z=-0.78)’.

Those in Type 3 were impressed with the scientific and technological development before robot pets and are interested in the benefits that would bring. They like that technological progress can help replace animals but are also worried about the downsides that may appear in the future. They are worried about humans being replaced by robots and human relations being undermined as a result of machines taking over. As such, Type 3 was named ‘Those who emphasize the convenience from technological development’.

Discussion

Type 1 are those who support the emotional advantages. They do not think that just because it is a robot the advantages of having a pet, such as emotional stability or maintenance of cognitive functions are undermined. They believe that emotional bonding can occur between the owner and robot pet and can even help in health management for the elderly living alone.

The social support function of animals is used as a way to meet the various health-related needs of the elderly. Animal-assisted therapy is found to have a positive effect on the mental state of the elderly with dementia^[7]. In other countries, animals are widely used in hospitals or nursing homes in the form of animal-assisted therapy (AAT) or animal-assisted activities (AAAs). AAT and AAAs are known to have an emotional effect of relaxing or motivating

the individual, as well as physical effects of improved vital signs or social effects such as improved communication between the admitted patient and nursing provider^[8].

Type 2 are those who emphasize the ease of pet management. Raising a pet requires time and money similar to raising a baby. In recent years, such animals are called as companions rather than pets, to emphasize the point that they live their life together with you. This signifies a shift from a concept of ownership to a concept of companionship^[9]. Basically, owners of such animals see the animals as an agent, that is more like a close friend or relative with whom they can have an affectionate relationship^[10].

Despite such positive benefits, most hospitals or nursing homes are concerned about allergies, infections, biting, scratching, diseases or stress of animals when applying animals to therapy^[11]. In particular, they can pose health threats to the elderly who have a weak immune system. There is also the challenges of taking care of animals^[12], making raising a pet difficult. In Korea, apartments being more common places a further restraint.

Type 3 are those who emphasize the convenience from technological development. This type is interested in the practical benefits brought by science and technology, as applied to robot pets. They believe that with scientific progress, there will be more convenience and life will become better. Meanwhile, they are concerned about undermined human relations and caretaking as robots replace humans. They feel melancholic about how emotions such as love, traditionally felt in human relations are now being shifted to come from machines.

People in this group see pets as providing psychological sense of stability and protection both at home and outside, the way a friend or companion would^[13], and as an object of affection similar to a family member. They also noted their satisfaction with the emotional intimacy they feel from their pets^[14]. Participants in this study think of their pets as family, get much consolation from them and considered taking care of them as important. They also noted that we need to think about whether such emotional aspects being met by machines or technology is going to be accepted by the elderly.

This study analyzed the subjective perception of medical professionals towards robot pets and categorized it into three types. The result showed that most medical professionals had a positive perception towards robot pets and saw the application of robot pets in a clinical setting as positive. When categorized by their characteristics, the perception of these medical professionals could be broken down into three types: Those who support the

emotional advantages, those who emphasize the ease of pet management, and those who emphasize the convenience from technological development.

This study on subjectivity can be used as basic data in developing measures to apply robot pets which are garnering increasing attention. Moreover, the presentation of the subjective structures and characteristics of each type is anticipated to help in developing education programs for medical professionals.

However, since convenience sampling was used and subjects were not selected by taking into consideration the factors affecting their perception towards robot pets, there is a limit to generalizing the study findings. As such, a follow-up verification of the types is needed by composing a Q sample with a variety of backgrounds in subjects.

Conclusion

This study provided the basic data required to adopt policies of applying robot pets, by categorizing the subjective perception of medical professionals towards robot pets. As this study analyzed the perception of medical professionals towards robot pets and verified the types, we anticipate educational programs that consider the characteristics of each type to be developed. In addition, it is suggested that a qualitative study be conducted to verify the various factors that affect the nursing of patients who would benefit from robot pets. It is also suggested that additional study be conducted by selecting samples that take into account various factors.

Study on the Relationship between Major Satisfaction, Career Resilience and Career Decision-Making Level

Kihun Ye¹, Soonyoung Yun², Shinhong Min²

¹Baekseok University, Professor, Department of Optometry, Korea,

²Baekseok University, Professor, Department of Nursing, Korea

Abstract

Background/Objectives: The study was intended to provide basic data on the career decisions-making level of students in optometry. The degree of major satisfaction, career resilience, and career decision-making level of the students of the optics department were identified, and their correlation was investigated.

Methods/Statistical analysis: The study included a total of 146 students, 64 boys (43.8 %) and 82 girls (56.2 %), all of which analyzed statistical differences through verification of various methods using the SPSS ver 18.0 statistics program.

Findings: The general characteristics of the subjects were 64 male students (43.8 %) and 82 female students (56.2 %), 58 first graders (39.7 %), 34 second graders (23.3 %), 31 third graders (21.2 %), and 23 fourth graders (15.8 %). Religion was composed of 49 Christians (33.6 %), Catholics (8.5 %), Buddhists (2.4 %), and No religion (79.6 %). The degree of major satisfaction was 3.20, career resilience was 3.37, and the level of career decision-making level was 3.12. The correlation between the three variables has shown that all three variables have significant correlations.

Improvements/Applications: To this end, it is deemed necessary to create an appropriate environment for students to show their visions of their majors and to encourage them to develop and participate in programs that can help them decide on their career paths through efforts

Keywords: Career decision-making level, Career resilience, College student, Major satisfaction, Optometry

Introduction

The choice of departments and majors should be made with due consideration to the conviction of the career path and their aptitude. However, the nation's college students tend to choose their majors according to their social atmosphere and their own grades rather than choosing one based on one's interests or aptitude. In many cases, students passively choose based on their high school entrance exam scores and recommendations from simple acquaintances rather than their own choices. As a result, it is reported that there are a lot of conflicts about career path since college entrance^[1]. In the same

vein, attempts are now being made to emphasize the authenticity of elementary, middle and high schools. In order to improve the choice of majors in universities, such as the introduction of a free semester system and the creation of new career courses, the government is providing support at the national level^[2].

Career resilience refers to the patient and flexible adaptation of an individual in a crisis, such as a frustrated or troubled one, while paying attention to how he or she responds to a negative environment with respect to his or her career path^[3]. A person with high career elasticity has the characteristics of achieving his or her goals, adapting to his or her work environment and pursuing success even in times of uncertainty and frustration^[4]. Career Resilience is an important element throughout career management, as well as a fragmentary process of career choice, achievement and adaptation^[5]. That is why it is time for job seekers to change their career policy and

Corresponding Author:

Shinhong Min

Professor, Baekseok University, Department of Nursing, Korea, e-mail: shmin@bu.ac.kr

career resilience is gaining attention^[6]. In short, career resilience is a specific characteristic of individuals who adapt to unexpected changes in their work environment, and those who are more likely to be able to cope more effectively with negative conditions related to their work or career, such as career obstruction, uncertainty, and worsening relations with colleagues^[7].⁶

One of the important development tasks of youth is employment, which leads to the growth and development of competent adults^[8]. At this time of year, planning and preparation for one's own career path is thorough and self-directed in making decisions^[9]. A career decision is a systematic and continuous process through which a person's life progresses. In order to enhance career decisions with a career mind-set, we need to learn a series of courses ranging from career recognition, exploration, and decision making^[10]. The career decision level should be the level at which an individual chooses and decides his or her career path with a firm sense of identity and solid information acquisition and thorough examination of his or her problems^[11].

Health-related students should take a heavy responsibility for the health of the people and take their own course. Therefore, students need to choose and cope with their careers with a strong sense of pride, knowledge and attitude toward their majors. The satisfaction of the choice of majors should be high in response to these situations. One of the ways to improve satisfaction with your major selection while attending college is when your interests and aptitude are well suited to your major due to on-site practice, service, volunteer work, and major classes^[12]. Another case is that students are satisfied with the various curricula, comparisons and curricula of their departments after entering the majors that suit their aptitude and interest in elementary, middle and high school^[13]. In both of these cases, the development of various programs that can attract active interest or interest in universities could be a practical alternative to increasing the satisfaction of the choice of majors.

Therefore, through this study, we will examine the correlation between major choice satisfaction, career resilience, and career decision-making level of university students, identify the influencing factors of each variable, and apply various program development and education in order to effectively respond to society that is diversifying through satisfactory career choice.

Method

The subjects of the study were students attending optometric major at a four-year university located in South Chungcheong Province. The survey was conducted from September 1 to November 30, 2018. It explained that personal information was kept confidential and that anonymity was thoroughly guaranteed.

In this study, the major selection satisfaction tool, which was modified and supplemented by Kim, was investigated for the major selection satisfaction test. The questionnaires calculated the average score using the five-point Likert scale for the three questions concerning confidence in the choice of majors and class satisfaction, and the higher the average score, the higher the choice of majors, the positive meaning.

The Career resilience of this study was modified and used by Kim^[14]. Based on the three levels of personal, professional, and social factors of Career resilience extracted through theoretical review, this scale is structured to reflect the respective attitudes and behaviors of the factors that have helped to overcome the crises and adversity experienced in the course of a college student's career development

This scale consists of a total of 30 questions and is measured by the Likert 5 point scale, with five sub-factors of 6 questions of self-confidence, 6 questions of achievement and passion, 6 questions of career self-reliance, 6 questions of change counterpoint and 6 questions of relationship utilization. The Cronbach α was 0.94 in this study.

The level of career determination is a measure of the degree of career choice and determination to identify obstacles that interfere with an individual's career decisions. In this study, a career decision scale (CDS) test was measured using a tool modified by Kim. This test consists of 18 self-reporting questions on the Likert 5-point scale.

The first two questions indicate a level of confidence in career choice, and the following 16 identify the prerequisites for education and for non-conformity. Scoring was conducted separately from paragraphs 1-2 and 3-18, because the higher the score, the higher the confidence level, the higher the score, the better the course is not determined. Therefore, the higher the score, the higher the score, the higher the grade, the higher the level of career decision.

Result and Discussion

1. General characteristics of the subjects

Sociodemographic characteristics of subjects are Table1.

Table 1: General characteristics of subjects

Characteristics	Category	N	%
Sex	Male	64	43.8

2. Mean value on Major Satisfaction, Career Resilience and Career Decision-Making Level

Major satisfaction, Career resilience and Career decision-making level are shown in Table 2. Overall Career resilience was 3.37, with the factors of Career resilience: self-confidence 3.54, achievement fervor 3.47, career self-reliance 3.35, transformation counterparty 3.12, and relationship utilization 3.41. And the Major satisfaction rate was 3.20, and the career decision-making level was 3.12.

Table 2: Mean value on Major satisfaction, Career resilience and Career decision-making level

	M	SD
Major satisfaction	3.20	.70
Career resilience	3.37	.62
Self-confidence	3.54	.73
Achievement fervor	3.47	.72
Career self-reliance	3.35	.70
Transformation counterparty	3.12	.75
Relationship utilization	3.41	.70
Career decision-making level	3.12	.57

3. Differences in Major Satisfaction according to sociodemographic characteristics

According to general characteristics, the results of comparing the choice satisfaction level of majors showed that there are differences between sex, motivation for applying for college entrance, and the level of study you think of. Male students were higher than female students, and students who said they were “fit their aptitude” in the application motive than students who said “consider their parents’ or others’ recommendations” or “in consideration of their high school grades.” Students who answered that their grades were average showed the highest satisfaction level of their choice of majors.

4. Differences in Career Resilience according to sociodemographic characteristics

Cognitive attitudes toward donating cornea have been shown to vary according to gender, presence of chronic and incurable patients in the family, your wish to donate organs, recommended that family donate their

organs, wish to participate in training on organ donation, Information on organ donation registration procedure is available, the one I want to receive when I donate my organs, Opinion on the absence of a price for an organ donor, and want to pay for organ donation.

5. Differences in Career Decision-Making Level according to sociodemographic characteristics

Behavioural attitudes toward donating cornea have been shown to vary according to your wish to donate organs, recommended that family donate their organs, presence of information about organ donation organizations, wish to participate in training on organ donation, Information on organ donation registration procedure is available, the one I want to receive when I donate my organs, Opinion on the absence of a price for an organ donor, and want to pay for organ donation.

6. Relation between Major satisfaction, Career resilience and Career decision-making level

The correlation between Major satisfaction, Career resilience and Career decision-making level has shown that all three variables have significant correlation<Table 3>. The degree of satisfaction with the major and career resilience were correlated, and the level of career resilience and career decision-making level were found to be very closely related.

Table 3: Relation between Major satisfaction, Career resilience and Career decision-making level

	Major satisfaction	Career resilience	Career decision-making level
Major satisfaction	1	.316**	.187*
Career resilience		1	.412**
Career decision-making level			1

*p<0.05, **p<0.01

Discussion

This study was conducted as a basic data for developing a program to develop a society that can flexibly adapt to the rapidly changing employment market after graduation by identifying differences in major selection satisfaction of college students in the health category, as it was determined that their major selection satisfaction would be affected by

the relationship between demographic characteristics and each variable.

Comparing the satisfaction level of choice of majors according to the general characteristics, the results show that there are differences in gender and motivation for applying for college entrance and those male students are higher than female students, which are why the nature of the health category requires a sense of mission and has a clear path to professional work. The lower the economic level and experience of part-time work experience, period, and experience of society, the higher the resilience of career. It is believed that the active attitude to overcome the work atmosphere and economic difficulties of society through part-time work may have influenced the work atmosphere of society. The level of career decision was found to differ only depending on the length of a part-time job, but the shorter the part-time period, the less experienced the society will be and the less judgment will be available to consider the career decision more.

The correlation between each variable showed that the higher the degree of satisfaction in the major, the higher the level of career decision, the clearer the decision on career path and the higher the interest in the profession related to the major. Path elasticity has shown a significant correlation with career decision level, which can be interpreted as a firm belief in one’s ability to effectively carry out difficult choices and decisions related to career path.

Conclusion

The factors that determine a satisfactory career path are based on not only individual interest and ability, but also job appreciation, and the more satisfied a university student is with his or her major and the more satisfied he or she is with his or her major professors and majors, the more active she is in collecting information for employment and the more self-identity she can improve her career resilience as well. Jobs may involve not only intrinsic motivations, such as those that suit one’s aptitude and personality, but also altruistic motives, such as a sense of calling. In particular, health care students need not only aptitude or personality but also a process of value recognition such as calling when choosing their careers. Therefore, universities need to develop programs to improve their belief that students can overcome difficulties in career selection and preparation, and provide appropriate counseling for developing career plans that meet their goals, interests, personalities, and talents to improve their professional satisfaction.

Manufacture and Useful Evaluation of Educational Mammography Phantom

Dong-Hee Hong

Professor, Dept. of Radiology Science, Shinhan University, 95, Hoam-ro, Uijeongbu, Gyeonggi-do, 11644, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to manufacture a new phantom in variety material and evaluate its usefulness.

Methods/Statistical analysis: Based on the modeling, pectoralis major muscles and mammary glands were printed; in order to express the soft material of the breast, we used the molding method. The assessment was conducted by 3 radiographers who have been in real clinical settings for more than five years.

Findings: The mammary gland tissue and pectoralis major muscles were printed using the SLA method and Polyjet method. At this time, the spheres with a diameter of 1 cm were printed and located at both sides of the mammary gland to test the degree of compression, which is the essential part of mammography and contributed to the phantom for a higher quality of education.

Improvements/Applications: After accessing the manufactured phantom at the clinical level, all of the evaluators concluded that the phantom may be applied for education.

Keywords: *Phantom, Education, Mammography, Manufacture, 3D printer*

Introduction

With an increase in the interest in women's cancers among the public, there is also a rising importance in the early diagnosis of breast cancer. Therefore women are regularly receiving mammograms, leading to a steady increase in the number of mammogram screening cases. A growing desire for a healthy life has triggered an increase in awareness and needs for screening for early detection of breast cancer. In accordance with this trend in Korea, the national health screening center has designated a mammogram as one of the essential tests and is recommended for those over 40 years old.

The most important thing in mammography is the fact that the use of radiation for medical purposes carries both significant medical benefits and the risk of radiation exposure; hence, improper care can lead to fatal side effects

for the patients [1-4]. For this reason, radiographers should refrain from having the patients retake a mammogram and exposing them to unnecessary radiation. It is also advisable that radiographers are fully trained in mammography and improve their practice skills before performing mammography in a real clinical setting.

Mammography is the most optimized test for early detection and diagnosis of breast cancer. Mammography is performed on symptomatic or asymptomatic women through basic examinations with the Cranio-Caudal and Mediolateral-Oblique (MLO) directions [5-9]. Therefore, radiographers should be fully aware of all screening methods for mammography and practice for a variety of patients in advance.

The main purpose of screening mammography is to detect any symptoms of diseases in advance by minutely screening the shape and size of breast masses, mammary gland expansion, and calcification. It can possibly detect lesions, but high-quality images with an appropriate amount of radiation are still required.

Corresponding Author:
Dong-Hee Hong,
hansound2@hanmail.net

During mammography, breast compression is applied using a compression paddle, which is to compress breasts to a film and reduce breast thickness, resulting in a decline in exposure to radiation while improving image quality [10]. As patients have different shapes and sizes of breasts, it is necessary for radiographers to practice on various types of breasts.

However, less than half of medical schools in Korea do not have a regular mammography curriculum for radiology majoring students. Even if a few does have one, practice is not being carried out properly. The reason is that breasts are a private part of the human body, and there are few phantoms available for practice. Mammography phantoms made in Japan are expensive and lose their shape after several practices. Moreover, it does not show parenchymal tissues in the breasts, and thus, radiographers cannot judge whether they are screening the object in a right position. Therefore, most of the current radiographers strive for mammography practice and training.

3D printers, which has been on the rise these days, have the advantages of reducing time for producing, customized manufacturing and saving the costs for producing, etc [11]. It makes a product from various materials by various methods according to a modeled design map [12]. In the case of breasts, as it is impossible to use hard materials, mammography phantoms should be manufactured with different or new materials. In a prior study, a phantom was manufactured with soft materials which led to a discovery of a transparent material which enables the internal structure to be identified. Therefore the purpose of this study is to manufacture a new phantom in this material and evaluate its usefulness. 3D printer technology has lately been utilized for various purposes, and in particular, it is actively used in the healthcare industry, which leads in a need of a variety of materials[13-14].

Materials and Method

1. Modeling

As seen in Figure 1, the breast images used in this study were based on MRI DICOM Volume data and obtained by 0.1 mm Volume Scanning from GE Signa HDxt 3.0T(GE Healthcare, Milwaukee, WI, USA) device. The obtained images were edited on TeraRecon, a 3D program in order to convert the file format into STL format. STLView (Module Works GmbH) was used to separate and obtain modelling of different structures. Through mesh tools provided by Rhinoceros (McNeel North America, USA), mammary gland, canal, and pectoralis major muscles were edited using a modeling

structure to distinguish more stably and clearly. The pectoralis minor muscle when modeled for the first time was manufactured without any differentiation from pectoralis major muscles and modeling was processed with pectoralis major muscle as the main object.

Figure 1. MRI DICOM file for breast, duct, muscle modeling

2. 3D Printing

Based on the modeling, pectoralis major muscles and mammary glands were printed; in order to express the soft material of the breast, we used the molding method. The molding method is to model and print the outer surface of the breast and fill the inside with silicone, which needs to be done carefully to prevent air bubbles. In addition, as seen in Figure 2, after mammography, contrast agents were mixed and printed to identify pectoralis major muscles and mammary glands in the images. Spheres of 1 cm in diameter were also printed to see how much compression has been applied when screening.

Figure 2. Made by mixing the colorant / contrast agent (barium) with silicone

The printer resources used for each printing are as follows:

In order to manufacture breasts using the molding method, when printing the outer surface of the breast, Projet660, a CJP (ColorJet Printing) printer, was used, which is an additive manufacturing technology involving two components – core and binder. It took 4 hours in total, and the printer material used was VisiJet PXL, which is like plaster.

Pectoralis major muscles, as show in Figure 3, were manufactured using Form 2 SLA (Stereolithography) and took 6 hours in total. Clear resin was used as printing materials.

Mammary glands were manufactured using Object 500 Connex 3 in the PolyJet method, which uses UV cured acrylic resins, and it took 2 hours. The spherical prints which enable radiographers to see the degree of compression were manufactured using a sponge material, and they were also printed by using the same method.

Figure 3. 3D printer model Form2 by SLA method

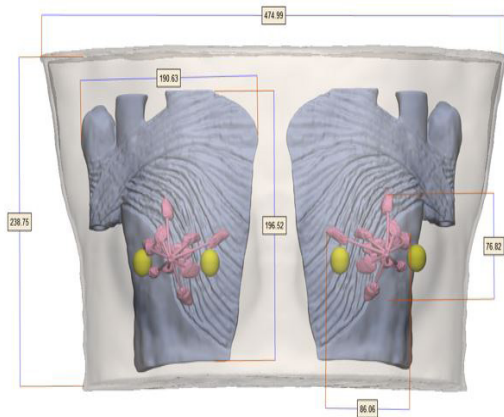

3. Useful evaluation

To assess the usefulness of mammography training phantom manufactured using a 3D printer, various assessments were conducted with mammography device currently used in hospitals. The following were assessed: whether pectoralis major muscle and mammary glands are clearly distinguished from each other in mammogram images; whether they show the appropriate concentration; whether the spheres were useful to check the degree of compression; and whether the quality of the materials were similar to actual breasts during mammography. The assessment was conducted by 3 radiographers who have been in real clinical settings for more than five years.

Results

1. Modeling

As seen in Figure 4, the modeling was based on MRI dicom images where the breast was scanned in 1 mm. The light gray colored outer surface of the breast was modeled by 474.99 x 238.75 mm in size, and the dark gray colored pectoralis major muscles were modeled by 190.63 x 196.52 mm in size. The pink colored mammary glands were modeled by 86.06 x 76.82 mm in size whereas the spheres for checking the degree of compression were colored in yellow and modeled by 10 mm in size.

(a)

(b)

Figure 4. (a) Frontal view of modeling and size of intramammary mammary gland and pectoral muscle and compression check circular sphere. (b) Lateral view of modeling and size of intramammary mammary gland and pectoral muscle and compression check circular sphere

As seen in Figure 4, the front and back sizes of the surface of the breast was modeled by 348.22 mm and those of mammary glands were modeled by 62.57 mm. the spheres for checking the degree of compression were placed in parallel to both ends of the mammary tissue so that they do not interfere with the breast image.

2. 3D Printing

As seen in Figure 5, the phantom was manufactured using silicone in the molding method to enhance the reality of parenchyma of the breast. To achieve this, the outer surface of the breast was modeled and printed for 14 hours in the additive manufacturing method and made it 2 cm thick to support the weight of silicone. The silicone was poured and hardened several times

in order to prevent air bubbles. The amount of silicone was readily controlled to be hardened while regulating the location of each component, and this was done repeatedly as this must be done at the final stage and all the tissues, pectoralis major muscles, mammary glands, and the spheres for checking compression should be placed inside the breast tissue.

(a)

(b)

(c)

Figure 5. (a) In order to produce a molding method by printing the outside of the breast. (b) Pectoral muscle of breast printed by SLA method. (C) Mammary gland tissue of breast printed by Polyjet method

As seen in Figure 5, the pectoralis major muscles in the breast were printed in the SLA method, which took 6 hours. To enhance the reality of the muscle, the comp pattern was modeled and printed at its top. Two were printed to place each on the left and right sides, and to reflect the end of the muscle as being adjacent to the humerus according to bone anatomy, the part of the bone was modeled and printed.

As seen in Figure 5, the mammary glands in the breast were printed for 2 hours in the Polyjet method using UV cured acrylic resins. To express the mammary tissue, the duct connecting the acini to the nipple was printed together, and as it may fall back during

mammography, each tip of the nipple and the duct were tied and fixed using a thread. Also, a colorant was used to produce a red color in order to visually identify the mammary gland tissue in the breast.

3. Useful evaluation

In order to assess the usefulness of the mammography training phantom manufactured by a 3d printer, a mammogram was taken using a mammography device currently used in hospitals. As seen in Figure 6, the results showed that pectoralis major muscles and mammary glands were distinguished from each other with showing adequate concentrations. Also, the spheres manufactured to check the appropriate degree of compression were pressed along with the breast when screening and it showed that there is an appropriate degree of compression when the phantoms were pressed up to the red borders from the quality control assessment. These were assessed by the 3 radiographers with more than five years of experience, and they all had the same opinions.

Figure 6. Radiographic image of 3D printed educational mammography phantom

Discussion

Mammography is a structure that must be represented in the image in Cranio-Caudal and Medio-Lateral views, but it must be practiced continuously using anatomically separated phantoms to express it. To achieve this, 3D modeling was implemented by retrieving MRI images to completely separate mammary gland, ductal and pectoral muscle tissue and to apply techniques to express them on radiographic images [15].

In a previous study, we developed a 3D printer system for the production of customized bone models of surgical patients based on open source [16]. Although the usefulness has been proved to be used in making a human bone model as described above, the usefulness of a soft material such as fat of breast is not proven.

In the previous study, we studied the materials and design for making phantom for mammography education. It is expected to contribute greatly to future research and education [17].

Conclusion

A mammography training phantom was manufactured using a 3D printer. The inside of the breast was filled with silicone and manufactured by the molding method in order to express the soft material of the breast. The mammary gland tissue and pectoralis major muscles were printed using the SLA method and Polyjet method. At this time, the spheres with a diameter of 1 cm were printed and located at both sides of the mammary gland to test the degree of compression, which is the essential part of mammography and contributed to the phantom for a higher quality of education. After accessing the manufactured phantom at the clinical level, all of the evaluators concluded that the phantom may be applied for education.

¹Professor, Dept. Faculty Food & Nutrition, Chung Cheong University, 38 Wolgok-Gil Gangnae-Myeon, Heungdeok-Gu, Cheongju-Si, Chungbuk, 28171, Republic of Korea, ²Professor, Dept. General Education, Kwangju Women's University, 201 Yeodae-gil, Gwangsan-gu, Gwangju, 62396, Republic of Korea, ³Professor, Dept. Emergency Medical Technology, ChungCheong University, 38 Wolgok-Gil Gangnae-Myeon, Heungdeok-Gu, Cheongju-Si, Chungbuk, 28171, Republic of Korea

Abstract

Background/Objectives: This study aimed to determine the effects of hypertension, dyslipidemia, myocardial infarction, and angina pectoris on stress by cardiovascular diseases.

Methods/Statistical analysis: The raw data from the Korea Health Statistics 2017: Korea National Health and Nutrition Examination Survey (KNHANES) VII-2 were used. A total of 6,458 out of 8,127 respondents were included, with the exception of 1,669 aged <20 years. The analyses were carried out by using an SPSS Version 20.0 program.

Findings: The group diagnosed with hypertension was more strongly correlated with stress than the group not diagnosed with hypertension (approx. 3.6 times, $p < .001$). It has been confirmed that hypertension among cardiovascular diseases is correlated with psychological, mental health related to stress. No statistical significance was found for the other items.

Improvements/Applications: The results of this study have demonstrated that hypertension among cardiovascular diseases is correlated with stress. Cardiovascular diseases can affect mental health (stress, depressive disorder, etc.); therefore, it is necessary to reinforce regular exercise and psychological relief programs. This is expected to help determine the morbidity of cardiovascular diseases and promote mental health.

Keywords: Myocardial infarction, Angina pectoris, Dyslipidemia, Hypertension, Mental health, Stress

Introduction

Cardiovascular diseases include hypertension, hyperlipidemia, myocardial infarction, and angina pectoris [1, 2]. Myocardial infarction and angina pectoris are classified as ischemic heart diseases [2, 3]. An ischemic heart disease is an acute or chronic type of heart disorder that can

occur with a reduction or discontinuation of blood supply to cardiac muscles as coronary artery disease develops [2].

Due to high prevalence, cardiovascular diseases can have an impact on life expectancy as well as on the quality of life [4]. The occurrence of cardiovascular diseases is affected by the lifestyle factors, including smoking, alcohol intake, and nutrition, as well as by the irreversible factors, such as gender, age, race, and family history [3]. Jung et al. [5] noted that depression affected hypertension and dyslipidemia; Cho [6] reported that stress affected myocardial ischemia and arrhythmia. The occurrence of

cardiovascular diseases is associated with various factors, including heredity, family history, lifestyle, anxiety, and stress.

The World Health Organization^[7] reported that the main causes of death around the world included ischemic heart disease, stroke, lower respiratory infection, chronic obstructive pulmonary disease (COPD), and diarrhea in 2000 and that the most frequent cause of death was ischemic heart disease, followed by stroke, COPD, lower respiratory infection, and Alzheimer's disease and dementia, in 2016^[7]. The Korea National Statistical Office^[8] reported that the most frequent cause of death in 2017 was malignant neoplasm, followed by heart disease, cerebrovascular disease, pneumonia, intentional self-harm (suicide), and diabetes.

Compared with WHO^[7], the Korea National Statistical Office^[8] was more likely to report noncommunicable diseases (NCDs) than communicable ones as principal causes of death. It was also more likely to report heart diseases related to the circulatory system^[7, 8]. Cardiovascular diseases are associated with lifestyle, stress, and psychological factors^[3, 5, 6]. Lamers et al.^[9] noted that emotional well-being positively affected the prognoses of physical diseases. Prince et al.^[10] contended that physical health might essentially coexist with mental health. Lamers et al.^[9] and Prince et al.^[10] emphasized that physical diseases might be correlated with psychological and mental convalescence. Cho^[6] noted that there might be little confidence in stress and cardiovascular diseases despite a lot of research on stress and cardiovascular diseases.

This study aimed to determine the association between hypertension, dyslipidemia, myocardial infarction, and angina pectoris among cardiovascular diseases and stress in adulthood. This study intended to determine the association between cardiovascular diseases and mental health, which involves stress, on the basis of the raw data disclosed by the Ministry of Health and Welfare (MOHW) and the Korea Centers for Disease Control and Prevention (KCDC). It aimed to provide basic data that could help relieve stress caused by cardiovascular diseases in the circulatory system and develop a stress reduction program.

Method

1. Instruments of Study

The raw data from the Korea Health Statistics 2017: Korea National Health and Nutrition Examination Survey (KNHANES) VII-2 disclosed by MOHW and KCDC^[11] were used.

The sampling framework was composed of the available data from the recent Population and Housing Census as the basic framework and those regarding the public noticed price for multi-unit houses. The □-1 and 2 (2016-2017) surveys had the sampling framework stratified by cities and provinces, eups, myeons, and dongs, and housing type and used the residence area ratio and the householder's education ratio as the stratification criteria. A circulatory sampling survey was conducted for 12 months from January to December. The sample size was 13,248 households in 576 research districts.

The raw data from KNHANES VII-2 disclosed by MOHW and KCDC^[11] were based on the data from the household member identification survey, health surveys, examinations, and the nutrition survey. The household member identification survey is to determine every residence and household status within selected districts through sample design and choose household members. The health surveys can be divided into household surveys, health interview, and health behavior surveys. The nutrition survey covered dietary life behavior, dietary supplements, nutritional knowledge, and food stability status and food consumption. The examinations were composed of somatometry, blood pressure and pulse rate measurement, blood test and urinalysis, oral examination, pulmonary function test, and so on.

To meet the theme of this study, the items concerning the household identification survey and the health surveys were included and the instruments related to the socio-demographic characteristics, cardiovascular diseases, and mental health were applied. The composition of the instruments is presented in [Table 1].

Table 1. Items of surveys

Category		Item
Household member identification survey		<ul style="list-style-type: none"> • Every household member’s status and household member inclusion within selected districts through sample design
Health survey	<ul style="list-style-type: none"> • Household survey • Health interview • Health behaviour survey 	<ul style="list-style-type: none"> • General characteristic <ul style="list-style-type: none"> • Morbidity • Medical check-up • Vaccination • Restricted activity <ul style="list-style-type: none"> • Quality of life <ul style="list-style-type: none"> • Damage • Smoking • Alcohol intake • Physical activity • Mental health • Safety consciousness • Obesity & weight control • Feminine health, etc.
Nutrition survey	<ul style="list-style-type: none"> • Dietary life behaviour & food stability survey 	<ul style="list-style-type: none"> • Dietary life • Food safety • Food intake frequency • Food intake
Examination	<ul style="list-style-type: none"> •Somatometry & pulmonary Function test, etc. 	<ul style="list-style-type: none"> • Somatometry • Blood pressure • Pulse rate • Blood test • Urinalysis • Oral examination •Pulmonary function test, etc.

2. Subjects of study

Based on the number of household members in the database (DB) of the raw data, 8,127 persons were included. Coding for the number of household members was identified to determine the concordance in the number of household members between health in basic DB and “cardiovascular diseases and mental health.”

Among the 8,127 persons in the raw data, those aged <20 years were excluded from the research. This is not only because cardiovascular diseases often occur in adulthood but also because those aged ≥20 years are legally permitted to drink and smoke. With the exception of 1,669 respondents aged <20 years, a total

of 6,458 respondents were finally included. Of the 6,458 respondents aged ≥20 years, those who had missing data or made no answer were excluded from the analysis. The subjects of this study are as presented in [Table 2].

Table 2. Subjects of study

Category		N : 6,458	%
Gender	Male	2,895	44.8
	Female	3,563	55.2
Age	20’s	731	11.3
	30’s	976	15.1
	40’s	1,202	18.6
	50’s	1,281	19.8
	60’s	1,142	17.7
	70’s≤	1,126	17.4
Self-rated health	Very good,	243	3.8
	Good,	1,278	19.8
	Average	3,118	48.3
	Bad,	931	14.4
	Very bad	235	3.6

3. Variable composition

The variables in this study included the general characteristics, morbidity of cardiovascular diseases, and mental health. The variables for the general characteristics included gender, age, household income, education, and occupation. The items concerning cardiovascular diseases were myocardial infarction, angina pectoris, hyperlipidemia, and hypertension. The variables for mental health included stress perception rate.

4. Ethical consideration and research procedure

For ethical consideration, approval exemption was obtained from the Institutional Review Board (IRB) of C University (human_007_20190523_1st)(Approval exemption) before starting the research. The procedure included research theme selection, literature review, IRB approval exemption, request of MOHW and KCDC for KNHANES □-2, KNHANES □-2 data review, selection of

items related to the cardiovascular system and stress, and result analysis.

5. Analysis

The analysis was performed by using an SPSS WIN 20.0 Version program. For empirical analyses, frequency analysis, χ^2 , and dichotomous logistic regression were used. The significance level was set at $p < .05$.

Result and Discussion

1. Variation in stress perception rate by general characteristics

The variation in the stress perception rate by the general characteristics is as presented in [Table 3]. Every group had a low stress status, regardless of gender, age, and self-rated health. Those who were male ($p < .01$) and who were in their thirties, forties, and fifties were more likely to perceive stress ($p < .001$). Those groups whose self-rated health was at the average level or bad were more likely to perceive stress ($p < .001$).

In terms of gender and age, 6,052 out of 6,458 respondents were included, with the exception of those having missing data. In terms of self-rated health, 5,785 out of 6,458 respondents were included, with the exception of those having missing data.

Table 3. Variation in stress perception rate by general characteristics

		Stress perception rate (6,052)		χ^2	p
		High : 1,662(27.5)	Low : 4,390(72.5)		
Gender	Male	686(25.5)	2,004(74.5)	9.340	.002**
	Female	976(29.0)	2,386(71.0)		
Age	20's	261(39.1)	407(60.9)	115.979	.000***
	30's	319(35.3)	585(64.7)		
	40's	307(27.4)	815(72.6)		
	50's	318(26.4)	886(73.6)		
	60's	227(20.9)	861(79.1)		
	70'≤	230(21.6)	4,143(78.4)		
Self-rated health (5,785)	Very good,	31(12.8)	836	221.057	.000***
	Good,	230(18.0)	1,045(82.0)		
	Average	833(26.8)	2,277(73.2)

	Very bad	114 (49.6)	116 (50.4)		

* $p < .01$, *** $p < .001$

2. Effects of general characteristics on stress perception rate

Dichotomous logistic regression was used to determine the effects of the general characteristics on the stress perception rate. The independent variables were gender, age, and self-rated health. The dependent variable was the stress perception rate, which was "high" or "low." The results of this study are presented in [Table 4].

The older the respondents in their forties to seventies were, the more likely they were to have the stress perception rate affected ($p < .001$). The poorer self-rated health the respondents had, the more likely they were to have the stress perception rate affected ($p < .001$).

Lee et al. [12] noted that the better self-rated health, the more satisfied with life and the less depressed. Park and Yang [13] contended that self-rated health affected stress perception. Lee et al. [12] and Park and Yang [13] suggested the association between self-rated health and stress, which is consistent with the results of this study.

Table 4. Effects of general characteristics on stress perception rate

Category		B	P	Exp(B)	95% Confidence interval	
					Lower	Upper
Gender		-.113	.069	.893	.791	1.009
Age	20's			1		
	30's	.218	.048*	1.243	1.002	1.544
	40's	.617	.000***	1.854	1.499	2.293

	Very bad	-2.379	.000***	.093	.058	.149

*p<.05, ***p<.001

3. Cardiovascular disease and stress perception rate

The association between cardiovascular diseases and the stress perception rate is as presented in [Table 5]. The group diagnosed with hypertension was wider-ranging than the group not diagnosed with hypertension. As for the association between hypertension and stress, the group diagnosed with hypertension showed a low rate of stress perception and the group not diagnosed with hypertension showed a statistically significantly low rate of stress perception (p<.001).

No significance was found for the other items. 6,050 persons were included to determine hypertension and dyslipidemia diagnosis status, with the exception of missing data. 5,781 and 5,780 persons were included to determine myocardial infarction and angina pectoris diagnosis status, respectively, with the exception of missing data.

Table 5. Cardiovascular disease and stress perception rate

		Stress perception rate (6,050)		χ ²	P
		High: 1,661 (27.5)	Low: 4,389 (72.5)		
Hypertension diagnosis status	Yes	340(22.6)	1,165(77.4)	23.789	.000***
	No	1,321(29.1)	3,224(70.9)		
Dyslipidemia diagnosis status	Yes	300(26.0)	853(74.0)	1.474	.225
	No	1,361(27.8)	3,563(72.2)

	No	1,566(27.4)	4,143(72.6)		
Angina pectoris diagnosis status (5,780)	Yes	29(25.2)	86(74.8)	.274	.601
	No	1,553(27.4)	4,112(72.6)		

***p<.001

4. Effects of cardiovascular disease on stress perception rate

Dichotomous logistic regression was used to determine the effects of cardiovascular diseases on the stress perception rate. The independent variables were hypertension diagnosis status, dyslipidemia diagnosis status, myocardial infarction diagnosis status, and angina pectoris diagnosis status. The dependent variable was the stress perception rate, which was “high” or “low.” The results of this study are presented in [Table 6].

The group diagnosed with hypertension was more

strongly associated with stress than the group not diagnosed with hypertension ($p < .001$). No significance was found for the other items. As mentioned before, Lamers et al. [9] and Prince et al. [10] found that emotional well-being and mental health affected physical diseases. Similarly, this study found that the emotional, psychological condition of stress significantly affected the physical disease of hypertension. This result is also consistent with the finding of Jung et al. [5] that depression affected hypertension and dyslipidemia. Because emotional, psychological status is also associated with cardiovascular diseases and other diseases, it is necessary to develop relevant prevention programs.

Table 6. Effects of cardiovascular disease on stress perception rate

Category	B	P	Exp (B)	95% Confidence interval	
				lower	upper
Hypertension diagnosis status	-.347	.000***	.707	.609	.821
Dyslipidemia diagnosis status	.046	.569	1.047	.893	1.229
Myocardial infarction diagnosis status	-.097	.733	.907	.518	1.588
Angina pectoris diagnosis status	-.004	.986	.996	.644	1.540
*** $p < .001$					

Conclusion

This study aimed to determine the association between hypertension, dyslipidemia, myocardial infarction, and angina pectoris and the stress perception rate by cardiovascular diseases. The results of this study have demonstrated that hypertension among cardiovascular diseases is correlated with stress. Hypertension among cardiovascular diseases can affect stress and depressive disorder; therefore, it is necessary to reinforce regular exercise and psychological relief programs. This is expected to help determine the morbidity of cardiovascular diseases and promote mental health.

Emergency Medical Technology, Chung Cheong University, 38 Wolgok-Gil Gangnae-Myeon, Heungdeok-Gu, Cheongju-Si, Chungbuk, 28171, Republic of Korea

Abstract

Background/Objectives: This study aimed to analyze the risk of the infection disasters by outbreak status of Group 1 to 4 legal infectious diseases in South Korea.

Methods/Statistical analysis: The raw data regarding “legal infectious diseases under complete surveillance” disclosed by the Ministry of Health Welfare (MOHW) and the Korea Centers for Disease Control and Prevention (KCDC) were used. The infectious diseases are divided into Group 1, 2, 3, 4, and 5 infectious diseases, designated infectious diseases, infectious diseases supervised by the World Health Organization (WHO), bioterrorism-related infectious diseases, sex-mediated infectious diseases, zoonosis, and medically-related infectious diseases. Of these, Group 1 to 4 legal infectious diseases found between 2014 and 2018 were included in this study. The analyses were carried out by using an SPSS Version 20.0 program.

Findings: Between 2014 and 2018, the number of Group 2 legal infectious diseases (562,830 cases) was greatest, followed by Group 3 (194,847), Group 1 (25,844), and Group 4 (3,183). Group 3 (625 cases) resulted in the greatest number of deaths, followed by Group 2 (275), Group 4 (214), and Group 1 (18). Of these, Middle East Respiratory Syndrome (MERS), Group 4 infectious disease, resulted in 38 cases of death in 2015. Such a high death toll was due to the poor awareness of the risk of MERS introduced from abroad and the absence of a good control and coping system. Since the MERS outbreak in 2015, the awareness of infection disasters has changed, resulting in the absence of death in 2016.

Improvements/Applications: It is unclear how to determine the intensity of infection for infectious diseases introduced from abroad. It is necessary to make efforts to improve precautions, reinforce coping against the spread, enhance capabilities through mock drill, improve the legal system, and increase infrastructures with the objective of building an efficient crisis control system against infectious diseases.

Keywords: *Infectious disease, Legal infectious disease, Surveillance, Infection disaster, Prevention*

Introduction

The law regarding infectious disease prevention and control has been established to prevent the outbreak and prevalence of infectious diseases harmful to the people's health, define the requisites for their prevention and control, and contribute to the promotion and maintenance

of the people's health [1]. In 2014, some countries, including the United States, made an agreement among them to accelerate prevention, surveillance, and coping against the intentional, accidental, and natural threats of infectious diseases [2].

In this context, the law regarding infectious disease prevention and control has been established to classify the legal infectious diseases in pursuit of infectious disease prevention and control [1]. The legal infectious diseases are divided into Group 1, 2, 3, 4, and 5 infectious

woonseo@hanmail.net

diseases, designated infectious diseases, infectious diseases supervised by WHO, bioterrorism-related infectious diseases, sex-mediated infectious diseases, zoonoses, and medically-related infectious diseases [1].

While the infectious disease mortality is on the increase, there is no treatment for Ebola virus whose lethality is 50% to 90% [3]. Since its discovery in 2012, Middle East Respiratory Syndrome (MERS)-CoV has affected approximately 1,100 people, including children, in 12 countries and resulted in higher mortality than Severe Acute Respiratory Syndrome (SARS) (40% vs. 10%) [4].

In 2015, South Korea was at risk of national disaster due to the outbreak of MERS [5]. Since the introduction of MERS into South Korea in 2015, 38 out of 186 persons definitively diagnosed with the disease have died [6]. It can be said that the disease strongly affected its society, economy, and health [5, 6]. Five super-spreaders were very likely to affect infection: 82.7% of all those definitively diagnosed with the disease were reportedly able to spread it [6]. The prevalence of new infectious diseases, including SARS, Avian influenza, and MERS, which are sources of anxiety, requires efforts to cope with critical situations at the national level [7].

Benca [8] noted that regions having artificial disasters (war, terrorism, industrial accidents, etc.) and natural disasters (earthquake, flood, tsunami, volcano explosion, etc.) are strongly correlated with the factors for infectious disease outbreak. That is, disaster zones are at high risk of infectious disease outbreak. In addition, WHO [9] noted that people could be more susceptible to an infectious disease if it occurred at specific regions and was more likely to occur.

Infection may cause damage to spread rapidly from a certain area to vast regions. While research on some cases of infection has been conducted, few studies using annual data have been conducted and little research using the data disclosed by MOHW and KCDC [10] has been performed. This study aimed to use the annual data regarding “legal infectious diseases under complete surveillance” disclosed by MOHW and KCDC [10] to determine the risk of infection disasters.

It intended to determine the risk of infection disasters related to the annual outbreak of legal infectious diseases—Group 1 to 4—in South Korea on the basis of the data regarding “legal infectious diseases under complete surveillance” disclosed by MOHW and KCDC

[10]. The period between 2014 and 2018 was reviewed to determine the annual status of legal infectious diseases.

Method

1. Study design

The raw data regarding “legal infectious diseases under complete surveillance” disclosed by MOHW and KCDC [10] were used. On this basis, secondary data analysis was performed to determine the “risk of infection disasters by legal infectious disease outbreak status.”

2. Instruments and subjects

This study used the data regarding each of the “legal infectious diseases” disclosed by MOHW and KCDC [10] to determine the risk of infection disasters between 2014 and 2018. The data from the complete surveillance of legal infectious diseases during the period of five years from 2014 to 2018 were drawn.

The legal infectious diseases are divided into Group 1, 2, 3, 4, and 5 infectious diseases, designated infectious diseases, infectious diseases supervised by WHO, bioterrorism-related infectious diseases, sex-mediated infectious diseases, zoonoses, and medically-related infectious diseases [1, 11].

Among the legal infectious diseases, Group 1 to 4 infectious diseases were included in this study. Since there were raw data regarding Group 1 to 4 infectious diseases among the legal infectious diseases under complete surveillance, as disclosed by MOHW and KCDC [10], these four groups were included in this study. It is mandatory to report any of Group 1 to 4 legal infectious diseases without delay. If a legal infectious disease occurs, it is first reported to the target monitoring agency and then to the department of health at the level of cities, counties, and districts, the department of health at municipal and provincial levels, and KCDC [11].

There were 88,774 cases of Group 1 to 4 legal infectious diseases in 2014, 104,028 cases in 2016, and 170,498 cases in 2018.

3. Ethical consideration and Analysis

This study has obtained the approval of review exemption from the Institutional Review Board (IRB) of C University (Human-008-20190523-1st)(Review Exemption). The data were analysed using an SPSS

WIN 20.0 Version program.

Result and Discussion

1. Changes in trend of legal infectious disease outbreak and mortality

The trend of Group 1 to 4 legal infectious disease outbreak and mortality between 2014 and 2018 was presented in [Table 1], [Figure 1], and [Figure 2]. Between 2014 and 2018, the number of Group 2 legal infectious diseases (492,227) was greatest, followed by Group 3 (159,400), Group 1 (16,907), and Group 4 (2,623). Legal

infectious disease mortality was incongruous with outbreak size: Group 3 (456) resulted in the greatest number of deaths, followed by Group 2 (261), Group 4 (196), and Group 1 (12).

With the increase and decrease in outbreak and mortality of infectious diseases, international cooperation is made to control and cope with infectious diseases [2, 12]. WHO adopted the International Sanitary Regulations to prevent the global spread of infectious diseases in 1951 and the International Health Regulations in 2005 [12]. In 2014, the Global Health Security Agenda (GHSA) presented a vision [2].

Table 1. Changes in trend of legal infectious disease outbreak and mortality

Category		2014	2015	2016	2017	2018	Total
Group 1	Outbreak size	1,816	2,128	5,077	4,875	3,011	16,907
	Number of deaths	1	1	2	3	5	12
Group 2	Outbreak size	70,535	70,446	72,127	98,308	117,811	429,227
	Number of deaths	11	36	23	70	121	261
Group 3	Outbreak size	16,178	18,851	26,208	49,100	49,063	159,400
	Number of deaths	64	33	43	105	211	456
Group 4	Outbreak size	245	561	616	588	613	2,623
	Number of deaths	16	60	19	55	46	196
Total (Outbreak size)		88,774	91,986	104,028	152,871	170,498	608,157
Total (Number of deaths)		92	130	87	233	383	925

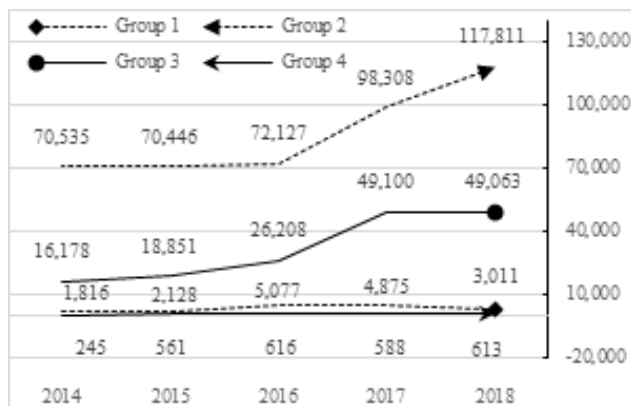

Figure 1. Changes in trend of legal infectious disease outbreak

Figure 2. Changes in trend of legal infectious disease mortality

2. Trend of mortality by criteria for Groups 1 and 2 legal infectious disease classification

The changes in the trend of mortality by the criteria for Group 1 and 2 legal infectious disease classification between 2014 and 2018 are presented in [Table 2]. Among Group 1 infectious diseases, hepatitis A (8 cases) had high mortality, but cholera, paratyphoid fever, and bacillary dysentery resulted in no case of death.

Among Group 2 infectious diseases, Pheumococcus (240 cases) and Japanese encephalitis (12) had high

mortality, but diphtheria, pertussis, measles, mumps, poliovirus resulted in no case of death.

Group 1 infectious diseases, which are mediated by water or food and are very likely to have mass outbreak, require making anti-epidemic measures immediately after the outbreak or prevalence; Group 2 infectious diseases require national vaccination [1,11]. Group 1 and 2 infectious diseases have low mortality probably because of the prevention of food mediation and national vaccination. Lee [13] found that the awareness of legal infectious diseases was poor: an average of 6.56 out of 14.

Table 2. Trend of mortality by criteria for Groups 1 and 2 legal infectious disease classification

Category		2014	2015	2016	2017	2018	Total
Group 1	Cholera	0	0	0	0	0	0
	Typhoid fever	1	0	0	0	0	1
	Paratyphoid fever	0	0	0	0	0	0
	Bacillary dysentery	0	0	0	0	0	0
	Enterohemorrhagic Escherichiacoli	0	0	0	0	3	4
	Hapatitis A	0	1	2	3	2	8
	Total	1	1	2	3	5	12
Group 2	Diphtheria	0	0	0	0	0	0
	Pertussis	0	0	0	0	0	0
	Tetanus	0	0	2	0	2	4
	Measles	0	0	0	0	0	0
	Mumps	0	0	0	0	0	0
	Rubella	0	0	0	0	0	0
	Poliovirus	0	0	0	0	0	0
	Japanese encephalitis	4	2	3	2	1	12
	Varicella	0	0	0	0	1	1
	Acute hepatitis B	1	0	0	1	2	4
	Haemophilus influenzae type B	0	0	0	0	0	0
	Pheumococcus	6	34	18	67	115	240
Total	11	36	23	70	121	261	

3. Trend of mortality by criteria for Groups 3 and 4 legal infectious disease classification

The changes in the trend of mortality by the criteria for Group 3 and 4 legal infectious disease classification between 2014 and 2018 are presented in [Table 3]. Among Group 3 infectious diseases, *Vibrio vulnificus* septicemia (109 cases), Carbapenem-Resistant Enterobacteriaceae (CRE) (180), and Tsutsugamushi disease (60) had high mortality, but scarlatina, Hansen’s disease, leptospirosis, and anthrax resulted in no case of death.

Among Group 4 infectious diseases, Severe Fever with Thrombocytopenia Syndrome(SFTS)(156 cases) and MERS (38) had high mortality, but pest, Yellow fever, dengue fever, and rabbit fever resulted in no case of death.

Group 3 infectious disease requires continuous monitoring of outbreak and establishment of anti-epidemic measures due to the likelihood of intermittent

prevalence; Group 4 infectious disease is a new type of infectious disease that occurs or is likely to occur domestically or infectious disease prevalent overseas that can possibly be introduced into South Korea [1, 11]. Jang [7] indicated that simply controlling the existing infectious diseases could lead to easy collapse of the national network of anti-epidemic measures due to new types of infectious diseases, which can occur anytime, anywhere. Jeong et al. [14] suggested the need to give systematic education and management concerning vaccination and travel-related precautions prior to business trip and provide continuous control service following business trip according to destination in travel.

The mortality of Group 4 infectious disease was on a sudden increase in 2015. The absence of good control or coping with the introduction of MERS from abroad resulted in 38 cases of death. The outbreak of the infectious disease in 2015 led to the spread of infection disasters. Lee [13] reported that 74.9% of the respondents suggested the need to make anti-epidemic measures against introduction of SARS, SFTS, and MERS into South Korea [13].

Table 3. Trend of mortality by criteria for Groups 3 and 4 legal infectious disease classification

Conclusion

This study aimed to analyze the risk of the infection disasters by legal infectious disease outbreak. Of the legal infectious diseases, Group 1 to 4 infectious diseases were included in this study. Of these, MERS, Group 4 infectious disease introduced from abroad, resulted in 38 cases of death in 2015. It is unclear how to determine the intensity of infection for infectious diseases introduced from abroad. The efforts to supplement infection control facilities in healthcare institutions, supplement professional manpower, improve the manual, and give education and training are expected to help develop a program against infection disasters.

Factors Affecting Nursing Work Performance of Medium Sized Hospital Nurses

Ji-Hyeon Jeon¹, Sung-Ju Park²

¹Masters student, Nursing Science, University of Nambu, Korea, ²Professor, Nursing Science, University of Nambu, Korea

Abstract

Background/Objectives: This study is identifying the factors influencing their nursing work performance and to provide a preliminary data necessary for managing nursing manpower by examining the nursing work performance, job satisfaction, and self leadership of nurses in medium sized hospitals.

Methods/Statistical analysis: This study is a survey was carried out targeting nurses selected by using the convenience sampling method who have been working for more than 6 months in medium sized hospitals. Data analysis was descriptive statistics analysis, t-test, one-way ANOVA, correlation analysis, and multiple regression using SPSS/WIN 22.0 program.

Findings: This study showed that the job satisfaction and self leadership were factors significantly influencing the nursing work performance and the explanation power of job satisfaction and self leadership was 40.4%.

Improvements/Applications: Therefore, it is suggested that a strategy to improve the job satisfaction and self leadership as a continuous intervention strategy that can maximize the nursing work performance is necessary.

Keywords: *Nursing work Performance, Self leadership, Job Satisfaction, Nurses, Medium sized Hospitals*

Introduction

Medium sized hospitals are the secondary medical centers that connect the primary medical centers and the tertiary medical centers according to the health care delivery system in Korea. These small and medium-sized hospitals are located closely to the local community, promoting efficient use of medical resources and savings effect of medical expense. In addition, these hospitals play an important role in health care and provide professional treatment, surgery, and inpatient services. Nurses are important human resources among various members in the hospital organization as well as the largest expert group that accounts for 44.1% of total medical personnel^[1], and the improvement of nurses' competencies is crucial for improving their life satisfaction and producing efficient job performance^[2,3].

However, the nurses in medium-sized hospitals face poor working environments including excessive workload, low wage structure, irregular working hours, and insufficient treatment due to lack of nursing manpower. As a result, their self-esteem has been lowered and their job satisfaction and efficiency in nursing service has been reduced, negatively affecting the organizational performance consequently^[4,5].

In the nursing organization, the nursing competency is connected directly to the nursing performance, and sufficient knowledge, appropriate judgment, and excellent skills lead to the qualitative improvement of nursing, resulting in the successful achievement of the organizational goal. This is because there are many situations that need to be handled promptly and quickly when a nurse cares for a patient^[6]. Improved self-leadership of a nurse changes her/his actions and ideas and expands the influence on himself, creating the ability to control herself/himself and carry out the nursing service initiatively^[7].

Corresponding author:
Sung-Ju Park,
psung3144@nambu.ac.kr

The self-leadership of a nurse motivates herself/himself and helps herself/himself to respect coworkers, accept the goal of the hospital organization and the nursing organization actively and positively and increase his job satisfaction, improving the level of nursing service given to patients qualitatively^[4]. A nurse who has a high job satisfaction is effective for securing nursing manpower which is an important aspect in the manpower management of medium sized hospitals, affecting the improvement of hospital management and enabling the provision of higher quality nursing service^[8].

Therefore, small and medium-sized hospitals should make efforts to invest material resources and provide high quality health and medical services and nursing services based on a strategy to improve the productivity of hospital organization and a sufficient nursing manpower in response to the competition with large-sized hospitals.

The aim of this study is to identifying nursing work performance, job satisfaction, and self leadership level of nurses and analyzing the effects of on the nursing performance.

Method

This study is a descriptive research study to identify the degree of nursing work performance, job satisfaction, and self leadership of nurses in medium sized hospitals and analyzing the effects on the nursing work performance.

This study was conducted targeting at nurses who are working for more than 6 months in medium sized hospitals with more than 150 beds and less than 300 beds. For the research tool, the self leadership was measured developed by Manz^[9] and supplemented by Kim^[10]. This tool consists of 18 questions in six sub areas and a higher score, the higher self leadership level. The tool reliability was carried out by Cronbach's α of Kim^[10] was .87 and in this study was Cronbach's α was .86. For the job satisfaction, the job satisfaction measurement tool for nurses developed by Song^[11] was used and this tool consists of 25 questions in five sub areas and a higher score indicates a higher job satisfaction. The tool reliability was carried out Cronbach's α of Song^[11] was .84 and in this study was Cronbach's α was .92. For the nursing performance, the nursing performance measurement tool developed by Ko^[12] composes of 17 questions in four sub areas and a higher nursing work performance level. The tool reliability was carried out

by Cronbach's α of Ko^[12] was .92 and in this study was Cronbach's α was .91.

The analysis method is as follows.

A. The general characteristics of the target nurses were analyzed using real number and percentage.

B. The degree of nursing work performance, job satisfaction, and self leadership were obtained as average and standard deviation.

C. Nursing work performance, job satisfaction, and self leadership according to general characteristics were analyzed using t-test and one way ANOVA and the Scheffe's test was used for post-hoc analysis

D. Nursing work performance, self leadership, and job satisfaction were analyzed using the Pearson's correlation coefficient.

E. Factors influencing the nursing work performance analyzed using multiple regression analysis and stepwise multiple regression.

Result and Discussion

1. Degree of Nursing work performance, Job satisfaction, and Self leadership of Subjects

Degree of nursing work performance, job satisfaction, and self leadership are shown in [Table 1].

For the nursing work performance, there were 17 questions with 3.54 points on average on a five-point scale. According to the sub areas, the nursing competency showed the highest score, followed by nursing attitude, improvement of nursing service level, and application of nursing process. For the job satisfaction, there were 25 questions with 3.13 points on average on a five-point scale. According to the sub areas, the relationship with coworkers showed the highest score, followed by relationship with senior nurse, job, personnel system, and work environment and welfare. For the self leadership, the score was 3.46 ± 0.40 points on average on a five-point scale. According to the sub areas, the self-compensation showed the highest score, followed by rehearsal, self expectation, constructive thinking, self-criticism, and goal setting.

Table 1. Degree of Nursing work performance, job satisfaction, and self leadership of subjects**(N=176)**

variables	mean \pm SD
nursing work performance	3.54 \pm 0.43
nursing competency	3.64 \pm 0.48
nursing attitude	3.58 \pm 0.49
improvement of nursing service	3.41 \pm 0.57
nursing process application	3.39 \pm 0.60
job satisfaction	3.13 \pm 0.45
job system	3.26 \pm 0.50
work environment and welfare	2.72 \pm 0.67
personnel system	2.82 \pm 0.62
relationship with coworkers	3.53 \pm 0.56
relationship with senior nurse	3.51 \pm 0.63
self-leadership	3.46 \pm 0.40
self-compensation	3.50 \pm 0.55
rehearsal	3.56 \pm 0.59
goal setting.	3.30 \pm 0.65
self expectation	3.69 \pm 0.60
self-criticism	3.34 \pm 0.75
constructive thinking	3.39 \pm 0.57

2. The Difference in Nursing work performance, Job satisfaction, and Self leadership of the Subjects according to General Characteristics

The difference in nursing work performance, job satisfaction, and self leadership of the target nurses according to general characteristics are shown in [Table 2].

Nursing work performance shown in age($F=2.89$, $p=.024$), marital status($t=2.24$, $p=.026$), and position($t=-2.99$, $p=.003$) were statistically significant difference. Job satisfaction shown in the highest level of education($t=-2.13$, $p=.034$), position($t=-2.14$, $p=.033$), work unit($F=4.63$, $p=.004$), and payment($f=4.42$, $p=.013$) were statistically significant difference and the Self leadership shown in age($F=4.65$, $p=.001$) was statistically significant difference.

Table 2. Difference in nursing work performance, job satisfaction, and self leadership of the subjects according to general characteristics ((N=176))

characteristic	Self leadership		job satisfaction		nursing work performance		
	Mean ±SD	t/F (p)	Mean±SD	t/F (p)	Mean±SD	t/F (p)	
Age (years)	under 25	59.89±6.23		78.16±12.81		56.58±5.08	
	26-30(b)	62.67±6.93	4.65 (.001) a<c<e	78.34±9.87	1.21 (.305)	60.79±6.83

3. Correlation between Nursing work performance, Job satisfaction, and Self leadership

The correlation between nursing work performance, job satisfaction, and self leadership of the subjects is shown in [Table 3]. Self leadership was statistically

significant correlation with job satisfaction and nursing work performance, the job satisfaction was statistically significant correlation with nursing work performance, and the nursing work performance was statistically significant positive correlation with self leadership and job satisfaction. In other words, the nursing work

performance was higher as the self leadership and the job satisfaction were higher.

Table 3. Correlation between nursing work performance, self leadership, and job satisfaction (N=176)

Variable	self leadership r(p)	job satisfaction r(p)	nursing performance r(p)
self leadership	1		
job satisfaction	.24 ($<.001$)	1	
nursing work performance	.57 ($<.001$)	.40 ($<.001$)	1

4. Factors Influencing Nursing work performance

The factors influencing nursing work performance is as shown in [Table 4]. The self leadership and job satisfaction had a statistically significant influence on nursing work performance, and the explanation power of the model was 40.4%.

Discussion

For nursing work performance, job satisfaction, and self leadership, the score was and 3.54 points, 3.13 points, 3.46 points on average on a five-point scale in this study.

The self leadership of the nurses in medium sized hospitals was lower than the self leadership of the nurses in university hospitals^[13]. The job satisfaction varied between the nurses in general hospitals^[14], university hospitals^[15], so it is difficult to generalize and conclude that job satisfaction depends on the size of hospital.

It is considered that job satisfaction varies according to working environment at a hospital, pay level, and hospital systems. The nursing work performance of the nurses in university hospitals^[16], head nurses in general hospitals^[17], and nurses in intensive care units^[18] showed different results by the size of the hospital, indicating that nursing performance is related to regional difference or the distinctiveness of duties in each department in the hospital.

According to the correlation between nursing work performance, self leadership, and job satisfaction of

the subjects, self leadership and job satisfaction had a positive correlation with nursing work performance. As the self leadership and the job satisfaction were higher, the nursing work performance was also higher. According to other variable factors having a positive correlation with nursing work performance, communication and self leadership had a positive correlation with the nursing work performance of nurses in university hospitals^[7], self leadership and self efficacy had a positive correlation with the nursing work performance of nurses in care hospitals^[19], and self leadership and self esteem had a positive correlation with the nursing work performance of nurses in general hospitals^[20]. There were many precedent studies showing the correlation between various variable factors and nursing work performance, however, it was difficult to find a precedent study for examining the correlation of nursing work performance by applying self leadership and job satisfaction at the same time targeting the nurses in small and medium hospitals, so there was a difficulty in performing a comparison.

According to the influential factors on nursing work performance in this study, there was no significant variable in the general characteristics. However, self leadership and job satisfaction were found to be the significant influential factors on nursing work performance, and the explanation power was 40.4%. The self leadership and job satisfaction^[4] and communication and self leadership^[7] were presented to be the significant influential factors for the nursing work performance of nurses in university hospitals. The self leadership and self esteem^[20] for the nursing work performance of nurses in general hospitals and self leadership for the nursing work performance of nurses in care hospitals were confirmed to be the significant influential factors. Likewise, many precedent studies reported that higher self leadership of a nurse had a significant effect on the nursing work performance, which was consistent with the results of this study.

The nurses in small and medium hospitals face special circumstances that the working environment is not appropriate and there is also a shortage in human resources compared to university hospitals or general hospitals. Therefore, it is necessary to seek various measures that can influence the nursing performance of nurses in medium sized hospitals. The self-leadership allows nurses to motivate themselves internally, improving their ability, enhancing their confidence and will at work, and improving their job satisfaction. This

leads to the enhancement of personal job performance and qualitative patient nursing, becoming the foundation for improving the business performance of the hospital eventually.

Conclusion

To sum up the results, it was confirmed that self leadership and job satisfaction were the factors influencing the nursing work performance. Higher self leadership and job satisfaction had greater influence on nursing work performance. The development of a training program that can help nurses to set a goal by themselves and to provide a service with responsibility and a strategy that can induce active participation is necessary for improving the nurses' self leadership. It is also necessary to properly place the manpower and establish a practical wage structure for improving the nurses' job satisfaction.

Effects of Applying Flipped Learning to Simulation Training in Nursing Students

Hyun-Jung Kim¹, Dahye Park²

¹Professor, Department of Nursing, Daewon University College, Korea, ²Professor, Department of Nursing, Semyung University, Korea

Abstract

Background/Objectives: This study was conducted to confirm the effect of applying flipped learning to simulation training of nursing students.

Methods/Statistical analysis: The study was the experiment with pre and post design in single group. The subjects of this study were 88 nursing students who were taking the simulation training course of nursing college. The learning model was designed with a total of 11 programs based on the 'PRTNER' model. Collected data were analyzed using descriptive statistics and paired t-test using SPSS 22.0.

Findings: Although there was no statistically significant difference in the problem solving ability($t=-1.342$, $p=.183$) between before and after applying flipped learning to simulation training, the significant improvement was achieved in self-directed learning ability($t=-2.187$, $p=.031$), communication ability($t=-5.316$, $p<.001$), and satisfaction of instruction($t=-2.830$, $p=.006$). Therefore, using the teaching and learning method with flipped learning, the learning outcomes can be maximized by improving the core competencies that nursing students should have. These results are useful as basic data for the development of teaching and learning methods that can improve the core competencies of nursing students.

Improvements/Applications: Based on this results, we propose the follow-up study to confirm the effectiveness of various teaching and learning methods applying flipped learning to the theoretical curriculum in nursing science.s

Keywords: *Flipped Learning, Nursing Students, Communication Competency, Self-directed Learning, Problem Solving Ability*

Introduction

Recently, due to changes in health care, patient safety is important and patient rights are guaranteed, so nursing students' nursing care during clinical practice is limited, making it difficult to acquire knowledge and in various and complex diseases in clinical practice. Also, because a lot of major knowledge should be delivered in a short time, and there are many lecture-oriented classes centered on teachers, it is difficult to strengthen the core competency required at graduation for nursing college students. The nursing education requires various method

of training that can experience on-the-job-oriented learning^[1], so flipped learning, team based learning, problem-based learning and simulation training have been used for several years, and effectiveness has been evaluated^[2-3].

Simulation exercise training provides nursing students with an opportunity, including safe environment^[4], to learn repeatedly through various scenarios in the situation similar to clinical practice based on high fidelity simulator. Flipped learning means 'learning backwards', and it is a teaching method that enables students to learn outside the classroom by changing the learning order and to experience the transfer of knowledge acquired before the class in various ways^[5]. The flipped learning also has shown to improve

Corresponding Author :
Dahye Park,
pooh400@hanmail.net

critical thinking, communication, and self-directed learning through pre-learning, constant interaction and discussion with peers^[5-7]. However, according to the amount of pre-learning and the method of teaching and learning, students' dissatisfaction and limited increase in satisfaction of the class have been reported^[8]. Therefore, simulation and flipped learning can be the effective teaching and learning methods to enhance the learning outcomes. So, it is necessary to apply them to various curriculum subjects and confirm the effects including the limitations. After developing and applying flipped learning method which is the learner-centered teaching method in the course of simulation practice, we confirmed the effect and performed the study to provide the basic data in education.

The specific objectives of the research are as follows. First, it confirms the level of problem solving ability, self-directed learning ability, communication competency and class satisfaction before and after applying flipped learning to simulation training. Second, it compares the difference of problem solving ability, self-directed ability and communication competency before and after applying flipped learning to simulation training.

Method

This study is an experimental study using pretest-posttest design in one group to investigate the effect of nursing student's simulation practice training, applied with flipped learning, on problem solving ability, self-directed ability, communication competency and instructional satisfaction.

The subjects were the students who participated in the simulation exercise course and agreed to participate in the research from department of nursing at D University in J city. The number of the subjects was 88 with the effect size of .30, significance level of .05, and test power of .90 using G*power 3.1.9. However, 95 subjects were selected considering the dropout rate. The final analysis included 88 subjects.

In this study, the effectiveness of the simulation practice education using the flipped learning in nursing students was verified by using the life ability measurement tool^[9] for college students and general adults and the class satisfaction^[10] tool.

For problem solving ability, we used the life ability measurement tool developed by Lee, Jang, Lee, and

Park^[9]. There are 45 questions in total, consisting of the Likert scale. The higher the score, the higher the problem solving ability. In the reliability of problem solving ability, Cronbach's α was .94 at the time of development and .96 in this study.

In evaluation self-directed learning ability, we also used the life ability measurement tool developed by Lee, Jang, Lee, and Park^[9]. There are a total of 40 questions, which are composed of the Likert scale, the higher the self-directed learning ability. In the reliability of self-directed learning ability, Cronbach's α was .95 at the time of development and .95 in this study.

In evaluate communication competency, we used the life ability measurement tool developed by Lee, Jang, Lee, and Park^[9]. A total of 49 questions, which are composed of the Likert, the higher score means better communication competency. In the reliability of communication competency, Cronbach's α was .80 at the time of development and .89 in this study.

In order to evaluate class satisfaction, we used the class satisfaction tool developed by Choi^[10]. There are a total 12 questions indicating the higher the score, the higher class satisfaction. In the reliability of class satisfaction, Cronbach's α was .89 at the time of development and .91 in this study.

In order to improve the learning outcomes of nursing college students through simulation training with flipped learning and to strengthen core competencies, the 'PARTNER' model, the flipped learning teaching and learning model developed by Choi and Kim was used^[11]. In the study, 'PARTNER' model was applied to 6 revised levels of 'Preparation', 'Relevance', 'Team activity', 'Nub lecture', 'Evaluation', and 'Reflection' and the program was performed 11 times in total. First, We analyzed the learner, subject, and simulation practice environment for the learner-centered class in the preliminary stage(pre-class) and developed the simulation practice guide applying the flipped learning. In addition, we have developed preliminary learning materials such as video and handout to help self-directed learning. Second, the pre-learning linkage(In-class) enables quizzes and question-and-answer on the pre-learning so that cooperative learning can be achieved. Third, in the team activity, nursing process and debriefing were applied to simulation exercises according to scenarios to improve learner's problem solving ability, critical thinking ability and communication competency.

The instructor acted as facilitators to help learners collaborate to solve problems and share the knowledge to make up and improve what is lacking. Fourth, at the end of the lesson, the key summary lecture was used to accurately convey the main goal and the core contents on weekly basis. Fifth, various scenarios were applied to perform the mid-term evaluation and the overall evaluation for each team. Finally, in post-reflection, after the weekly lecture was finished, the reflection diary was made to be able to reflect on the contents on team-by-team basis or individually, and the professor gave feedback on it[Table 1].

Table 1. Flipped learning model based on PRTNER model

This study was conducted from March to April, 2019, and the preliminary survey was carried out by online questionnaires after the orientation of simulation exercise course, and the post-test was carried out by post-question in the same way after the 11th program. To analyze the collected data, the reliability of each tool was measured using the SPSS WINDOW 22.0 program. The general characteristics of the subjects were described using descriptive statistics of frequency, percentage, mean

and standard deviation, and paired t-test was to analyze differences between pre-and-post-experiment.

Considering the ethical side of the subject, this study was reviewed and approved by the Institution Review Board(IRB No: D**-2019-02-002-01), D University at J city, and data were collected. In addition, approval for using the tool in the study was obtained from its developer. The research assistant without conflict of interest explained

the purpose, the method, the outcome, and the potential problems of the study to the subjects and explained that they may wish to remain anonymous and refuse to participate if they do not. The survey was conducted after obtaining the informed consent from subjects who agreed to participate in the study and the complimentary product was provided in return.

Result

In general characteristics of the subject, the average age of the subjects was 22.85(\pm 2.93), and the number of female students was 78(88.6%). In terms of average grades for all semesters, the number of students who received less than 3.0-3.5 points was the highest with 33 students(37.5%), and the number of students with the score below 3.5-4.0 was 30 students(34.1%) [Table 2]. From the effects of simulation training practice

using flipped learning of nursing students, the results of the preliminary survey showed the problem solving ability of 3.53(\pm 0.46), self-directed learning ability of 3.51(\pm 0.45), communication competency of 3.37(\pm 0.33), and class satisfaction was 3.79(\pm 0.63). The results of the follow-up were improved to 3.63(\pm 0.52) for problem solving ability, 3.66(\pm 0.53), for self-directed ability, 3.66(\pm 0.38), for communication competency and 4.05(\pm 0.61) for class satisfaction. Although there was no statistically significant difference in the problem solving ability($t=-1.342$, $p=.183$) of nursing students, before and after applying flipped learning in the simulation training, there were statistically significant difference in self-directed learning ability($t=-2.187$, $p=.031$), communication competency ($t=-5.316$, $p<.001$) and class satisfaction($t=-2.830$, $p=.006$) [Table 3].

Table 2. General characteristics of the subjects

Characteristics	Categories	n(%)	Mean \pm SD
Age	<20-25	78(88.6)	22.85 \pm 2.93
	<25-30	7(8.0)	
	>30	3(3.4)	
Sex	Male	10(11.4)	
	Female	78(88.6)	
Average of all semesters	<2.0-2.5	3(3.4)	
	<2.5-3.0	20(22.7)	
	<3.0-3.5	33(37.5)	
	<3.5-4.0	30(34.1)	
	>4.0	2(2.3)	
Major satisfaction	Not at all	2(2.3)	
	Not satisfied	11(12.5)	
	Satisfied	55(62.5)	
	Very satisfied	20(22.7)	
Preferred teaching method	Instructor-centered lecture	75(85.2)	
	Learner-centered lecture	13(14.8)	

Table 3. Comparison of difference before and after applying flipped learning in simulation exercise course

Variable	Reliability	Pre-test	Post-test	t	p
Problem solving ability	.96	3.53±0.46	3.63±0.52	-1.342	.183
Self-directed learning ability	.95	3.51±0.45	3.66±0.53	-2.187	.031
Communication competency	.89	3.37±0.33	3.66±0.38	-5.316	<.001
Class satisfaction	.91	3.79±0.63	4.05±0.61	-2.830	.006

Discussion

Based on the results of this study, the problem solving ability increased with flipped learning in the simulation training program, but it was not statistically significant. This was different from the one that 5-6 team members could improve their problem solving ability by constant interaction while thinking about what is right and best, what should be improved in order to solve the problem through critical thinking^[5]. Therefore, repeated studies are needed to verify the effect after analyzing other factors influencing problem solving ability.

The self-directed learning ability was significantly improved by flipped learning. It is the same result as Choi and Kim that self-directed ability improved with flipped learning in the basic nursing practice course^[5]. In addition, flipped learning can be the most effective teaching method for self-directed learning ability which is supported by previous researches.^[12-13] Furthermore, it is the result of self-directed pre-study to achieve the learning goal by the members in the preliminary stage and the pre-learning link of the flipped learning method, and active learning based on the learner such as continuous interaction with the peers and discussion. In addition, it seems that the learner performed self-directed nursing process and debriefing to solve the problem of various situation in team activity.

The Communication competency statistically improved after application of flipped learning method to the simulation training. This result is consistent with previous studies that have improved communication competency by flipped learning applied to other curriculums, such as health assessment and adult nursing^[7,14]. This result seems to be attributed to the fact that learners applied continuous cooperative learning and therapeutic communication

method with members to solve the problem of various scenario situations in the simulation practice education using flipped learning.. In addition, as a facilitator, the instructor has been able to make continuous interaction among the members, and the communication competency has been improve by experiencing what was well done, the improvement and the debriefing about what is important in the scenario situation. Therefore, it is necessary to apply the teaching method of flipped learning to the theoretical subject.

The class satisfaction increased significantly after application of the flipped learning which appeared to be ineffective in the study of Choi^[10] college students, but the results of our study are consistent with those of Lee, Han and Je, Nam^[8,15]. The results showed that the learner created the self-directed environment to solve the problem of subjects, and through the class design using the 'PRTNER' model, the continuous interaction with in pre-class, in-class and post-class. However, there were various results in the previous research, so it is necessary to develop various contents about the control of pre-learning amount and the pre-learning method which can be the negative factor in the learning satisfaction.

Conclusion

The study was conducted to confirm that application of flipped learning is effective in the problem solving ability, self-directed ability, communication competency, and class satisfaction in the simulation training of nursing students. The results showed that self-directed learning ability, communication competency, and satisfaction of class were improved after applying simulation training practice with flipped learning. These results, which is meaningful as the basic data, proved that the simulation practice

education applied with flipped learning is effective as the learner-centered teaching and learning method in nursing science and is a learning strategy for strengthening the core competency of nursing students.

The follow-up study is necessary to develop the teaching and learning methods applying flipped learning to various theoretical curriculums besides the practice subjects in nursing while confirming its effect.

Development of Multifunctional Cosmetic Products with Anti-Photoaging Effect

Eun-Suk Kim¹, Hye-Jin Kwon²

¹Professor, Seokyeonh Univ, Dept. Beauty Art, Seoul Korea, ²Professor, Soongsil Univ, Dept. Chemical Engineering, Seoul Korea

Abstract

Background/Objectives: Ultraviolet rays induce erythema, allergy, and skin aging. We investigated the anti-photoaging effect of stem-cell culture media and Polygona Multiflora Radix extract (GMF).

Methods/Statistical analysis: An emulsion containing natural GMF and a mixed emulsion containing stem-cell culture medium and Polygona Multiflora Radix emulsion (DMF) were prepared. Photoaging was induced in hairless mice (SKH-1) by irradiation of UVB rays thrice per week for 6 weeks. Pathological changes were examined following 5 or 10 days of emulsion application.

Findings: These mice exhibited typical signs of photoaging including increased epithelial thickness, accumulation of abnormal elastic and collagen fibers, and dermal accumulation of inflammatory and mast cells. Photoaging was significantly inhibited in all experimental groups. The group treated with DMF for 10 days showed similar levels of improvement as those observed in the control group.

Improvements/Applications: Thus, both natural GMF and DMF can reduce wrinkles caused by photoaging. In addition, our findings verify the potential of GMF and stem-cell culture media as ingredients for anti-photoaging cosmetic products.

Keywords: Polygona Multiflora Radix, photoaging, multifunctional cosmetics, stem-cell, Korean herbal

Introduction

Ultraviolet (UV) rays, a major cause of skin aging, cause wrinkle formation, pigmentation, and dermal deformation. Aging induced by UV rays differs from natural aging^[1,2]. Photoaging causes deeper wrinkles than natural aging and accelerates aging by inducing the accumulation of abnormal collagen fibers that leads to reduced skin elasticity^[3]. UV rays increase the synthesis of MMP-1, -3, -9 and -12 enzymes in fibroblasts and epithelial cells, thereby destroying matrix proteins including collagen and elastic fibers. Inflammatory cells gather and release cytokines to signal the production of enzymes required to eliminate UV-damaged cells. During this process, collagen and elastic cells are broken down, thereby promoting aging^[4,5]. Researchers have

been proposing various scientific methods that combine oriental medicine, microbiology, and food science to identify novel functional molecules that can prevent and reduce skin damage due to photoaging. Stem-cell culture media, commonly used in the field of cosmetics, contain active compounds such as proteins, cytokines, minerals, and vitamins that promote stem-cell differentiation and activity. In addition, stem-cell culture media can regulate skin differentiation and immune functions, prevent apoptosis, and treat wounds^[6,7]. Media containing only those substances that are approved to be safe can be used to make highly functional and biocompatible cosmetic products^[8]. Interest in cosmetic products containing natural herbal medicine has increased in Korean as well as in Asian and North American markets. Oriental herbal medicines contain glucose and amino acids involved in the primary metabolism of plants, and secondary substances including phenol, terpenoids, and alkaloids. Oriental herbal medicines have high potential as an ingredient for functional skin-whitening anti-aging

cosmetic products^{9,10}. In the present study, we prepared multifunctional cosmetic products with stem-cell culture media and natural substances and tested their effect on photoaging in hairless mice.

Method

Polygonia Multiflora Radix extract (GMF), listed in Korean Herbal Pharmacopoeia, was obtained by hot water extraction. A 10% o/w emulsion (GMF) was prepared and used in the experiment. Stem-cell culture media (DCCM4), used as a cosmetic ingredient, listed in the INCI were provided by Eseumedio Co., Ltd. The culture media and GMF were concentrated two-fold to produce a 10% o/w emulsion (DMF) to be used in the final experiment. All reagents used were special grade chemicals.

Six-week-old male and female ICR/HR hairless mice (SKH-1) purchased from Orient. Co., Ltd. were bred for 18 months. The mice had *ad-libitum* access to food and water. The cage conditions were as follows: temperature, $24 \pm 2^\circ\text{C}$; humidity, $50\% \pm 10\%$; and 12:12 day/night cycle. Six experimental groups were formed containing six mice each. The mice were subjected to one of the following treatments: natural aging, photoaging, 5 days of GMF treatment after photoaging, 5 days of DMF treatment after photoaging, 10 days of GMF treatment after photoaging, and 10 days of DMF treatment after photoaging. The study was approved by the Institutional Review Board of Chonbuk National University.

A UVB lamp (Sankyo Denki, Tokyo, Japan) with an emission spectrum of 280–360 nm and a maximum peak at 360 nm was used for UVB irradiation. UVB rays were irradiated on the dorsal skin of the experimental animals thrice per week with a minimal erythral dose (MED) of 60 mJ/cm². The irradiation was performed at 1, 2, and 4 MED at 1, 2, and 4 weeks, respectively, and thereafter for total 6 weeks. Irradiation was not performed for the last 3 days to eliminate the direct effect of UVB rays. An AHA peeling solution was prepared by dissolving 30 g of glycolic acid in 50 mL of distilled water, titrating it with NaOH to pH 3.2, and adjusting the total volume to 100 mL. The solution was stored in a fridge. AHA peeling was performed once for 10 min. After neutralization with PBS and complete drying of the skin, an emulsion corresponding to the designated treatment of each group was applied. The sample was applied twice a day for 10 days, and 200 μL of the cosmetic product was applied to the entire surface of dorsal skin each time. Skin tissues

were extracted at 5 and 10 days after AHA peeling, fixed in 10% neutral formalin, and used in for histological analysis.

To study microstructures on the skin surface following irradiation, skin sections were made and examined at 40 \times , 100 \times , 400 \times , 1000 \times , and 1500 \times magnification using a scanning electron microscope.

A sharp knife was used to obtain skin tissues from the mice. The tissues were fixed in 2.5% paraformaldehyde-glutaraldehyde, washed several times with a phosphate buffer solution (4°C , 0.4 M phosphate buffer, pH 7.4), and fixed in 1% OsO₄. The fixed samples were washed with the same buffer solution, dehydrated (60%–100% ethanol), and substituted with isoamyl acetate. The treated samples were completely dehydrated and placed on a sample holder. The samples were then coated with platinum until their thickness was 20 nm using an ioncoater (IB-5ioncoater, Eiko, Japan) and examined under a scanning electron microscope.

The skin tissues were fixed in a 10% neutral formalin solution at room temperature for 24 hours. They were washed, dehydrated, cleared, infiltrated, and embedded in paraffin. Thereafter, 4- μm sections were prepared and examined under an optic microscope to study changes in the skin tissues. Paraffin blocks were stained using Hematoxylin & Eosin (H&E), Masson trichrome, and Toluidine blue Verhoeff-van Gieson stains. The stained tissue slides were histomorphometrically analyzed using an image program. Tissue thickness, number of inflammatory and mast cells, surface area of collagen and elastin, and distribution and surface area of lamella were quantified.

PASW Statistics 18.0 for Windows (SPSS Inc., USA) was used for all statistical analyses. A one-way ANOVA was performed to compare differences between the experimental groups. For measurements repeated during a certain period, repeated measures ANOVA was used to examine interaction between time and the experimental groups. A post-hoc analysis was performed to confirm statistical significance. Statistical significance was set at $p < 0.05$.

Result and Discussion

1. Changes in epithelial thickness

The skin tissues of SKH-1 hairless mice were stained with H&E, and proliferation of epithelial cells

and epithelial thickness were examined as skin markers. The control group, not subjected to UVB irradiation, had an epithelial thickness of 22.46 μm for the dorsal skin, whereas the photoaging group subjected to 4 weeks of UVB irradiation had an epithelial thickness of 203.38 \pm 23.07 μm , indicating epithelial cell proliferation. After UVB irradiation, GMF and DMF were applied for 5 and 10 days, respectively. Epithelial thickness was 86.19 \pm 12.06, 53.69 \pm 12.60, 69.76 \pm 13.31, and 32.52 \pm 11.02 μm in the GMF-5, DMF-5, GMF-10, and DMF-10 groups, respectively. These treatments reduced epithelial thickness by -40.84%, -67.16%, -62.99%, and -75.58%, respectively. The DMF-10 group showed the highest reduction in epithelial thickness and similar epithelial thickness as that of the control group [Figure 1].

Figure 1. Photographs of histological sections of hairless mice (SKH-1) dorsal back skin by Hematoxylin&Eosin staining (Original magnification: x40, scale bar : 100 μm , a: Intact, b: Aging, c: GMF-5, d: DMF-5, e: GMF-10, f : DMF-10)

The epithelium repeatedly undergoes differentiation and proliferation to act as a barrier. Its permeable membrane minimizes the loss of skin moisture. Abnormal epithelial proliferation, which is a characteristic of photoaging, compromises the skin and causes allergy. When the skin loses its protective function, skin aging and secondary diseases can be induced, which in turn leads to inflammation. Frequent inflammation promotes aging in the surrounding cells^[11]. The reduction in abnormal epithelial proliferation observed in the DMF-10 group indicates that the mixed extract has anti-aging effect.

2. Change in dermal collagen and elastin

The dermis consists of elastic and collagen fibers. Collagen fibers are the major components of the dermis responsible for the elasticity and structural integrity of the skin^[12]. Elastic fibers, which are less abundant than

collagen fibers, contribute to skin elasticity. Skin aging is histologically defined as a decrease in the number of fibroblasts as well as elastin and collagen fibers, resulting in shrinkage of the extracellular matrix^[13,14]. In the present study, we used wrinkle patterns as a marker of photoaging and observed the accumulation of abnormal elastic and collagen fibers.

Collagen networks are destroyed and become dysfunctional due to UV rays. The accumulation of damaged collagen networks induces aging. We performed Masson's trichrome staining to evaluate the number and density of collagen fibers in the dermis [Figure 2]. The control group showed dense and regular patterns of collagen fibers, whereas the photoaging groups showed an irregular and less dense arrangement of collagen fibers due to destroyed collagen fibers. The positive control group and treatment groups showed more dense and regular patterns of collagen fibers compared with those in the photoaging groups. The density of collagen fibers increased as the concentration of emulsion increased. Elastic fibers are degraded in the dermis upon exposure to UV rays. UV rays activate elastase that promote elastic fiber degeneration, destroys the elastic fiber network, and induces neutrophil-mediated inflammation, thereby causing elastosis. We performed Verhoeff's staining to evaluate the number and density of elastic fibers in the dermis [Figure 3].

Figure 2. Photographs of histological sections of hairless mice (SKH-1) dorsal back skin by Masson trichrome staining (Original magnification: 200x, Arrow : collagen fiber, scale bar : 100 μm , a: Intact, b: Aging, c: GMF-5, d: DMF-5, e: GMF-10, f : DMF-10)

The control group showed dense and regular patterns of elastic fibers, whereas the photoaging group showed clumped and distorted elastic fibers, resulting in elastosis. The positive control group and treatment groups had reduced size and frequency of defective elastic fibers compared with those in the photoaging groups. The size and frequency of defective elastic fibers

evidently decreased as the concentration of emulsion increased. Table 1 shows changes in the measurements of the markers in the dermis. The level of dermal elastic fibers decreased by -30.48%, -52.96%, -38.58%, and -62.7% following 5 and 10 days of GMF and DMF treatments, respectively, compared with the non-photoaging control group.

Figure 3. Photographs of histological sections of hairless mice (SKH-1) dorsal back skin by Verboeff-van Gieson staining(Original magnification: 400x, Arrow : elastin fiber, scale bar : 100 μm, a: Intact, b: Aging, c: GMF-5, d: DMF-5, e: GMF-10, f : DMF-10)

E : Elastic fiber (%/mm²)

3. Change in the number of mast cells in the skin

Examined changes in the number of mast cells by staining the skin tissues obtained from SKH-1 hairless mice with Toluidine blue. A total of 19.33 ± 3.27 mast cells were found in the dorsal dermis of mice that were not exposed to UVB rays. On the other hand, the number of mast cells in the dermis significantly increased to 128.17 ± 31.29 in the toluidine photoaging group subjected to 4 weeks of UVB irradiation compared with the control group (p < 0.01). The number of mast cells decreased by -35.37%, -57.61%, -47.85%, and -60.73% following 5 and 10 days of GMF and DMF treatments, respectively. Mast cell overproduction was inhibited in the DMF and GMF

groups. Moreover, UVB-induced mast cell overproduction was significantly inhibited in the GMF group (p < 0.01) [Figure 4].

Figure 4. Photographs of histological sections of hairless mice (SKH-1) dorsal back skin by Verboeff-van Gieson staining(Original magnification: 400x, Arrow : elastin fiber, scale bar : 100 μm, a: Intact, b: Aging, c: GMF-5, d: DMF-5, e: GMF-10, f : DMF-10)

4. General characteristics of the subjects

Table 2 shows inflammatory counts. The control group showed almost no inflammatory cells, whereas the number of inflammatory cells significantly increased in the aging group. The number of inflammatory cells decreased following 5 and 10 days of GMF and DMF treatments. Similar results were reported by studies on anti-aging effect in animal skin models of photoaging. Typical characteristics of photoaging including increased epithelial thickness, accumulation of abnormal collagen and elastic fibers, and dermal accumulation of inflammatory and mast cells could be observed

following the induction of photoaging using UVB rays. The normalization of the epithelial thickness may indicate that the GMF and DMF treatments can protect and recover the skin barrier as reported in previous studies^[15]. Normalization of the skin barrier helps alleviate inflammation in the epithelium and dermis. In the present study, 5 and 10 days of DMF treatments significantly inhibited UVB-induced photoaging ($p < 0.01$, $p < 0.05$). Photoaging was more significantly inhibited in the DMF group than that in the GMF group ($p < 0.01$). Thus, GMF and DMF may be useful as ingredients of functional cosmetic products.

National Research Foundation of Korea funded by the Education, Science and Technology. (No.2018008274)

Conflict of Interest: Nil

Conclusion

We induced wrinkle formation in hairless mice using UVB rays and found that an emulsion containing natural GMF and DMF can improve skin damage due to photoaging. The emulsions inhibited and mitigated the characteristics of photoaging including increased epithelial thickness, accumulation of abnormal elastic and collagen fibers, and dermal accumulation of inflammatory and mast cells. DMF has a significantly higher efficacy than GMF. These results demonstrate that an emulsion containing natural GMF and DMF inhibits the activity of skin aging factors induced by UVB. Thus, GMF and DMF may be used as functional, bioactive materials for anti-photoaging cosmetic products.

A Study on Improvement of Quality of Care-givers to Long Term Care Old Age

Do-Young Lee¹, Joo-Young Lee²

¹Professor, Department of Nursing, Changshin University, 262 Palyongro, Masanhoewon-gu, Changwon-si, Gyeongsangnam-do, 51352, Korea, ²Professor, Department of Nursing, Seoul Women's College of Nursing, 38 Ganhodaero-ro, Seodaemun-gu, Seoul, 03617, Korea

Abstract

Background/Objectives: This study is a survey research to identify relationship among organizational commitment, job training satisfaction, and empowerment.

Methods/Statistical analysis: This research analyzed factors affecting satisfaction with college life using 112 nursing school students in S city as research objects. Specifically, this research examined self-resilience, communication capacity, and self-respect. In the results of this study, the organizational commitment of the subjects did not show the significant difference with the job training satisfaction and the empowerment.

Findings: There was significant positive relationship between job satisfaction and empowerment. Therefore, it is necessary to improve the quality by using the correlation between job satisfaction and empowerment.

Improvements/Applications: while this study did not find any relationship between organizational commitment and job training satisfaction, there have been other researches which report that work education improves organizational commitment. Thus, it is necessary to do repetitive researches on organizational commitment and job training satisfaction.

Keywords: *Quality, Care-givers, Job training satisfaction, Empowerment, Organizational Commitment*

Introduction

In Korea, the population aging is under way rapidly. In 2018, as the population over 65 years old occupied 14.3% of entire population, it already entered in aged society and in 2030, it is expected to super-aged society as the population over 65 would be increased to 24.3%^[1]. As the olds in modern age experienced the role loss, reduction of economic power, degradation of physical health and mental health by the aging, and the sense of loss like the death of spouse or friend, they are facing with diverse stress situations^[2, 3]. In addition, for the family and society, the very important issue of care burden by aging is arisen and the protection and care are needed by the lack of health and the independent living ability^[4]. According to the data on the survey analysis

of parents support by Statistics Korea, since the opinion that the living of the elderly over 65 years old should be taken care by the family, government and the society was 35.7%, the opinion that the responsibility for the elderly support would be shared by the family, government and society is increasing trend^[5].

Reflecting this reality, in Korea, the long-term elderly care insurance system is being implemented from July, 2008 and it was intended to promote the health and the stabilization of livelihood in later life by providing the matters on the long-term care benefits for the elderly who are hard to manage the daily living alone for the reason of old age or geriatric diseases, which have been implemented over 10 years^[6]. As the subjects who are using the care institution are increased constantly, the importance of securing the manpower to provide the high quality services is emphasized^[7], and for the quality management, the needs to complement constantly the problems by the low inflow of young manpower, lack of

Corresponding Author :

Joo-Young Lee,

E-mail: daisy58@hanmail.net

systematic educational foundation for the practitioners, low social recognition, etc. are arisen because the care services are repetitive services and career path is limited [8].

Although the poor working environment of the caregivers and the difficulties suffered in the process of services are appealed constantly, in reality, the management system is not sufficient. Since the medical fee system of long-term care system is hard to improve the compensation system or treatment of caregivers and the method to enhance the job satisfaction of caregivers is extremely limited, one of the most effective measures can be to enhance the organizational commitment^[9]. Commitment is defined as the mental and physical exited state that is felt by the people while they are concentrated on that state^[10] and those who are in the state of commitment can regulate their act and environment, work harder than other workers during their services, are have high pride and produce positive results that can exert highest ability^[11]. If such commitment is achieved during the service, diverse desires such sense of achievement, self-respect, self-efficacy, self-development, etc. are satisfied^[12].

While the number of the highly educated elderly, subject of long-term care service is increased and diverse desires are shown, the education level and the age of the caregivers is not limited causing the degradation of service quality^[13]. Foundation of national competitiveness is the human resources having knowledge, skills, motive, etc. and it is important to develop and educate them continuously^[13]. In addition, the research on the factor influencing the empowerment of caregivers^[14] reported that to solve the problem of caregiver's education level, professional skills and to make the caregivers to engage in the service with self-confidence, the constant education through the refresher training or reeducation is needed. Therefore, the systematic measures for the job training of caregivers should be prepared and the research on the effects of job training satisfaction on the organizational commitment and the empower is needed^[13]

Therefore, to enhance the quality of caregivers and to induce their job performance to more effective and positive direction, this study examined the organizational commitment, job training satisfaction and the empowerment.

Method

1. Research Design

This study is a descriptive and investigative study conducted to identify the association and correlation among the organizational commitment, empowerment and job training satisfaction of caregivers.

2. Research Subjects

Study subjects were caregivers working at long term caregiving facilities located in city S. To select subjects, convenience sampling was used to select 139 caregivers working at long term care facilities. These participants understood the objectives of the study and gave their consent to the questionnaire. Excluding^[15] copies of the questionnaire that were not retrieved or that had insufficient responses, the data from 124 subjects were used for final analysis.

3. Research Tool

3.1. Organizational Commitment

To measure the organizational commitment, the measurement items developed by^[15] and used in the research by^[16] was used. To measure the organizational commitment, the sub-level factors were measured with the total 18 questions: 6 questions of affective commitment, 6 questions of continuance commitment and 6 questions of normative commitment and all the questions were measured 5 point-Likert scale: 1 point for 'Not at all' 2 points for 'No', 3 points for 'Normal', 4 points for 'Yes' and 5 points for 'Absolutely yes'. The reliability in this study was Cronbach's $\alpha = .86$.

3.2. Job Training satisfaction

Job training satisfaction was measured using the measurement items with the contents about caregivers job training satisfaction by Ministry of Health and Welfare used in the research by^[17]. The sub-level factors of the job training satisfaction were measured with questions evaluating the satisfaction with 17 sub-level educational contents by 5 job training area composed of the human rights of elderly and vocational ethics, understanding of dementia, safety management of daily living and exercise in elderly, description of health care benefit and system, and related regulations. All the questions were measured 5 point-Likert scale: 1 point for 'Not at all' 2 points for 'No', 3 points for 'Normal', 4 points for 'Yes' and 5 points for 'Absolutely yes'. The reliability in this

study was Cronbach’s $\alpha = .91$.

3.3. Empowerment

To measure the empowerment, the empowerment scale of caregivers developed by^[18] and corrected and complemented by^[19] was used

The detailed domain of empowerment was composed of environmental empowerment, relational empowerment and individual empowerment and they are measured with 5-point Likert scale: 1 point for “Not at all” and 5 points for “Absolutely yes”. It means that the higher the score, the higher the level of empowerment. In this study, the reliability is Cronbach $\alpha = .83$.

3.4. Data Collection

Data for the study were conducted using a self-reported structured questionnaire on caregivers working at long term care facilities in city S, from April 15 to April 30, 2018. To abide by ethical standards, the objectives of the study, an explanation was given on the time it will take to fill out the questionnaire, and details regarding privacy protection of study participants before asking for their voluntary consent. A consent form and signature of caregivers wishing to take part in the study were collected. Participants were told that they are free to withdraw from the study at any point in time. They were also informed that the collected data would be used for no other purpose than this study, and the anonymity of the participants will be upheld. It took approximately 10-15 minutes to complete the questionnaire. Participants were given an explanation that the collected data would not be used for any other purpose than this study.

Result

1. General characteristics of the subjects

The subject was 100% female and age between 40 and 49 was 64% the most. In the marital status, married was 91.9% the most, in the education level, college graduate was 63.7% the most and in the religion, Christian was 64.5%, Catholic was 21.0% and Buddhist was 7.3% in order. In the service period, 2-3 year was 41.1% the most and in the certification acquisition type, the acquisition by qualification test was 90.3% the most. In the health, “So-so” was 50.0% and “Healthy” was 28.2%[Table 1].

Table 1. General characteristics (N=124)

Characteristics	Categories	N (%)
Gender	Female	124(100)
	Male	0(0)
Age(year)	40-49	64(51.6)
	50-59	42(33.9)
	50 upper	18(14.5)
Marital status	Married	114(91.9)
	Single	6(4.8)
	Divorce and Bereavement	4(3.2)
Final education	High school	45(36.3)
	University	79(63.7)
Religion	Christian	80(64.5)
	Catholic	26(21.0)
	Buddhism	9(7.3)
	Etc	1(0.8)
	None	8(6.5)
Work experience	1-2 Year	48(38.7)
	2-3 Year	51(41.1)
	3-5 Year	23(18.5)
	5 Year upper	2(1.6)
Type of Certification	No test /education	12(9.7)
	Acquired by Examination	112(90.3)
Health	Very Health	3(2.4)
	Healthy	35(28.2)
	Normal	62(50.0)
	Unhealthy	24(19.4)

2. Empowerment according to General Characteristics

In the results of analyzing the difference in the empowerment according to general characteristics of the subjects, there was significant difference in the religion ($F=1.97, p=.03$) [Table 2].

Table 2. Empowerment according to general characteristics (N=124)

Characteristics	Categories	N (%)	M±SD	t or F(p)
Gender	Female	124(100)	3.21±0.18	-
	Male	0(0)		
Age(year)	40-49	64(51.6)	3.23±0.16	1.82 (.48)

	Unhealthy	24(19.4)	3.15±0.20	

3. Degree of the Variable of the Subject

The organizational commitment of the subject was 3.18±0.16, the job training satisfaction was 3.23±0.16 and the empowerment was 3.21±0.18[Table 3].

Table 3. Degree of the Variable of the Subject (N=124)

Variables	M±SD	Min.	Max.
Organizational commitment	3.18±0.16	2.78	3.33
Job training satisfaction	3.23±0.16	2.82	3.52
Empowerment	3.21±0.18	2.71	3.64

4. Relationships among the Study Variable

The organizational commitment of the subjects did not show significant correlation with the organizational commitment ($r=.05$, $p=.589$) and the empowerment($r=.50$, $p=.600$). However, the job satisfaction showed the significant positive correlation with the empowerment ($r=.22$, $p=.016$)[Table 4].

Table 4. Relationships among the Study Variable (N=124)

Variables	Organizational commitment	Job training satisfaction	Empowerment
	r(p)	r(p)	r(p)
Organizational commitment	1	.05(.589)	.50(.600)
Job training satisfaction		1	.22(.016)*
Empowerment			1

Discussion

In the results of this study, the organizational commitment of the subjects did not show the significant difference with the job training satisfaction and the empowerment. However, the job training satisfaction showed the significant positive correlation with the empowerment.

The organizational commitment means that a member of organization has strong desire and pride for the goal of organization and the value creation with high confidence on the his organization^[20]. If the organization commitment is achieved, the positive functions are appeared from the member of organization ^[21], strong belief on the goal and the value of organization is generated and the effort of the individual demanded by organization is made voluntarily^[22].

According to the research on the needs of job training for caregivers and the training plan, to satisfy

their needs and reinforce the expertise, the job training should be implemented^[23], and it reported that in the results of identifying the demand of caregivers for the training, more than 80% of the caregivers working in the elderly nursing home answered that the refresher training is required^[24]. In addition, it reported that for the organizational commitment of caregivers, the job training is needed^[25], and together with the quality improvement and the expertise of the caregivers, diversification of job training is needed ^[26]. Through this preceding research, the job training for caregivers is needed and the job training satisfaction should be enhanced through the reflection of the diverse programs for job training and the demand, based on which, it is deemed that the empowerment can be enhanced

Conclusion

For the limitation of this study and the quality improvement of caregivers in future, the author propose followings.

First, to determine the relations among the organizational commitment, job training satisfaction and the empowerment of the caregivers, the subjects should be expanded and the replication research is required.

Second, to enhance the job training satisfaction of the caregivers, diverse programs and systematic policies are required. The research on them and constant management are required.

Finally, this study is the research to examine the relations among the organizational commitment, job training satisfaction and the empowerment and in future, the research that will analyze their factors is needed

Factors Affecting the Clinical Competency of Nursing Students in Pediatric Nursing Clinical Practice

Sung-Yun Ahn¹, Young-Ju Kim²

¹Professor, Pai Chai University, Dept. of Nursing, Korea, ²Professor, Daejeon Health Institute of Technology, Dept. of Nursing, Korea

Abstract

Background/Objectives: This study aims to investigate the effects of clinical training stress and clinical training satisfaction on clinical competency during pediatric nursing training in nursing students.

Methods/Statistical analysis: Ninety-one nursing students participated in this study, and data were collected from May 29 to November 10, 2017. The collected data were analyzed using SPSS 22.0.

Findings: This study found that clinical competency had a significant negative correlation with clinical training stress ($r = -.356, p < .001$) and a significant positive correlation with clinical training satisfaction ($r = .524, p < .001$). Clinical training satisfaction ($\beta = .439, p < .001$) and conflict with pediatric patients, a component of clinical training stress ($\beta = -.226, p = .019$), were identified as factors having significant effects on clinical competency during pediatric nursing clinical training.

Improvements/Applications: It is important to plan clinical training while considering the factors affecting it to enhance nursing students' clinical competency during pediatric nursing clinical training.

Keywords: *Nursing students, Clinical practice stress, Clinical practice satisfaction, Clinical competency, Pediatric nursing clinical practice*

Introduction

Clinical practice is a crucial component in cultivating nursing professionals, in that it is a learning process that fosters students' creativity and practical abilities by applying theoretical education to clinical practice [1]. However, the stress students accumulate during clinical training diminishes their interest in clinical training and reduces their learning abilities, ultimately undermining their clinical competency [2]. Many studies have reported the effects of stress and satisfaction with clinical training in all disciplines on clinical competency, which may differ from pediatric nursing training, where the needs and coping skills may differ according to the stage of development [3]. Even though pediatric nursing training has more restrictions than other nursing training programs [4], only a handful of studies have examined pediatric nursing training.

Thus, this study aims to investigate the effects of stress and satisfaction with pediatric nursing training on clinical competency in nursing students to provide baseline data for enhancing the clinical competency of nursing students who provide care for pediatric patients.

Method

1. Study design

This study is a descriptive correlational study investigating the effects of stress and satisfaction with pediatric nursing training on clinical competency in nursing students.

2. Participants

Ninety-two nursing students undergoing pediatric nursing training who provided informed consent to participate were enrolled in this study. The minimum sample size was calculated using the G*Power 3.1.9.2

Corresponding Author:
Young-Ju Kim,
yjkim@hit.ac.kr

software. With a moderate effect size of .15, significance level of .05, and power of .90 for two variables for multiple regression, the required sample size was calculated to be 88. After excluding one questionnaire considered inappropriate, questionnaires from 91 (98.9%) participants were included in the final analysis.

3. Research variables

3.1. Clinical practice stress

Clinical training stress was assessed using the clinical training stress scale developed by Beck and Srivastava (1991) [3] and modified and adapted by Kim and Lee (2005) [5] for use in pediatric nursing training. This 24-item tool comprises five domains: Training and educational environment (5 items), inappropriate role models (6 items), burden of training work (4 items), interpersonal conflict (4 items), and conflict with patient (5 items). Each item is rated on a 5-point Likert scale, with a higher score indicating a higher level of clinical training stress. The Cronbach's alpha in Kim and Lee's (2005) [5] study was .91, and that in our study was .96.

3.2. Clinical practice satisfaction

Clinical training satisfaction was assessed using the clinical training satisfaction scale developed by Cho and Kang (1984) [6] and modified and adapted by Lee et al. (2004) [7] for use in pediatric nursing training. This 31-item tool comprises six domains: Courses (3 items), content (6 items), guidance (9 items), circumstances (7 items), hours (3 items), and evaluation (3 items). Each item is rated on a 5-point Likert scale, with negative-worded items reverse scored, and a higher score indicates a higher level of satisfaction with clinical training. The Cronbach's alpha in Lee et al.'s (2004) [7] study was .89, and that in our study was .92.

3.3. Clinical competency

Clinical competency was assessed using the scale of nursing performance developed by Schwirian (1978) [8] and modified and adapted by Choi (2005) [9] for use in pediatric nursing training. This 45-item tool comprises five domains: Comprehensive nursing (11 items), nursing skills (11 items), teaching/collaboration (8 items), interpersonal relationships/communication (6 items), and professional development (9 items). Each item is rated on a 5-point Likert scale, with a higher score indicating a higher level of clinical competency. The Cronbach's alpha in Choi's (2005) [9] study was .92, and that in our study was .94.

4. Survey method

The study was conducted from May 29 to November 10, 2017, and the participants were informed about the purpose and procedure of the study and the guarantee of anonymity and confidentiality. After guaranteeing that the collected data would be used only for research purposes, written consent was obtained and the participants were informed that the collected data can be withdrawn at any time without any disadvantages.

5. Data analysis method

The collected data were analyzed using the IBM SPSS 22.0 software according to the following analyses:

1) Participants' general characteristics, clinical training stress, clinical training satisfaction, and clinical training competency were analyzed with descriptive statistics.

2) Correlations among participants' clinical training stress, clinical training satisfaction, and clinical competency were analyzed using Pearson's correlation coefficients.

3) The factors that affect clinical competency were identified using stepwise multiple regression analysis.

Result

1. Differences in variables by general characteristics

As shown in Table 1, the mean age was 21.8 years, and the majority of the participants were female ($n = 82$). Altogether 51 participants were third-year students undergoing clinical training in the nursery, while 40 participants were fourth-year students undergoing clinical training in the pediatric ward.

Clinical training stress was significantly higher among fourth-year students, while clinical training satisfaction was significantly higher among third-year students. However, there were no significant differences in clinical competency according to grade level. There were no statistically significant differences in the study variables by sex. The mean clinical training stress score was 2.25 (0.57), and the mean clinical training satisfaction score was 3.81 (0.56). The mean clinical competency score was 3.98 (0.53).

Table 1. Differences in variables by general characteristics**(n = 91)**

Characteristics	Categories	N(%) or Mean(SD)	Clinical practice stress		Clinical practice satisfaction		Clinical competency	
			M (SD)	t(p)	M(SD)	t(p)	M(SD)	t(p)
Gender	Male	9(9.9)	2.02 (0.48)	-1.26(.21)	3.92(0.53)	0.63 (.53)	4.11(0.59)	0.80(.43)
	Female	82 (90.1)	2.27 (0.58)		3.80(0.57)		3.96(0.53)	
Year of study	Third	51 (56.0)	2.04 (0.54)	-4.18 (< .001)	3.93(0.51)	2.22(.03)	4.06(0.52)	1.76(.08)
	Fourth	40 (44.0)	2.51 (0.51)		3.67(0.60)		3.87(0.53)	
Age (years)	-	21.8 (0.87)	2.25(0.57)		3.81(0.56)		3.98(0.53)	

2. Levels of clinical practice stress, clinical practice satisfaction, and clinical competency

The mean scores for each domain for each variable are shown in Table 2.

Table 2. Levels of clinical practice stress, clinical practice satisfaction, and clinical competency (n = 91)

Variables		Min.	Max.	Mean	SD
Clinical practice stress	Environment for clinical practice	1.00	4.60	2.91	0.79
	Inappropriate role models	1.00	4.00	2.24	0.69
	Burden of clinical practice activity	1.00	4.50	2.62	0.74
	Interpersonal conflicts	1.00	4.00	1.76	0.67
	Conflicts with children patients	1.00	3.20	1.68	0.65
Clinical practice satisfaction	Courses	1.67	5.00	4.06	0.77
	Content	2.33	5.00	3.55	0.51
	Guidance	2.22	5.00	3.82	0.75
	Circumstances	2.14	5.00	3.80	0.67
	Hours	1.67	5.00	3.95	0.85
	Evaluation	2.33	5.00	3.95	0.75
Clinical competency	Comprehensive nursing	2.91	5.00	3.97	0.53
	Nursing skills	2.27	5.00	3.97	0.60
	Teaching/collaboration	2.25	5.00	3.87	0.72
	Interpersonal relationship/communication	2.33	5.00	3.97	0.69
	Professional development	2.78	5.00	4.09	0.62

3. Correlations among clinical practice stress, clinical practice satisfaction, and clinical competency

Clinical competency is significantly correlated with clinical practice stress ($r = -.356, p < .001$) and with clinical practice satisfaction ($r = .524, p < .001$), as shown in Table 3.

Table 3. Correlations among clinical practice stress, clinical practice satisfaction, and clinical competency
(n = 91)

Variables	1 r(p)	2 r(p)
Clinical competency1	1	
Clinical practice stress2	-.356(< .001)	1
Clinical practice satisfaction	.524(< .001)	-.542(< .001)

4. Influencing factors of clinical competency

Stepwise multiple regression analysis was performed with clinical competency as the dependent variable and the domains of clinical training satisfaction and clinical training stress as the independent variables to examine the explanatory power of the factors related to clinical competency. The Durbin-Watson statistic was 1.93, confirming no problem of autocorrelation. Tolerance was above 0.1 (0.857), and the variance inflation factor (VIF) was below 10 (1.167), confirming that there was no problem of multicollinearity.

As a result of the regression analysis, the model of the regression equation was appropriate ($F = 20.606, p < .001$), and the explanatory power of the model was 30.3%. The factors affecting clinical competency during pediatric nursing clinical practice were clinical practice satisfaction ($\beta = .439, p < .001$) and conflicts with patient children as a sub-factor of clinical practice stress ($\beta = -.226, p = .019$), as shown in Table 4.

Table 4. Factors influencing clinical competency
(n = 91)

Variables	B	SE	β	t	p
Constant	2.700	.414		6.526	<.001
Clinical practice satisfaction	.416	.090	.439	4.617	<.001
Conflicts with children patients	-.185	.078	-.226	-2.383	.019
Adj. RI = .303, F = 20.606, p < .001					

Discussion

This study aimed to examine the effects of stress and satisfaction with pediatric nursing training on clinical competency in nursing students.

Stress during pediatric nursing training was significantly higher among fourth-year students, while satisfaction with training was significantly higher among third-year students. Considering that clinical stress tends to decline while satisfaction increases as students advance in years of study, our results seem to be attributable not to the difference in years of study but to the difference in the unit where the pediatric nursing training occurs, as third-year students undergo training in the nursery unit while fourth-year students undergo training in the pediatric ward.

The mean clinical training stress score was 2.25, which was lower than that found in Kim et al. [10] (3.16), Kim et al. [5] (3.33), Lee et al. [11] (3.49), and Yang [12] (3.6). Although these studies examined the entire clinical training experience, we limited our study to pediatric nursing training. In our study, satisfaction was the greatest with the courses, suggesting that clinical training involving pediatric patients is less stressful than caring for adult patients. Regarding the mean score for each domain, the score for clinical training environment was the highest and that for conflicts with pediatric patient was the lowest, which was consistent with the results of Yang [12]. Because environment is a major factor contributing to stress [13], clinical training environments should be improved to lower students' stress.

The mean score for clinical training satisfaction was the highest for courses and lowest for content. The high satisfaction with courses is consistent with the finding of Lee et al. [7], and the low satisfaction with content (caring for children) is consistent with the results of Lee et al. [7], Kim et al. [14], and Lee [15]. Therefore, to enhance the content of clinical training, it is necessary to provide opportunities for students to perform problem-focused nursing, as opposed to simple and functional activities.

There were no statistically significant differences in clinical competency during pediatric nursing training according to sex. There were both reports that male students show higher clinical competency than female students [16-18] and that there are no differences by sex [10,19]. Our results may be influenced by children's familiarity with female students, but further studies are needed of sex-specific differences in clinical competency. In terms of the domains of clinical competency, professional development was rated the highest, which is consistent with previous findings [9,16-17,19]. However, unlike previous studies, where comprehensive nursing was rated the lowest [9,16-17,19], teaching/collaboration was rated the lowest in our study. This seems to reflect the recent advances in the clinical teaching environment, whereby comprehensive nursing is faithfully applied.

Clinical competency during pediatric nursing training had a significant negative correlation with clinical training stress and a significant positive correlation with clinical training satisfaction; clinical training stress and clinical training satisfaction were significantly negatively correlated. This suggests that students demonstrate increased clinical competency with decreasing clinical training stress and increasing clinical training satisfaction during pediatric nursing training, which is in line with previous findings^[9,20].

In our study, stress from conflict with pediatric patients and clinical training satisfaction during pediatric nursing training were identified as factors that affect clinical competency, and they explained 30.3% of the variance. This suggests that methods to lower stress while boosting satisfaction should be included in measures to promote clinical competency during pediatric nursing training.

Conclusion

The goal of clinical nursing training is to boost nursing students' clinical competency, so clinical training is a core component of nursing education. Nursing students' stress and satisfaction with clinical training transcend the psychological dimension; they show how supportive the training environment and role have been, and a quality clinical training experience helps students demonstrate their competency in the corresponding nursing practice following the completion of education.

Our findings showed that lowering stress and increasing satisfaction during pediatric nursing training are an important target to promote clinical competency, so subsequent studies should examine this in relation to various forms of training education

Development Strategy for National Fitness Award 100 via comparison and Analysis of the Korean Government's Health Policy Projects

Mi-Suk Kim¹, Sang-Wan Jeon²

¹Senior Researcher, Korea Institute of Sport Science, Korea Sports Promotion Foundation, Korea,

²Doctor, Department of Exercise Rehabilitation & Welfare, Gachon University, Korea

Abstract

Background/Objectives: This study aims to offer development strategy for public policies to be implemented more efficiently by conducting comparative analysis of the Ministry of Culture, Sports and Tourism's (MCST's) National Fitness Award 100, Korea's iconic health policy project, with the Ministry of Health and Welfare's (MOHW's) Integrated Health Promotion Program.

Methods: Content analysis was used to compare and analyze the materials on health policies and a group of experts were brought together to devise differentiated development strategies for National Fitness Award 100.

Findings: First, systematic foundation enabling the sharing of professionals, facilities and programs should be built through law revision. Second, a system should be in place to cooperate with relevant agencies dealing with health policies. Third, programs for physical activities should be developed and advanced. Fourth, the participant target should be expanded so that the project can become the foundation of lifetime physical activity. Fifth, promotions and campaigns to facilitate the program should be conducted to attract citizens to National Fitness Award 100.

Conclusion: National Fitness Award 100 program can become a differentiated project through legal revisions and operation system building for the cooperative operation of health policy projects.

Keywords: Health policy project, National Fitness Award, Integrated Health Promotion Program, Development strategy

Introduction

According to the recently announced demographic structure data of Korea, the median age is to increase from 40.9 in 2015 to over 50 in 2033, and even further to 58.7 in 2065, while the aging index will exceed 100 in 2017 and multiply by 4.4 times to 442.3 in 2065^[1].

Such an escalation in the elderly population will boost the overall chronic disease prevalence rate, thereby pushing up the medical expenses of the senior population

and having an absolute impact on the national medical expenses^[2]. This causes an anxiety over social finance.

Above all, Organization for Economic Co-operation and Development's (OECD's) member average of annual medical expenditures were 3.6% in 2003-2009 and 1.4% in 2009-2016. On the contrary, Korea's corresponding figures were 8.5% and 5.7%, increments of 4.9% and 4.3%, respectively^[3], higher than the OECD average. The fact that Korea's health expenditures displayed an upsurge, going against the global trend^[4], exhibits the inevitability of the need to change and revise the current health policy.

The Korean government has shifted its health and medical policy direction from focusing on treatment to

Corresponding Author :

Sang-wan Jeon,

jsw3972@kspo.or.kr

disease prevention, legislated National Health Promotion Law and implemented health promotion projects since 1998 in order to contribute to national health promotion and expenditure reduction. Starting in 2011, it initiated National Fitness Award 100 under Article 16 Section 2 of the National Sports Promotion Act, and has been expanding the scope of health policies^[5]. Although the two projects differ in the drivers and competent ministries, they operate similar programs in detail such as fitness measurement, exercise prescription, sports classes, etc. with the purpose of promoting national health and fitness^[6], which are mostly pro bono with state funding^[5]. However, an issue was recently raised at the public project operation evaluation that government's investment in similar projects may lead to wasting the budget, calling for discussions among relevant government agencies about the operation and operational reexamination as the issue may hinder the efficient operation and sustainable and effective service for the citizens^[7].

Nevertheless, the controversies and criticisms of similar projects without in-depth and comprehensive analysis of the two projects may actually damage their purposes and values. Such problems may not only make it difficult for the agencies to run the projects but it may also be neglecting and countering the citizens' demands to achieve the fundamental purpose - personal health and happiness.

Therefore, the overlap or difference of the two projects should be judged only after comparing and analyzing them. This research conducts a comparative analysis of National Fitness Award 100, Korea's representative health policy project, and Integrated Health Promotion Program to overcome concerns and problems of overlapping projects and suggest development strategies that could boost the efficiency of government budget spending by allowing the projects to learn each other's strengths and expertise.

Method

1. Subject

This study selected the MCST's National Fitness Award 100, Korea's iconic health policy project, and the MOHW's Integrated Health Promotion Program as the subject according to the research objectives. Relevant reports and papers on the specifics of physical activity projects, meeting materials and activity report on policies and services, comprehensive communication documentaries provided on the websites of related agencies, etc. were collected for analysis.

2. Analysis methods

This research applied content analysis to compare and analyze the detailed project materials regarding physical activities in the National Fitness Award 100, Korea's iconic health policy project, and the Integrated Health Promotion Program. Content analysis, through which the information acquired indirectly on the subject is switched and computed, is useful to analyze secondary qualitative data^[8].

In addition, an expert group (experts on MOHW's Integrated Health Promotion Program policies (2), experts on MCST's National Fitness Award 100 policies (2), on-site experts (4), doctor and professor in public health (2), doctor and professor in physical education (2)) was organized to compare and analyze the two programs and formulate strategies to develop policies. From data collection to its interpretation, the experts discussed to come to a consensus in order to secure the objectivity and integrity of the data.

Result

1. Comparative analysis of National Fitness Award 100 vs Integrated Health Promotion Program

1-1. Project implementation basis and objective

The objective of National Fitness Award 100, based on National Sports Promotion Act Article 16-2, is to conduct sports-for-all activities and certification of fitness by encouraging citizens' voluntary participation in sports for all and supporting scientific fitness management. Integrated Health Promotion Program, based on National Health Promotion Act Article 6, Article 19, Article 19 of the Enforcement Decree of the same Act, Law for Community Health Article 9, aims to practice healthy life, prevent chronic diseases and manage health of vulnerable class^[9].

According to the analysis of project implementation basis, the two projects have different legal grounds: National Sports Promotion Act and National Health Promotion Act. While National Fitness Award 100 supports scientific fitness management and encourages sports-for-all participation through physical activity-oriented program operation, Integrated Health Promotion Program includes physical activities for health management as a part of its entire project.

1-2. Project progress

National Fitness Award 100 built a citizen fitness certification system in 2011 and ran a pilot version of national fitness certification program in order to support scientific fitness management and encourage participation

in sport for all by offering customized exercise prescription service and fitness promotion program. After switching to an official program, the participant range was expanded to senior citizens in 2013 and teenagers in 2014, thereby increasing the number of Citizen Fitness Assessment Centers constantly (43 centers as of 2018). In 2018, on-demand teams (2), National Fitness Award On-Demand Bus (1) and mobile sports activity certification affiliated with private app additionally began operation, extending the support for those marginalized from physical activities. On the other hand, Integrated Health Promotion Program initiated a pilot program at 18 public health centers in 1998, which expanded to all the centers across the country in 2005. Physical activity, in particular, began operation as an individual program of the Integrated Health Promotion Program for local communities in 2013-2015 and was created as a new area on the regional medical information system in 2016

1-3. Project target

National Fitness Award 100 targets youth aged 13 or older, adults and seniors, while Integrated Health Promotion Program is operated for all citizens from infants to the elderly, the disadvantaged group and multicultural families.

According to the project target analysis, the two projects appeared to be different because National Fitness Award 100 targets those aged 13 and over, while Integrated Health Promotion Program provides services to citizens of all ages. The latter, in particular, has a difficulty in drawing the youth because it conducts physical activity programs along with nutrition, anti-smoking, anti-alcoholism, etc. programs.

1-4. Standardization of operation process

As the operational process of National Fitness Award 100 is standardized, anyone who visits Citizen Fitness Assessment Centers will go through identical procedures. Such standardization of the process has been validated and applied via pilot programs and research on national fitness and health promotion that preceded National Fitness Award 100. The process was also standardized because it is important to constantly motivate citizens to take part in sport for all.

However, Integrated Health Promotion Program's operation process for physical activity program has not been standardized. Hence, it takes different forms according to the situations at the public health centers. Among fitness measurement, exercise prescription

and sports classes, the centers either select one or mix multiple services.

1-5. Professionalism of project contents

1-5-1. Professionalism of fitness measurement items and assessment criteria

National Fitness Award 100 categorizes its targets into youth aged 13 or older, adults and the elderly. The experts measure each group's fitness and develop as well as apply the required fitness items themselves. As fitness certification is conducted based on the fitness measurement results, the project guarantees the professionalism of the fitness measurement items and criteria, which are necessary for the scientific fitness management of the citizens, through an objective and valid procedures.

On the other hand, Integrated Health Promotion Program only provides guidelines based on study findings from Establishing Cut-off Point of Physical Fitness by Age in Early Childhood^[10], youth physical activity promotion system (PAPS) manual^[11], Korean national fitness assessment 2011^[13], etc.

1-5-2. Sports and fitness promotion class operation environment

National Fitness Award 100 has two exercise prescriptors and two fitness measurement staff with the state registered sport-for-all instructor certification working at each Citizen Fitness Assessment Center and requires by regulation that an exercise prescriptor has to participate in a fitness promotion class if in operation.

Integrated Health Promotion Program, however, is being operated without any standard in dispatching instructors. Citizen Fitness Assessment Centers were selected because they fulfill the sports facility requirements, enabling them to operate sports programs considering the participant needs. However, Integrated Health Promotion Program has a trouble providing programs according to the user needs because it did not have any facility standards related to sports classes.

1-5-3. Building system to share information and secure big data

National Fitness Award 100 has computerized and managed all the information acquired through the program including the fitness measurement results and assessment levels upon receiving the consent

to collection of personal information. However, as Integrated Health Promotion Program does not have a system in place to share information or secure big data, it cannot gather data to analyze an individual's continued fitness and health management as well as the mid- to long-term effect of the government investment.

2. Development strategies for National Fitness Award 100

2-1. Legal revisions to vitalize physical activities

Most exercise specialists currently working at public health centers vary in terms of the professional education they received on strengthening fitness and have different level of competencies according to the work environment and characteristics^[13]. On the other hand, National Fitness Award 100 specialists are qualified by the government, meaning they have the suitable expertise to teach physical activities. Furthermore, the obligatory regulation that they must be on site at all times enhanced the user safety and satisfaction, thereby boosting re-participation rate. As such, vitalizing physical activities is an important factor affecting health promotion, which is why these instructors should be utilized more widely. Moreover, the law should be revised so that facilities and programs, on top of the instructors, can be discussed for sharing and affiliation. Legal revision will lead to cooperative and affiliated health policies and programs, which will bring about positive effects, save the government budget and become an effective tool to utilize a wide pool of experts.

2-2. Cooperative system building to enable constant physical activity participation

Both programs are merely recommending all participants to work out in their daily lives at the moment. To resolve such issues, National Fitness Award 100 should take advantage of the fact that public health centers are highly accessible and advertise its programs there, while Integrated Health Promotion Program could be advertised through National Fitness Award 100's promotions and campaigns as they are comparatively more well known. In addition, since medical-based basic health examination and dietary consultation are available^[16], measures to prompt physical activities in a safe manner should be conceived

2-3. Development and advancement of physical activity programs

The major reason holding Koreans back from participating in physical or sports activities is lack of time^[14]. To minimize such problem in reality, the On-Demand program operated as a part of National Fitness

Award 100 should be expanded and a system to support the operation of integrated health management should be installed for venues that want to take part.

Meanwhile, the ministries should maintain and step up cooperation with the Ministry of Education to utilize the physical activity promotion system (PAPS) that was introduced to address youth obesity and strengthen fitness. They should also collaborate to advance the health management programs to render them fun and interesting by reflecting teenager characteristics. As the level of youth physical activities, arbitrated by social support, is relevant to those of parents and friends^[15], such factors should be considered when developing programs and devise strategies to constantly update the existing ones.

2-4. Expansion of targets

National Fitness Award 100 only targets citizens who are 13 years old and up, unlike Integrated Health Promotion Program, which provides the service to all nationals. The US and Germany offer President's Challenge and Sports Badge programs, which are similar to National Fitness Award 100, to citizens at the age of 6, while also operating programs for all age groups^[7] to encourage participation in physical activities according to the life cycle.

It is crucial for National Fitness Award 100 to expand its targets to under 13 as the participation in sports during childhood forms a lifetime exercising habit and a foundation for lifetime physical activities. It is also imperative to categorize subjects into more detailed groups in order to achieve its goals. Close cooperation with relevant agencies will be conducive to reducing operational costs for physical activities and maximizing the effect.

2-5. Promotion and vitalization campaign

National Fitness Award 100 consists of fitness certification and fitness promotion classes. The number of citizens participating in the fitness certification started at 4,583 in 2011 and recorded 211,807 in 2017, an increase of 50,685 compared to 2016. As for the fitness promotion classes, 1,250 took part in 2012 and grew to 9,492 in 2017, an increase of 1,928 year-on-year^[14]. As such, the participating population is growing by the year but is still very low when seeing the entire ratio. Therefore, it should attract more participants by collaborating with Integrated Health Promotion Program, which operates with a myriad of public health centers, a much larger number compared to the Citizen Fitness Assessment Centers, hold diverse events and provide various benefits (health mileage) to outstanding participants.

Conclusion

In a nutshell, legislative revision and establishment of operation system for cooperative operation of health policy projects will differentiate National Fitness Award 100. Moreover, such cooperative operation system will drive the development and advancement of the programs that could offer professional physical activity service, one that only National Fitness Award 100 would be capable of providing, resulting in high user satisfaction and motivating sustained physical activities. On top of this, continuing the strategic advertisement and campaign will also play a crucial role in building an environment where National Fitness Award 100 is more prevalent.

The Factors affecting Burnout of the Small and Medium Hospital Nurses

HyunMee Park¹, KyungSook Kim²

¹Head Nurse, Dept. of Nursing, Shihwa Medical Center, Korea, ²Associate professor, Dept. of Nursing, Namseoul University, South Korea

Abstract

Background/Objectives: The purpose of this study was to identify the factors affecting burnout among nurses in small and medium sized hospitals.

Methods/Statistical analysis: A Participants in the study were 200 nurses. As the instruments, a subscale of the Professional Life of Quality Scale and structured questionnaire on self-esteem and job satisfaction was used. Data were analyzed using descriptive statistics, and hierarchical regression.

Findings: The mean scores of burnout, self-esteem, compassion satisfaction, and secondary traumatic stress were 2.68 ± 0.63 , 3.48 ± 0.75 , 3.49 ± 0.68 , and 2.77 ± 0.53 respectively. And also, the mean score job satisfaction was 3.53 ± 0.57 . As a result of hierarchical regression analysis, Of the variables added in Model 3, only the reward system was a significant factor affecting burnout. Self-esteem, compassion satisfaction, and secondary traumatic stress were also statistically significant factors affecting burnout.

Improvements/Applications: The current study suggests that in order to solve the burnout of nurses, secondary traumatic stress should be alleviated, and the reward system in hospitals of Korea should be improved.

Keywords: *Burnout, Compassion satisfaction, Secondary traumatic stress, Self-esteem, Job satisfaction*

Introduction

A hospital is a place where various occupations provide medical services and are maintained by professional personnel. In health care environments, there is a growing interest in not only patient care but also service satisfaction and quality of care. Since nurses represent the largest number of staff in hospitals, efficient staff management for nurses is very important. According to the survey by Korean Hospital Nurses Association^[1], the average turnover rate of nurses was 16.8%, and the turnover rate of nurses in small and medium sized hospitals was higher than that of the upper grade general hospital. In upper grade general hospitals, the main causes of turnover were maladjustment, marriage, childbirth. But in small and medium hospitals,

turnover to other hospitals was the main cause^[1]. Hospitals with 200 to 300 beds have a poorer working environment and welfare benefits than upper grade general hospitals, and the high turnover rate of nurses causes the remaining nurses to become overworked. As a result, small and medium sized hospitals continue to lack nurse manpower^[2]. In addition, the overwork and stress of nurses remaining in hospitals can increase burnout.

Burnout is a form of reaction that occurs when one can no longer deal with stress, which causes negative self-concepts, work attitudes, and loss of interest in patients^[3]. This exhaustion can lead to decreased work motivation or work efficiency, which can increase the likelihood of causing medical accidents and lead to frequent absences and high turnover rates^[4].

Corresponding Author:

Kyung Sook Kim,
kgs4321@nsu.ac.kr

Compassion satisfaction is the pleasure of helping others, and it is a pleasant feeling that results from the goodwill of one's colleagues and the ability to help

others^[5]. People with high compassion satisfaction can reduce burnout by acting as a source of strength to continue working even if their work conditions are very dangerous or high in stress^[6]. Traumatic stress has a different response pattern depending on whether the stressor is primary or secondary. Secondary traumatic stress is an emotion that arises from knowing about a traumatic event experienced by another meaningful person^[7]. Lack of adequate treatment for these secondary traumatic stresses causes burnout^[8]. Nurses can experience secondary traumatic stress in contact with patients who have experienced traumatic events^[9].

Another factors affecting burnout is self-esteem. The higher self-esteem, the higher the organizational commitment and job satisfaction, and the lower the intention to turnover^[10]. Brouwers et al^[11] found that high self-esteem could be an effective means of preventing burnout in conflict caused by emotional labor. Jurado et al^[12] also found that the higher the self-esteem, the lower the burnout.

Job satisfaction is a positive influence on job performance as a positive attitude about the job ^[13]. In particular, the job satisfaction of nurses has a positive effect on the reduction of nurse turnover rate, patient satisfaction^[14]. Therefore, job satisfaction can be a factor of job involvement and motivation ^[15], and if job satisfaction decreases, burnout increases ^[16]. Therefore, this study was to identify the factors affecting burnout.

Method

The subjects of the study were two small and medium hospital nurses. To measure burnout,

compassion satisfaction and secondary traumatic stress was used Professional Quality of Life Scale(ProQOL-5) revised by Stamm^[17]. The tool was approved through the website, and the Korean version was used. The self-esteem scale developed by Rosenberg^[18] was used by Jon ^[19], a tool adapted to the Korean situation. The job satisfaction of nurses was assessed the Minnesota Satisfaction Questionnaire (MSQ) Short Form Korean Version developed by the Institute of Vocational Psychology Research at the University of Minnesota^[20]. The tools are composed of sub domain such as work itself, prospects, sense of achievement, reward system, and human relations.

All data were statistically analyzed using SPSS 23.0. Descriptive statistics, t-test, ANOVAs were conducted and hierarchical regression analysis identified the factors affecting burnout. All subjects completed the informed consent form and agreed to participate prior to administering the study. Participants also received information on this study including research aims, possible risks, and collection procedures.

Result

1. General characteristics of the subjects

The sample data consisted of 200 nurses, 11 males (5.5%), and 189 females (94.5%). Of the 200 nurses, 103 nurses (51.5%) did not have a religion, and 48.5% had a religion. Most participants worked 3 shift duty (121, 60.5%).The Burnout showed a statically significant difference according to age group ($F=7.138$, $p=.001$), religion ($t=2.441$, $p=.016$), working style($t=3.048$, $p=.003$) and position ($t=2.572$, $p=.012$).

Table 1. General Characteristics

Variables	Categories	N	%	Mean	SD	t/F(p)
Gender	Male	11	5.5	2.81	.73	.626 (.544)
	Female	189	94.5	2.67	.63	
Age group	21-30	104	52.0	2.82	.59	7.138 (.001)
	31-40	49	24.5	2.66	.69	
	More than 41	47	23.5	2.41	.57	
Religion	Don't have	103	51.5	2.79	.62	2.441 (.016)
	Have	97	48.5	2.57	.62	
Level of Education	College (3yr)	85	42.5	2.74	.63	1.088 (.278)
	University (4yr)	115	57.5	2.64	.63	

Cont... Table 1. General Characteristics

Working style	3 shift work	121	60.5	2.79	.65	3.048 (.003)
	Fixed work	79	39.5	2.52	.57	
Position	Staff nurse	156	78.0	2.74	.63	2.572 (.012)
	Head nurse or manager	44	22.0	2.47	.59	

2. Descriptive statistics and correlations

The mean scores of burnout, self-esteem, compassion satisfaction, and secondary traumatic stress were 2.68±0.63, 3.48±0.75, 3.49±0.68, and 2.77±.53 respectively. And also, the mean score job satisfaction was 3.53±.57 and work itself, prospects, sense of achievement, reward system and personal relations of sub domain were 3.67±.71, 3.40±.86 3.97±.73, 2.72±.68, 3.88±.78 respectively. Burnout was significantly negatively related to self-esteem (r= -.768, p<.001), compassion satisfaction (r=-.732, p<.001).

Table 2. Descriptive Statistics

Variables	Mean ± SD	Min	Max	Range
Burnout	2.68±.63	1	4.40	1-4.40
Self-esteem	3.48±.75	1.40	5	1.4-50
Compassion satisfaction	3.49±.68	1.60	5	1.6-50
Secondary traumatic stress	2.77±.53	1.60	5	1.6-50
Job satisfaction(total)	3.53±.57	1.75	5	1.75-5
Work itself	3.67±.71	1.50	5	1.50-5
Prospects	3.40±.86	1	5	1-5
Sense of achievement	3.97±.73	2.25	5	2.25-5
Reward system	2.72±.68	1	5	1-5

Compassion satisfaction	-.732**	.647**	1	
Secondary traumatic stress	.422**	-.308*	.799	1

**p<.001, *p<.01

3. Factors influencing the burnout of the nurses

The hierarchical regression analysis was conducted to examine the factors affecting burnout. Model 1 included religion, work style, position and age group. Model 2 added self-esteem, compassion satisfaction, and secondary traumatic stress to Model 1, and Model 3 added 6 subdomain of job satisfaction. Multi collinearity was found to be acceptable through tolerances and VIF. In Model 2, self-esteem, compassion satisfaction and secondary traumatic stress were found to be factors significantly associated with burnout. Theadjusted explanatory power was 77.1% and increased by 69.5% compared to Model 1. Of the variables added in Model 3, only the reward system was a significant factor affecting burnout. Self-esteem, compassion satisfaction, and secondary traumatic stress were also statistically significant factors affecting burnout. Theadjusted explanatory power was 79.0% and increased by 0.5%over Model 2.

Table 4. Factors affecting nurses' burnout

Discussion

The burnout experience of nurses not only harms their own health^[21], but also reduces the quality of patient care^[22]. Due to these problems, especially small and medium-sized hospitals with high turnover rates, should be concerned about burnout of nurses.

In present research, the level of burnout was 2.68 point (range 1-5) indicating a moderate level and it was similar to those of Lee's study^[23]. And also, compassion satisfaction, and secondary traumatic stress were similar to of Cho and Park's study^[24]. In addition, the average score of job satisfaction was 3.53 and the reward system had the lowest satisfaction level with an average of 2.72 among the sub scales. These results, the lowest scores in the reward system have been consistently

reported in most other studies measuring nurse job satisfaction^[25-26]. Moreover, the results showed that predictors of burnout were self-esteem, compassion satisfaction, and secondary traumatic stress.

Compassion satisfaction is an emotional reward that nurses can feel, and because it acts as a mitigating factor to reduce burnout^[6], it can be a fundamental factor to improve nursing services. Wagaman and his colleagues found that it was possible to increase empathy through education^[27]. Increased compassion satisfaction can be expected to have a positive impact on patient and hospital organization by increasing the quality of care. In order to increase nurses' empathy satisfaction, nurse' leaders should recognize the importance and impact of compassion satisfaction, and make efforts to increase the empathy satisfaction capability of nurses.

In order to decrease nurses' burnout, it is necessary to mediate factors such as secondary traumatic stress, low self-esteem and compassion satisfaction. Trauma can occur not only for individuals who have directly experienced a traumatic event (primary victims), but also for aid specialists who have been indirectly exposed to trauma while witnessing damage or providing assistance to the primary victim. Nurses who are in close contact with patients who are victims of various traumatic events may experience secondary traumatic stress^[28]. Increased secondary traumatic stress negatively affects a variety of physical and mental health^[29] and leading to increased burnout^[28]. Nursing managers should endeavor to reduce burnout by monitoring secondary traumatic stress.

Previous studies^[10,12] emphasized the importance of self-esteem as a variable to alleviate burnout, and this study supports the results. Lee and Hong^[30] reported that the higher the self-esteem, the more positive the thinking, the higher the achievement and life satisfaction. As a result, it is necessary to increase nurses' self-esteem to reduce burnout.

Of the subscales of job satisfaction added in Model 3, only the reward system was a significant factor affecting burnout. These results mean the importance of compensation as affecting factor for burnout. In the previous study, the rate of turnover was high when the salary satisfaction and job satisfaction of small and medium hospital nurses were very low^[16,26]. Therefore, it is necessary to increase the satisfaction level through appropriate compensation to small and medium hospital nurses.

Burnout is a topic that has been studied for a long time, but it is still an unsolved challenge. As the complexity of society changes, the influencing factor of burnout can also change. Therefore, it is necessary to reinforce the psychological capacity of nurses through educational programs for improving the awareness of individuals and hospital organizations. As a result, the factors affecting burnout were identified as compassion satisfaction, secondary traumatic stress, self-esteem, and reward system. Therefore, in order to reduce burnout of small and medium sized hospital' nurses, it is necessary to develop and apply an intervention program considering these factors.

This study was conducted for nurses working in two hospitals with less than 300 beds, so there are limitations to generalizing these results to all nurses. However,

this study suggests that in order to solve the burnout of nurses, compassion satisfaction and self-esteem should be improved, secondary traumatic stress should be alleviated, and the reward system should be improved. If the nurse managers such efforts, nurses working in hospitals with 200 to 300 beds will help improve their work motivation, provide high quality nursing services, and address the shortage of nursing staffs.

Conclusion

This study was attempted to examine the factors affecting burnout of nurses. The results of hierarchical regression analysis showed that the reward system, Self-esteem, compassion satisfaction, and secondary traumatic stress was a significant factor affecting burnout.

In order to resolve the burnout of a nurse, it should be a review of the compensation system. In addition, efforts to increase compensation satisfaction, self-esteem and to alleviate secondary trauma stress are needed.

Self-efficacy Mediating Effect in Health Communication Campaign

Jin-Woo Lee

*Professor, Dept. of Advertising & PR Namseoul University,
91 Daehak-ro Seonghwan-eup Seobuk-gu Cheonan Chungnam, Korea*

Abstract

Background/Objectives: This study reflects the unique characteristics of health communication, which is basically based on interactive interactions, and communicates the effects of unintended communication stress and self-efficacy.

Method/Statistical Analysis: The subjects were 295 male and female students attending four-year colleges. Of the 295 respondents, 161 males accounted for 54.6% of the total, and did not focus on specific genders. The mean age was 24.3 year for men and 22.6 years for women. And also for the self-efficacy mediation effect, in Baron and Kenny (1986), the mediation effect was verified through three regression analysis.

Findings: This study is the unintended negative effect that occurs in the health communication campaign. In this relationship between the health communication stress and the effect of the health communication campaign, the stress of the health communication campaign depends on the importance of the stress situation and the control ability. The effects of the health communication campaign appear differently depending on how large the self-efficacy is felt. As the self-efficacy of health communication campaign stress increased, the negative effect of health communication campaign stress on the health communication campaign effect was expected to be smaller. However, the expectation that self-efficacy would play a moderating role in the relationship between health communication campaign stress and health communication campaign effect was not supported but rather mediated. The greater the stress of the health communication campaign, the smaller the effectiveness of the health communication campaign was expected to be. The regression analysis showed that the health communication stress had a negative effect on the goodwill of the health communication campaign.

Improvements/Applications: The purpose of study is to identify the role of self-efficacy in health campaign stress and to reduce the health campaign stress when it becomes a health campaign.

Keywords: *Health Communication, Self-Efficacy, Stress, Health Campaign, Interactive Communication.*

Introduction

The key to researching health communication campaigns is to induce healthy behavioral change through

the efficient transfer of health-related information^[1]. The importance of communication behavior is important because it is the focus of communication for the study of health communication, because communication behavior causes positive or negative health behavior, and furthermore, communication behavior itself is the result of a positive/negative health condition. It should be emphasized^[2].

For example, when people see advertising communications about Starbucks, they can enjoy the pleasure of consumption. For smokers, however,

Corresponding Author:

Jin-Woo Lee

e-mail: winwin@nsu.ac.kr

quitting campaigns can be stressful as feelings of deprivation, although they may also consider the pleasure or benefits of quitting. In other words, health communication in the public sector, such as a smoking cessation campaign, may have unintended consequences of perceived deprivation of smoking opportunities even if it expresses “the pleasure of non-smoking” as a communication message. Because diseases that cause social illnesses, such as smoking, alcohol, drugs, and drugs, are hard to break when adopted by people forbidding them to use them can cause backlash such as depriving them of their enjoyment^[3]. Context of health communication campaigns are the boomerang effect, which implies the reaction of the audience against the intended response of the persuasion message^[4]. As such, health communication campaigns can result in unintended activation of social systems around them.

Communication stress is unstable due to unintended effects such as confusion, disharmony, boomerang, transmission of worry, loss of sensitivity, and reproof, resulting in unstable conditions and inducing negative advertising reactions, such as fear control reactions or ad meeting attention^{[4][5][6][7][8]}. In other words, even when stress occurs in the communication process, such as an imbalance may cause trouble, difficulty, pain, and fatigue^[9].

Self-efficacy is a belief in one’s ability to take and carry out a set of actions necessary to achieve a given goal, and is a concept that includes specific practical skills^[10]. Self-efficacy is also a conviction of one’s own ability in relation to the performance of a particular task, as well as practical skills, as well as the performance of tasks such as choice of behavior, effort and persistence^{[11][12][13]}.

Bandura’s theory of self-efficacy is based on Social cognitive theory as an explanation between cognitive belief and behavioral change^[14]. Social cognitive theory forms a single model that explains the relationship between past performance experience, self-efficacy, and personal performance^[15]. Looking at the relationship between health communication stress and self-efficacy, one can infer that people’s self-efficacy can play a role in controlling health communication stress. In other words, when a cause of stress occurs, people go through a process to reduce stress. In this process, individuals try to make manual or active control^[16]. In this active regulation, emotional and functional self-efficacy as a social psychological factor can affect the

level of stress by affecting the perception, interpretation, and response to problems^{[17][18]}. This study focuses on the communication stress of consumers, which can contribute to the improvement of the health communication campaign by identifying the unintended effects of the health communication campaign.

Method

The preliminary survey on five health communication campaigns, including cancer, influenza, blood donation, smoking cessation, and AIDS, was conducted for about a week. Determined whether or not. This study was conducted for three weeks based on the variables verified through these preliminary surveys. Hypothesis 1 is a hypothesis about the moderating effect of self-efficacy on the health communication campaign effect. The Intensity of maladaptation due to stress has been shown to be reduced by various buffer factors^[24]. In general, factors that act as stress buffers include personal resources such as internal and external control, self-esteem, and self-efficacy, and environmental resources such as positive social support and active participation in social activities. It is known to have a buffering effect^[25]. In particular, self-efficacy, which is a personal resource among stress buffers, is a factor that affects the behaviors we pursue and choose^{[12][19]}. Accordingly, we set the following hypothesis.

Hypothesis 1 As the self-efficacy for health communication campaign stress increases, the negative effect of health communication campaign stress on health communication campaign effect will be smaller.

Hypothesis 2 is a hypothesis about the effect of stress on health communication campaign on the effect of health communication campaign. Psychological stress means breaking an equilibrium state as an unpleasant emotional state that is assessed to threaten an individual’s well-being by exceeding an individual’s resources or ability to perform^[22]. Understanding stress from an interactive perspective means that stress is not just a stimulus and response but an influence between the individual and the situation^[26]. In general, stress causes negative emotions such as depression, triggers mental and physical diseases, and adversely affects mental health^[27]. Communication stress is an unintended negative effect of communication situations that leads to a negative perception of health communication^[4].

In other words, communication stress can lead to negative advertising reactions such as fear control

reactions and ad skepticism, resulting in unstable conditions beyond human coping limits^{[4][5][6][7][20]}. Avoiding complaints about TV campaigns can lead to poor TV campaign activity, leading to negative sentiment for TV campaign^[21]. For these psychological imbalances, people may perceive communication problems as they perceive difficulties, difficulties, pain, and fatigue^[9].

Hypothesis 2 The greater the stress of the health communication campaign, the less effective the health communication campaign will be.

The measurement of self-efficacy must be measured by a micro analytical approach that includes three dimensions: level, strength and generality^{[12][15]}. In the Table 1 below, the Counselor Activity Self-Efficacy Scale (CASES), which measures three types of self-efficacy: assistance technology self-efficacy, session management self-efficacy, and counseling difficulty self-efficacy.

Table. 1: Questionare of Self-efficacy

Category	Questionare
Exploration Technology	I understand the message that this health communication ad appeals.
	I can clarify the thoughts and feelings appealed by this health communication ad.
	I can understand clearly and concisely what this health communication ad appeals.
	I pay attention to what this health communication ad appeals.
Activity Technology	I can present or teach information about this health communication advertisement.
	I can tell others the suggestions, directions, and advice of behavior that this health communication ad suggests.
	I can watch this health communication ad and suggest some things to do and tasks for the future.

Stress is important in how subjective perception is perceived^[22]. Stress perception measures include behavioral stress in the physical stress of the CMI

(Cornel Medical Index). The communication ability scale was modified according to the research subject's situation. So, Stress Questionare is devided four factors. First, Body factors. The questionnaire is as follows: This health communication ad gets frustrating. This health communication ad will dry your throat or mouth. This health communication ad makes your eyes tired easily. This health communication ad makes me feel vomited. Second is Action factor. The questionnaire is as follows: This health communication ad increases the number of mistakes. This health communication ad increases the amount of alcohol you drink. This health communication ad immerses you in more than you need. And Psychological factor. The questionnaire is as follows: This health communication ad seems frustrating. Last Questionare factor is emotion. The questionnaire is as follows: If you look at this health communication advertisement, you might be easily excited or angry. This health communication ad depresses and depresses easily. This health communication ad is annoying to do something. The communication effect's communication ability scale was modified according to the research subject's situation. The communication effect is attractive Factor. The questionnaire is as follows:

This health communication ad is favorable. This health communication ad is beneficial. This health communication ad is attractive. I like this health communication ad. This health communication ad is amazing.

Result and Discussion

The subjects were 295 male and female students attending four-year colleges. Of the 295 respondents, 161 males accounted for 54.6% of the total, and did not focus on specific genders. The mean age was 24.3 year for men and 22.6 years for women.

In the Table 2, following is the correlation between the descriptive statistics and the composite variables of the composite variables created by the arithmetic mean of the response values for each construct and dimension.

Table 2: Descriptive Statistics of Main Variables

Variable	Item	Average	Standard Deviation	Male Average	Female Average	t-value
Stress	11	2.23	1.09	2.31	2.13	1.424
Self-Efficacy	6	5.01	1.28	4.84	5.21	-2.547**
Attractiveness	6	4.18	1.52	4.13	4.25	-.727

***: p<.01, **: p<.05

In the Table 3, Correlation was found to be significantly correlated between the dimensions that compose the same construct. Likely, the effect of communication, which is the dependent variable, showed positive correlation with self-efficacy.

Table 3: Correlation Analysis of Key Variables

Variable	Self-Efficacy	Attractiveness
Stress	-.250***	-.293***
Self-Efficacy		.381***

***: p<.01, **: p<.05

According to the below the Table 4, 5 the results show that the stress on health communication, the independent variable, is less influenced on the attractiveness of the health communication campaign, which is dependent on the third regression than on the second regression (β -.381, $p < 0.01$). .275, $p < 0.01$), and the conditions of mediating effects, indicating that self-efficacy had a mediating effect on the relationship between the health communication campaign stress and the effect of the health communication campaign^[23].

In the Table 6, to test hypothesis 2, the regression analysis of the health communication stress with the positive variable as the dependent variable showed that the health communication stress had a negative effect

on the good feeling ($\beta = -.381$). Hypothesis 2 that the effectiveness will be small is supported.

Conclusion

The purpose of this study is to investigate the health communication stress as an unintended effect generated when the health communication campaign is executed, and to contribute to the improvement of the health communication campaign.

Hypothesis 1 examines the effects of health communication stress perception and self-efficacy on the effectiveness of health communication campaigns. Specifically, as the self-efficacy for health communication campaign stress increases, the negative effect of health communication campaign stress on health communication campaign effect is expected to be smaller. This hypothesis is to find out the moderating effect of self-efficacy that induces stress not to be felt in the relationship between health communication campaign stress and health communication campaign effect. Three regressions were used to verify the mediating effect. As a result of regression analysis to verify the mediating effect, self-efficacy meets all the conditions of the mediating effect. In other words, it can be said that the higher the self-efficacy has the function of filtering the stress of the health communication campaign. These results indicate that self-efficacy plays a mediating role in the relationship between health communication campaign stress and health communication campaign effect. In other words, Hypothesis 1, which expected self-efficacy to play a moderating role in the relationship between health communication campaign stress and health communication campaign effect, was not supported. And also Health, disease, and health-related issues are a hot topic in various sectors of society, such as health care decision-making in public institutions such as the government, and private institutions such as hospitals and corporations. In other words, problems

related to health, disease, and medical care have a major impact on public well-being, and finding appropriate solutions to them is of concern to all members of society. Efforts have been made to utilize health communication as one of the appropriate solutions to this concern, and this research has been conducted as part of the effort. In other words, this study first examines the relationship between health communication and stress, a key factor in health, disease, and medical care.

The Dual Mediating Effects of Self-esteem and Hope in the Relationship between Boss's Incivility and Life Satisfaction

Yeoun Kyoung Hwang¹, Dong Hyun Yoon², Chang Seek Lee³

¹Professor for Academic Research, Multicultural Education and Welfare Institute, Hanseo University, ²Doctoral Student, Dept. of Public Administration, Graduate School, Kongju National University, ³Professor, Dept. of Health, Counseling and Welfare, Hanseo University, Korea

Abstract

Background/Objectives: The purpose of this study was to examine the double mediation effects of self-esteem and hope on how a boss's incivility affects life satisfaction in 339 Korean workers.

Method/Statistical Analysis: SPSS Win. 25.0 and PROCESS macro for SPSS version 3.4 were used for descriptive statistics analysis, reliability analysis, correlation analysis, and double mediation effect analysis.

Findings: First, Pearson correlation analysis showed statistically significant correlations between a boss's incivility, life satisfaction, self-esteem and hope. Second, PROCESS macro analysis showed that a boss's incivility negatively affected self-esteem and life satisfaction, self-esteem positively influenced hope and satisfaction with life, and hope positively influenced the satisfaction with life. Third, in the relationship between a boss's incivility and life satisfaction, self-esteem and hope were double-mediators.

Improvements/Applications: This result is expected to contribute to the formation of a new workplace culture in Korea as a new model in which self-esteem and hope mediate how a boss's incivility affects life satisfaction.

Keywords: *Boss's Incivility, Life Satisfaction, Self-esteem, Hope, Mediation effect, PROCESS macro.*

Introduction

Many companies around the world are concentrating on creating a good corporate culture in order to create a "workable workplace." Since the workplace is where hierarchies exist, it is necessary to form a smooth relationship between the supervisor and the subordinates in order to form a proper organizational culture, and the core of the relationship is 'incivility'. Nevertheless, research on this is not active in Korea,

perhaps because, even if the boss speaks unfairly in the organization, employees are allowed to implicitly avoid the response and are reluctant to expose it to the outside world^[1]. Incivility is a violation of mutually respectful norms, a weak robbery with no clear intention to harm others^[2]. Examples of incivility include criticizing others, spreading negative stories about others, checking on or e-mailing during meeting times, and publicly disparaging others. That is, incivility is a different concept from deviations, such as abuse, aggression, bullying, and mobbing. Already in 2010, the World Health Organization^[3] raised the severity of incivility-related issues in most organizations around the world, especially the physical and mental problems caused by incivility in the workplace.

Incivility in the workplace is important because incivility may seem seemingly mild, but it causes severe stress on the victim^[4] and harms the physical

and psychological health of the individual, because it tends to spread quickly within organizations as if it were transmitted^[2]. This is called the organizational incivility spiral, and victims of incivility develop negative emotions, revenge, and aggression, which sometimes leads to intense violence and aggressive behavior beyond incivility^[2]. In particular, contact with the boss is avoided in the course of performing the job, and the boss is the most influential person in the workplace^[5]. Since the findings suggest that incivility offenders are three times more likely to be in a higher position than victims^[6], it is worth paying attention to superior's incivility.

Office workers' incivility is closely related to life satisfaction, and workplace incivility decreases employee satisfaction with life^[7], and the incivility and psychological well-being are negatively interrelated^[8]. Life satisfaction is a very subjective value judgment and the feeling of fullness in daily life^[9] and is defined as the satisfaction and dissatisfaction with life, happiness, unhappiness, and feelings of individual well-being^[10].

The variables expected to pass through the incivility and life satisfaction paths of the superior are self-esteem and hope. Self-esteem is related to a positive or negative evaluation of one's own self and to the degree of respect for oneself^[11]. Self-esteem has been proven numerous times to be a powerful variable influencing life satisfaction^[12-14]. People with high self-esteem are satisfied with themselves, because they see themselves as valuable and capable, whereas those with low self-esteem are not satisfied with themselves because they are valued and incapable. In particular, workers with high self-esteem had positive feelings about their jobs^[15] and had higher job satisfaction than did those who did not^[16]. The incivility of the boss is based on the subjective judgment that the victim feels. Therefore, the self-esteem of office workers is thought to mediate between the incivility and life satisfaction of supervisors.

Hope, on the other hand, is a positive characteristic that contributes to an individual's setting and pursuing goals^[17], an agency thinking that leads to motivation and pathways thinking that leads to the perception of the ability to create a variety of pathways to achieve that goal^[18]. People with high hopes are less depressed, more active, and more confident and challenging to achieve their goals^[19]. In addition, even if they face difficulties, they focus on achieving their goals and synchronize themselves, which lowers their negative emotions and

increases their life satisfaction^[20]. In Korea, there was a positive correlation between hope and life satisfaction^[21], and among the predictors of happiness, self-esteem had the highest relative influence, followed by hope^[22]. It was demonstrated that hope is closely related to life satisfaction.

There are some accumulated studies that analyze indirect effects using self-esteem and hope as mediators. Specifically, self-esteem had a mediation effect on the relationship between stress and adaptation to school life^[23], and between parental abuse and school violence^[24]. Hope also mediated the relationship between job stress and happiness^[25], between efficacy and adaptation of migrant women^[26], and between parenting stress and child happiness^[27].

Therefore, this study aimed to examine the dual mediation effects of self-esteem and hope on the effect of a boss's incivility on life satisfaction, and to provide a new model for improving the satisfaction with life for employees.

Method for Research

- 1. Model for Research:** This study used model 6, a serial mediating-effect analysis method of PROCESS macro ver. 3.4. The research model was set based on previous studies is shown in [Figure 1].

Figure 1. Conceptual Research Model

- 2. Survey subject and data collection method:** The subjects were 339 people in D city in Chungcheongnam-do. The subjects were 173 women (51.0%) and 166 men (49.0%). The ages were 45 (13.3%) in their 20s, 128 (37.8%) in their 30s, and 166 (49.0%) in their 40s or older.
- 3. Research tools**
 - (a) Boss's Incivility:** The incivility of the superiors was measured by modifying and supplementing some items in the organization-incivility scale of Cortina et al.^[28]. This measure is a total of

five questions, and each item was converted to a 5-point Likert scale, and the higher the score, the more the incivility of the boss was experienced. In this study, the superior-incivility reliability of Cronbach’s α was .907.

- (b) **Self-esteem:** Self-esteem measurements were taken from Rosenberg^[29]. This scale consists of a total of 10 questions and a 5-point Likert scale. The higher the score, the higher the level of respect for self. In this study, the reliability level for self-esteem was Cronbach’s α of .826.
- (c) **Hope:** Hope was measured by the scale of Snyder et al.^[30] revised and validated for Korea by Choi et al.^[31]. This scale is composed of four agency thinking and four pathways thinking. In this study, the reliability of the hope Cronbach’s α was .889.
- (d) **Life satisfaction:** Life satisfaction was measured using three items of life satisfaction among the short-term happiness scale (COMOSWB) developed and validated by Seo and Koo^[32]. Each item measures the satisfaction with life in personal, relational, and group aspects. It uses a 7-point Likert scale. The higher the score, the higher the satisfaction with life. In this study, Cronbach’s α was .874.

4. **Data Analysis:** SPSS PC + Win. 25.0 and SPSS PROCESS macro 3.4 were used to analysis descriptive statistics, frequency analysis, reliability analysis, correlation analysis, and mediation effect analysis.

Results and Discussion

Table 1. Correlation and Descriptive Statistics

	Boss’s Incivility	Life Satisfaction	Self-esteem	Hope
Boss’s Incivility	1			
Life Satisfaction	-.323**	1		
Self-esteem	-.291**	.466**	1	
Hope	-.212**	.498**	.683**	1
M	2.353	4.184	3.597	3.545
SD	1.066	0.867	0.498	0.540

**p < .01

1. **Correlation and descriptive statistics:** We used Pearson’s analysis to find the correlations between variables. The result is shown in [Table 1]. There was a statistically significant correlation between each pair of variables. There was a statistically significant relationship between life satisfaction, self-esteem, and hope, but a negative relationship with superior incivility. The mean of self-esteem, hope, and life satisfaction (7-point scale) exceeded the middle score, but the incivility mean of the boss was less than the middle value.

2. Model Verification:

Verification of multiple mediation effects: In order to verify the dual mediation effects of self-esteem and hope between boss’s incivility and life satisfaction experienced by office workers, we analyzed the model number 6 of the PROCESS macro for SPSS. We used bootstrapping to verify the mediation effects. We set up 5,000 samples and set the confidence interval to 95%. The analysis results are shown in [Figure 2] and [Table 2].

First, the incivility of the superiors in the mediating model had a negatively significant effect on self-esteem ($\beta = -.1361, p < .001$), but not the hope ($\beta = -.0073, p > .05$). Self-esteem had a significant positive effect on hope ($\beta = .7366, p < .001$). In other words, experiencing the boss’s incivility in the workplace not only negatively affects the worker’s self-esteem, but also lowers the hope by the lower self-esteem.

Second, the incivility of superiors in the dependent-variable model had a statistically significant negative effect on life satisfaction ($\beta = -.1626, p < .001$), but self-esteem ($\beta = .3144, p < .01$) and hope ($\beta = .5328, p < .001$) had a significant positive effect on life satisfaction. This suggests that incivility in organizations decreases employees’ satisfaction with life^[7] and has a negative relationship between incivility and psychological well-being^[8].

Third, the total effect of the path between the boss’s incivility and life satisfaction was $\beta = -.2627 (p < .001)$, but when the parameters were introduced, the direct effect of the path between the boss’s incivility and life satisfaction decreased to $\beta = -.1626 (p < .001)$; therefore, self-esteem and hope double mediated the relationship between superior incivility and life satisfaction.

Fourth, the magnitude of the overall indirect effect was -.1001 in the relationship between supervisor’s

incivility and life satisfaction, which was significant. In addition, M1 was -.0428, and there was no '0' in the 95.0% confidence interval. M2 was -.0039 with '0' in 95% confidence interval, so there was no mediation effect. As a result of verifying the size of the dual mediation effect, M1 & M2 is -.0534, and there is no value of '0' in 95% confidence interval. Therefore, the dual mediation effects were verified.

Figure 2. Effect size for each path

Conclusion

This study was intended to investigate the dual mediation effects of self-esteem and hope on the effects of supervisor's incivility on life satisfaction in Korean office workers.

First, according to the Pearson correlation analysis, superior incivility was negatively correlated with life satisfaction, self-esteem and hope, and life satisfaction, self-esteem, and hope were positively correlated.

Second, as a result of analyzing the mediation effect, the incivility of the boss had a negative effect on self-esteem and life satisfaction, and self-esteem had a positive effect on hope and life satisfaction. Hope also positively influenced life satisfaction.

Third, by bootstrap, we found a dual mediation effect of self-esteem and hope on the relationship between incivility of superiors and life satisfaction. In other words, the incivility of supervisors experienced by office workers directly affects life satisfaction, but it also affects life satisfaction through dual mediation of self-esteem and hope.

This study verified the theoretical validity of incivility, which is still in the early stages of research, by analyzing the dual mediation effects on the relationship between supervisor's incivility and office workers' life satisfaction. On the other hand, by empirically analyzing the dual mediation effects of self-esteem and hope, we identified the paths that affect life satisfaction when experiencing the incivility of the supervisor. Therefore, it is necessary to develop and apply an effective worker program that can increase self-esteem and hope, which have been proven to be mediators. In addition, incivility is likely to occur in organizations consisting of two or more people. Therefore, incivility research, which is focused on service occupations, should be expanded to more diverse subjects.

Study on Minimum Transmission Dose for Establishing X-Ray Imaging

Sinyoung Yu

Doctoral Course, Far East University, Department of Health Science, Graduate School, Korea

Abstract

Background/Objectives: When acquiring medical images using X-ray, optimal medical imaging quality must be achieved with minimal exposure of the x-ray generator.

Method/Statistical Analysis: The experiment was conducted based on the exposure conditions that are mainly used in the clinic. The exposure conditions of Hand, Skull, and Chest examinations were determined as the test subjects, and X-Rays were exposed to each partial phantom. The original data was obtained by exposing X-Rays three times for each phantom, and the values of the pixels were analyzed using the Image J program.

Findings: As the transmitted dose increased, the pixel value increased in proportion to the average intensity. As the X-ray exposure conditions were reduced, the maximum, minimum, and average values of the entire pixel were lowered. In step 1, which is the basic exposure condition of Hand, the average value of all pixels was reduced from 818.311 in step 5, which was the lowest exposure condition. Similar reductions were observed in the skull and chest exposure. When the pixel value is viewed as the transmitted dose value, it is confirmed that the pixel value of the image reflects the transmitted dose value. Signal-to-noise ratios varied with exposure conditions.

Improvements/Applications: These results alone made it difficult to find the optimal transmission dose for making images. Additional measurements of the doses exposed at each step will yield better results. Later we will continue to study through more diverse and accurate experiments.

Keywords: *Pixel value, Radiation dose, Transmission dose, Exposure dose, Histogram.*

Introduction

The use of medical radiation can benefit society as well as patients. However, inadequate use of radiation can pose a risk to the patient. Therefore, proper protection and management of medical radiation has been proposed. The principle of medical radiation shielding lies in the justification and optimization of actions^[1-2]. Justification is determined by careful judgment when the

benefit of the purpose of the test can be obtained more than the damage to the patient due to the radiological test^[3]. And optimization is to keep the exposure dose as low as possible while obtaining optimal results from radiography applied to the patient. Radiologists who use medical radiation to examine patients will need ongoing effort and research^[4-5].

In addition, due to the accident of a nuclear power plant, the public's interest in radiation is increasing and anxiety is rising. The radiologist is an expert in the field of radiation, and it is desirable to use the radiation as safely as possible and to reduce the exposure dose to the patient to solve the anxiety caused by the test^[6].

X-ray is a non-invasive technique that provides image information in the human body, and is currently a

large part of the medical imaging field^[7-8]. Since the use of X-rays is indispensable for the diagnosis of diseases in the human body, optimal medical image quality need to be obtained with minimal exposure of the X-ray generator when acquiring medical images^[9-10].

Digital X-ray equipment has a broader range of dynamic range and linearity of dose than film-screen system, and this reduces the resampling rate and enables consistent image quality through adjusting the gray scale.

However, since the image quality can be maintained even when excessive dose is used, efforts are needed to reduce the radiation dose of patient by radiologist, and related studies and research on the improvement of the performance of the digital detector for dose reduction have been continuously reported^[11].

Therefore in this study, we will analyze some conditions of x-ray examinations currently used in the clinic and examine how the image quality deteriorates as the exposure conditions are lowered^[12]. In addition, the goal of this study is to find the exposure conditions that can be inspected without degrading the image quality while decreasing the exposure conditions step by step.

Method

The subjects were the exposure conditions of Chest, Hand and Skull that are currently used in the clinical trial. The standard was used as the exposure conditions that are commonly used, and the experiment was performed by reducing kVp and ma in five steps. Subject to be imaged for each exposure condition was used as a Kyotokagaku body phantom PBU-50. The equipment used in the study was DR-GEM GXR-C40SD X-ray. Raw data of the image obtained as a result of the test was obtained and analyzed by Image J program.

In order to see the reproducibility of the x-ray equipment before the experiment, 10 x-ray exposures were performed without a phantom in a 35 * 35cm field.

All 10 times were set as the same exposure condition. The purpose of the Image J program is to determine the mean, standard deviation, and to determine whether similar values are produced under the same exposure conditions.

Original images are obtained under five exposure conditions using the human body phantom of Chest, Hand and Skull. Analyze raw data using Image J program. Set the part with phantom as the region of interest and the part without phantom in the background and measure it.

Hand exposure condition 1 is 50kVp 100mA 5mAs. Hand exposure condition 2 is 48kVp 100mA 4mAs. Exposure condition number 3 is 46kVp 100mA 3.2mAs. Exposure condition number 4 is 44kVp 100mA 2.5mAs. The final exposure condition number 5 is 42kVp 100mA 1.6mAs. The original data is obtained by exposing three times for each exposure condition.

Skull exposure condition 1 is 70kVp 200mA 12.8mAs. Skull exposure condition 2 is 65kVp200mA 10mAs. Exposure condition number 3 is 60kVp200mA 8mAs. Exposure condition number 4 is 55kVp200mA 6.4mAs. The final exposure condition number 5 is 50kVp200mA 5mAs. The original data is obtained by exposing three times for each exposure condition.

Abdomen exposure condition 1 is 85kVp 200mA 32mAs. Abdomen exposure condition 2 is 80kVp200mA 25mAs. Exposure condition number 3 is 75kVp200mA 20mAs. Exposure condition number 4 is 70kVp200mA 16mAs. The final exposure condition number 5 is 65kVp200mA 12.8mAs. The original data is obtained by exposing three times for each exposure condition.

Result and Discussion

The results of the first reproducibility test showed no significant difference in all 10 times [Figure 1]. Therefore, the reproducibility of the equipment was determined to be reliable.

Figure 1. Reproducibility test

The results under Hand and abdomen exposure showed that the average value of all pixels decreased as the dose decreased. The average pixel value was reduced 33.42% when a 2 times the exposure conditions in the first time exposure conditions. When changing from exposure condition 2 to exposure condition 3, the average pixel value decreased by 55.42% based on condition 1. The change from exposure 3 to exposure 4 decreased 71.86% based on condition 1. In the last five exposure conditions, the average pixel value decreased by 85.35% based on the first exposure condition.

Even under abdomen exposure conditions, as the dose decreased, the average value of all pixels decreased. The average pixel value was reduced 20.77% when a 2 times the exposure conditions in the first time exposure conditions. When changing from exposure condition 2 to exposure condition 3, the average pixel value decreased by 39.00% based on condition 1. The change from exposure 3 to exposure 4 decreased 56.15% based on condition 1. In the last five exposure conditions, the average pixel value decreased 74.16% based on the first exposure condition [Figure 2].

Figure 2. Hand and Abdomen mean value

When visually assessing the five-stage image, the difference between the fourth and fifth exposure conditions of the hand was significantly different [Figure 3].

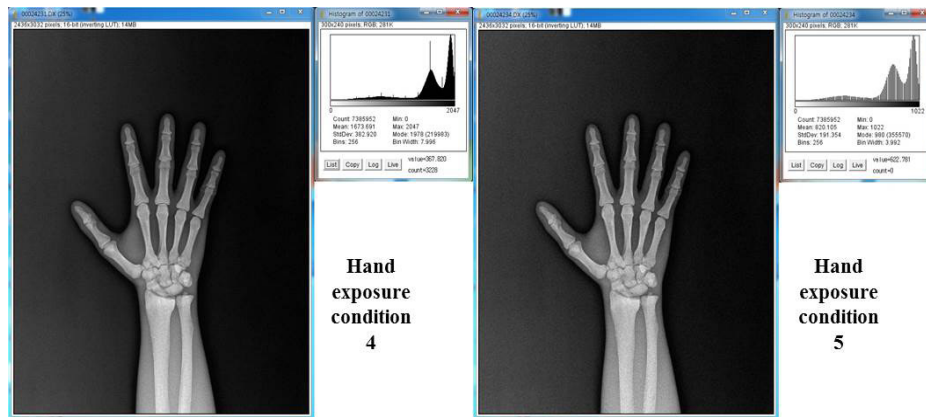

Figure 3. Visual evaluation of Hand images

When evaluated by visual observation of the image of 5 showed a definite difference between image Abdomen second exposure condition, and the third exposure condition [Figure 4].

Figure 4. Visual evaluation of Abdomen images

[Table 1] shows the skull exposure condition, as the dose decreased, the average value of all pixels decreased. The average pixel value was reduced 41.88% when a 2 times the exposure conditions in the first time exposure conditions. When changing from exposure condition 2 to exposure condition 3, the average pixel value decreased

66.58% based on condition 1. When changing from exposure 3 to exposure 4 it was 81.68% decrease based on condition 1. In the last five exposure conditions, the average pixel value decreased by 85.78% based on the first exposure condition.

Table 1. Skull exposure condition mean value

Exposure Condition	Mean Value	Percent Ratio
skull 1 (70kV 200mA 12.8mAs)	31310.00	100%
skull 2 (65kV 200mA 10mAs)	18195.17	41.88% decrease
skull 3 (60kV 200mA 8mAs)	10462.85	66.58% decrease
skull 4 (55kV 200mA 6.4mAs)	5733.41	81.68% decrease
skull 5 (50kV 200mA 5mAs)	4451.10	85.78% decrease

When visually assessing the five-stage image, the difference between the fourth and fifth exposure conditions of the Skull was significantly different [Figure 5].

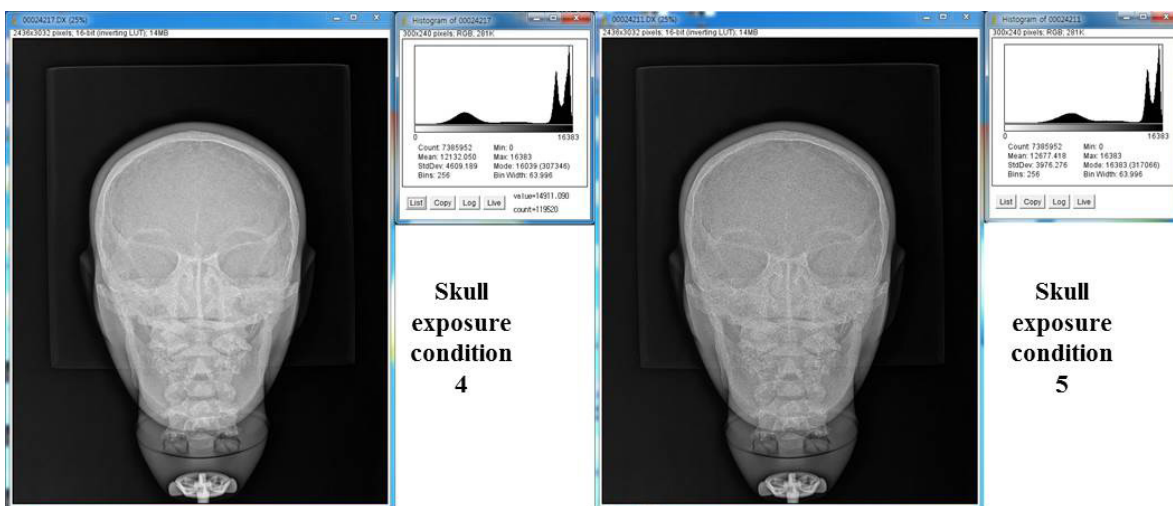

Figure 5. Visual evaluation of Skull images

Discussion

As a result of this study, it was confirmed that the pixel value decreased as the exposure dose decreased. It was also found that the value of the pixel reflected the amount of transmitted X-rays. In the case of the hand examination condition, it can be seen that the fourth condition is the most optimal condition in the visually determined image. In the abdominal examination condition, the second condition before the image suddenly deteriorated was the optimal condition to reduce and obtain the dose. In the case of Skull examination, the fourth condition was found to reduce the transmission dose and obtain a good image.

However, further experimentation will be required for these data to be reliable. The reduced transmission dose can be measured with a dosimetry to compensate for the reliability. In addition, more cases of data can be obtained to ensure the reliability of the data.

Conclusion

The X-ray ray imaging equipment used in the medical field differs from each manufacturer and the performance of each component, so the X-ray dose required to acquire an appropriate image is different. In addition, since the transmission dose is different for each site, it is necessary to adjust the exposure conditions.

When examining the change of the pixel value according to the change of the exposure condition, it was

found that the pixel value reflects the dose. In this study, the change of pixel value according to the change of exposure condition and percent reduction of pixel value by condition were analyzed and confirmed. When the image was evaluated by the pixel value and the naked eye, the fourth exposure condition in the Hand and the fourth exposure condition in the Skull were found to be good conditions. And in Abdomen, the second exposure condition was good. However, with these results alone, it is difficult to find the optimal transmission dose to make an image. I will continue to study through more accurate experiments later.

The Effect of Verbal and Non-verbal Violence Experienced at Clinical Training Institutions on Major Satisfaction of Dental Hygiene Students

Jung-Eun Ha¹, Ki-Hun Ye²

¹Professor, Department of Dental Hygiene, ²Professor, Department of Optometry, Baekseok University, South Korea

Abstract

Background/Objectives: This study investigated Department of Dental Hygiene students' experiences of verbal and nonverbal violence during their clinical training, and the effects of these experiences on their training site satisfaction and major satisfaction.

Method/Statistical Analysis: The present study involved 80 students of the Departments of Dental Hygiene of the B, S, and D Colleges in Chungnam who had experience of on-site clinical training. The subjects were asked to answer a questionnaire that included questions about their demographic characteristics, their experience of verbal and nonverbal violence. Independent samples t-test was used to analyze differences in clinical training satisfaction and major satisfaction between experience of verbal and non-verbal violence at clinical training sites.

Findings: Regarding the effect of experiences of verbal and nonverbal violence on the clinical training satisfaction, the clinical training satisfaction score was 2.95 out of 5 among the students who had experienced verbal violence, while it was 3.88 among those who had not experienced verbal violence. In addition, the clinical training satisfaction score was 2.85 out of 5 among the students who had experienced nonverbal violence, while it was 3.68 among those who had not experienced nonverbal violence. Regarding the effect of the experience of verbal and nonverbal violence on the major satisfaction, the major satisfaction score was 3.58 out of 5 among the students who had experienced verbal violence, while it was 4.05 among those who had not experienced verbal violence. In addition, the major satisfaction score was 3.33 out of 5 among the students who had experienced nonverbal violence, while it was 4.04 points among those who had not experienced nonverbal violence, indicating that the major satisfaction was higher in the students who had not experienced nonverbal violence, although the difference between the two groups was not significant.

Improvements/Applications: The results showed that a significantly high ratio of dental hygiene students had experienced violence, but that they had failed to react positively. Therefore, various efforts and countermeasures must be implemented to reduce the violence that may occur during clinical training.

Introduction

Violence in medical settings basically refers to violence occurring in a medical institution during the work time. It can include injury, assault, rape, and indecent assault, which are criminal offenses. Verbal abuse may be considered verbal violence in a broad sense. Violence in medical settings may be directed at patients or medical workers. In the case of violence directed

Corresponding Author:

Jung-Eun Ha

Professor, Department of Dental Hygiene, Baekseok University, South Korea

e-mail: hajungeun@bu.ac.kr

at medical workers, the attacker may be a patient, a caregiver, or a fellow medical worker. Violence directed at a fellow medical worker includes violence between physicians, nurses, and medical technicians, between nurses, and between physicians. Therefore, violence in medical settings can take various forms^[1].

The ratio of medical workers who have experienced violence in healthcare and medical settings has been increasing continuously over the last few years. A 2016 report about healthcare and medical workers revealed that 47.6% of workers in hospitals and medical institutions had experienced verbal abuse, assault, or sexual violence, with verbal abuse representing the highest rate (41.0%). The report also showed that in incidents of verbal abuse and assault, most of the attackers were patients, caregivers, physicians, or the workers' superiors.

Dental hygienist is the most common of the dental occupations in dental institutions^[2]. As dental hygienists' work requires close interactions with patients, caregivers, dentists, and their superiors, they are the most exposed to violence in dental settings. Experiences of violence in medical institutions have been known to cause post-traumatic stress disorder or emotional instability, with symptoms of avoidance, hyperarousal, sleep disorder, emotional paralysis, and dissociation, eventually resulting in an increase in reassignment or turnover^[3,4].

Students undergoing on-site training at dental institutions may also be subject to the violence described above. Healthcare and medical educational institutions provide students with on-site clinical training at actual medical institutions to help them develop relevant practical capabilities. The Departments of Dental Hygiene of four-year-course colleges that foster dental hygienists also let them participate in on-site clinical training programs for about one year to learn the actual tasks of dental hygienists and the work performed at dental institutions. In those dental institutions, violence may take place between dentists, dental hygienists, and nurse aids, as well as between patients or caregivers and the dental institution workers. Participating students who experience verbal or nonverbal violence feel anger, sadness, discomfort, and frustration^[5,6]. Moreover, these experiences may reduce their training site satisfaction and even their department satisfaction, causing them to discontinue their college life or to change majors.

This study investigated Department of Dental Hygiene students' experiences of verbal and nonverbal violence during their clinical training, and the effects of

these experiences on their training site satisfaction and major satisfaction.

Method

The present study involved 80 students (juniors and seniors) of the Departments of Dental Hygiene of the B, S, and D Colleges in Chungnam who had experience of on-site clinical training. [Table 1] shows the subjects' demographic characteristics. Their average age was 21.08 years. There were 69 female students (97.2%) and only 2 male students (2.8%). At the time of their clinical training, 39 (54.9%) of the respondents were sophomores and 32 (45.1%) were juniors or higher.

Table 1. Demographic characteristics of study subject

	N	%
Age	21.08±1.32*	
Gender		
Female Students	69	97.2
Male Students	2	2.8
Grade at the time of clinical training		
Sophomores	39	54.9
Juniors or Higher	32	45.1

* Mean and standard deviation

The subjects were asked to answer a questionnaire that included questions about their demographic characteristics (gender, age, and grade), their experience of verbal and nonverbal violence, the size of the hospital where their training was provided, the degree of verbal and nonverbal violence experienced, the attackers in the incidents of verbal and nonverbal violence, their clinical training satisfaction, and their major satisfaction. The subjects were asked open-type questions to allow them to describe their experiences of verbal and nonverbal violence. Data were analyzed using SPSS (Windows version 19, SPSS INC) program. Independent samples t-test was used to analyze differences in clinical training satisfaction and major satisfaction between experience of verbal and non-verbal violence at clinical training sites and the significance level was set at 0.05.

Result

As shown in [Table 2], 33 subjects (46.5%) had experienced verbal violence. With regard to the size of the hospital where the training was provided, 13 subjects (39.4%) had experienced verbal violence in university hospitals, 10 (30.3%) in dental hospitals, and 14 (42.4%)

in dental clinics, indicating that verbal violence had been experienced in dental clinics the most. In verbal violence incidents, the attackers had been dentists for 9 subjects (27.3%), dental hygienists for 23 subjects (69.7%), and patients or caregivers for 9 subjects (27.3%), indicating that in most verbal violence incidents, the attackers were the trainees' superiors.

Table 2. Subjects' experiences of verbal violence

	N	%
Experiences of verbal violence		
Yes	33	46.5
No	38	53.5
The size of the training hospital		
University hospital	13	39.4

Dental clinics	14	42.4
Attackers of verbal violence		
Dentist	9	27.3
Dental hygienists	23	69.7
Patients of caregivers	9	27.3

As shown in [Table 3], 22 (31.0%) of the subjects had experienced nonverbal violence. With regard to the size of the hospital where the training was provided, 4 subjects (18.2%) had experienced nonverbal violence in university hospitals, 6 (27.3%) in dental hospitals, and 13 (59.1%) in dental clinics, indicating that just like verbal violence, nonverbal violence had been experienced in dental clinics the most. In nonverbal violence incidents, the attackers had been dentists for 4 subjects (18.2%), dental hygienists for 15 subjects (68.2%), and patients or caregivers for 4 subjects (18.1%), indicating that in most nonverbal violence incidents, the attackers were the trainees' superiors.

Table 3. Subjects' experiences of nonverbal violence

	N	%
Experiences of non-verbal violence

Patients of caregivers	4	18.1

With regard to the effect of experiences of verbal and nonverbal violence on the clinical training satisfaction, [Table 4] shows that the clinical training satisfaction score was 2.95 out of 5 among the students who had experienced verbal violence, while it was 3.88 among those who had not experienced verbal violence, indicating that the training satisfaction was significantly lower in the students who had experienced verbal violence ($p = 0.007$). In addition, the clinical training satisfaction score was 2.85 out of 5 among the students who had experienced nonverbal violence, while it was 3.68 among those who had not experienced nonverbal violence, indicating that the training satisfaction was lower in the students who had experienced nonverbal violence, although the difference between the two groups was not significant ($p = 0.089$). With regard to the effect of the experience of verbal and nonverbal violence on the major satisfaction, [Table 4] shows that the major satisfaction score was 3.58 out of 5 among the students who had experienced verbal violence, while it was 4.05 among those who had not experienced verbal violence, indicating that the major satisfaction was significantly higher in the students who had not experienced verbal violence ($p = 0.026$). In addition, the major satisfaction score was 3.33 out of 5 among the students who had experienced nonverbal violence, while it was 4.04 points among those who had not experienced nonverbal violence, indicating that the major satisfaction was higher in the students who had not experienced nonverbal violence, although the difference between the two groups was not significant ($p = 0.079$).

Discussion

The present study was designed to investigate the verbal and nonverbal violence experienced by Department of Dental Hygiene students during their on-

site clinical training, and the effects of the experience of violence on the students' clinical training satisfaction and major satisfaction, in order to consider the violence experienced by students at dental institutions during their training and to offer them the necessary support. Most Department of Dental Hygiene students prepare themselves in their college to make sure they are equipped with the essential skills before undergoing on-site training at dental institutions. However, because students who are new to clinical settings are less experienced and lack the communication skills and empathy needed, they are less capable of forming relationships with dentists, dental hygienists, and patients. In addition, while students are continuously exposed to new environments as they frequently move between departments for training, they have little time to adapt. Therefore, students are particularly vulnerable to violence at clinical sites^[7].

The present study on the verbal and nonverbal violence experienced by Department of Dental Hygiene students showed that 46.5% of the students had experienced verbal violence during their clinical training and 31.0% had experienced nonverbal violence. The attackers in verbal violence incidents had most frequently been dental hygienists (69.7%), followed by dentists (27.3%) and others (27.3%). The attackers in nonverbal violence incidents followed the same prevalence order: dental hygienists (68.2%), dentists (18.2%), and others (18.1%). It is likely that dental hygienists were the most frequent attackers in both verbal and nonverbal incidents because they provide direct instructions and teachings to Department of Dental Hygiene students in dental institutions. The results of the present study also revealed that experiences of verbal and nonverbal violence had a significant effect on the clinical training satisfaction and the major satisfaction. The clinical training satisfaction and major satisfaction of the students who had experienced verbal or nonverbal violence were significantly lower than those of the students who had not experienced violence. These results are similar to those of previous studies that showed that the various types of violence experienced by nursing students at clinical training sites cause the students pain and may affect their attitudes toward the nursing profession they have chosen^[3-6]. Trainees exposed to violence may be negatively affected in their career identity due to the sense of isolation, stress, and negative impression of the organizations they may develop^[8].

Students participating in clinical training undergo on-site training as learning students. As their on-site roles are not as clear as those of the actual dental hygienists, their self-esteem and morale may be easily lowered by verbal violence. When facing violence, students show immediate emotional reactions in the following order: anger, shock, impression, sadness, anxiety, shame, helplessness, doubt of self-worth, desire to quit, and sense of loss. This indirectly reveals that students lack stress control skills and have difficulties communicating and expressing emotions. The negative emotions caused by the violence they experience may have a negative effect on their college curriculum, resulting in maladaptation to the dental hygienist profession. Therefore, from a mental health perspective, the effects of violence on individuals should never be underestimated. In particular, additional support needs to be provided to help prepare students for difficult situations and teach them to manage them^[9]. Keely argued that having sufficient knowledge and skills to protect oneself from violence may minimize the damage caused by violence at hospitals^[10]. This suggests that education to prevent violence is necessary. However, the online safety education provided to students focuses on the physical environment of clinical settings. Therefore, the regular curriculum also needs to include strategies to prevent and deal with violence in human relationships.

The orientation provided to the students before their participation in training must include information to understand the violence that can occur at clinical training sites and to identify the types of violence and how to report incidents. Students must be assured that they can receive ex-post supports such as counseling and reporting, and that incidents can be handled appropriately without causing them prejudice. In addition, the college training managers must evaluate the on-site training environments and communicate closely with the people in charge of the training programs provided at the institutions.

Conclusion

The present study investigated the verbal and nonverbal violence experienced by department of dental hygiene students during their on-site clinical training, and the effects of experiences of violence on the students' clinical training satisfaction and major satisfaction. The results showed that a significantly high ratio of dental hygiene students had experienced violence, but that they had failed to react positively. Therefore, various efforts

and countermeasures must be implemented to reduce the violence that may occur during clinical training.

The Claim State of Dental Institutions for Payment from the NHIC

Bo- Kyoung Oh¹, Eun-Mi Yoo¹, Min-Young Kim², Hye-Sook Choi³

¹Professor, Shingu University, ²Professor, Howon University, Dept. of Dental Hygiene,

³Professor, Kyungdong University, Dept. of Dental Hygiene, Korea

Abstract

Background/Objectives: This study was performed to identify the causes that affect care benefits expense claim work of dental health insurance to provide basic data on efficient dental health insurance claim.

Method/Statistical Analysis: The study was conducted in the survey of Korean dental medical institution workers. The chi-square test was conducted to analyse the difference according to the health insurance claim method and the difference in health insurance reception result. A logistic regression analysis was conducted to verify the factors affecting the charge of health insurance claims.

Findings: Compared to the case of the absence of a dental hygienist, in case of 2 people, the probability of being in charge of a claim increased by 8.275 times ($p = .001$), and in case that the number of dental hygienists is 3 people or more, the probability of being in charge of a claim increased by 5.524 times ($p = .005$). Compared to the case of 1-4 employees, in case of more than 10 employees or more, the probability of being in charge of a claim is reduced by 0.119 times ($p = .002$). In the work experience, the probability of being in charge of a claim in case of more than 5 years and less than 10 years was 1.505 times higher than in case of less than 5 years ($p = .001$), and that of the case of more than 10 years was 6.440 times higher ($p < .001$).

Improvements/Applications: The introduction of a qualification system for the dental health insurance claim professional can reduce the burden on insurance claims by dental institutions.

Keywords: Claim status, Dental institution, Health insurance, National Health Insurance, Korea.

Introduction

Health insurance system is a social security system that prevents an excessive burden on households due to disease or injury and ensures that appropriate medical services are provided and the people ordinarily pay an insurance fee, and the National Health Insurance Service that is the insurer manages and operates them and provides insurance benefits if needed [1]. The health

insurance system adopts a third-party payment system where the medical provider does not request the full cost of medical treatment to the medical consumer but request it to Health Insurance Review and Assessment Service. For the payment method for medical expense, both Fee-for-service that is to pay a medical fee by setting a price for each medical treatment provided by a medical provider and case-payment that is a system that bears a predetermined amount of medical expenses for some disease groups such as payment implants and payment dentures have been applied [2].

In Dental Health Insurance, with the start of tooth sealant in 2009, the attention and knowledge on the criteria for calculating care benefits expense are required according to that the insurance coverage of resin dentures, partial dentures, metal dentures, scaling, dental

implants, etc. has been expanded and the importance of knowledge about the criteria for calculating care benefits of dental insurance claimants has been reported [3,4]. The expansion of insurance coverage in dental health insurance has an effect on reducing the consumer's burden on medical use, which leads to an increase in medical consumption and it has a positive influence on dental management [5].

Although the importance of accurate claims in insurance claims by medical institutions has been emphasized through various studies [3,5-7] related to the claim actual status and knowledge level for care benefits expense of claim professional workforce, the error in application continues to occur due to the unskilled knowledge of the work related to the health insurance claim. Dental hygienists' understanding about the change of system according to expand the insurance coverage of dental health insurance and their accurate calculations regarding insurance claim affect the competitiveness enhancement of dental management and in a broad sense, the stabilization of insurance finances [8]. As the work importance of dental hygienists in charge of insurance claims is rising with the increase of the use of medical services due to the expansion of insurance coverage, alternatives on the provider side will be necessary for the quality of medical service and the efficient management of insurance claim work. Therefore, this study was performed to identify the causes that affect care benefits expense claim work of dental health insurance to provide basic data on an alternative for continuous and efficient dental health insurance claim professional workforce management.

Method

The study was conducted for 2 months from July to August 2015 in the survey of Korean dental medical institution workers. A total of 400 questionnaires were distributed and 333 questionnaires (83.3%) except for 67 questionnaires which had insufficient responses were analyzed. The questionnaires, which had a total of 23 questions, consisted of 8 general questions and 13 questions for the actual status of the dental health insurance claim. For the survey, the questionnaire was revised and supplemented after a preliminary survey with 20 questionnaires.

Statistical analysis was performed using SPSS WIN 21.0 program. The frequency and percentage of the subject's sociodemographic characteristics, the characteristics of medical institutions and the actual status of dental health insurance claims were calculated, and a chi-square test was conducted to analyze the difference according to the health insurance claim method and the difference in health insurance reception result. A logistic regression analysis was conducted to verify the factors affecting the charge of health insurance claims. The statistical significance level was set to .05.

Result and Discussion

The general characteristics of the study subjects are shown in Table 1. The occupation was dental hygienists 82.9% and nursing assistants 10.8%. The age was 59.4% under 30 years old, 28.2% under 30 - 40 years old. The work experience was 39.3% for less than 5 years, 31.5% for less than 5 ~ 10 years. The number of employees was 31.2% under 5 people, 42.6% under 5-10 people.

Table 1. General characteristics of the study subjects

Variables		N	%

	etc	1(0.4)	5(7.8)	
Total		234(100.0)	64(100.0)	

Table 3 shows that the results, as a result of analyzing the cuts field, cuts items, the main causes of cuts, and claims improvement according to differences in health

insurance claims method, it was analyzed that there was a statistically significant difference in the main causes of cuts and claims improvement.

A multivariate logistic regression analysis was conducted to analyze factors affecting the charge of claim work. (Table 4.) The status of the responsibility of health insurance claim work was statistically significant in the number of dental hygienists (2, 3 people or more), the number of employees (10 people or more), the claims amount (more than 9 million won), and the work experience (more than 5 years and less than 10 years, more than 10 years). Compared to the case of the absence of a dental hygienist, in case of 2 people, the probability of being in charge of a claim increased by 8.275 times ($p = .001$). In the work experience, the probability of being in charge of a claim in case of more than 5 years and less than 10 years was 1.505 times higher than in case of less than 5 years ($p = .001$), and that of the case of more than 10 years was 6.440 times higher ($p < .001$).

	≥10	6.44(3.33-12.45)	.000

Discussion

As hospital management deteriorated recently, the number of hospitals which rely on health insurance claims rather than non-payment medical treatment or surgery increased [9]. As the coverage of insurance benefits gradually increases by expanding the insurance coverage of tooth sealant, which was previously a non-payment treatment item, and applying the dentures, one-time tooth scaling a year, and dental implants of the elderly as insurance benefits, health insurance treatment is recognized as a factor that can enhance the competitiveness of dental management [10].

Whether or not the health insurance system has been satisfactory and there have been no financial problems should be reviewed and whether or not the finances were reasonably managed should also be reviewed [11]. Additionally, as there are also a number of difficulties related with health insurance in dental institutions [12], to compensate for this, institutional review should be made to ensure that health insurance claim work can be performed independently and professionally [13], by recognizing the need for professional claimants with whom the effectiveness of treatment can be increased in the clinic, and by cultivating medical treatment claim professionals who are dedicated to health insurance claims to enhance the quality of medical services through coordinating the workforce [14].

The study of Oh [15] that the reason for making the agency claim is due to the time loss and complicated administrative procedures experienced when making the exclusive claim. As noted in the study of Kim and Jung [13], it is necessary to cultivate medical treatment claim professionals who are dedicated to health insurance claim works in order to enhance the quality of medical services by recognizing the need for professional claimants to increase the efficiency of medical practitioners in the clinic, and by performing efficiently and effectively the medical insurance claim works which are currently requested at medical institutions, and reducing medical practitioners' treatment works.

Moreover, it is also needed to provide special expertise to dental hygienists because there are many views that dental hygienists are the most suitable people for the professional management of health insurance claim work and self-examination work in dental care institutions [16].

In terms of the claims improvement, in the Exclusive claim, 'education to enhance employees' skills' 37.6% and 'securing claim personnel and time' 23.4% were high. In the agency claim, 'simplification of claim and administrative procedures' 35.9%, and 'education to enhance employees' skills' 29.7% were shown high. This is the same result as the study of Yoo [4] that insurance claims were not made properly due to lack of time, workforce and lack of knowledge of health insurance in dental institutions. In the study of Park [17], it was described that dental clinics emphasized the need for systematic education of not only the claimants but also employees with explaining the difficulties of claim

works and health insurance-related education would help them execute their works.

As a dental health insurance claim work is not just a job, but establishes a credible trust with patients and provides medical services, and further affects hospital management performance, need for intensive insurance claim education is required^[17]. Thus, as dental hygienists are in a position to calculate accurately the medical expenses, the role of dental hygienists is emphasized to prevent any possible revenue cuts, and with awareness of the insurance fee system of dental hygienist, to claim promptly the medical services provided to patients by the hospital without errors and omissions^[18].

Therefore, as suggested in the study of Ahn^[19], it is necessary to consider being able to exert their abilities after employment in the hospital by selecting professional dental hygienists for dental insurance claims with introducing the dental health insurance claim professional qualification system as a national qualification system. The introduction of the qualification system can reduce the burden on insurance claims by dental institutions, and it is considered that the dental hygienists can exert their abilities to enter into the Health Insurance Review and Assessment Service later after building their clinical career as professional dental hygienists for dental insurance claims.

Conclusion

The introduction of a qualification system for the dental health insurance claim professional can reduce the burden on insurance claims by dental institutions. Furthermore, it is considered that the efficiency of claim work will be inclined if professional dental hygienists are actively made to work in the field of dental insurance claims. Therefore, a foundation for cultivating claim professionals should be established, and it is believed that, for this purpose, it is necessary to introduce a private-centered claim professional qualification system as a national qualification system.

Measurement and Analysis of Exposure Dose According to Radiological Survey Films of Dental Hygiene Students in Oral Imaging Practice

Kam Ji Young¹, Yamaguchi Tokutaro², Lim kun Ok³

¹Professor, Department of Dental Hygiene, SunMoon University, Asan, ²Professor, Department of Pharmaceutical Engineering and Biotechnology, Sun Moon University Korea, ³Professor, Department of Dental Hygiene, College of Health Science and Genome-based BioIT Convergence Institute, Sun Moon University, Asan

Abstract

Background: The class of oral imaging practice in undergraduate course of the department of dental hygiene is very important to enhance work performance of dental hygienists' radiologic examination after students graduate.

Method: We divided inside and outside of 8 exposure dosimeters into shielded ones and unshielded ones, performed irradiation 1,000 times, 2,000 times and 3,000 times respectively and compared and analyzed depth dose, shallow dose and accumulation dose.

Findings: The accumulation dose of shielded ones examined 1,000 times, 2,000 times and 3,000 times was 0.1 msv, which doesn't exceed 1 msv of normal person's dose limit and 50 msv of occupational dose per year by International Commission on Radiological Protection Recommendation. All of the examinations were safe results regardless of frequency, and when they were unshielded, it was 1.23 msv at 1,000 times of examination, 29.25 msv at 2,000 times and 40.26 msv at 3,000 times, which indicates the higher the frequency is, the higher the exposure dose, showing the importance of shield.

Improvement: We intend to provide a basic resource that in the undergraduate course of the department of dental hygiene, learning radiologic examination technique through actual mutual practice rather than pandom practice in the irradiation practice is more effective and safer.

Keywords: Department of dental hygiene, dental hygienist, oral imaging, examination practice, exposure dose, shield.

Introduction

According to Article 2, Clause 1, Section 6 of Enforcement Decree of the Act on Medical Articles, etc., dental hygienists can perform radiography for oral diagnosis at health agency or medical institution that has radiation generating device for diagnosis suitable for safety management standards^[1]. and the radiography at dental institution is mostly done by dental hygienists.^[2]

Kim^[3] claimed that dental hygienists play a main role at dental clinics as staff of radiography, and as the level of their knowledge and attitude is higher, the level of radiography defense behavior is higher. Lee^[4] revealed in the research on radiation safety management that the

level of knowledge about radiation safety management is higher, the level of the attitude and behavior is higher, and the level of the attitude is higher, the degree of behavior is higher in the relation among the knowledge, attitude and behavior of radiation safety management.

However, the use of radiation in the medical field provides critical benefits in diagnosis and treatment, but it can't be denied that there are damages caused by radiation exposure^[5].

The exposure by dental radiation is remarkably lower than other diagnostic medical radiographic inspections, but the frequency is very high^[6].

Therefore, when irradiation is done, the choice of radiation generating device and irradiation dose is needed according to the purpose, irradiated part, and patient's characteristics, and the understanding on the physical property of radiation along with the knowledge and experience required in the application to device and technique should be accumulated^[7].

The clinical performance ability, an important performance index of the dental hygiene education, is a critical part to evaluate the performance ability as a dental hygienist after a student graduates. The clinical practice education is an integrated form of all curriculums and becomes direct education for a dental hygienist's duty and responsibility by giving the behavior change in the knowledge, technique and attitude that a student acquires^[8].

Thus, this study is intended to reveal dental hygiene students obey safety levels of exposure dose, perform safety regulations, and the accumulation dose is safe in their performance as radiation workers, and to provide a basic resource that in the undergraduate course of the department of dental hygiene, learning radiologic examination technique through actual mutual practice rather than pandom practice in the irradiation practice is more effective and safer.

Method

- 1. Measurement tool:** We implemented an experiment using 8 personal exposure dosimeters offered by Seoul Radiology Services for research purpose from January 1 to March 31, 2019. After attaching each number to the exposure dosimeters for distinction in order to reduce errors during the experiment, we irradiated and performed a radiation exposure experiment using rootapex shooting equipment in the oral imaging laboratory of Sunmoon University.
- 2. Measurement method:** We measured the exposure dose by dividing the exposure dosimeters in the root apex shooting room inside the oral imaging laboratory of Sunmoon University into inside and outside.

The exposure dosimeters in the room were divided into 3 shielded ones and 3 unshielded ones, and 2 exposure dosimeters were set out of the door to find the amount of exposure dose out of the room with the doors closed during the X-ray irradiation.

Regarding the frequency of irradiation, the 3

exposure dosimeters inside of the room were divided into 1000 times, 2000 times and 3000 times for accumulation irradiation, and the exposure dose was measured in the exposure dosimeters with the irradiation completed by a professional interpretation company.

- 3. Analysis of date:** For the exposure dosimeters with the irradiation completed, we requested a professional interpretation company to compare and analyze exposure dose according to shielded and unshielded ones, and the frequency of shooting by dividing into depth dose, shallow dose and accumulation dose for precise analysis of exposure dose.

Result and Discussion

In dental medicine, radiographic inspection is useful in the diagnosis of oral diseases and the establishment of treatment plan, and as demands of orthodontics, denture and dental implant increase nowadays due to the improvement of income, the areas of radiographic inspection are expanded from intraoral radiography to external-oral radiography, panoramic radiography and digital radiography^[9].

Accordingly, the clinical practice education to reinforce the field performance ability of dental hygienists, which are oral health specialists, is essential. The clinical training of the department of dental hygiene curriculum is the process that students actually perform the theory and practice that they learn during the undergraduate course at the dental clinic. Through this clinical training education, students can form their occupational values and improve capability as an oral medical specialists^[10]. Yang and Moon^[11] reported in their research that when the satisfaction level of clinical training is high, autonomic and responsible learning is performed, along with effective and efficiency clinical training education.

This study experimented the actual accumulation exposure dose and the importance of shielding by repeating irradiation based on 1,000 times of irradiation done during the radiation practice process, and compared and analyzed whether the irradiation act and exposure dose during the practice sessions during undergraduate course are safe. The results are as follows.

- 1. Comparison of exposure dose levels according to irradiation accumulation frequency:** In the result of irradiation 1,000 times, 2,000 times and

3,000 times, the levels of directly irradiated shallow exposure dose are 1.22 msv, 32.98 msv and 43.18 msv respectively, and those of depth dose are 1.23 msv, 29.25 msv and 40.26 msv in the same condition. [Table 1, Table 2, Table 3].

2. Comparison of exposure dose levels according to shielding: In the result of comparing the change of accumulation exposure dose levels according to shielding at irradiation of 1,000 times, 2,000 times

and 3,000 times, when they were shielded, it was 0.1 msv according to irradiation frequency change, which indicates there is no change in levels, but there was a drastic change in the level of exposure dose when they were unshielded. In other words, the accumulation exposure dose irradiated 1,000 times was 1.23 msv, 2,000 times was 29.25 msv and 3,000 times was 40.26 msv, so as the frequency is higher, the levels of accumulation exposure dose are higher. [Figure 1].

Fig. 1. Comparison of the cumulative measurement result figures among the results measured by radiation under different shooting conditions

Table 1. Exposure dose investigated 1000 times in radiation with different filming conditions

	Shallow	Depth	Yearly accumulation
No shielding	1.22	1.23	1.23
shielding	0.01	0.01	0.01
outside	0.02	0.02	0.02

Table 3. Exposure dose investigated 3000 times in radiation with different filming conditions

	Shallow	Depth	Yearly accumulation
No shielding	43.18	40.26	40.26
shielding	0.01	0.01	0.01
outside	0.02	0.02	0.02

Nuclear Safety And Security reinforced the safety management system on frequent visitors such as radiation safety education, implement of medical examination and maintenance of radiation exposure dose record by reflecting opinions that it is necessary to improve the safety management system for frequent visitors of radiation management zones as it revised Nuclear Safety Act in April, 2016^[12-14].

Regarding overseas cases, International Commission on Radiological Protection recommends at ICRP 103 to classify the degree of risk of radiation work areas instead of classifying radiation workers and frequent accessors to maintain the management function for protection of radiation workers with occupational exposure, which means it recommends to reorganize radiation safety management system of frequent accessors by reflecting the degree of hazard of radiation access areas where students perform shooting practice^[15-16].

According to the recommendation of International Commission on Radiological Protection(ICRP 60), the limit of exposure dose of normal people at planned exposure situations is 1 mSv per year, and occupational exposure shouldn't exceed maximum 50 mSv for one year, and the exposure limit is average 20 mSv for five years^[17-18].

Therefore, workers who work in radiation controlled areas where medical radiologic equipment is operated are strictly managed by having them wear personal exposure dosimeter regardless of their work type^[19].

This study confirmed that the actual accumulation exposure dose occurring in the training process of undergraduate course is within the safety level in the experiment of accumulation exposure dose based on the actual radiation exposure amount of personal exposure dosimeter that students wear during the radiology practice course in accordance with the radiation safety system.

Conclusion

This study researched the exposure dose of dental hygiene students during the oral imaging clinical practice course. Due to the regulation of Nuclear Safety Act, undergraduate students are not allowed to shoot directly at the mutual practice, so they do pandom practice, and directly shoot at the clinical field after they graduate. Even though both supervisors and students must execute radiation safety education, and the oral imaging practice is done in the safe environment under the management supervision, accurate practice and training for radiography in the undergraduate course are needed to reduce unnecessary radiation exposure dose in the clinical field, so I did the experiment of exposure dose in order to confirm that the accumulation exposure dose shot at the pandom during the oral imaging practice is the safe level.

In addition, the experiment is done by being divided into shielding and unshielding to highlight the importance of shielding at the clinical practice and the clinical field.

The result shows that the accumulation dose of shielded ones examined 1,000 times, 2,000 times and 3,000 times was 0.1 msv, which doesn't exceed 1 msv of normal person's dose limit and 50 msv of occupational dose per year by International Commission on Radiological Protection Recommendation. All of the results were safe results regardless of frequency, and when they were unshielded, it was 1.23 msv at 1,000 times of examination, 29.25 msv at 2,000 times and 40.26 msv at 3,000 times, which indicates the higher the frequency is, the higher the exposure dose, showing the importance of shield.

The result of measuring exposure dose generating during the clinical practice shows that it is safe level to human body. The safety education for management of radiation exposure should be done from the school training courses to prevent radiation mistake or unnecessary radiation exposure. This study can be provided as a resource for revision of Nuclear Safety Act into actual irradiation for students to practice. Furthermore, there should be various comparison experiments and actual surveys on exposure dose based on the guidelines of dental clinicians' exposure safety management.

The Effect of Action Observation Training Combined with Intrinsic Muscle Stimulation on the Upper Limb of Function in Stroke Patients

Ha-Na Kim¹, Bo-Kyoung Song², So-Young Han³, Jung-Woo Jeong³

^{1 2 3} Doctoral Course, Graduate School, Kangwon National University, Dept. of Occupational Therapy, Republic of Korea

Abstract

Background/Objectives: The aim of this study was to investigate the effect of action observation training combined with intrinsic muscle stimulation intervention on the function of upper extremity in patients with stroke.

Method/Statistical Analysis: Twenty-two stroke patients were prospectively randomized to action observation training with intrinsic muscle stimulation group (N = 11) or action observation (N = 11). The upper limb of motor function and sensory function were evaluated before intervention, and intervention was performed 3 times a week, 40 minutes, 4 weeks, and the same evaluation was performed after intervention. The outcome measure was used by manual function test and sensory test.

Findings: The results of this study showed that there was a significant difference in the test within the group. There was statistically significant difference in manual function test and sensory test in the inter body test.

Improvements/Applications: This study demonstrated that action observation training combined with intrinsic muscle stimulation significantly improves the function of patients with stroke.

Keywords: Stroke, Upper extremity, Intrinsic muscle stimulation, Action observation, Sensory.

Introduction

Stroke is a sudden interruption of blood supply to a part of the brain owing to infraction or rupture of the blood vessels. It causes various impairments in physical, cognitive, or emotional functions [1]. Up to 80% of stroke survivors have upper limb dysfunction, and the burden of upper limb injury after stroke is still high. [2]. The recovery of the upper limb function of stroke patients is very difficult, most patients have limitations

in functional movements such as reaching, grasping, and ability to activities daily living. Each year after a stroke, upper extremity dysfunction is associated with the quality of life, anxiety, and prejudice of a health-related individual.[3]. Recovering upper limb function is considered to be a very important factor in improving occupation ability and overall physical abilities as well as activities daily living performances[4]. Therefore, many therapists have applied various neurological interventions for the maximal recovery of the upper extremity functions of people with hemiplegia. Including the promotion of alternative movements, aerobic exercise, somatosensory stimulation, action observation training, constraint-induced movement therapy, task-oriented training, bilateral arm training, brain stimulations, mental practice, mirror therapy, virtual reality etc.[5]. Movement and somatosensory awareness can be improved in a variety of ways, including techniques such as sensory

reeducation, tactile kinesthetic guiding, repetitive sensory practice or desensitization [6]. The intrinsic muscle of a hand is provided stability of the fingers, and the size and amount of muscle in the hand are small, but it generates a strong force equivalent to about 50% of the grasping strength of the hand [7]. Observation training is a method of repeatedly tracing an activity or activity performed by another person, or observing an activity or activity appearing in the image and imitating an observed activity or activity [8]. Action observation therapy facilitates physical training for motor memory formation and is based on mirror neurons, which were first described in monkeys [9]. In previous studies, action observation training using visual information to provide goal-oriented activities and motivational information has a positive effect on upper extremity function of stroke patients. In addition, intrinsic muscle stimulation by providing various sensory information also has a positive effect. However, there has been no research on the combination of motion observation through visual perception and intrinsic muscle stimulation training through somatosensory. The purpose of this study was to investigate the effect of action observation training combined with intrinsic muscle stimulation on the upper limb of function and muscle activity in stroke patients.

Method

1. Subjects: In this study, 22 patients who were admitted to B clinic in Gyeonggi province were randomly assigned to two groups. The specific criteria of the subject are as follows: (1) Adults receiving a stroke diagnosis from a rehabilitation doctor, (2) Shoulders and wrists, hand joints and painlessness, (3) Those who have no problem with visual perception, (4) Communication difficulties, (5) Those who have no problem with their visibility (4) Those who have voluntarily participated in this study with the consent

2. Materials:

(a) Upper limb of motor function: The Manual Function Test (MFT) was developed for the evaluation and analysis of hand, and upper limb dysfunction. A total of 32 items were examined. Three major areas were assessed for upper extremity function (4 items), gripping (2 items), and finger manipulation (2 items) [10].

(b) Upper limb of sensory function: In this study, sensory evaluation was used for three subjects (2-point discrimination test, proprioception test,

stereognosis test) for the affected arm. For each sense, two points were set to exactly match the position and type of the stimulus, one point to match either one of the position or type of the stimulus, and zero points if the position or type of the stimulus were different. [11].

3. Method: Twenty-two stroke patients were prospectively randomized to action observation training with intrinsic muscle stimulation group (N = 11) or action observation (N = 11). In the experimental group, 40 min of action observation training with intrinsic muscle stimulation and 40 min of action observation training in the control group were performed. Both groups received general physical therapy and occupational therapy for 30 minutes per day, five days a week, for 4 weeks.

(a) Action observation training with intrinsic muscle stimulation on experimental group:

The action observation video presented four daily activities. The video duration for each subtask was 3-4 minutes, and the video duration for one assignment was 12-15 minutes. The video showed that the object was manipulated using one or two hands according to the task, and after the observation, the subjects were asked to imitate the movement [8]. The intrinsic muscle stimulation training was applied in this study was modified and supplemented by referring to the contents suggested by Sue Raine et al [12]. This training was consisted of specific activation of lumbricals, specific activation of abductor digiti minimi, and specific activation of thenar eminence. The experimental group was treated for intrinsic muscle stimulation after observing action observation for 15 minutes in table 2.

(b) Action observation training on control group:

The control group observed only 30 minutes of action observation without intrinsic muscle stimulation training in [Table 1].

Table 1. Intervention program

Variables	Intrinsic muscle stimulation training	Action observation training
Intervention	specific activation of lumbricals,	Observing the action
	specific activation of abductor digiti minimi	Following the action
	specific activation of thenar eminence	

4. Statistical Analysis: The result analysis of collected data was statistically processed using SPSS 18.0 program for Windows. The general characteristics of the study subjects were descriptive statistics and frequency analysis, and the data collected through the study were tested for normality, indicating that all variables were normal distributed. Paired t-tests were performed for pre and post-treatment in the experimental and control groups, and independent t-tests were performed for comparison between the experimental and control groups. All statistical significance was set at 0.05

Result and Discussion

1. General characteristics of experimental subjects:

The general characteristics of the participants in this study are as follows. According to gender, there were 5 males (45.5%) and 6 females (54.5%) in the action observation training group combined with intrinsic muscle stimulation and there were 5 males (45.5%) and 6 women (54.5%) in the action observation training group without intrinsic muscle stimulation. The causes were 6 patients (54.5%) with cerebral hemorrhage and 5 patients (45.5%) with cerebral hemorrhage in the action observation training group combined with intrinsic muscle stimulation and 6 patients (54.5%) with cerebral hemorrhage, Five cerebral infarctions (45.5%) in the action observation training group without intrinsic muscle stimulation. Paralyzed patients had left hemiplegia (45.5%) and right hemiplegia (54.5%) in the action observation training group combined with intrinsic muscle stimulation and left hemiplegia (45.5%) and right hemiplegia (54.5%) in the action observation training group without intrinsic muscle stimulation.

2. Comparison of results before and after intervention of experimental groups:

The MFT of the experimental group showed a significant improvement from 11.69±7.21 points before intervention to 13.69±7.2 points after intervention (p <.05). The 2-point discrimination of the experimental group showed no significant improvement from 0.45±0.52 points before intervention to 0.73±0.47 points after intervention (p >.05).The proprioception of the experimental group showed significant improvement from 0.45±0.52 points before intervention to 0.91±0.54 points after intervention (p <.05).The stereognosis of the experimental group showed no significant improvement from 0.55±0.52 points before

intervention to 0.82±0.6 points after intervention in [Table 2] (p >.05).

Table 2. Comparison of results before and after intervention in experimental group (N = 22)

Variables	Pre-test	Post-test	p
Manual function test	11.69±7.21	13.69±7.2	.02*
2 point discrimination	0.45±0.52	0.73±0.47	.08
Proprioception	0.45±0.52	0.91±0.54	.01*
Stereognosis	0.55±0.52	0.82±0.6	.08

The values are mean (standard deviation), *p<0.05 by paired t-test

3. Comparison of results before and after intervention of control groups:

The MFT of the experimental group showed no significant improvement from 11.69±7.21 points before intervention to 13.69±7.2 points after intervention (p >.05). The 2-point discrimination of the experimental group showed no significant improvement from 0.36±0.5 points before intervention to 0.64±0.67 points after intervention (p >.05).The proprioception of the experimental group showed no significant improvement from 0.64±0.5 points before intervention to 0.73±0.47 points after intervention (p >.05). The stereognosis of the experimental group showed no significant improvement from 0.45±0.52 points before intervention to 0.55±0.52 points after intervention in [Table 3] (p >.05).

Table 3. Comparison of results before and after intervention in control group (N = 22)

Variables	Pre-test	Post-test	p
Manual Function Test	11.62±7.2	12±7.09	.17
2 point Discrimination	0.36±0.50	0.64±0.67	.08
Proprioception	0.64±0.50	0.73±0.47	.34
Stereognosis	0.45±0.52	0.55±0.52	.34

The values are mean (standard deviation)

Discussion

The prognosis for recovering upper extremity dysfunction in stroke patients is poor and only 20% of patients report some upper limb function [13]. As a therapeutic intervention that is widely used in clinical practice to improve upper limb function, it is based on cerebral plasticity. (robot training), task-specific training, virtual reality training, somatosensory training, imagery training, etc. are being applied in various forms[14]. Action observation training is a method of imitating and repeatedly training movement by observing other

people's goal-oriented activities or observing activities appearing in the video [15]. Intrinsic muscle stimulation of hands is a principle that strengthens the ability to modify movement in the physiological aspect based on the theory of motor learning and provides the basis for eliciting the change of functional performance of hand through treatment [7]. Treatment using these tasks is a treatment that causes changes in the nervous system by patients with disabilities performing their tasks on their own [16]. The purpose of this study was to investigate the effect of action observation training combined with intrinsic muscle stimulation on the upper limb of function and muscle activity in stroke patients. In the study of the change in upper limb of motor function before and after intervention experimental group showed statistically significant difference in MFT ($p < .05$) and control group did not show statistically significant difference ($p > .05$). In previous studies, lumbricals and interossei, which are intrinsic muscles of the hands, play an important role in generating the shape and holding force of the hands [12]. Action observation training has been shown to be helpful for the upper limb function and activities daily living in stroke patients [17]. The visual stimulus of observing and imitating behavior is thought to influence the pre-shaping of the hand when it reaches the object. Intrinsic muscle stimulation based on direct sensory stimulation within the body is considered to have a positive effect by making the hand easier and more efficient as anticipatory postural adjustments. In the study of the change in upper limb sensory function before and after intervention experimental group showed statistically significant difference in proprioception ($p < .05$) and control group did not show statistically significant difference ($p > .05$). In the study of the change in upper limb sensory function before and after intervention experimental group did not show statistically significant difference in 2-point discrimination ($p > .05$) and control group did not show statistically significant difference ($p > .05$). In the study of the change in upper limb sensory function before and after intervention experimental group did not show statistically significant difference in stereognosis ($p > .05$) and control group did not show statistically significant difference ($p > .05$). Unlike other parts of the body, the human hand and upper limbs have a large number of sensory receptors, which play an important role in processing a lot of information and delivering real-time body information to the central nervous system [18]. In previous research, training was carried out to improve the senses and to improve motor control. Training was conducted to distinguish between object and texture

through tactile sensation, to discriminate joint position, and to discriminate the weight of an object. The functional improvement was reported [19]. This suggests that intrinsic muscle stimulation is a factor that improves sensory function of the upper limb as in this study. Action observation also mimics elements of movement, such as proprioception, by imitating it. Observation alone is difficult to influence. The limitation of this study was that the study period of 4 weeks had difficulty in demonstrating the effectiveness of the intervention and the number of subjects was small due to the difficulty in recruiting the subjects meeting the selection criteria. In future studies, it is necessary to specify the upper extremity function and to prove the effect of action observation and intrinsic muscle stimulation on the recovery of upper extremity function.

Conclusion

The aim of this study was to investigate the effect of action observation training combined with intrinsic muscle stimulation intervention on the function of upper extremity in patients with stroke. First, there was a statistically significant difference in manual function test in the action observation training group with intrinsic muscle stimulation ($p < .05$), but there was no statistically significant difference in the action observation training group without intrinsic muscle stimulation ($p > .05$). Second, there was statistically significant difference in sensory function in the action observation training group with intrinsic muscle stimulation after intervention ($p < .05$). There was no statistically significant difference between action observation training group without intrinsic muscle stimulation ($p > .05$).

Recognition of Health and Non-Health Care Related College Students on the Safety Management of Dental Radiography

Sun-Mi Lee¹, Jung-Eun Ha², Min-Ji Kim³

¹Professor, Department Dental Hygiene, Kyungnam College of Information & Technology, ²Professor, Department of Dental Hygiene, Baekseok University, ³Professor, Department Dental Hygiene, Dongseo University, South Korea

Abstract

Background/Objectives: The aim of this paper is to provide basic data for preparing measures to improve the level of behavior for the dental radiation workers' safety management on the radiation usage.

Method/Statistical Analysis: The survey was conducted over a 15-day period from October 30, 2018 to November 13, 2018. A total of 300 copies of the questionnaire were distributed, of which 237 were collected, except 63, which were incompletely prepared. The questionnaire used for this study was modified and supplemented with reference to Park's questionnaire. The questionnaires used in the survey consisted total of 27 questions which were 5 general characteristics questions, 8 items related to radiation exposure knowledge.

Findings: The highest level of radiation exposure anxiety was 41 (65.1%) out of 123 health related students said 'do not fear', where 56 (58.9%) out of 114 non-health related students said 'normal' so that non-health related students had higher anxiety on radiation exposure and there was a significant difference. The questionnaire on radiation safety management was the highest among the total 123 health related students, with 71 (57.7%) said 'do not have it', 30 (24.4%) said 'do not know well', 22 (17.9%) said 'have it'. Among the 115 non-health related students, the highest was 57 (49.6%) with 'do not have it', 53 (46.1%) with 'do not know well', 5 (4.3%) with 'have it' so that safety management was not well managed in dental hospitals and there was a significant difference.

Improvements/Applications: Therefore, radiation workers need education and the importance of education related to radiation defense.

Keywords: Recognition, Health, Non-health, dental radiography, safety management.

Introduction

The average life span of humans was 67.2 years for males and 77.5 years for females as of the 1990s. However, in 2016, the average life expectancy of Koreans was 79.3 years and 85.4 years^[1]. As life extends, interest

in health has increased, and medical radiation has been used to protect health from diseases, and medical radiation equipment has also been advanced that is used for diagnosis, treatment and research^[2]. In addition, radiography performed for the objective determination of the disease has become an important role for the accurate determination of the disease. As the demand for prosthetics and implants increases in the dental field, such radiography techniques rapidly increase in the proportion of intraoral radiography, panorama radiography, digital radiography, and etc., so that accurate diagnosis and treatment can be made using radiological equipment. As a result, the quality of medical care as well as the diagnosis using radiography are becoming more

common^[3-6]. Although, the Chernobyl nuclear accident in 1986, and the recent Fukushima nuclear accident in March 2011 have increased public awareness of radiation and fear of exposure. However, despite the increased anxiety about radiation exposure, most dental offices lack the manpower assigned to radiography, and there is a lack of awareness of radiation protection equipment and explanation of exposure during radiation treatment. Prior research papers on the degree of awareness of safety management of radiography include the patient's awareness^[7] of dental digital radiography, the current status and use of dental radiation in Korea, and the knowledge^[8], attitudes and behaviors^[9] of radiation protection of dental workers has been reported. However, research on radiation safety management of university students is insufficient. Therefore, this study grasped the knowledge, attitude, and behavior of radiation safety management for health and non-health care, measured the degree of anxiety of radiation exposure, and analyzed the relationship between them. The aim of this paper is to provide basic data for preparing measures to improve the level of behavior for the dental radiation workers' safety management on the radiation usage.

Method

This study collected data by distributing a self-reported questionnaire to 300 university students in health and non-health related students who live in Busan. The survey was conducted over a 15-day period from October 30, 2018 to November 13, 2018. A total of 300 copies of the questionnaire were distributed, of which 237 were collected, except 63, which were incompletely prepared. The questionnaire used for this study was modified and supplemented with reference to Park's questionnaire^[10]. The questionnaires used in the survey consisted total of 27 questions which were 5 general characteristics questions, 8 items related to radiation exposure knowledge, 4 items related to dental radiography experience, 2 items related to dental radiography awareness, four items related to dental radiography exposure anxiety, and 4 items on dental radiation safety.

Frequency and crossover analyzes were used to identify general characteristics of respondents. The significance level was $\alpha < 0.05$. For data analysis, SPSS 24.0 (IBM SPSS statistics) was used to analyze general characteristics and frequency of radiation therapy purposes. Recognition of radiographic needs was analyzed by chi-square test.

Results and Discussion

The gender distribution of 238 subjects was 55 males (23.2%) and 182 females (76.8%), with 53.6% more women. The most common age distribution was 214 (90.3%) for 20-24 years old, followed by 19 (8%) for 25-29 years old, 2 (0.8%) for 30-34 years old, and 2 (0.8%) over 35 years old in order. By marital status, 234 singles (98.7%) were the majority and 3 (1.3%) were married. According to the final education, 217 high school graduates (91.6%) were the most, 16 college graduates (6.8%), and 4 others (1.7%). By occupation, there were 122 health related students (51.5%) and 115 non-health related students (48.5%) [Table 1].

Among the 143, 41 patients (28.7%) were treated with dental caries, 38 patients (26.6%) for basic checkup, 38 patients (26.6%) for correction, and 24 patients (16.8%) for others, and 2 patients (1.4%) for implants [Table 2].

In the health field, 73 of the 123 students (59.3%) said 'do not know well about radiation awareness', which was the highest, followed by 35 students (28.5%) said 'know about radiation awareness', 9 students (7%) said 'do not know anything about radiation awareness', and 6 students (5%) said 'know about the radiation awareness very well'. In the non-health related students, 86 out of 115 (74.8%) said 'do not know well about radiation awareness', which was the highest, followed by 19 (16.5%) said 'do not know anything about radiation awareness', 9 (7.9%) said 'know about radiation awareness', and 1 (0.9%) said 'know about the radiation awareness very well' ($p < 0.001$) [Table 3].

Table 1. General Characteristics of Subjects

		N(%)
Gender	Male	55(23.1)
	Female	183(76.9)
Age	20-24	215(90.3)
	25-29	19(8)
	30-34	2(0.8)
	Over 35	2(0.8)
Marital Status	Single	234(98.3)
	Married	4(1.7)
Final Education	High School Graduates	218(91.6)
	University Graduates	16(6.7)
	Others	4(1.7)
Occupation	Health Related	123(51.7)
	Non-health Related	115(48.3)
Total		238(100)

Table 2. Purpose of radiation therapy

Sort	N(%)
Basic Checkup	38(26.6)
Implants	2(1.4)
Dental Caries Treatment	41(28.7)
Correction	33(26.6)
Others	24(16.8)

Out of 123 in health related students, 109 (69.0%) said ‘yes’ 3 (50%) said ‘no’, and 11 (14.9%) said ‘do not know’, where out of 115 in non-health related students, 49 (31%) said ‘yes’, 3 (50%) said ‘no’, and 63 (85.1%) said ‘do not know’ (p<0.001). As a result of the knowledge of ‘radioprotective substance’, within

the health related students, 58 (81.7%) said ‘yes’, 29 (56.9%) said ‘no’, and 36 (31%) said ‘do not know’ where with the non-health related students, 13 (18.3%) said ‘yes’, 22 (43.2%) said ‘no’, 80 (69%) said ‘do not know’ (p<0.001). On ‘Natural radiation’ knowledge degree within health related students, 99 (63.9%) said ‘yes’, 5 (62.5%) said ‘no’, 19 (25.3%) said ‘do not know’ where with the non-health related students out of 115, 56 (36.1%) said ‘yes’, 3 (37.5%) said ‘no’, and 56 (74.7%) said ‘do not know’ (p<0.001). The knowledge of radiation intensity in health related students, 80 (64%) said ‘yes’, 20 (58.8%) said ‘no’, and 23 (29.1%) said ‘do not know’, where in non-health related students, 49 (31%) said ‘yes’, 3 (50%) said ‘no’, and 63 (58.1%) said ‘do not know’ (p<0.001) [Table 4].

Table 3. Radiation Awareness of Subjects

Sort	Radiation Awareness					p-value
	Know it Very Well	Know it Well	Do not Know	Do not Know Anything	Total	
Health Related	6(85.7)	35(79.5)	73(45.9)	9(32.1)	123(51.7)	<0.001
Non-health Related	1(14.3)	9(20.5)	86(54.1)	19(67.9)	115(48.3)	
Total	7(100)	44(100)	159(100)	28(100)	238(100)	

Table 4. Radiation Exposure Knowledge

Sort		Radiation exposure knowledge				p-value*
		Yes	No	Do not know	Total	
Radiation sensitivity of the human body	Health related	109 (69)	3 (50)	11 (14.9)	123 (51.7)	<0.001
	Non-health related	49 (31)	3 (50)	63 (85.1)	115 (48.3)	
	Total	158 (100)	6 (100)	74 (100)	238 (100)	
Radiation protective material	Health related	58 (81.7)	29 (56.9)	36 (31)	123 (51.7)	<0.001
	Non-health related	13 (18.3)	22 (43.1)	80 (69)	115 (48.3)	
	Total	71 (100)	51 (100)	116 (100)	238 (100)	
Natural radiation	Health related	99 (63.9)	5 (62.5)	19 (25.3)	123 (51.7)	<0.001
	Non-health related	56 (36.1)	3 (37.5)	56 (74.7)	115 (48.3)	
	Total	155 (100)	8 (100)	75 (100)	238 (100)	
Radiation intensity	Health related	80 (64)	20 (58.8)	23 (29.1)	123 (51.7)	<0.001
	Non-health related	49 (31)	3 (50)	63 (85.1)	115 (48.3)	
	Total	129 (100)	23 (100)	86 (100)	238 (100)	

Table 5. Awareness of the Need for Dental Radiography

Sort	Radiography awareness					p-value*
	Very need	Need	Normal	Do not need	Do not need it at all	
Health related	21(75.0)	52(65.8)	43(39.8)	6(37.5)	1(14.3)	<0.001
Non-health related	7(25.0)	27(34.2)	65(60.2)	10(62.5)	6(85.7)	
Total	28(100)	79(100)	108(100)	16(100)	7(100)	

Table 6. Radiation Exposure Anxiety

Sort	Radiation exposure anxiety						p-value
	Do fear very much	Do fear	Normal	Do not fear	Do not fear at all	Total	
Health related	4(57.1)	21(61.8)	39(41.1)	41(65.1)	18(46.2)	123(51.7)	0.029
Non-health related	3(42.9)	13(38.2)	56(58.9)	22(34.9)	21(53.8)	115(48.3)	
Total	7(100)	34(100)	95(100)	63(100)	39(100)	238(100)	

Among the 123 health related students, the highest was 52 (65.8%) said 'need', followed by 43 (39.8%) said 'normal', 21 (75.0%) said 'very need', 6 (37.5%) said 'do not need', and 1 (14.3%) said 'do not need it at all' where among the 115 non-health related students, 65 (60.2%) for 'normal' which was the highest, followed by 27 (34.2%) said 'need', 10 (62.5%) said 'do not need', 7 (25%) said 'very need', and 6 (85.7%) said 'do not it at all' ($p < 0.001$) [Table 5]. Among the 123 health related students, the highest was 41 (65.1%) said 'Do not fear', followed by 39 (41.1%) said 'normal', 21 (61.8%) said 'Do fear', 18 (46.2%) said 'Do not fear at all, and 18 (46.2%) said 'do fear very much'. Whereas among the 115 non-health related students, 56 (58.9%) for 'normal' which was the highest, followed by 22 (34.9%) said 'do not fear', 22 (53.8%) said 'do not fear at all', 13 (38.2%) said 'do fear', and 3 (42.9%) said 'do fear very much' ($p = 0.029$) [Table 6].

Among the 123 health related students, the highest was 71 (57.7%) said 'do not have it', followed by 30 (24.4%) said 'do not know well', and 22 (17.9%) said 'Have it', where among the 115 non-health related students, 57 (49.6%) for 'do not have it' which was the highest, followed by 53 (46.1%) said 'do not know well', and 5 (4.3%) said 'have it' ($p = 0.001$).

Radiography has become an integral part of modern medicine for accurate diagnostic and therapeutic purposes. In addition, anyone who handles radiation is interested, but most people are not properly trained in radiation safety management because they have neglected their attention due to lack of knowledge or underestimation of self-confidence and risks in handling radiation.^[9]

The purpose of this study is to investigate the exposure knowledge, experience, exposure anxiety, safety management, radiographic consciousness and awareness of radiation in health and non-health related students, and the main areas collected through surveys to compare the awareness of radiation safety management are as follows:

The radiation awareness of the study subjects was 52 (65.8%) of the health related students said 'know it well, and 65 (60.2%) of the non-health related students were 'normal' so that health related students is highly recognized about this matter. This is considered to be high because the health related students have more opportunities to access radiological expertise through lectures and exercises than non-health related students.

The anxiety about radiation exposure was 41 (65.1%) in the health related students and 56 (58.9%) in the non-health related students in which health related students' result was slightly higher. It is thought that this is because the knowledge of radiation in health related students is higher, so that effective dose will not reach the level that can cause disorder in human body.

There was a statistically significant difference in the awareness of radiation safety management among the 81 (81.4%) health related students and 100 (55.2%) non-health related students which shows non-health related students was significantly higher than the others. The majority of the respondents between these two groups answered 'Do not know well'. This is because non-health related students do not know radiation shielding well unless the dentist explains about it. The health related students are the future radiation workers, so the awareness of radiation defense is high, but it is not actually managed by dental hospitals. Therefore, we need to plan education or program on radiation defense to defend against radiation safety management.

In this study, there are limitations in the interpretation and utilization of results due to the following limitations. Since the survey target was selected from some universities located in Gyeongnam, Busan, it was difficult to represent the whole group. There is a limitation that uncertainties exist in the evaluation of the criteria. However, based on the contents of this paper, the training program for radiation defense in dental hospitals and the importance and necessity of radiation defense can be trained to raise the awareness of radiation safety management by radiation workers in the future. It may

be possible to provide a guideline for the preparation of such a plan.

Conclusion

In this study, questionnaires were distributed from October 30 to November 13, 2018 to grasp the knowledge, attitudes and behavior of radiation safety management in Busan, Gyeongsangnam-do, by measuring the degree of radiation anxiety and analyzing their relevance, the collected data were obtained using the SPSS 24.0 statistical program and the results are as follows:

1. The radiation awareness was highest among 123 health related students, with 52 (65.8%) said 'know it well' and the highest among the 115 non-health related students with 65 (60.2%) said 'normal' so that health related students showed higher radiation awareness and there was a significant difference ($p < 0.001$).
2. In radiological consciousness, it was the highest among the 123 health related students with 52 (65.8%) said 'need', and the highest among non-health related students with 65 (60.2%) said 'normal' so that health related students showed higher radiographic consciousness and there was a significant difference ($p < 0.001$).
3. The highest level of radiation exposure anxiety was 41 (65.1%) out of 123 health related students said 'do not fear', where 56 (58.9%) out of 114 non-health related students said 'normal' so that non-health related students had higher anxiety on radiation exposure and there was a significant difference ($p < 0.029$).
4. The questionnaire on radiation safety management was the highest among the total 123 health related students, with 71 (57.7%) said 'do not have it', 30 (24.4%) said 'do not know well', 22 (17.9%) said 'have it'. Among the 115 non-health related students, the highest was 57 (49.6%) with 'do not have it', 53 (46.1%) with 'do not know well', 5 (4.3%) with 'have it' so that safety management was not well managed in dental hospitals and there was a significant difference. ($p < 0.001$).
5. As a result of examining the radiation knowledge of the subjects, out of the total 123 health related students, 109 (69.0%) said 'yes', 3 (50%) said 'no', and 11 (14.9%) said 'do not know', where out of 115

non-health related students, 49 (31%) said 'yes', 3 (50%) said 'no', and 63 (85.1%) said 'do not know'.

In this study, the non-health related students had lower radiation knowledge and higher exposure anxiety than health related students. Therefore, radiation workers are considered to be in need of education and the importance of education related to radiation defense.

Relationship between Pain-induced Temporomandibular Joint Pain According to Cell Phone Use Frequency

Sun-Mi Lee¹, Jung-Eun Ha², Min-Ji Kim³

¹Professor, Dept. Dental Hygiene, Kyungnam College of Information & Technology, ²Professor, Department of Dental Hygiene, Baekseok University, ³Professor, Dept. Dental Hygiene, Dongseo University, South Korea

Abstract

Background/Objectives: The purpose of this study is to investigate whether the use of mobile phone is related to the pain of the jaw joints.

Method/Statistical Analysis: This study was designed as a cross-sectional survey. The purpose of this study was to explain the research objectives of 304 university students in Busan and the data was collected using the convenience sampling method. Of the total 304 subjects, 300 were included from the questionnaire, except for four who were inappropriate to use the data.

Findings: The general characteristics of the subjects were 227 females (75.7%) and 73 males (24.3%) among the 300 respondents. In the index of pain of the joint with the average number of calls per day, 44 people (14.7%) for less than 1 time, 36 people (12%) for 1 to 2 times, 100 (33.3%) for 3 to 4 times, 106 (35.3%) for 4 to 5 times, 14 people (4.7%) for more than 5 times, and analyzed the pain index according to the average number of calls per day showed a significant difference in pain index for 'hard food' ($p = 0.019$) and 'discomfort during closing' ($p = 0.037$). Jaw joint pain index was significantly different between male and female, 4.62 points and 4.35 points, respectively ($p = 0.001$). However, there was no significant difference from other joint pain symptoms.

Improvements/Applications: It was difficult to generalize the results to all university students because the study was limited to university students in some universities in Busan area. In addition, it is necessary to consider other factors of pain in the joint, and further study on cell phone and joint pain through the diversification of the sample area and the increase in the number of samples is considered. However, it is hoped that it can contribute as a basic data for more systematic epidemiological studies for all citizens in the future.

Keywords: Temporomandibular joint, pain, cell phone, Frequency, Joint noise.

Introduction

Recently, with the development of information technology at home and abroad, the use of mobile phones is increasing rapidly. 63.6% of the general public in Korea use smartphones, and the first time smartphones were

used in 2011 was 47.8%^[1]. Compared to 40% of total distributed smartphones in Korea, the utilization rate is somewhat higher, but considering that the survey targets 15 to 49 years old and are major cities by region, it can be seen that 3 out of 5 adults live in major cities using a smartphone^[2]. In addition, it is analyzed that the rapid spread of smartphones has been continued since 2010 and 2011 are almost equally proportioned^[3]. As society becomes more sophisticated, specialized, and more competitive, societal stress increases and more patients complain of symptoms of jaw joint disorder. Recently, as patients acquire information about the disease of the jaw joint through various media and increase their interest,

the demand for treatment of the jaw joint disorder is increasing and the share of dental sector is expected to increase. Frequent use of mobile phones can cause temporomandibular disorders if the habits of talking on the phone between the chin and shoulders, jaw-gripping habits, bad posture, etc. Temporomandibular disorders (TMD) is a generic term that includes many clinical problems in the masticatory and temporomandibular joint sites and refers to a complex of several disorders that occur in the chewing system^[4]. In addition, the causes of temporomandibular disorders include direct facial trauma such as traffic accidents, beatings and shocks, bad habits such as cracking, dent bites, poor posture, lip or cheek bites, occlusion or malocclusion, stress, depression, and anxiety. Psychological factors, such as these various factors act in combination, causing, persisting and worsening temporomandibular disorders. The main symptoms of temporomandibular disorders are clinical features such as pain and discomfort in the jaw or masticator muscle, pain in occlusion, limitation and impairment of mandibular movement, and joint noise^[5]. The most common of these is pain, which can be painful to the masticatory muscles or dislocations (the area corresponding to the front of the ear)^[6]. The causes of temporomandibular disorders have a variety of factors, of which five major factors are occlusion, trauma, emotional stress, influx of deep pain, and dysfunctional activity^[7]. In other words, the symptoms of temporomandibular disorders and oral facial pain are very diverse, the causes are also very complex, and interest and research on temporomandibular disorder diseases continue^[8]. However, there have been many reports on the prevalence and specific analysis of temporomandibular disorders, but few studies have investigated the relationship between cell phone usage and temporomandibular pain. Therefore, the purpose of this study is to investigate whether the use of mobile phone is related to the pain of the jaw joints.

Method

This study was designed as a cross-sectional survey. From November 3, 2018 to November 10, 2018, the purpose of this study was to explain the research objectives of 304 university students in Busan and the data was collected using the convenience sampling method. Of the total 304 subjects, 300 were included from the questionnaire, except for four who were inappropriate to use the data.

Mention the statistical details, the number of

samples used, statistical tools/software used/SD/level of significance, repeatability etc.

Self-investigated questionnaire using structured questionnaire, the general subjects, the presence of traumatic trauma and treatment experience, subjective symptoms of temporomandibular joint and habits related to temporomandibular joint health, and diaphragmatic disorder related to temporomandibular disorder were identified.

The questionnaire used in this study included 7 questions about general matters, 2 questions about trauma and presence of treatment experience, 23 questions about subjective symptoms of temporomandibular joints, and 20 related habits related to temporomandibular health. A total of 53 questions consisted to 1 item of opening disorder related to temporomandibular disorder.

Statistical analysis of the collected data was done using IBM SPSS Statistics 24 program. The general subjects were calculated by frequency analysis, and the pain index according to gender, daily call volume, and average weekly talk time was calculated by One-Way ANOVA.

Results and Discussion

The general characteristics of the subjects were 227 females (75.7%) and 73 males (24.3%) among the 300 respondents. The number of respondents was 209 (69.7%) under 18-20 years old and 91 (30.3%) under 21-33 years old. The distribution of mobile phone usage by type was 211 students (70.3%) who frequently use SNS during the day, 73 students (24.3%) who did not, and 16 students (5.3%) who do not know. Average number of calls per day was 14 (4.7%) for less than 1 time, 106(35.3%) for one to two times, 100 (33.3%) for three to four times, 36 (12%) for four to five times, and 44 (14.7%) for more than five times. The average weekly talk time on cell phones was 105 people (35%) under two hours, 69 people (23%) between two to three hours, 58 people (19.3%) between three to four hours, 19 people (6.3%) between four to five hours, and 48 people (16%) for more than five hours [Table 1].

Table 1. General Characteristics of Subjects

			%
Gender	Male	73	24.3
	Female	227	75.7
Age	Between 18 to 20	209	69.7
	Between 21 to 33	91	30.3

			%
Possession of a mobile phone	Yes	300	100
	No	0	0
SNS usage	Frequent use	211	70.3
	Do not use	73	24.3
	Do not know	26	5.3
Call count	Less than 1 time	14	4.7
	1 to 2 times	106	35.3
	3 to 4 times	100	33.3
	4 to 5 times	36	12
	More than 5 times	44	14.7
Average talk time per week	Less than 2 hours	105	35
	Between 2 to 3 hours	69	23
	Between 3 to 4 hours	58	19.3
	Between 4 to 5 hours	19	6.3
	More than 5 hours	47	16.0

In the index of pain of the joint with the average number of calls per day, 44 people (14.7%) for less than

1 time, 36 people (12%) for 1 to 2 times, 100 (33.3%) for 3 to 4 times, 106 (35.3%) for 4 to 5 times, 14 people (4.7%) for more than 5 times, and analyzed the pain index according to the average number of calls per day showed a significant difference in pain index for ‘hard food’ ($p = 0.019$) and ‘discomfort during closing’ ($p = 0.037$) [Table 2]. Jaw joint pain index was significantly different between male and female, 4.62 points and 4.35 points, respectively ($p = 0.001$). However, there was no significant difference from other joint pain symptoms [Table 3].

In the case of pain in the joints according to the average weekly talk time, 106 less than 2 hours (35%), 69 between 2 to 3 hours (23%), 58 between 3 to 4 hours (19.3%), 19 between 4 to five hours (6.3%), and 48 for over 5 hours (16.0%). As a result of analyzing the pain index of the joint according to the average weekly talk time, there was a significant mean difference between group in ‘Joint noise’ ($p = 0.050$) [Table 4].

Table 2. Joint pain in accordance with the average number of calls per day

Sort	Average number of calls per day					p-value*
	Less than 1 time	1 to 2 times	3 to 4 times	4 to 5 times	More than 5 times

*p-value was calculated by One-Way ANOVA

In recent years, the prevalence of pain disorders in the neck and shoulders has increased due to inadequate sedentary work^[9]. In addition, studies have been linked to the occurrence of temporomandibular disorders^[10], and a study on the change in the prevalence of jaw joint disorders in Korean has shown that the prevalence of jaw joint disorders gradually increases over the last three years^[11]. Therefore, the purpose of this study was to investigate the relationship with the jaw joint pain according to the frequency of cell phone use. According to the study, the average number of calls per day was 44 people (14.7%) for less than 1 time, 36 people (12%) between 1 to 2 times, 100 people (33.3%) between 3 to 4 times, 106 people (35.3%) between 4 to 5 times, 14 people (4.7%) for more than 5 times. In other words, the average number of call per day was 180 or more (60%). The higher the volume, the more significant differences there were between 'hard food' and 'discomfort during closing'. The higher the number of phone calls per day, the more relevant the pain in the jaw joints. The most significant difference in symptom of 'discomfort during closing' in the pain of the joints by gender seems to be because women reach puberty earlier than men and this affects the teeth. Average weekly talk time was 106 people (35%) for under 2 hours, 69 people (23%) between 2 to 3 hours, 58 people (19.3%) between 3 to 4 hours, 19 people (6.3%) between 4 to 5 hours, and 48 people (16.0%) for more than 5 hours. As the average weekly talk time increased, the question 'I feel pain when I opened my mouth or closed' was found to be significantly related. The average weekly talk time is

increasing, indicating that you are experiencing joint pain. However, it was difficult to generalize the results to all university students because the study was limited to university students in some universities in Busan area. This study examined the use of mobile phones and the pain related to the jaw joints through a limited number of university students in Busan. As a frequency of use of mobile phones increased, we expected that the pain of the jaw joints would vary. However, the lack of questionnaire questions resulted in disappointing results. In addition, it is necessary to consider other factors of pain in the joint, and further study on cell phone and joint pain through the diversification of the sample area and the increase in the number of samples is considered. However, it is hoped that it can contribute as a basic data for more systematic epidemiological studies for all citizens in the future.

Conclusion

The purpose of this study was to examine 300 university students in Busan to investigate the association with the incidence of pain the jaw joint as the frequency of cell phone usage increases by using SPSS WIN 24 to analyze and the results are as follows:

1. In the index of pain of the joint with the average number of calls per day, 44 people (14.7%) for less than 1 time, 36 people (12%) for 1 to 2 times, 100 (33.3%) for 3 to 4 times, 106 (35.3%) for 4 to 5 times, 14 people (4.7%) for more than 5 times, and analyzed the pain index according to the average

number of calls per day showed a significant difference ($p < 0.05$) in pain index for 'hard food' ($p = 0.019$) and 'discomfort during closing' ($p = 0.037$)

2. Jaw joint pain index was significantly different between male and female, 4.62 points and 4.35 points, respectively ($p = 0.001$). However, there was no significant difference from other joint pain symptoms.
3. In the case of pain in the joints according to the average weekly talk time, 106 less than 2 hours (35%), 69 between 2 to 3 hours (23%), 58 between 3 to 4 hours (19.3%), 19 between 4 to five hours (6.3%), and 48 for over 5 hours (16.0%). As a result of analyzing the pain index of the joint according to the average weekly talk time, there was a significant mean difference between group in 'Joint noise' ($p = 0.050$).

The Effects of Nursing Ethics and Major Satisfaction on Patient Safety Management Activities of Nursing Students

Eun-Ju Kim¹, Seung-Ju Kang²

¹Professor, Dept. of Nursing, Jeonbuk Science College, Korea, ²Professor, Dept. of Nursing, Chunnam Techno University, Korea

Abstract

Background/Objectives: The purpose of this study is to determine the relationships between nursing ethics, major satisfaction, and the patient safety management activities of nursing students and find the factors that affect the patient safety management activities of nursing students.

Method/Statistical Analysis: This is a descriptive research study for which 240 participants were selected from nursing students in Jeollabuk-do and Jeollanam-do. Data were collected from March to April 2019. Descriptive statistics, independent t-test, one-way ANOVA, Pearson correlation coefficient and multiple regression were used for analysis.

Findings: This study confirmed that factors of nursing ethics and major satisfaction directly affect the patient safety management activities of nursing students.

Improvements/Applications: The purpose of this study is to identify the correlation between nursing ethics, major satisfaction, and patient safety management activities, to understand what factors affect patient safety management activities, and to develop programs for improving the students' nursing ethics.

Keywords: *Nursing students, nursing ethics, patient safety management activities, major satisfaction, correlation.*

Introduction

Patients and people who care for them who visit medical institutions expect to receive high-quality treatment in a safe environment without accidents or side effects^[1]. The number of patients who are injured or die in hospitals due to increasing medical technologies and complex procedures^[2]. Such patient safety accidents include all kinds of accidents that occur without protecting the safety of patients, including all kinds of errors, mistakes and accidents that occur in hospitals^[3].

Patient safety accidents have emerged as a major threat to patients, and the number of incidents has become an important issue in terms of medical quality management^[4]. In order to prevent patient safety accidents, systematic activities are needed to prevent and manage the occurrence of various errors, including medical accidents. Nursing ethics is being newly emphasized by expanding the rights of patients and strengthening their responsibility for the rights of patients by raising the medical awareness of patient safety^[5].

Ethical issues are becoming more important due to extended life expectancy as a result of the development of medical technology, shortage of health care resources, and the conflicts with sociocultural and religious norms^[6]. In addition, with the revision of the 2017 Medical Law, health care professionals' ethics are included in conservative education, emphasizing the importance of

e-mail: ejkim3223@jbsc.ac.kr

ethical literacy, and the nursing community emphasizes the ethical thinking of students by emphasizing nursing ethics^[5]. Since nurses have basic responsibilities to promote the health of subjects, prevent illness, restore health and alleviate pain^[7], nursing students are encouraged not only to have human dignity but also morality and clear nursing ethics with knowledge and literacy education^[8]. If nursing students are fully aware of the need for nursing ethics and patient safety management and practice proper knowledge, they will be able to play a role in strengthening ethical nursing and patient safety after graduation^[9].

Major satisfaction refers to the level of satisfaction with a major determined by an individual based on a job and the evaluation from the people around him or her. It is influenced by various factors. The higher the level of satisfaction with their major, the clearer their thoughts on their career and the more comfortable they are in their decisions^[10]. As discussed above, if a nurse has the right decision making, clear nursing ethics with satisfaction with his or her major, he/she is expected to actively conduct patient safety management. Prior studies on nursing ethics, major satisfaction, and patient safety activities are inadequate. The purpose of this study was to investigate the effects of ethics and major satisfaction of nursing students on patient safety management activities, and to present basic data for improving ethics, major satisfaction, and the patient safety management activities of nursing students

Method

This is a descriptive research study to identify the factors affecting the ethics of nursing students in safety management activities. For this, 240 participants were recruited from nursing students in Jeollabuk-do and Jeollanam-do. Sufficient information about this study was given to them and the students who agreed to participate in this study were selected. The data were collected from March to April 2019. In order to protect the study subjects, the contents and purpose of the study were explained, and a consent form was signed only if they agreed to participate in the study. We also discussed privacy, anonymity, and the possibility of withdrawing from the research. The students who participated in the survey were given a gift.

Structured questionnaires were used as a study instrument, which included the general characteristics, nursing ethics^[3], and patient safety management

activities^[4] of nursing students. General characteristics consisted of gender, age, marital status, motivation to enter, friendship, and religion. For ethical awareness, the ethical awareness measuring tool devised by Jang Deok-pil was used^[11]. There was a total of 30 questions in three areas consisting of 10 questions on ethics for patients, 10 questions on professional work, and 10 questions on ethics for partners. The tool ranged from 1 point not at all to 4 points at all times, with higher scores indicating higher ethical awareness. In this study, Cronbach's α was .77. The inverse of the measurement tool was inverted.

The Major Satisfaction Index was used a 34-item satisfaction survey made by Kim & Ha^[12] was used by Lee^[13]. The higher the score on the 5-point Likertscale, the higher the major satisfaction. In this study, Cronbach's α was .94.

In order to measure patient safety management activities, a tool developed by Lee^[14] and revised and supplemented by Lee^[15] was used. A total of 17 questions consisted of five on patient confirmations, two oral prescriptions, five on medicines, one on surgery/procedure, one on infection control, two on fall prevention, and one on pressure control. This tool used a 5-point Likertscale ranging from "not at all" to "very yes much," meaning that the higher the score, the higher the performance of the individual's patient safety management activities. Reliability with Cronbach's α was .95 in this study. The inverse of the measurement tool was inverted.

The collected data were statistically analyzed using IBM SPSS Statistics 18.0. A descriptive statistical method was used to calculate the general characteristics, frequency, percentage, mean and standard deviation of subjects' characteristics. Differences in nursing ethics according to the general characteristics of the subjects were analyzed by independent t-test and ANOVA. The correlation between subjects' nursing ethics and patient safety management activities was calculated using the Pearson correlation coefficient. Finally, hierarchical multiple regression analysis was used to identify the factors affecting patient safety management activities.

Result and Discussion

1. **Differences in Nursing Ethics by General Characteristics:** According to the general characteristics of the subjects, the degree of patient safety management activities was determined by

Admission ($F = 2.834, p = .025$), and Relationship ($t = 5.036, p = .001$), Prospects for Nursing ($t = -2.508, p = .013$), Ethical Education Experience ($t = -2.615, p = .009$) showed a difference. In contrast, there were no statistically significant differences

among gender ($t = -.394, p = .694$), age ($F = .852, p = .467$), marital status ($t = 1.695, p = .091$), religion ($t = 1.939, p = .054$), and achievement ($F = .386, p = .081$) [Table 1].

Table 1. Differences in Nursing Ethics by General Characteristics (N = 240)

Characteristics	Categories	N()	M±SD	t or F	p
Gender	Man	59	4.04±.57	-.394	.694
	Women	181	4.08±.60		
Age	20-24	163	4.04±.60	.852	.467
	25-29	47	4.10±.63

	Yes	159	4.14±.60		

2. Description statistics of the measured variable:

The Nursing Ethics score was 2.84 (SD = .23), which was similar to that of Song [8]. It was similar to the results of Yun & Kim [16], which studied nursing college students. The patient's Major Satisfaction score was 3.76 (SD = .71), similar to

Whang's [17] report (3.71). The mean score for Patient Safety Management Activities was 4.07 (SD = .59), which was similar to that of Song [8] based on clinical nurses. The study of nursing students by Song & Moon [18] was 3.96 and Kim & Oh's [19] showed 3.99; the subjects here were slightly higher. [Table 2].

Table 2. Description statistics of the measured variable (N = 240)

Variable	M±SD	Minimum value	Maximum value
Nursing Ethics	2.84±.23	2.23	3.80
Major Satisfaction	3.76±.71	1.00	5.00
Patient Safety Management Activities	4.07±.59	2.88	5.00

3. Correlations between Nursing Ethics, Major Satisfaction and Patient Safety Management Activities: Correlation analysis was conducted for nursing ethics, major satisfaction, and patient safety management activities, including motivation for admission, experience of ethics education, and relationships. The results are as follows.

Patient safety management activities and Motive for Admission ($r = .138, p = .033$), safety management activities and Ethical Education Experience ($r = .167, p < .001$), patient safety management activities and Prospects for Nursing ($r = .191, p = .003$), patient safety management activities and Nursing Ethics ($r = .484, p < .001$), patient safety management activities and Major Satisfaction ($r = .431, p < .001$), Major Satisfaction and relationship ($r = .131, p = .042$), major Satisfaction and Motive for Admission ($r = .208, p < .001$), Major Satisfaction and Prospects for Nursing ($r = -.245, p < .001$), Major Satisfaction and Nursing Ethics ($r = -.428, p < .001$), Nursing Ethics and Major Satisfaction ($r = .150, p < .02$), Nursing Ethics and Prospects for Nursing ($r = -.189, p = .003$) were all statistically significant correlations. Shown [Table 3].

Table 3. Correlations between Nursing Ethics and Patient Safety Management Activities (n = 240)

Variable	Rel	MA	EEE	PN	NE	MS	PMA
	r(p)	r(p)	r(p)	r(p)	r(p)	r(p)	r(p)
Rel	1	-.006(.923)	.118(.068)	-.091(0.16)	.033(.613)	.131*(.042)	.086(.185)

Correlation is significant at the 0.01 level., Rel: Relationship, MA: Motive for Admission, EEE: Ethical Education Experience, PN: Prospects for Nursing, NE: Nursing Ethics, MS: Major Satisfaction, PMA: Patient Safety Management Activities

4. Factors Influencing Patient Safety Management Activities: In order to identify factors affecting the patient safety management activities of nursing college students, patient safety management activities were the dependent variables, and motivation for admission, ethical education experience, prospects of nursing jobs, and nursing ethics all showed a significant correlation with patient safety management activities. In addition, multiple regression analysis was conducted using major satisfaction as the explanatory variable.

As a result of testing the multicollinearity between the variables included in the regression analysis, the tolerance limit was .58 and the variation information factor was 1.76, so there was no multicollinearity problem. This 1.82 confirms that there is no auto correlation.

The results showed that the nursing ethics ($\beta = .35, p < .001$) and major satisfaction ($\beta = .25, p < .001$) of nursing students had a positive effect on the patient safety management activities of nursing students ($F = 178.65, p < .001$), and the explanatory power of the model was 20.9% [Table 4].

Discussion

In the case of a patient safety accident in a hospital, the impact is not only directly related to the patient's life, but is also a legal issue. However, the accidents that may occur with patients can be prevented by medical institutions and their workers by reducing or eliminating risks. Therefore, systematic patient safety management activities are very important for nurses and an important factor in determining the quality of care^[20].

The purpose of this study was to investigate the effects of ethics and major satisfaction of nursing students on patient safety management activities, and to present basic data for improving the ethics, major satisfaction, and patient safety management activities of nursing students.

The relationship between nursing ethics and the patient safety management activities of nursing students was positively correlated with statistically significant results. In other words, the higher the ethics of nursing students, the higher the performance of patient safety management activities. This is consistent with Song's results measured for clinical nurses using the same tool^[8]. Nursing students should be trained in correct and positive nursing ethics with the right education so that they can be more actively involved in patient safety management. They should also be provided with clear and positive nursing ethics to ensure proper patient safety management activities.

The relationship between major satisfaction and the patient safety management activities of nursing students was positively correlated with statistically significant results. In other words, the higher the major satisfaction of nursing students, the higher the performance of patient safety management activities.

As a result, this study confirmed that factors of nursing ethics and major satisfaction directly affect the patient safety management activities of nursing students. This implies that it is necessary to develop strategies for educational programs to improve students' nursing ethics.

It is difficult to compare the effect of major satisfaction on patient safety management activities in this study with previous studies. However, the direct effects of higher nursing ethics and higher degree of major satisfaction were found to improve patient safety management. Based on this, the development

of education programs and other programs to improve nursing ethics is needed.

Conclusion

This is an explanatory study to identify factors that affect the ethics of nursing students in safety management activities.

As a result, it was found that nursing ethics and key satisfaction factors have a direct impact on nursing students' patient safety management activities.

As a result of this study, it is necessary to develop programs that can improve the degree of satisfaction and inspire the right ethics by acquiring the right values and beliefs for nursing students. We also need to develop strategies for patient safety management programs to prevent life-threatening safety accidents.

The Effects of Maternity Video and Simulation Based Education on Critical Thinking, Interpersonal Relationship, Self Leadership and Major Satisfaction

Seung-Ju Kang¹, Eun-Ju Kim²

¹Professor Department of Nursing, Chunnam Techno University, ²Professor Department of Nursing, Jeonbuk Science College, Korea

Abstract

Background/Objectives: In this study, the clinical nursing skills of nursing students are strengthened through delivery video training and delivery simulations based on the difficulties in labor training, so that critical thinking, interpersonal ability, self-leadership, and major satisfaction could be analyzed.

Method/Statistical Analysis: The purpose of this study is to investigate the effects of video teaching and simulation training on nursing college students. The subjects of this study were 170 out of 178 participants excluding eight dropouts in the G city nursing department in the J area. Structured questionnaires were used as learning tools including general characteristics, critical thinking, interpersonal relationships, self-leadership and major satisfaction. Data were collected from September 2018 to April 2019 and technical statistics, t-test, and paired t-test were conducted.

Findings: Critical thinking($t = -4.53, p = .000$), interpersonal relationship($t = -2.89, p = .005$), self-leadership ($t = -3.00, p = .004$), and major satisfaction($t = -2.31, p = .023$) are all significant, and simulation is more effective than video, and critical thinking, interpersonal relationship, self-initiative, and major satisfaction are positively correlated. The simulation education was significantly lower in the subdomain than the education.

Improvements/Applications: The simulation of training in childbirth showed significant differences in critical thinking, interpersonal relationship, self-leadership, and majors in video education.

Keywords: Video, simulation, critical thinking, interpersonal relationships, self-leadership, majors satisfaction.

Introduction

Nursing education is nurturing professional nurses to meet increasing demand for better medical quality. Nursing theory education and practice education are provided to nursing students so that they can combine their skills in order to work to meet changes in medical

environments. Among them, clinical training is essential for nursing science in order to have the knowledge, skills, and attitudes necessary for nursing practice. However, appropriate fields of practice cannot be secured or there are difficulties for nursing students to have sufficient opportunities for training due to the recent increases in the entrance quota of nursing departments and the enhancement of patients' rights^[1-2]. Since fields of practices where observation and firsthand nursing activities are limited have been increasing due to increases in the number of nursing students participating in training institutions, clinical training is carried out centering on indirect activities. Medical environments require more diverse and active nursing

Seung-Ju Kang

Professor Department of Nursing, Chunnam Techno University, Korea

e-mail: puoo7808@naver.com

practices because patients' diseases are becoming more complicated and the number of critically ill patients is increasing. Although theory education should combine practice education to fill the shortcomings of theory education, at least 70% of practice education in the field is noninvasive nursing such as vital signs and observations and even securing the opportunities for observations is becoming difficult. As for maternal nursing science, although the Korean Accreditation Board of Nursing Education currently requires that maternity nursing science practice should be delivery room practice, it is difficult to obtain firsthand experience in delivery room practice in clinical training unlike other subjects of clinical training because personal privacy is regarded important in the case of delivery room practice. Furthermore, due to the recent increase in male students, opportunities for not only delivery room practice but also other subjects of maternity nursing science practice became scarce. Therefore, measures that can replace practices should be prepared for nursing education that will enable nursing students to efficiently respond in the nursing of subjects.

Simulation education enables students to obtain firsthand experience in virtual reality by preparing simulation practice rooms similar to the environment of hospitals in the school. It enables repeated practices in safe environments so that students' fear of practice due to insufficient training or situations where the patient can be damaged due to the lack of skills can be reduced thereby improving students' confidence as well as helping the improvement of students' knowledge, critical thinking, satisfaction, and clinical nursing practice competency. Since simulation-based training is run in teams, simulation education is helpful not only for personal skills and theories, but also the development of team competencies as nurses. Simulation education can be said to be capable of reducing differences from clinical training in environments very similar to clinics and improving readership, interpersonal ability, and satisfaction as nursing students.

Recently, studies on simulation education have been conducted steadily, but studies that compared simulation education with other education have been hardly conducted. There was a study that compared videos and simulations focusing on respiratory distress cases^[3] and a study that examined the effects of videos regarding childcare takeover and simulation-based training^[4], but no simulation education on maternity nursing science practice could be found. Therefore, this study aims to identify the effects of simulation education and provide

basic data for the expanded application of simulation education thereby contributing to the improvement of the quality of education.

Method

The study was a group of pretested posttest designs. Video training was conducted in the 2nd semester of 3rd grade before simulation training. Simulation training was conducted for 4 hours in the 1st semester of 4th grade. This class was conducted as a simulation exercise by a team of 6 students or less using the Noell Early Childhood Simulator. In G city of J province, 170 nursing students were recruited except 8 dropouts. We chose students who gave them enough information about the study and agreed to participate in the study. Data is collected from September 2018 to April 2019. Researchers have fully explained that before participating in this study, students with negative emotions, such as impulse control and difficulty with depression, can stop participating. Immediately. In addition, the researchers were careful in case some subjects may need treatment or guidance depending on the results of the survey.

The critical thinking ability was measured using the critical thinking ability measuring tool developed by Yoon (2004) for nursing students^[5]. Higher scores mean higher levels of critical thinking. The interpersonal ability was used by the interpersonal change scale, which was revised by Moon^[6] and higher scores mean better interpersonal relationships. Self-leadership used Self-leadership questionnaire developed by Manz (1986)^[7] as a modified version by Kim(2007)^[8] to measure self-leadership level. The higher the score, the higher the self-leadership Key satisfaction scores were measured on a 5-point scale, with 18 items written by Ha (2000).^[9]

SPSS WIN 23.0 Version program is used for data analysis. General characteristic of the subject is used for frequency analysis and descriptive statistic, paired t-test and Pearson's correlation was used for analysis.

Result and Discussion

1. **Difference of Communication Ability after Simulation-Based Education Program:** The average score for critical thinking skills was 7.07 ($t = -4.531, p = .000$), 5.98 for interpersonal relationships ($t = -2.893, p = .005$), and 3.47 for Self-Foldership ($t = -3.000, p = .004$), major satisfaction increased 3.34 points ($t = -2.313, p = .023$). Simulation-based training programs influenced critical thinking skills more than video. [Table 1].

Table 1. The Difference between video training and simulation-based training program (N = 170)

	Video	Simulation	P-D	t	p
CT	91.54±8.90	98.61±10.65	-7.07±14.22	-4.531	.000***

Unit: cm, ***: p<0.005, **: p<0.05

4. Differences in self-leadership after Video and Simulation Program: The mean score of self-leadership was 55.04±8.19 pre-intermediate to

58.51±7.57 post-intervention behavioral strategy ($t = -2.65, p = .010$), cognitive strategy ($t = -2.83, p = .006$) was significantly different [Table 4].

Table 4. Self-leadership After Video and Simulation Training (N = 170)

	Video	Simulation	P-D	t	p
Selfleadership	55.04±8.19	58.51±7.57	-3.47±10.54	-3.000	.004***
Behavioral Strategy	32.92±5.39	34.98±4.78	-2.06±7.09	-2.65	.010**
Cognitive strategy	22.12±3.36	23.53±3.43	-1.41±4.54	-2.83	.006**

Unit: cm, ***: $p < 0.005$, **: $p < 0.05$

Discussion

Few studies measured the effects of video training and simulation-based training using the same tools. The findings of a study conducted by Park and Lim^[4] showed no significant difference in takeover confidence, problem-solving ability, or takeover ability. In a study conducted by Kim et al^[3], the effects of video training were shown to be more significant on nursing performance, readiness, nursing assessment, and nursing intervention. Findings are regarding classes centered on performance and skills and the core of educational programs is not skills but critical thinking, interpersonal ability, self-leadership, and major satisfaction, differences according to the contents of classes should be also considered.

Critical thinking was statistically identical to the results of Kim et al.^[9] The research conducted by Kim & Yu.^[10] who measured the effectiveness of simulation-based teaching method using the same tool, showed the same results as the results of this study because there were no significant differences in subareas. . The tools used were not the same, but objectivity, confidence and intellectual fairness. Kim & Kim^[11], in a study on the effectiveness of simulation learning with problem-based learning, showed an increase in the mean score, unlike this study, but the difference was not significant. The study of Lee.^[12] impact on critical thinking, communication, and clinical practice skills in nursing students differed only in intellectual fairness and objectivity. The significant difference is considered to be due to improvement through peer review.

In interpersonal competence, the research conducted by Kang et al^[13] showed the same results as the above findings, although the tools used were not identical,

but there were significant differences in interpersonal competence through simulation training^[14] and the results of measuring the effects of e-learning and simulation showed the same significant difference as this study. Important differences shown in the subarea. Sensitivity, communication, intimacy, comprehension, and openness are considered due to the fact that simulation training is more like real practice than video. Due to the fact that video and simulation training are not real clinical practice, a slight difference in satisfaction and reliability is taken into account.

The research conducted by Kim and Song^[15] on major satisfaction showed a significant difference in the self-leadership created by simulation education, consistent with the above findings. The significant differences in behavioral strategy and cognitive strategy, which are sub-areas, are considered attributable to the fact that unlike video training, simulation education was carried out in teams so that the students could become a leader to solve problems in situations.

Conclusion

This study was conducted to examine nursing students' critical thinking, interpersonal ability, self-leadership, and major satisfaction after conducting video training and simulation training so that the findings of this study can be used as basic data later in revising the direction of guidance of maternity nursing practice. Although nursing students complete maternity nursing practices together with maternity nursing science, there are problems such as the lack of training institutions, poor training environments, and the phenomenon of avoiding male student training. Therefore, educational programs that can supplement the training should be

operated. Therefore, the students who started the training were educated on the shortcomings of practices through videos in classes, and thereafter, those parts that could not be practiced and those parts that were insufficiently practiced were educated through simulations.

The findings of this study showed significant differences in critical thinking, interpersonal ability, self-leadership, and major satisfaction between video education and simulation education consistently with previous studies. The study findings in some subareas were consistent with those of previous studies but those in other subareas were not. This is considered attributable to the effects of differences in the compositions and contents classes and the characteristics of students and professors who participated in the classes. In particular, interpersonal ability, self-leadership, and major satisfaction were not studied very much as variables after the simulation education programs and were not compared among different educational programs. Therefore, the foregoing variables should be studied later because teaching-learning method that will enable students to learn the knowledge and skills the most efficiently instead of practices should be selected.

Based on the findings of this study, simulation-based educational programs can be said to be appropriate education and learning method that can fill the shortcomings of practices because they provide students with experiences of firsthand playing professional roles and studying and thinking things necessary for the roles in advance instead of practices in which they just observe what others do. In addition, simulation-based educational programs are considered helpful in clinical fields after graduation because they affect interpersonal ability, self-leadership, and major satisfaction. Recently, diverse teaching and learning method have been presented, smart education using diverse electronic devices and applications has been strengthened, and integrated simulation education programs have been operated. Therefore, this researcher wishes to propose studies to develop diverse and appropriate nursing education method, studies of diverse variables of such nursing education method, and studies of education method.

Differences of Muscle Activities of Various Bridge Postures Using Thera-band on the Stable Surface

Seol-Ah Kang¹, Soo-Jeong Kwon¹, Dong-Yoep Lee², Ji-Heon Hong², Jae-Ho Yu², Jin-Seop Kim²

¹Student, ²Professor, Sunmoon University, Physical Therapy, South Korea

Abstract

Background/Objectives: This study was conducted to compare and analyze the muscle activity of vastus lateralis, muscle vastus medialis, spinal erector muscles and gluteus maximus muscle using the EMG measuring device and suggest effective results of the bridge exercise when conducting the bridge exercise with various bridge postures using resistance of Thera-band on the stable support surface.

Method/Statistical Analysis: In order to examine the difference in the muscle activity of vastus lateralis, vastus medialis, erector spinae and gluteus maximus, a total of 3 exercises were conducted by each different posture; the normal bridge posture, the hip adduction bridge posture using the resistance of Thera-band and the hip abduction bridge posture using the resistance of Thera-band. The measured results of the experiment was analyzed by repeated measure analysis of variance

Findings: The results showed that muscle activity was all higher when conducting the bridge exercise using the resistance of Thera-band for vastus lateralis, vastus medialis, erector spinae and gluteus maximus, In the hip adduction bridge posture, vastus lateralis and vastus medialis showed significant difference, and in the hip abduction posture, gluteus maximus showed significant difference compared to the normal bridge posture.

Improvements/Applications: It is considered that the hip abduction bridge exercise and the hip adduction bridge exercise using the resistance of Thera-band can help stabilize the body.

Keywords: Bridge exercise, Thera-Band, Hip Adduction, Hip Abduction, Muscle activity.

Introduction

More than 50% of the modern people are often experiencing low back pain in their lifetime. The strength of the body stabilization muscle is weakened by the decrease of physical activity. And there is a lot of time for the modern people sitting in abnormal posture for a long time and having excessive tension, which also weakens gluteus maximus muscle, the one of the strong hip joint extensor^[1,2,3]. According to Sahrman and Van

Wingerden, the weakening of gluteus maximus muscle, declines and function cause instability and dysfunction of the hip joint and excessive activity of spinal erector muscles^[4,5,6]. Therefore, exercise for the body stabilization muscle has been applied for the lumbar region and the back pain. It has been recognized as an effective exercise therapy for the low back pain and prevention^[7,8]. The muscles related to the body stabilization maintain the center of body and stabilize the back when body is moving^[9]. Previous studied that exercise for the body stabilization restores muscle and moving control ability, especially stabilizes erector normal muscle and gluteus maximus muscle are strengthened and more effective for balance. In particular, gluteus maximus muscle is the most strong muscle among the muscles related to the body stabilization exercise and improves stabilization of joints and delivers power to pelvis from

lower body at initial contact because direction of fibers is vertical on sacroiliac joint and it plays an important role in daily lives^[7,8,10]. O. Sullivan and Moon reported that the body stabilization exercise protects the spine from repetitive damage, increases stability, reduces pain relief, dysfunction and improves muscle strength to restore balance and exercise control capacity. It is more effective than preservation treatment^[11,12,13]. In recent days, bridge exercise is recommended interventions for the low back pain among various exercise treatments^[9]. The bridge movement is a closed chain exercise that increases strength by strengthening of the vastus lateralis muscle, vastus medialis muscle, erector spinae and gluteus maximus muscle. It also increases the stability of the body including the spine and lumbosacral region. Everyone can easily learn and practice therefore it is used often. As it activates local muscle fatigue and global muscle, it helps muscular cooperation^[7,9,14]. Some studies reported that resistance exercise of the closed chain exercise which strengthens the lower body with Thera-band is very effective and resistance exercise using the Thera-band is the most effective way to improve the balance of activities of daily living^[14,15]. As Thera-band has elasticity, it can avoid the risk of excessive exercise and easily used by anyone to do exercises. It has advantages of stability and practical and effective results in improving muscle strength^[16,17]. Likewise, there are many studies on the effect of the bridge exercise to reduce the back pain but studies on various bridge postures on the stable support surface using thera-band is insufficient. The purpose of this study is to compare the changes of muscle activity such as vastus lateralis, vastus medialis, erector spinae and gluteus maximus muscle depending on various bridge posture.

Table 1. Study subjects general characteristic (n=17)

Division	Mean Value
Gender (M/F)	8/9
Age	21.4±1.12
Height	167.5±6.19
Weight	63.2±13.39

Method

The subjects of this study were healthy men and women. As a total of 17 subjects had no medical history of knee, ankle, hip joint and spine (8 men, 9 women). Before they participate in this study, the subjects were

fully explained the content and purpose of the study and received the consent to participate in the experiment. The normal characteristics of the study subjects are as follows [Table 1]. Before the exercise, bridge exercise was conducted in a lying position after attaching the electromyogram pad to the regions of vastus lateralis, vastus medialis, erector spinae and gluteus maximus muscle for the experiment measurement. Exercise was divided into three types and normal bridge exercise on the stable support surface, bridge exercise in the hip joint posture, and bridge exercise in the hip open posture were conducted for 10 seconds for each exercise. When the bridge exercise was conducted, both arms of the subject were placed 30 degrees far from each body. Both toes were facing forward, and the width of both feet was between 15cm. The angle of the knee was bent at 90 degrees and scapula, lumbar, pelvis, hip knee and ankle were made straight. The bridge exercise is to lift the hips and lumbar with bending the knee at 90 degrees when lying down and facing ceiling. It promotes the stability of the body including the spine and lumbosacral range. They were guided to make a smooth slope and keep lifting foot from the ground when lifting waist and hip and they kept making their scapula, lumbar, pelvis, hip, knee and ankle straight. First, the width of the feet was fixed to about 15cm before the exercise on the stable surface and both of arms angle was at 30 degrees, the normal bridge posture without Thera-band was measured. Secondly, the bridge posture of the hip adduction was measured by giving resistance using Thera-band under the same conditions. Thirdly, the bridge posture of the hip abduction was measured by giving resistance using Thera-band under the same conditions. In this study, we used OQUS100 (Zero WIRE EMG, Noraxon) to measure the muscle activity of vastus lateralis, vastus medialis, erector normal and gluteus maximus muscle. The sampling rate was 1,024 Hz when measuring the surface EMG. In order to remove the noise, 60Hz band stop filter and 10 to 500Hz band pass filter were used. The EMG signal was amplified by 1785 times. Signals of the collected muscle activity were recorded by full wave rectification and root mean square (RMS). For data analysis, SPSS 20.0 version program was used. And one way repeated measured test and Bonferroni was used to examine the difference between individual interventions according to muscle activity during various bridge exercises using Thera-band on the stable support. Statistical significance level was set to p<.05.

Result

There was statistically significant difference between NBE and HABT (p<.05) but there was no statistically significant difference between NBE, HABT, HDBT and HABT (p>.05)[Table 2][Figure 1]. Difference of activity level of vastus lateralis depending on various bridge postures using Thera-band. There was statistically significant difference between NBE and HDBT, HDBT and HABT (p<.05), but there was no statistically significant difference between NBE and HABT (p>.05) [Table 2] [Figure 1]. There was no statistically significant difference between NBE and HDBT, HDBT and HABT, NBE and HABT (p>.05)[Table 2] [Figure 1]. There was statistically significant difference between NBE and HABT, HDBT and HABT (p<.05) but there was no statistically significant difference between NBE and HDBT (p>.05) [Table 2] [Figure 1].

Discussion

In this study, the muscle activity of vastus lateralis, vastus medialis, erector spinae and gluteus maximus was measured and analyzed using resistance of Thera-band on the stable support.. As a result of the bridge exercise using Thera-band, there was a significant difference between NBE and HDBT in vastus lateralis. However, Vastus medialis, there was significant difference between NBE, HDBT and HDBT and HABT. There was no significant difference between NBE, HDBT, and HABT in erector spinae. And there was a significant difference between NBE, HABT and HDBT, HABT in gluteus maximus muscle. Therefore this study recorded about high muscle activity when conducting HDBT and HABT. The vastus lateralis and vastus medialis related to knee extension among quadriceps femoris is the strongest muscle. In the study, the bridge exercise in HDBT showed higher muscle activity than the bridge exercise in NBE or HABT. The bridge exercise in HDBT showed more activation rather than the bridge exercise in NBE and HABT because it tightens hip and hip adduction. Therefore it is considered that the muscle activity of vastus lateralis and vastus medialis is increased. Quadriceps femoris that is related to the bridge exercise conducted by many precedent researches is the main muscle that maintains the normal posture of the knee joint and stabilizes the hip joint, as it contracts the hip joint adductor muscles when exercising, it increases vastus lateralis muscle and vastus medialis muscle. It is reported that it is more effective to increase muscle activity when exercising the hip joint adductor muscle and

abduction activity^[9,15,18,19]. The erector spinae stretches the body and acts against gravity when conducting the bridge exercise, therefore the muscle activity of each muscle is not different from other muscles. And it is considered that the muscle activity of gluteus maximus muscle was increased and the muscle activity of erector spinae was decreased. Both of them had interaction for each other. The bridge exercise is useful for increasing the lower part of spine, lumbar vertebrae, abdominal muscle, pelvis, hip joint extensor strength and motor control ability, the activation of abdominal muscle acts an effective element to stabilize the pelvis toward the pulling force of hip joint muscles and the power of the body goes to the lower part and hip joint muscles when pelvis is stabilized^[20]. As gluteus maximus stretches the body like the erector spinae and acts a role of the hip joint extension and external rotation, muscle action was stronger when conducting HABT rather than NBE and HDBT. This was consistent with the results of previous studies which suggested that muscle pulling direction can increase the amplitude of muscle activity because it is to be optimized when in horizontal line with the muscle fibers. It also helps prevent damage of the local muscles such as spine, joints, and ligaments. This exercise is a basic exercise for the body stabilization exercise practicing on a normal mat by drawing up a knee at 90 degrees. It is an important exercise to make a posture of drawing up knee with loading weights on both feet. As it develops the control of sitting and standing, it is widely used as a useful exercise for improving muscle strength^[13]. However, there was no significant difference when all muscles exercise were conducted in various bridge postures using the resistance of theraband. This is because there can be difference in muscle activity depending on the existence and nonexistence of the resistance of theraband when exercising with Thera-band. When conducting exercise in NBE on the stable support, it maintains a more normal posture because of no resistance. However, HDBT and HABT use more strength against resistance and have difficulty in maintaining posture and balance. Therefore, It is believed that muscle activity of vastus lateralis, vastus medialis, erector spinae and gluteus maximus was more increased. In addition, when conducting exercise in NBE without resistance of theraband on the stable support, it uses less strength rather than the muscle activity of vastus lateralis, vastus medialis, erector spinae and gluteus maximus when conducting exercise in HDBT and HABT. This study suggests some limitations. First, the noise of the signal may be generated according to

the muscle movement or the fine movement due to the characteristics of the surface EMG measurement when having the bridge exercise. Second, in this study did not focus on one gender of the subjects, therefore there can be difference of muscle activity depending on gender. It is expected to have a study on differences of muscle activity for the same gender in future studies.

Conclusion

This study was carried out to investigate the changes of muscle activity on various bridge postures using the resistance of Thera-band on the stable support during the bridge exercise. The results showed that VLO and VMO when conducting exercise in HDBT increased muscle activity. And GM when conducting exercise in HABT increased muscle activity than NBE. Therefore, it is expected that it will be a more effective bridge exercise method if use necessary intervention method for each posture to increase activity of certain muscle.

Abstract

Background/Objectives: The kettle bell exercise is effective in improving the strength and physical strength of the whole body as a popular exercise for modern people. The purpose of this study was to compare the muscle activity of Biceps femoris, Vastus medialis oblique, Erector spine and Anterior deltoid depending on shoulder joint flexion angle when conducting kettle bell swing.

Method/Statistical Analysis: The kettle bell exercise is effective in improving the strength and physical strength of the whole body as a popular exercise for modern people. The purpose of this study was to compare the muscle activity of Biceps femoris, Vastus medialis oblique, Erector spine and Anterior deltoid depending on shoulder joint A total of 30 healthy men and women who agreed to participate in the study were the subjects. All of the kettle bell swing starting positions were conducting with flexion knee about 50° and the whole body. The shoulder flexion angle was set 90°, 140°, 180° and the end position was the same as the starting position. For comparison of the muscle activity depending on shoulder joint angle, One-way Repeated ANOVA was used and Bonferroni method for post-test.

Findings: Biceps femoris showed significant differences at all degrees ($P < .05$). And vastus medialis oblique and anterior deltoid showed significant difference at 90°, 140°, 180°. And there was no significant difference between 140° and 180° ($p > .05$). There was no significant difference in the spinal erector muscle ($p > .05$).

Improvements/Applications: Therefore the muscle activity degree for each muscle was clearly different depending on the shoulder angle.

Keywords: Kettle bell, kettle bell swing, muscle activity, exercise, peak value.

Introduction

In the modern industrialized society, physical labor work has become rare due to technological advance and sedentary style of living has spread widely^[1]. Therefore the average amount of daily physical activity in humans has decreased dramatically over the past century^[1]. However, regular physical activity is essential for the prevention of health problems such as chronic

diseases. It is known that physical exercise is beneficial to the body in various ways^[1]. People are getting more recognized on how health care impacts on the quality of life. The World Health Organization defined the health as “a dynamic and complete state of physical, mental, social, and spiritual well-being and absence of disease.” It means absence of physical anomalies and active physical activity. Physical activity does a positive influence on physical health and is an essential factor for health promotion as it is also effective in mental health. Especially kettle bell training has been very popular by the strength and conditioning community in recent years. Fitness experts and coaches often suggest that kettle bell training is an excellent way to develop explosive strength^[2]. Manocchia et al study stated that the kettle bell is an effective way to improve physical

e-mail: skylove3373@sunmoon.ac.kr

fitness and has the effects of increased body strength. And the kettle bell is not only limited to athletes' sport training^[3]. Basically, the kettle bell swing is technically a simple and full-body exercise^[4]. Also the kettle bell exercise reduces neck and shoulder pain and back pain, improves muscle strength, hips and waist, pelvic muscle strength and endurance^[5-6]. Among the studies related to the kettle bell exercise, studies on the swing type have been conducted for comparison of peak force and muscle activity^[7-8]. A study on peak values in three swings of shoulder height, overhead, and Indian club swing did not measure muscle activity even though the shoulder joint flexion or abduction angle was different for each type^[7]. In the study comparing the muscle activity of each type; kettle bell arm swing (Swing), arm swing style snatch (Snatch), arm clean (Clean) were not classified according to the shoulder joint flexion angle^[8]. Studies on observation of the muscle activity of the whole body including the upper limb and the lower limb according to arm lifting angle with flexion shoulder are lacking. Thus, this study is to investigate the most effective type of kettle bell swing by comparing the muscle activity of various parts according to the shoulder joint flexion angle.

Method

This study subjects were 30 healthy male and female adults in S university located in Asan, Chungnam. They had no medical history or visiting for shoulder, knee or back pain. All the subjects voluntarily participated through advertisement invitation and were finally selected after confirming that they meet the following criteria. The subjects should have meet the following criteria. 1) Those who did not visit the hospital due to shoulder, knee, and back pain 2) Those who have no pain or discomfort when moving shoulder, knee or waist 3) Those who did not get surgery on shoulder, knee or waist. 4) Those who have no inflammatory, degenerative joint or connective tissue disease 5) Those who have musculoskeletal disease in shoulder, knee, or waist. The physical characteristics of the subjects were as follows. In this study, a total of 30 subjects (15 men and 15 women) were randomly selected and the muscle activity of Biceps femoris, Vastus medialis oblique, Erector spine and Anterior deltoid when conducting kettle bell swing depending on shoulder joint flexion 90°, 140° and 180°. The weight of kettle bell was 8kg for male and 4kg for female. For the starting position, they bent the hips and knees slightly at degree 50°. They left up kettle bell at shoulder flexion angle and the shoulder flexion angle

was 90°, 140° and 180°. After 3 times of shoulder joint flexion angle and 3 minutes of rest time, they moved on the next experiment. The end position was the same as the starting position.

And the peak value of muscle activity of each muscle was found when conducting kettle bell exercise. In order to examine the muscle activity of Biceps femoris, Vastus medialis oblique, Erector spine and Anterior deltoid, EMG (Zero WIRE EMG, EMG OQUS100, Italy, 2009) was used. The collected EMG analog signals from 4 channels were converted to digital signals by MP150 system and the study is analyzed using EMG software myoresearch 1.06.44 software. The sampling rate of EMG signal was set to 1,000Hz and the subsequently smoothed by a RMS filter of 50ms. In order to examine the muscle activity of the subjects' shoulder joint flexion depending on 90°, 140°, 180° when conducting kettle bell swing, surface EMG was attached on each muscle. The attachment part is as follows. 1) The EMG attachment part of Biceps femoris is 15cm below the ischial tuberosity. 2) The EMG attachment part of Vastus medialis oblique is attached to the inner oblique direction of the center line from 2cm above the knee bone. 3) The EMG attachment site of Erector spine is attached on the outside of neural spine 3cm far from lumbar vertebrae number 4 and 5. 4) The EMG attachment part of Anterior deltoid is attached 3.5cm below the front of the acromion. For precise measurement, electromyography was performed to clean the attachment part before attaching surface electrode adherence. It minimized skin resistance and wiped the electrode attachment part by alcohol cotton. In order to analyze the data of this study, SPSS 22.0 version program was used. And one-way repeated ANOVA was used to compare the muscle activity depending on shoulder joint flexion angle and post-test was conducted with Bonferroni. The statistical significance level of this study was set at $p < .05$.

Result

The EMG signals of the muscles was measured depending on 90°, 140°, 180° flexion when conducting kettle bell swing. As a result, there was significant difference between the muscle activity of lower limbs muscle and deltoid muscle depending on flexion angle ($p < .05$). The peak value of Biceps femoris was $284.93 \pm 133.65\%$ when flexion shoulder joint at 90° and $404.66 \pm 143.23\%$ when flexion shoulder joint 140°. And $356.80 \pm 164.48\%$ when flexion shoulder joint 180°. All flexion shoulder joint showed significant differences

($p < .05$). The peak value of vastus medialis oblique was $619.47 \pm 130.26\%$ when flexion shoulder joint at 90° , $680.45 \pm 120.65\%$ when flexion shoulder joint at 140° and $718.77 \pm 144.34\%$ when flexion shoulder joint at 180° . All flexion shoulder joint showed significant differences ($p < .05$). However, flexion angle 140° and 180° had no significant differences ($p > .05$). The peak value of anterior fiber of deltoid muscle was $507.15 \pm 206.03\%$ when flexion shoulder joint at 90° , $596.91 \pm 206.46\%$ when flexion shoulder joint at 140° , $623.01 \pm 190.94\%$

when flexion shoulder joint at 180° . All flexion shoulder joint showed significant differences ($p < .05$). However, flexion angle 140° and 180° had no significant differences ($p > .05$). The peak value of the erector spine was $389.75 \pm 204.35\%$ when flexion shoulder joint at 90° , $428.51 \pm 181.92\%$ when flexion shoulder joint at 140° and $446.59 \pm 148.56\%$ when flexion shoulder joint at 180° . All flexion shoulder joint showed no significant differences ($p < .05$). [Table 1] [Figure 1].

Table 1. EMG of muscles depending on shoulder joint flexion 90° , 140° and 180° when conducting kettle bell swing

	90°	140°	180°	F
Biceps femoris	284.93±133.65	303.66±143.23	356.80±164.48	6.42*
Vastus medialis oblique	619.47±130.26	680.45±120.65	718.77±144.34	12.81*
Erector spine	389.75±204.35	428.51±181.91	446.59±148.56	1.40
Anterior deltoid	507.15±206.03	596.91±206.46	623.01±190.94	11.79*

Figure 1. Comparison of muscle activity depending on shoulder joint flexion angle

Discussion

This study compared the muscle activity of various muscles when conducting kettle bell swing depending on the change of shoulder joint flexion angle. As a result, there was a statistically significant difference in Biceps femoris, Vastus medialis oblique, Erector spine and Anterior deltoid depending on shoulder joint flexion angle. In biceps femoris, as shoulder joint increased, the signal intensity of the EMG signal was higher. And vastus medialis oblique and anterior deltoid showed higher muscle activity at flexion angle 140° and 180° rather 90°. There was no significant difference between 140° and 180° flexion of vastus medialis oblique and anterior deltoid. The study on peak values according to three swing method of Bullock et al suggested that shoulder height kettle bell swing; SKS, overhead kettle bell swing; OKS, indian club swing; ICS resulted that SKS was shorter in cycle than OKS and vertical impacts were relatively low^[7]. And this study measured foot flexion of the ankle joint, extension of the knee joint and extension of the hip joint using Visual 3D (C-Motion, Bethesda, Maryland, USA) when conducting kettle bell exercise. As a result, SKS and OKS showed greater maximum force in foot flexion of the ankle joint and extension of the hip joint compared to ICS. And vertical ground reaction force was also greater^[7]. In this study, the shoulder joint flexion angle was divided into 90°, 140° and 180° to conduct kettle bell swing. The study was conducted to find the effects of kettle bell swing depending on shoulder joint flexion size. Bullock's et al similarly studied the swing type by dividing into three. However OKS and ICS was similar in terms of flexion shoulder maximumly when considering kettle bell swing and focusing on shoulder joint movement. Therefore there was lack of examining muscle activity depending on flexion angle. The kettle bell exercise is for whole body but this study was insufficient to examine various muscles depending on swing type by measuring the peak value of the lower part of muscles. For this reason, this experiment was conducted. The study above showed that the cycle time of OKS was 34% longer than that SKS and ICS. This study also showed that the operation time of the swing with shoulder joint flexion at 180° was the longest. And the peak value of OKS was higher than that SKS when the hip joint was opened. This study showed that the muscle activity of biceps femoris which opens the hip joint was higher at 140° than 90° and was also higher at 180° than 140°. The results were similar to the previous studies. According to Studies by McGill and Marshall said healthy subjects did kettle bell

swing with both hands and resulted in an activation of MVIC (maximal voluntary isometric contraction) of $70.1\% \pm 23.6\%$ ^[5]. This was within 50% to 60% of MVIC which is proposed to be stimulating enough to muscle strengthening^[9-11]. This suggests that the swing method with both hands is more effective than the one-handed swing. Therefore, this study was designed as a swing method with both hands. And the most effective and responsible reaction was measured by dividing shoulder flexion angle into three stages rather than simply focusing on swing with both hands. Lyons et al measured the muscle activity of biceps femoris, anterior deltoid and posterior deltoid, spinal erector muscle, vastus lateralis, external oblique abdominal muscle and gluteus maximus muscle^[8]. In particular, the spinal erector muscle showed greater muscle activity in the swing type than the Snatch type^[8]. Since the Kettle bell exercise method of this study was also the swing, it measured the EMG of the spinal erector muscle when conducting kettle bell swing. However, there was no difference in the effect according to the height of the shoulder joint because it was the intervention method using the similar type. In the hip joint exercise, the muscle activity of biceps femoris was also measured when conducting the kettle bell swing. As he subject of this study was the result of muscle activity depending on shoulder joint flexion angle, it measured the anterior fiber of deltoid muscle and the EMG signal of biceps femoris which is one of the important factors in the kettle bell swing exercise and stretches knee. Especially, vastus medialis oblique is the weakest physiologically as an inner support surface and muscle weakness appears first^[12]. The weakening of vastus medialis oblique breaks the balance of the muscular development of biceps femoris and responds outsider support surface and decreases inner power when stretching knee joint. Therefore it can cause PFPS (Patella Femoral Pain Syndrome) and subluxation of knee bone. Since the role of vastus medialis oblique is important, the study examined which position causes the highest muscle activity when conducting the kettle bell swing. As a result, it is considered that vastus medialis oblique increases momentum in range of shoulder joint angle over 90 degree and causes the higher muscle activity. Therefore, it can be applied effectively to patients with PFPS. The limitation of this study is that subjects were all healthy 20s' generation people but not various ages or professionals. Therefore it is difficult to generalize the result of the study. And the subjects' fat mass, body fat percentage, muscle mass, and normal exercise status were not taken into considerations. The

experiment group was divided into each gender without considering weight differences. Because the subjects exercised kettle bell of the same weight, it caused the limitation. It would be possible to suggest better results if the limitation of this study is to be removed in future studies.

Conclusion

The results of this study showed significant difference in the muscle activity of biceps femoris, vastus medialis oblique, erector spine and anterior deltoid but no significant difference in the erector spine. Therefore the muscle activity degree for each muscle was clearly different depending on the shoulder angle. The kettle bell exercise of various shoulders joint is recommended on basis of the results of the study.

Change in Lower Extremity Muscle Activity with Visual and Noises During Walking

Eun-Hye Kim¹, Da-Hyun Lee¹, Su-Bin An¹, Dong-Yoep Lee², Ji-Heon Hong², Jae-Ho Yu², Jin-Seop Kim²

¹Student, ²Professor, Sunmoon University, Physical Therapy, South Korea

Abstract

Background/Objectives: In this study, four conditions of visual and noises were examined to determine the inferior limb muscle activity after walking for 10 minutes on a treadmill.

Method/Statistical Analysis: Nine males and nine females, who agreed to participate in the study, were recruited. Participants were asked to walk on a treadmill for 10 minutes on each of the four conditions (a), (b), (c), and (d) depending on visual acuity and noise. Electromyograph was used to measure and compare muscle activity.

Findings: There was no significant difference in biceps femoris muscle ($p > .05$). The comparison of the tibialis anterior muscle resulted in a significant difference between the conditions a-c, a-d, b-c and b-d ($p < .05$). This indicates that conditions in those visually impaired became more vital in comparison to those that were not visually impaired. The muscle activation by condition was $d > c > b > a$, followed by de-conditioned vision and dB was the highest when it was higher 90. The comparison of the lateral gastrocnemius muscle resulted in a significant difference between the a-c, b-c and b-d conditions ($p < .05$). This indicates that conditions without vision have become more vital than those with vision. The muscle activation by condition was $d > c > b > a$, followed by de-conditioned vision and dB was the highest when it was > 90 . The comparison of the medial gastrocnemius muscle showed that not all four conditions differed significantly ($p > .05$).

Improvements/Applications: There was significant difference in muscle activity between TA, LGM than when vision was blocked, that the muscle activity has improved when walking over 90 dB than 60 dB.

Keywords: Gait, Visual, Noise, Treadmill, Electromyography.

Introduction

Walking is a routine human activity and a continuing event involving multiple systems simultaneously including the nervous system, sensory motor, musculoskeletal, and visual vestibular systems^[1,2]. Walking is a very complex behavior, and normal walking should precisely control limb movements,

posture and strength, a very complex process involving the entire nervous system^[1,3,4]. Human walking is one of the most common forms of exercise, but it is important to understand what specific functions of the leg can be used to perform effective walking^[5,6]. Increasing walking speed increases leg muscle activity and energy consumption^[2,7]. Visual deprivation of gait stability reduces dynamic stability and increases dependence on somatosensory and vestibular systems to control gait stability^[4,8]. Walking is a beneficial means of transportation for individuals and communities and provides health benefits that improve balance, improve bone growth and improve mobility^[2,9]. Today, the use of trade mills is used as a tool for rehabilitation and exercise as well as gait assessment, and trade mill training has become an important therapeutic

e-mail: skylove3373@sunmoon.ac.kr

intervention in neurological rehabilitation over the last few years^[2,10]. The difference between walking on the ground and walking on the trade track is that people can choose speed, walk shorter or wider, and spend less time at the swing^[11]. According to preliminary studies, only 90% of the information about the human brain is transmitted to the eye^[12]. Obstructing other parts of the visual field, including the peripheral vision, has an important effect on gait dynamics^[13,14]. Vision provides information about the environment from a distance and plays a crucial role in mobility in maintaining stability and path when visually recognizing the environment on the move. In order to adjust the foot spacing and foot position and to control the walking speed, it is important to visual recognition of self motion, limb position, and limb movement^[15]. Auditory information affects the sensory motor control of gait. During walking, people are accustomed to body-related and environmental sounds, and the reduction of auditory information using active noise reduction has surprisingly improved walking stability when using active noise reduction compared to normal walking^[16]. In addition, auditory noise has been shown to have additional effects on postural stability independent of vision^[17]. Viljanen et al show that people with poor hearing are at high risk of falls and are partially explained by poor posture. For safe mobility, hearing information on the environment is important^[18]. Previous studied physiological decline in visual, auditory, physical stability and muscle strength can mitigate accident risk and lead to slower defensive responses^[19]. Hafström et al have shown that visual perception is important for controlling multiple senses in posture and contributes to spatial direction and self-motion perception^[20]. Saucedo et al also provides essential sensory information to maintain dynamic stability during human motion^[21]. Negahban et al report that hearing and vestibular systems are closely related anatomically and physiologically^[22]. In previous studies, there have been studies to confirm the effects of visual, noise, and gait, but no studies have been done to confirm the gait activity of the gait with visual and noise. The purpose of this study was to investigate the effect of muscle activity on the gait during gait with respect to noise and visual acuity in healthy adult males and females.

Method

The subjects of this study were 18 healthy adult students (9 males and 9 females) who were admitted to S university in Asan city, Chungnam. The general

characteristics of the participants are shown in [Table 1]. The study participants consisted of those who agreed to participate in the study, and the muscle activity was measured in the dominant foot direction. The EMG QUS100 (Zero Wire EMG, Italy, 2009) was used to measure muscle activation, with the biceps femoris muscle, the anterior tibial muscle, the lateral gastrocnemius muscle, and the medial gastrocnemius muscle. EMG was attached to each muscle after shaving to reduce skin resistance of EMG. When measuring the surface EMG, the sampling rate was 1024 Hz, the EMG signal was 1785 times, the bandpass filter was 20 to 500 Hz, and the notch filter was 60 Hz. The collected EMG signals were recorded in root mean square (RMS). In this study, one person participated in all four conditions and selected the subjects without musculoskeletal diseases according to four conditions according to the presence of visual block and decibel size. The test items were height, weight, and dominant foot. Before the experiment, subjects were instructed about the purpose of the experiment and the study procedure, and the same clothes were worn for the same settings of all the subjects. The first condition is that the eyes are not blocked on the treadmill and that you are walking at a comfortable speed for 10 minutes under 60dB. During walking, the gaze was directed toward the front. The second condition is that you do not block your eyes and you walk for 10 minutes at 90dB. During walking, the gaze was directed toward the front. The third condition is that you are walking at a comfortable speed for 10 minutes in an environment where the time is blocked and the decibel is below 60dB. SPSS/PC ver. 22.0 for windows program (SPSS INC, Chicago, IL). Each mean and standard deviation were calculated to see the characteristics of subjects, and one-way repeated measures ANOVA was used to see the activity of each leg muscle according to the conditions. A significant level of analysis of all statistics was set at $p < .05$.

Result

Four conditions on the treadmill in the environment where the time is not blocked, the environment is 60dB or less, the time is not blocked, the environment is 90dB or more, the time is blocked, the decibel is 60dB or less, the time is blocked and the time is over 90dB. First, the results of biceps femoris muscle, there was no significant difference in all four conditions ($p > .05$) Second, the results of tibialis anterior muscle, there was a significant difference between the conditions of a-c, a-d, b-c and b-d ($p < .05$)[Table 2][Figure 1]. $d > c > a > b$ are shown

in [Table 2][Figure 1]. Third, The results of lateral gastrocnemius muscle, there was a significant difference between the a-c, b-c and b-d conditions ($p < .05$) [Table 2]][Figure 1] and $d > c > a > b$ are shown in [Table 2] [Figure 1]. Fourth, the results of medial gastrocnemius muscle, there was no significant difference in all four conditions ($p > .05$) [Table 2] [Figure 1].

Discussion

The purpose of this study was to investigate the change of muscular activity of the lower extremity muscles according to visual and loudness in human walking. As a result, there was a significant difference ($p > .05$) between the mean and peak values of the tibialis anterior muscle group and the peak value of the lateral gastrocnemius muscle group ($p > .05$) and the mean value and peak value of biceps femoris muscle and medial gastrocnemius muscle. There was no significant difference in the mean value of lateral gastrocnemius muscle. Mendonça et al attempted to observe the effect of a rhythmic signal while walking on a treadmill, because walking with his or her gait as an auditory cue synchronized with hearing cues, There was no difference between the effects of gait or music stimulation. This means that it is not effective to use his/her gait as an auditory clue and to use musical stimulation as an auditory cue^[23]. In this study, musical stimulation due to difference in decibel influences muscle activity during gait. Do not. Saucedo et al reported that the decrease in stability due to visual deprivation during treadmill walking is similar among age groups. This suggests that visual deprivation, regardless of age, reduced gait stability^[21]. In general, it is consistent with the study that muscle activation is more likely to occur when walking under conditions of walking without visual intervention than when walking with visual interception. However, when there is a difference in visual intercept, not all muscles show significant differences. There was no significant difference between biceps femoris muscle and medial gastrocnemius muscle. In this study, muscle activity showed the highest value when the time was blocked at the maximum value of tibialis anterior muscle and lateral gastrocnemius muscle. Hamacher et al reported that hearing information has an effect on walking control and improved walking stability when using active noise elimination compared to normal hearing. As a result, noise reduction is required to improve walking stability^[16]. This is consistent with the results of our study that the condition of noise removal resulted in low muscle activity. Sejdic et al studied the effect of music appreciation on walking. Walking is accomplished through neural control systems such as visual, vestibular, and proprioceptive systems, and walking with music leads to a more unstable stride interval sequence than with no music. This means that walking with music is unstable walking^[24]. In this study, we prove that the effect of muscle activity is affected by presenting unstable walking factors. Karim et al reported

that the presence of sound significantly improved walking ability when sight was limited. This proves that noise enhances walking ability in time-interrupted conditions^[25]. Palm et al indicate that visual information improves posture stability. In the 75-80 dB auditory information, the postural control is not deteriorated without visual input, but maintains postural stability^[26].

Conclusion

The purpose of this study was to investigate the effect of muscle activity on the gait during gait with respect to noise and visual acuity in healthy adults. When the walking time was not blocked, the TA muscle activity was improved compared to when the time was blocked. Noise was not significantly different in the four muscles during walking. In conclusion, the condition that does not block the visual acuity during walking will help to activate the anterior tibialis anterior muscles. The results of this study showed that muscle activity was not related to noise. Rather, it showed that muscle activation was decreased when the eyes were blocked. Therefore, it is recommended to use visual factor rather than auditory factor for muscle activation.

Immediate Changes of Shoulder External Rotation Exercise of Various Angle on the Distance of Subacromial Space

Da-Young Choo¹, Hae-Young Lee¹, Seung-Hee Jang¹,
Dong-Yoep Lee², Ji-Heon Hong², Jae-Ho Yu², Jin-Seop Kim²

¹Student, ²Professor, Sunmoon University, Physical Therapy, South Korea

Abstract

Background/Objectives: This study was conducted to examine the distance of the subacromial space when conducting external rotation according to the shoulder joint abduction angle

Method/Statistical Analysis: The study subjects were 40 volunteer participants. The abduction angle of the shoulder joint was set 0°, 45°, 90° and 120° with 10 subjects per angle as a total of 4 groups and the examined changes the subacromial space when conducting external rotation before and after. Ultrasonography was used for the measurement, and the measurement part was the subacromial space.

Findings: 0° and 45° did not show any significant difference before and after exercise. But At 90 degree, there was significant difference, pre-exercise was 10.0±0.92 and post-exercise was 10.3±0.95 (p<0.05). And at 120 degree, there was significant difference, pre-exercise was 11.5±2.62 and post-exercise was 12.05±2.51 (p<0.05).

Improvements/Applications: The distance changes according to the posture cannot be found. Because it was conducted with normal subjects, it seems to have a heavy burden to apply to patients with shoulder injury. There is a limit to generalize toward all patients. Exercise period for muscles was short. Future studies may provide better results if intervention is conducted for a long period of time in various postures and patients.

Keywords: *Subacromial space, external rotation, abduction, acromion, ultrasonography.*

Introduction

The shoulder joint is the largest range of motion in the body and it is anatomically prone to instability between the acromion and the humeral head. Therefore, shoulder disease is one of the most frequently occurring musculoskeletal diseases^[1]. The most common cause of shoulder pain is rotator cuff(RCD), impingement syndrome, bursitis, and tendonitis^[2]. Shoulder pain and

stiffness may impair work or leisure activities and cause burden on both the patient and society. Most shoulder pain does not go away in a few weeks or months and causes discomfort for long periods of time^[3,4]. In particular, impingement syndromes covers the half^[5]. Shoulder impingement syndrome refers to a disease that causes pain due to repeated trauma or compression on subacromial bursa, biceps brachii long head tendon and rotator cuff tendon which through the subacromial space becomes narrowed^[6-9]. Recently, the distance of the subacromial space is related to the functional disturbance from shoulder disease and the suffering of the patient^[9]. Exterior factors affecting the distance of the subacromial space include scapular rotation, shoulder rotation range, length of pectoralis minor muscles, thorax curve and load which are subject to rehabilitation program^[10]. The supraspinous muscle tendon goes through the

Professor, Sunmoon University, Physical Therapy,
South Korea

e-mail: skylove3373@sunmoon.ac.kr

subacromial space, and the reduction in the distance of the subacromial space causes impingement in moving the arms^[11]. In this course, collision under the acromion causes damage to the rotator cuff^[12]. According to the value of this defect, the damaged force in the shoulder joint is noticeable^[13]. In general, exercise using external rotation is most well known and commonly used for strengthening the rotator cuff for rehabilitation and prevention of injury^[11,14]. In order to increase the subacromial space, it is described that the shoulder internal/external rotation resistance exercise should be regularly conducted in various ways for strengthening the rotator cuff of shoulder impact syndrome patients^[14]. In addition, the strengthening of infraspinatus muscle helps some patients to prevent collision syndrome by increasing the subacromial space^[11]. It has also been found that the subacromial space changes with the angle of the shoulder abduction and the activity degree of shoulder abductor muscles^[15]. The more gradually the shoulder abducted, the more gradually the scapula upward rotation^[16]. Sliva and Thomas studied on the relation between the scapular position and the distance of the subacromial space. They reported that the elevation of acromion during upward rotation increases distance of the subacromial space^[17,18]. In another study, it is compared with the shoulder abduction at 90 and the external rotation with abduction together, as a result, the subacromial space was wider when having the external rotation with abduction together. In the case of a group, it is compared with giving constant load and non load. And the distance of the subacromial space was wider when there was constant load group than non load group^[19]. Ultrasonography shows a successful image in evaluating the rotator cuff. In addition, it can clearly focus on where you want to measure^[20]. As such, exercising external rotation is effective in expanding the subacromial space. In particular, it is proved that it is more effective to carry out the external rotation exercise with the shoulder abduction at 90 degree rather than no abduction. However, there is a lack of research on external rotation due to various abduction angles. Thus, this study was conducted to examine the effect of external rotation on the subacromial space at various angle of shoulder abduction through the subjects those who do not have any shoulder joint damage.

Method

This study was conducted on 40 healthy male and female students attending S University in Asan, Chungnam. The subjects were selected as those who

had no pain or discomfort of shoulder disease, nor undergone previous shoulder surgery. After determining their health status, subjects who are able to move their arms more than 120° abduction and external rotation were selected. This study provided the

participants with sufficient explanation and understanding of the purpose and method of the study. They participated in the study voluntarily. And the general characteristics of the subjects are shown in [Table 1]. 40 subjects were randomly assigned to the 0 degree group, the 45 degree group, the 90 degree group, and the 120 degree group according to shoulder abduction angle. In this study, dumbbells were used as exercise equipment. When conducting exercise depending on different loads, 2kg (4lb) showed the largest muscle activity. In the previous paper, the target of male only conducted experiment with 4kg (6lb). Based on this, the load applied to the subjects of all groups. It was set to 6lb for male and 4lb for female. And experiments were conducted on the dominant side. The 0 degree group, the 45 degree group, the 90 degree group, and the 120 degree group used the protractor to conduct three sets of external rotation exercises 10 times at each shoulder joint abduction angle [Figure 1] An experiment was conducted using metronome to measure the speed of all subjects' movements at the same speed. Measurements were carried out with the shoulder abduction angle at 0 degree sitting in the chair. For accuracy, the mean value was calculated by repeating the measurement three times before and after exercise according to the corresponding angle. For measurement tool, ultrasonography (eZono 3000, Germany, 2011) was used for the measurement, and the measurement part was the subacromial space. The length between humeral head and acromion was measured. The frequency was 7~10MHz and the image was fixed at a depth of 3cm. The position of the probe was parallel to the flat part of acromion and humeral head and located in slightly behind the upper side and middle of acromion. Data were analyzed using the IBM SPSS ver.20.0 statistical program. One-way analysis of variance (ANOVA) was used for the normality test to determine the difference in subacromial space depending on shoulder joint abduction angle. In addition, the study was conducted using LSD as a post test to examine the difference before and after intervention in group. The significance level (p) was set 0.05 for all statistical tests.

Result

The results of this study was no significant difference

between groups as a result of the external rotation according to shoulder joint abduction angle ($p > 0.05$). As a result of comparing the results before and after the external rotation exercise depending on shoulder abduction angle (0° , 45° , 90° , 120°) [Table 2], 0° and 45° did not show any significant difference before and

after exercise. But At 90° degree, there was significant difference, pre-exercise was 10.0 ± 0.92 and post-exercise was 10.3 ± 0.95 ($p < 0.05$). And at 120° degree, there was significant difference, pre-exercise was 11.5 ± 2.62 and post-exercise was 12.05 ± 2.51 ($p < 0.05$).

Discussion

Recently, shoulder disease among musculoskeletal diseases is one of the most frequent diseases^[1]. In particular, shoulder impingement syndrome and rotator

cuff tear are the most common^[5]. For those patients, the distance of the subacromial space is considered clinically important. The subacromial space causes a source of interference when moving arms. In this process, the

interference is repeatedly generated and causes rupture of supraspinatus tendon which passes through the space. Therefore eventually, it causes inflammation or damage^[21]. This suggests that it is necessary to focus on broadening the subacromial space when planning a treatment program^[22]. The measurement consists of various method and instruments^[23]. Sasiponganan measured the subacromial space using clinical radiography and magnetic resonance imaging (MRI)^[24] and Lochmuller measured the subacromial space using 3D computer image. The subacromial space is reported as three dimensional space within the human body^[25]. However, it is only possible to be measured in a two-dimensional space for radiation measurement, and it is difficult to change the posture of the patient when measuring the subacromial space and it is risky to exposure of radiation. Ultrasonography can move during measurement and use fast^[20]. The shoulders of 40 subjects were measured in sitting position. The external rotation was measured at 0 degree, 45 degree, 90 degree and 120 degree. The women subjects received 4lb dumbbell and the men subjects received 6lb dumbbell. As a result, there was no significant difference between the groups because it was instant effect. It should have carried out for a long time in order to activate the muscles. However, as the shoulder abduction angle increases more than 90 degrees, the subacromial space tends to increased. Therefore, it is considered that as the angle increases, the space can be increased. In the comparison group, there was a significant difference at shoulder joint abduction 90 degrees and 120 degree when conducting external rotation exercise. Celeste et al. have reported that reinforcement of adductor muscle such as latissimus dorsi and the teres major when abduction shoulder joint may be effective for the treatment of subacromial pain syndrome^[26]. Alizadehkhayat et al. have said that the muscle activity of latissimus dorsi muscle, muscle teres major and rotator cuff increases when conducting external rotation at 90 degree rather than 0 degree from shoulder abduction^[27]. It is considered that there is no significant difference because there was low activity of muscle in 0 and 45 degree compared to 90 and 120 degree. According to this study, the effect of adductor muscle of eccentricity and strengthening exercise of adductor muscle and rotator cuff pulls humeral head down. There were limitations in this study. First, it was not measured in various postures such as prone and supine and the measurement was made only in the sitting position. Therefore the distance changes according to the posture cannot be found. Second, because it was conducted with

normal subjects, it seems to have a heavy burden to apply to patients with shoulder injury. Therefore, there is a limit to generalize toward all patients.

Conclusion

In the conclusion, there was no significant difference between the groups and there was no significant difference at 0 degree and 45 degree 120 degree. Based on this study, it is considered that the patients with shoulder pain impingement in the subacromial space, and the space was increased by mechanically moving the shoulder bone head downward with the most effective rotator cuff at 120 degree in the group. However there was a significant difference at 90 degree and 120 degree. Especially, there was a big difference in 120 degree. Based on this study, it is considered that the patients with shoulder pain impingement in the subacromial space, and the space was increased by mechanically moving the shoulder bone head downward with the most effective rotator cuff at 120 degree.

Abstract

Background/Objectives: This study examined the effects of balance training using a Wii Fit balance board on the balance, gait, and activities of daily living in patients with Parkinson disease.

Method/Statistical Analysis: Our study included 15 patients with Parkinson disease who scored 2–3 on the Hoehn and Yahr scale and underwent occupational therapy. Participants were randomly assigned to two groups: the experimental group with 8 patients or the control group with 7 patients. All subjects in two groups received traditional occupational therapy (TOT) for 30 min/day, 3 times a week, for 8 weeks, and the participants in the experimental group additionally received a balance training using a Wii Fit (BTWF) for 30 min per session. All patients in both groups were evaluated using the Berg balance scale (BBS), the time up & go test, and the modified Barthel index.

Findings: The experimental and control groups showed significant improvements in all outcome measures after intervention. In particular, the experimental group showed a more significant improvement in the BBS score than the control group.

Improvements/Applications: BTWF could be effectively used to improve the balance of Parkinson's disease patients in the clinic.

Keywords: *Activities of daily living, Balance, Gait, Parkinson disease, Wii Fit.*

Introduction

Parkinson disease is a progressive retrograde motor disability caused by degeneration of the substantia nigra and lack of dopamine generation^[1]. Common symptoms of Parkinson's disease are hypokinesia, tremor, bradykinesia, postural instability, rigidity, and disequilibrium^[2].

Gait and balance disturbance are common in patients with this condition^[3], and they have concerns about falling because their movements and functional ability are impaired^[4]. They also lack self-confidence regarding functional movements and postural balance, compared to healthy people^[5], because of which they cannot perform activities of daily living (ADL) independently and their quality of living is decreased^[6-7].

Over the last few decades, several studies have reported a variety of rehabilitation therapies that mediate the symptoms associated with Parkinson's disease^[8]. Rehabilitation exercise, in particular, increased the balance and lower extremity strength and prevented depression of Parkinson's patients^[9-11].

Among them, virtual reality (VR) therapy using Wii Nintendo is becoming popular nowadays because it efficiently improves function of people with Parkinson disease. This intervention is affordable, accessible, and is fun and interesting to patients, so their motivation and concentration toward exercising are better^[12].

Previous studies showed that therapeutic exercise training using a Wii Fit balance board has a positive effect on balance, cognitive function, gait, and actual ADL in patients with Parkinson disease^[13-15]. Mhatre et al.^[13] reported that Nintendo Wii™-based exercise and cognitive-training (VR games) effectively improves gait ability and balance function in the individual with parkinson disease. Further, Hertz et al.^[14] reported that the Wii Nintendo Virtual Reality system is effective in improving motor function, depression, and ADL in patients with parkinson disease.

However, Santos et al.^[16] reported that Nintendo Wii intervention had no additional positive-effects on conventional exercises in functional mobility, and balance of patients with parkinson disease. According to a recent systematic review, most previous studies were performed without the control groups and the research conducted by randomized controlled trials (RCT) study design is insufficient^[12].

Therefore, the present study aimed to assess the effects of balance training using a Wii Fit balance board on balance, gait, and ADL in individuals with Parkinson disease.

Method

We recruited 15 subjects with Parkinson disease who were undergoing occupational therapy at in-and out-patients rehabilitation hospital. The inclusion criteria were (1) age exceeding 30 years and a diagnosis of idiopathic parkinson disease, (2) moderate motor impairment (a Hoehn and Yahr scale score of 2–3), (3) having been on the same medication for management of neurologic or other reasons for longer than 2 weeks, (4) ability to walk longer than 50 m independently with or without orthosis, and (5) a score exceeding 24 on the Mini–Mental State Examination. The exclusion criteria were (1) other orthopedic or neurological problems, (2) cardiac problems, (3) migraine or dizziness, (4) participation in any regular exercise program or other rehabilitation programs, and (5) auditory and/or visual deficits. All subjects participated in this study were informed about the procedure and consented to the

study. Our study was approved by the Institutional Review Board of Gachon University (1044396-201708-HR-136-01). Also, present study is in accordance with the Declaration of Helsinki.

The Berg balance scale (BBS), time up & go test (TUG), and modified Barthel index (MBI) were used to evaluate balance, gait, and ADL in both groups. All outcome tests were performed under blinded condition by a physical therapist with minimum 5 years of experience. In order to perform more accurate measurements, the measurer was trained and checked on the measurement method used in this study one week before the test.

The BBS was used to assess subjects' balance. It has 13 categories and a total score of fifty six. Higher score indicates a better balance. It is known that the risk of falls is higher and orthosis is required when the score is lower than 45^[17]. The intra-rater reliability of this test is $r = .97$ and its inter-rater reliability is $r = .98$ ^[18].

The TUG was developed to improve objectivity and reliability, and it was performed by determining the time required to stand up from a chair, walk comfortably for three meter, and then return to the chair. The rater used a stopwatch and checked the time between when the subject stood up from the chair until they sat back down on the chair. The intra-rater reliability of this test was found to be $r = .99$ and its inter-rater reliability was $r = .98$ ^[19].

The MBI was used to evaluate ADL. This tool has 10 categories and the scores range from zero to one hundred. A score of 0 indicates complete dependence, while 100 indicates complete independence while performing modified ADL. The intra-rater reliability of the MBI is $r = .89$ and the inter-rater reliability is $r = .95$ ^[20].

Fifteen participants were randomly assigned and divided into the experimental group ($n = 8$) and the control group ($n = 7$) after a pre-test evaluation. Every subject underwent traditional occupational therapy (TOT) for 30 min/day, 3 times a week, for 8 weeks, but the experimental group had an additional 30 min of balance training using Wii Fit (BTWF) per session.

The BTWF consists of three games: a bubble game, a ski game, and a marble game. In the initial session, all subjects were trained to learn how to use the Wii Fit balance board. The occupational therapist informed the therapeutic goals of these games and provided feedback

at all sessions. Subjects are assigned 10 min for each game with 5-10 min of rest in between games. Subjects wore a safety belt during the training. If necessary, subjects used static walkers for balance and safety. The control group received TOT. TOT consisted of ADL training targeting basic activity, repetitive training, stretching, range of motion (ROM) of the upper and lower limbs.

SPSS version 23.0 was used for all statistical analyses. The Wilcoxon-signed rank test was performed to compare dependent variables within the groups before and after intervention. The Mann-Whitney U test was used to compare differences in the dependent variables between the groups. A p-value of <0.05 was considered statistically significant.

Result and Discussion

- 1. General characteristics:** No significant differences were found between the groups ($p>0.05$) in any parameter [Table 1]. The findings from the BBS, TUG test, and MBI before the interventions did not differ significantly between the groups ($p>0.05$) [Table 2].
- 2. Difference for BBS, TUG, MBI within groups:** The both groups showed a significant difference in every evaluation after the intervention ($p<0.05$) [Table 3].
- 3. Change score of BBS, TUG, MBI between two groups:** The change in the BBS findings was higher in the BTWF group than in the TOT group ($p<0.05$). No significant between-group differences were found in the findings of the TUG test and MBI ($p>0.05$) [Table 4].

Discussion

Our findings showed significant improvements after the interventions in both the BTWF and TOT groups. The former showed better improvements in BBS findings than the TOT group did, although the difference in the findings of other tests were not considerable. Thus, BTWF can improve the balance of patients with Parkinson disease. The experimental group got higher scores on the TUG test and MBI than the control group did, but the difference was not significant. This can be explained by a few reasons.

First, the sample size in this study was small. Second, BBS and ADL are strongly related^[21], and the categories of MBI are related not only to the functions of lower extremities but also to those of upper extremities, such as feeding, personal hygiene, and dressing^[20]. A difference in the MBI score indicates a difference in upper extremity function. However, we did not evaluate upper extremity function in this study. Lastly, we did not control for Parkinson disease drugs, although none of the subjects reported using Parkinson disease drugs.

It has been reported that in hospitals, occupational therapy is not usually administered for improving lower extremity function or balance but for improving upper extremity function. Our findings indicate that using Wii Fit is a good way to effectively improve upper extremity function as well as balance and lower extremity function. There are some benefits to using virtual reality devices like Wii Fit. They cost less than other VR programs and are easy to use at home^[12]. There is a high chance of people with Parkinson disease have depression, and this increases fatigue and helplessness^[6,11]. Depression is not just a psychological problem; it limits motivation for rehabilitation. Their confidence, social participation, and quality of life are decreased because of this problem. Although the subjects' motivation or depression was not evaluated, Wii Fit is expected to positively affect

depression or rehabilitation training by promoting patients' interest.

Present study has limitations. First, because of the limited subjects, the changes in test findings before and after the intervention were not clear. Further, patients with scores of 2 or 3 on the Hoehn and Yahr scale may not represent all patients with Parkinson disease. Lastly, we did not follow up the subjects after the study, so we could not evaluate how long the effects exist. Further studies are required to overcome these limitations.

Conclusion

This study examined the effects of balance training using a Wii Fit balance board on the balance, gait, and ADL in people with Parkinson disease. In conclusion, BTWF for 8 weeks is more effective than TOT in improving the balance of people with Parkinson disease. Next studies are needed to examine motivation, satisfaction, or quality of life as well as physical function among people with parkinson disease who are administered BTWF, and more patients should be included for long-term effects.

Antibacterial Activity of Essential Oils Against *Streptococcus Mutans*

Young-Soon Choi¹, Seoul-Hee Nam²

¹Professor, Dep., of Nursing, ²Professor, Dep., of Dental Hygiene, College of Health Sciences, Kangwon National University, Samcheok-si, 25949, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to investigate the antimicrobial activity against bacteria in oral cavity by selecting tea tree and pepper, which are natural essential oils with aroma suitable for oral use

Method/Statistical Analysis: *Streptococcus mutans* (*S. mutans*) was used for the antibacterial activity measurement after subculture in brain heart infusion (BHI; Sigma-Aldrich, St. Louis, MO, USA). Tea tree and peppermint essential oil concentrations of 0.5%, 1%, 5%, 10%, 20% and 30% were divided into 5×10^5 colony forming units; CFUs/ml diluted *S. mutans* 10ul, BHI 900ul, 10% Tween 20 90ul was applied to prepare the final 1mL to check the CFUs according to 24h at 37°C to evaluate the antimicrobial effect.

Findings: The CFUs of the essential oils of tea tree and peppermint showed a reduction of 10^{-6} in 30% tea tree compared to the control without natural essential oil, 30% Peppermint showed 10^{-8} deaths. Although the difference in natural essential oils is different, it is shown that the higher the concentration of the essential oil, the higher the bacterial death.

Improvements/Applications: Peppermint and tea tree essential oils were found to be antimicrobial. Especially, tea tree essential oil has excellent antimicrobial activity compared to peppermint essential oil.

Keywords: Essential oils, Antibacterial activity, *Streptococcus mutans*, Oral health, Dental caries.

Introduction

The oral cavity is a space that is always invasive due to saliva and has an environment suitable for bacteria to reside. More than 700 kinds of bacteria exist in the oral cavity of these people by being involved in oral health and morbidity^[1].

Dental caries is the most common oral disease^[2]. It is a multi factorial disease, caused by harmful changes

in bacterial ecology due to the formation of bio films that adhere to the tooth surface^[3]. In the past decades, many reports around the world have shown an overall decline in tooth decay. However, recent studies have shown a surprising increase in caries prevalence, especially in the underprivileged^[4].

Streptococcus mutans (*S. mutans*) is related to dental caries^[5]. *S. mutans* can colonize the oral cavity, and bacterial bio film formation. There are other microorganisms with the ability to interact and this ecosystem to survive in the acidic environment in the colony^[3].

Dental caries are caused by an imbalance between demineralization and remineralization of tooth structure. Acid bacteria ferment dietary carbohydrates to produce organic acids to dissolve tooth enamel and disintegrate tooth tissue^[6].

e-mail: nshee@kangwon.ac.kr

The extent of the pH fall is affected by a number of factors, including the composition of the micro flora, as well as the type and frequency of sugar intake^[7]. *Streptococcus mutans* produce glucosyltransferase (GTF) enzymes, which are recognized as virulence factors in the pathogenesis of caries. GTF enzymes synthesize extra cellular glucans and contribute significantly to the formation of polysaccharides in dental plaque matrices. Sucrose-dependent mechanism of plaque formation is based on GTF produced by *Streptococcus mutans*^[8].

It is known that this microorganism is involved not only in smooth surface caries, but also in fissure and in muscle caries^[9-11].

The use of topical antimicrobial agents, widely used to prevent dental caries^[12], the effect is exhibited by reducing the number of bacteria or inhibiting the formation of bacterial membrane at the tooth surface, but it causes side effects such as tooth coloring^[13-14], substances with low toxicity to humans and the environment are required and studies on natural substances capable of satisfying this is actively conducted^[15].

Oral treatment agents used to kill or inhibit microorganisms in the oral cavity by chemical method, prevent oral cleanliness, bad breath removal, and prevent dental caries and periodontal disease^[16]. Oral treatment of chemicals contributes to the suppression of oral microorganisms, but due to side effects, continuous oral hygiene management requires the development of natural oral products that can be safely used for a long time without side effects^[17]. Recently, interest in natural products for the prevention of dental caries or periodontal disease associated with dental plaques is increasing, and as the resistance to antibiotics has increased, interest in natural antibiotics as a new next-generation antibiotic material has increased^[18].

Essential oil refers to volatile substances that are physically separated from fragrant plants. In general, essential oils are named after the extracted plant and have been called essential oils as the essence of taste and aroma^[19].

Essential oil has been used for a long time since ancient times and is mainly used as fragrance, cosmetics, perfume, soap, detergent, spice^[20]. Antimicrobial, anti-inflammatory, antifungal, antiviral and anti-cancer effects of Essential oil have recently been reported, and they have been applied to various industrial fields such as

animal feed, insecticide, dental products and alternative medicine^[21-23].

These materials have various scents and show useful bio active effects by their unique ingredients, but they contain odors that are inappropriate for use, and despite their excellent effects, they have been considered somewhat limited in clinical treatment including oral diseases^[18].

Peppermint, called 'mint' has been used by the Egyptians and Romans in its digestive system for history and is known as the "mate of the intestines." Peppermint is the antipathetic medication equivalent to aspirin in medicine. The main ingredient, menthol, helps to cool the skin and muscles, and has a strong local analgesic effect, which is used as a pain relief and massage oil or cream for the neck. The oral effect has a refreshing feeling, which prevents bad breath and has excellent sterilizing effect^[24-27].

Tea tree was introduced to Europe around 1927 and quickly gained attention due to its disinfectant properties. It is the most powerful immunostimulant with antibacterial, antiviral and anti fungal effects. It activates leukocytes to establish a line of defense against invading organisms. It is also effective against viral diseases such as chickenpox, shingles, herpes and warts, and fungal diseases and candida rhinitis. It is also widely used for sore throats and mouth gargles, and boosts immunity, so doctors in France use it as an aid to immune systems such as AIDS and cancer^[24-27].

Therefore, in this study, we tried to investigate the antibacterial activity against oral bacteria by selecting tea tree and peppermint, which are natural essential oils with fragrance suitable for oral use.

In addition, as part of the interest in the new generation of antimicrobial materials, by confirming the value of tea tree and pepper essential oil extracted from plants as a natural antimicrobial agent against oral bacteria, it provides the possibility of being used as an oral disease treatment agent. The purpose of this study is to present practical basic data on the prevention and treatment of oral infectious diseases.

Method

Two natural essential oils, tea tree and peppermint, refined in Kaput, England, were purchased through Dong-seong science. *S. mutans* (KCTC 3065/ATCC 25175)

was used for the antibacterial activity measurement after subculture in brain heart infusion (BHI; Sigma-Aldrich, St. Louis, MO, USA). *S. mutans* was diluted at a 5×10^5 ratio, which was anaerobically incubated at 37°C for 24 h.

Tea tree and peppermint essential oil concentrations of 0.5%, 1%, 5%, 10%, 20% and 30% were divided into 5×10^5 colony forming units; CFUs/ml diluted *S. mutans* 10ul, BHI 900ul, 10% Tween 20 90ul was applied to prepare the final 1mL to check the CFUs according to 24h at 37° C to evaluate the antimicrobial effect.

Result and Discussion

CFUs according to the essential oil concentrations of refined tea tree and peppermint are *S. mutans* (control;

8.8×10^{11}), Peppermint CFUs are 0.5% (1.6×10^{10}), 1% (8.0×10^9), 5% (1.5×10^9), 10% (2.5×10^8), 20% (2.4×10^7), and 30% (9.5×10^5). In contrast, the tea tree's CFUs were 0.5% (5.4×10^9), 1% (3.4×10^9), 5% (3.8×10^8), 10% (1.4×10^7), 20% (8.2×10^4), and 30% (2.3×10^3) [Figure 1].

Compared with the control without natural essential oil, the 30% tea tree showed a 10^{-8} reduction, and the 30% peppermint showed 10^{-6} death [Figure 2].

The difference in the antibacterial effect of natural essential oils was shown, but as the concentration of % was increased, it showed higher killing of bacteria. Also, tea tree showed higher antibacterial effect than peppermint.

Figure 1. Antibacterial effect of various concentrations of essential oils on *S. mutans*

Figure 2. The survival rate of CFU by application of essential oils on *S. mutans*

Discussion

Essential oils are known to destroy bacteria by destroying their cell walls and disrupting their enzymatic activity^[28]. Essential oil also reduces oral bacteria by preventing the colonization of Gram-positive bacteria that cause plaque, slowing the replication of bacteria and removing endotoxins from Gram-negative bacteria^[28]. Essential oil used in this experiment showed antimicrobial effect against oral bacteria.

In addition, because of comparing the effects of aroma oil mixed with tea tree, lemon, and peppermint with the experiment group, tantum and saline, the degree of bad breath was significantly lower in the experimental group^[29]. After providing oral care using aroma solution of tea tree, peppermint and lemon, the concentration of bad breath and volatile sulfur compounds decreased significantly^[30].

S. mutans is a Gram-positive bacterium, discovered by Clark in human caries lesions in 1924, that breaks down monosaccharides and fructose to produce organic acids, causing demineralization of teeth and causing dental caries, it is known as a major causative agent of dental caries by actively producing lactic acid in acidic environment due to its acid resistance^[31].

Previous studies have shown that the use of natural extracts in oral treatments has the effect of inhibiting

S. mutans^[16], this results showed similar results to this study showing antibacterial effect.

In addition, there was a significant difference in the antibacterial effect of natural essential oils, but as the concentration was increased, the bactericidal effect of higher bacteria appeared. Comparing the effects of different types of aromatic oils, tea tree was found to have a higher antibacterial effect even at lower concentrations than peppermint.

Therefore, based on the results of this study, if various types of research are conducted in the future, it is expected that next-generation antibacterial materials using essential oils can be developed for the prevention and treatment of infectious diseases in the oral cavity.

Conclusion

The purpose of this study was to investigate the antimicrobial effects on oral bacteria by selecting tea tree and peppermint, which are natural essential oils with fragrance suitable for oral treatment.

As a result of this study, the following suggestions are made.

First, it is necessary to repeat research to confirm the antibacterial effect using various essential oils.

Second, it is suggested to carry out an iterative study to confirm the antibacterial effect according to the concentration difference of various essential oils.

Third, continuous attention is needed to develop next-generation antimicrobial materials that use essential oils as a natural oral treatment that can be safely used for a long time without side effects.

A Study on the Emotional Intelligence of Optometrist

Ki-Hun Ye¹, Jung-Eun Ha²

¹Professor, Department of Optometry, ²Professor, Department of Dental Hygiene,
Baekseok University, South Korea

Abstract

Background/Objectives: This study was designed to look into the actual state of optometrist's emotional intelligence, and thereby to provide fundamental material for the public's better eye health through the development of optometrist's emotional intelligence.

Method/Statistical Analysis: The study subjects comprised 175 optometrist, of whom 96 were men (54.85%) and 79 were women (45.15%). They were asked to answer an online questionnaire survey in order to assess their emotional intelligence. The collected data on their emotional intelligence were compared and analyzed using SPSS 18.0 at a significance level of 0.05.

Findings: The optometrist's emotional intelligence scores were analyzed according to their general characteristics. In respect of sex, men scored 3.26 and women 3.24. Regarding age, those younger than 25 scored 3.13, those aged between 25 and 29 scored 3.33, those aged between 30 and 39 scored 3.18, and those aged 40 and older scored 3.25. As a function of marriage, the study subjects who were married scored 3.22 and those who were not scored 3.30. Regarding education, those who had graduated from college scored 3.11, those who had graduated from a 4-year university scored 3.37, and those who had graduated from graduate school or higher scored 3.48. According to the employment type, those who were regularly employed scored 3.29, those who were irregularly employed scored 2.82, and those who had part-time jobs scored 3.33.

Improvements/Applications: The differences in optometrist's emotional intelligence were analyzed according to their general characteristics. Their emotional intelligence was found to differ significantly according to their education, employment type, and salary. All the types of emotional intelligence had statistically significant correlations. Optometrist who were men and older, those who had a higher education level and monthly pay, and those with more experiences of turnover tended to have more emotional intelligence.

Keywords: *Optometrist, emotional intelligence, self-emotion appraisal, others' emotion appraisal, regulation of emotion, use of emotion.*

Introduction

Humans have a spirit, a body, and a mind, with the latter divided into reason and sensitivity. Reason is

humans' essential attribute that differentiates them from other animals. As opposed to reason, sensitivity is the ability to trigger senses in response to changing stimuli and refers to the human characteristic of reacting to and feeling the influence of external forces^[1] In order to have a right approach to one's value in the social community and to live a life of truth, it is necessary to harmonize reason and sensitivity. Emotion based on sensitivity is a mental feeling. Emotional regulation and expression are essential to maintain and develop human relationships and live a happy life. As today's society has very complicated and diverse relationships,

Corresponding Author:

Ki-Hun Ye

Department of Optometry, Professor, Baekseok
University, South Korea
e-mail yelovebaekseok@bu.ac.kr

it is hard for people to express their emotions in society. At their workplaces, where they spend a lot of time, individuals' emotional regulation and expression are distorted and suppressed in relationships with their seniors, coworkers, and customers. There have been active studies and surveys on emotional regulation, emotional expression, and emotional labor at work. As medical professionals, optometrist are exposed to many conflicts in their relationships with their seniors (medical doctors), coworkers (nurses, nurse aides, optometrist), and customers, so that they experience emotional labor^[2-3].

Customers who visit optical shops and hospitals require a high-quality service and high satisfaction. In addition, they want a customized service. They have high requirements since they visit these places on account of their physical inconvenience and pain. Therefore, optometrist need to perform their medical work to live up to customers' expectations and meet their needs, which entails harder emotional labor. Accordingly, optometrist' emotional disharmony leads to work stress. The emotional labor increased by the emotional distortion can lower their customer service level^[4-5]. Optometrist need to regulate and express their emotions well on the job. Therefore, they need emotional intelligence to regulate and use their emotions appropriately based on their understanding of their own emotions and others'. Emotional intelligence means the "intelligence of the mind" to regulate self-emotion and have smooth relationships with other people^[6].

Optometrist with high emotional intelligence can control their emotions and their customers', to identify various types of emotions, and to regulate their self-emotions and others' emotions effectively to improve their job efficiency. In addition, optometrist can use their emotions and develop themselves further to plan their life and achieve their goals.^[7]

This study conducted a questionnaire survey to analyze the actual emotional intelligence state of optometrist, who are exposed to high emotional labor. Thereby, it aimed to provide fundamental material to help understand the occupation of optometrist, who are responsible for the public's eye health, and to offer a chance to improve optometrist' emotional intelligence and allow them to provide better eye health services.

Method

An online questionnaire survey on emotional

intelligence was conducted on 175 optometrist (96 men: 54.85%, 79 women: 45.15%) from January to July 2019. The questionnaire consisted of four items (self-emotion appraisal, others' emotion appraisal, the regulation of emotion, and the use of emotion), each of which comprised three questions.^[8] All the questions in the questionnaire were answered on a 5-point Likert scale (5: strongly agree, 4: agree, 3: somewhat agree, 2: somewhat disagree, 1: disagree, 0: strongly disagree). The full score for each item was 15 points, and the mean was based on the three questions. The collected data were applied to SPSS 18.0 at a significance level of 0.05 in order to compare and analyze optometrist' emotional intelligence.

The questionnaire on optometrist' emotional intelligence used in this study comprised four categories: self-emotion appraisal (I fully and truly understand what I feel, I understand my own emotions well, I always know whether I am happy or not), others' emotion appraisal (I fully understand others' emotions, I am excellent at observing others' emotions, I am always able to know my coworkers' emotions based on their behavior), regulation of emotion (I can control my own emotions well, I always come down from my anger easily when I am very upset, I control my emotions well), and use of emotion (I always establish my goals and do my best to achieve them, I always motivate myself, I always tell myself that I am competent). Optometrist' emotional intelligence was classified into these four types in order to compare and analyse their emotional intelligence.

Result and Discussion

Optometrist' general characteristics are presented in Table 1. Among the 175 optometrist, there were 96 men(54.85%) and 79 women (45.15%). By age, 24 were younger than 25 (13.7%), 75 were aged 25-29 (42.9%), 41 were aged 30-39 (23.4%), and 35 were aged 40 and older (20.0%). Regarding marriage, 115 were unmarried (65.7%) and 60 were married (34.3%). Regarding education, 82 had graduated from college (46.9%), 82 from a 4-year university (46.9%), and 11 from graduate school or higher (6.3%). Regarding the type of employment, 153 were regularly employed (87.4%), 16 were irregularly employed (9.1%), and 6 were employed part-time (3.4%). Regarding the monthly pay, 11 earned under 1.5 million KRW (6.3%), 50 earned between 1.5 million and 2 million KRW (28.6%), 51 earned between 2 million and 2.5 million KRW (29.1%), 47 earned between 2.5 million and 4 million KRW (26.9%), and

16 earned over 4 million KRW (9.1%). Regarding the turnover experience, 60 had had no experience of turnover (34.3), 36 had experienced turnover once (20.6%), 16 had experienced turnover twice (9.1%), 23 had experienced turnover three times (13.1%), and 40 had experienced turnover four times or more (22.9%). Optometrist's emotional intelligence differed significantly according to their education, employment, and monthly income ($p < 0.05$). Self-emotion appraisal is one's ability to understand one's own emotions accurately and to express them well; others' emotion appraisal is one's ability to understand and empathize with others' emotions well; the regulation of emotion is one's ability to make the best selection in a given situation based on reasonable conduct and thinking, rather than to express emotion in the situation, and thereby to control one's own emotions to behave properly; the use of emotion is one's ability to set one's own goals for an issue by organizing and using one's own emotional information, and thereby to do one's best concretely through motivation.^[8-9]

Table 2 shows the correlations in optometrist's emotional intelligence. All types of emotional intelligence had statistically significant correlations ($p < 0.05$).

Table 3 presents optometrist's emotional intelligence according to sex and age. Others' emotion appraisal and the regulation of emotion were statistically significantly different ($p < 0.05$). As an optician is a medical service occupation, in terms of others' emotion appraisal, women showed more emotional intelligence in understanding customers' emotions through empathy than men, while men showed more reasonable judgment and context awareness in somewhat difficult customer relationship situations than women. In the categories of self-emotion appraisal, regulation of emotion, and use of emotion, men showed somewhat higher emotional intelligence than women. Women only showed more emotional intelligence than men in the others' emotion appraisal category.

Others' emotion appraisal was statistically significantly different. The emotional intelligence increased with the age. Therefore, age was a very important positive factor ($p < 0.05$). In Kim et al.'s study on the emotional intelligence of employees in customer service centers, the use of emotion decreased with the age. The present study found an opposite result. Given the occupational characteristics of optometrist, the older they get, the lower their workload and the more time

they have. Therefore, it is judged that the use of emotion positively influenced the emotional intelligence.^[10] Table 4 presents optometrist's emotional intelligence according to marriage and education. The use of emotion was statistically significantly different ($p < 0.05$). Married optometrist has more responsibilities as family members than unmarried ones. Therefore, they organize and use emotional information to establish their own goals, motivate themselves, and do their best. This concrete activity is judged to influence their use of emotion positively. Married optometrist had higher self-emotion appraisal and use of emotion, whereas unmarried ones showed higher others' emotion appraisal and regulation of emotion. As a result, marriage was found to influence optometrist's emotional intelligence differently.

Others' emotion appraisal and the use of emotion were statistically significantly different ($p < 0.05$). The higher educated the optometrist were, the more they set goals, had a clear vision, did their best to take concrete action through motivation, and increased their use of emotion. However, their appraisal of others' emotions was somewhat low.

In other categories of emotional intelligence, the higher educated the optometrist were, the more emotional intelligence they had. As a result, a higher education was found to influence optometrist's emotional intelligence positively. Table 5 presents optometrist's emotional intelligence according to their type of employment and monthly income. The self-emotion appraisal and use of emotion were statistically significantly different ($p < 0.05$). Regularly employed optometrist had somewhat more emotional intelligence. This is due to their senses of stability from regular employment and of responsibility.

Others' emotion appraisal, the regulation of emotion, and the use of emotion showed a statistically significant difference ($p < 0.05$). In all categories of emotional intelligence, the emotional intelligence increased with the monthly income. A high-income influences optometrist's job satisfaction. Therefore, it is judged that it leads to the expansion of empathy with customers' emotions, reasonable thinking rather than direct emotional expression, and responsible behavior to elect the best course of action and choice in each situation. In addition, a greater use of emotion is judged to influence optometrist's goal awareness and motivation, which encourages them to do their best.

Conclusion

In terms of general characteristics, optometrist' emotional intelligence differed significantly according to their education, employment type, and monthly income. All types of emotional intelligence had statistically significant correlations. In terms of emotional intelligence according to sex, others' emotion appraisal and the regulation of emotion were statistically significantly different. Men had somewhat more emotional intelligence than women. In terms of emotional intelligence according to age, others' emotion appraisal showed a statistically significant difference. The emotional intelligence increased with the age. In terms of emotional intelligence according to marriage, the use of emotion was statistically significantly different. In terms of emotional intelligence according to education, others' emotion appraisal and the use of emotion were statistically significantly different. The emotional intelligence increased with the level of education. In terms of emotional intelligence according to the type of employment, the self-emotion appraisal and use of emotion were statistically significantly different. In terms of emotional intelligence according to the monthly income, others' emotion appraisal, the regulation of emotion, and the use of emotion were statistically significantly different. The emotional intelligence increased with the monthly income. In terms of emotional intelligence according to the turnover experience, the self-emotion appraisal, others' emotion appraisal, and the regulation of emotion were statistically significantly different. The emotional intelligence increased with the turnover experience.

The Effect of Cardiac Arrest Simulation Training Using Mechanical CPR Device on Chest Compression Quality of Paramedics in Pre-Hospital

Ji-Won Ahn¹, Byung-Jun Cho²

¹Researcher, ²Professor, Dept. Emergency Medical Technology, Kangwon National University, Republic of Korea

Abstract

Background/Objectives: It is to establish a transport plan in a situation where it is difficult to maintain the quality of CPR due to the building structure by measuring the difference in quality of CPR in the field and transport process of pre-hospital cardiac arrest patients.

Method/Statistical Analysis: For this purpose, simulated CPR training for OHCA patients who were not seen in the field was performed on the 78 EMT trainees enrolled in firefighter school in K region. The simulated training was performed by dividing them into two groups such as one group using manual CPR and the other group using mechanical CPR (LUCAS2™) in the stage of field and the transport composed of stairs and corridors in a four-story building.

Findings: The quality of chest compression implemented at the field does not satisfy all the requirements of the guideline, but provided sufficient depth and rate of the pressure. The values of the measured CPR quality showed that CPR in the transport was lower than that in the field. The chest press quality was lower- in particular the depth of chest press was about 20mm lower and it did not meet the 2015 Guidelines of the CPR Association in Korea. On the other hand, the group using LUCAS2™ in the transport stage showed steady and even press depth and appropriate press and relaxation without degradation of the quality comparing to CPR in the field, all guidelines are satisfied. Although there is much controversy about the improvement of chest compression quality using CPR devices leading to improved survival rates, the use of CPR devices should continue to be considered in these unstable environments.

Improvements/Applications: Conclusively, in the transport process where there are structural difficulties, the group using LUCAS2™ could meet the Guidelines of the CPR Association when performing CPR which plays important role in increasing revival rate of OHCA patients. It can be the ground of using mechanical CPR devices in the future.

Keywords: Pre-Hospital Cardiac Arrest, OHCA, CPR quality, Mechanical CPR device, LUCAS, Chest compression quality.

Introduction

The most important thing in pre-hospital cardiac arrest is high quality cardiopulmonary resuscitation

(CPR). The guidelines of the Korean Association of Cardiopulmonary Resuscitation (KACPR), revised in 2015, recommend the 5 cm depth of chest compression and suggest a rate of 100-120 times per minute in adult cardiac arrest patients. They suggest that cessation of chest compressions should be minimized to less than 10 seconds, and the artificial respiration should not be excessive [1].

In Korea, the person in charge of CPR at the pre-hospital level is 119 paramedics. Given the low bystander

CPR in Korea, 119 paramedics' CPR skills are very important, and the ability cultivation for paramedic's professional CPR play a significant role in improving the survival rate of cardiac arrest patients.

This study is designed to reveal differences in the quality of CPR at fields and transport stages, particularly in structurally poor buildings, and to identify the effectiveness of mechanical CPR devices. The domestic research on the transport stage is very poor compared to efforts to improve CPR quality at the field and the hospital, and as a result of that, the situation is that the planning for proper transport of paramedics is also not organized. Due to various complex structure of building types, the quality of the manual chest compressions during the transfer process is likely to decrease [2]. In addition, when cardiac arrest occurs in complex, high-rise building types, the most big problem is the time delaying for that paramedics contact the patient and do the initial CPR, and it is highly likely that they will not be able to provide high quality CPR in process of transfer to the hospital and the process of transfer to the hospital and the overall transfer time will likely be long [3-4]. Therefore, it is desirable to establish a transport plan accordingly and to use additional equipment if possible, in order to reduce the quality degradation of pre-hospital CPR at poor fields and to provide stable and consistent high-quality CPR [5-6]. In particular, it is necessary to discuss the application of a mechanical CPR device in a step, corridor, or ambulance, where the quality of the chest compression is inevitably structurally low [7].

There are many pros and cons of idea on the effectiveness mechanical CPR device. The 2015 guideline ofKACPR describes that when mechanical CPR devices were applied to patients with pre-hospital cardiac arrest, they showed almost the same figure in short-term and long-term survival rates, and that there was no evidence that they should replace manual CPR in both the method of the load distribution belts applied and the piston method that presses the sternum [8-10]. Some of research shows that patients have more internal damage compared to manual CPR, as a result of the experiments with equipment like mechanical CPR device [11]. However, these results are an example of CPR in a typical environment. We cannot exclude the characteristics of the Korean living environment, which accounts for 60% of apartments where is poor for transporting patients. Therefore, although there were no significant differences in typical CPR procedures, the separate studies on device application in poorly

structured buildings or other unfavorable conditions for patient transport are required. Significant improvement in survival rate and brain function recovery rate will be done if high quality chest compressions are possible during the transport stage from the field to the ambulance. Therefore, full-scale discussions on the application of CPR devices in poor conditions are required.

Method

Object of Study: The object of study is consisted of 55 firefighter and 23 new firefighter. The experiment was conducted on a total of 13 groups.

This study is organized into the team CPR simulation practice regular courses in the organization's curriculum. The researchers worked in the organization and have explained the purpose and effectiveness of the study directly to the objects of study. The additional training on the effectiveness and feedback of this study were given to the object of this study, and the face-to face consent from the study participants on the use of the result of study were obtained.

2. Study Design and Tool:

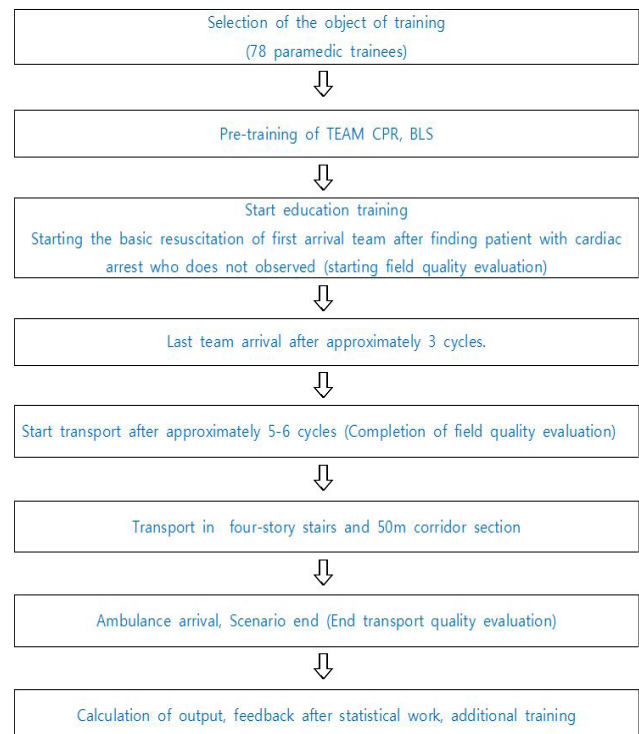

Figure 1. Study Design

In figure 1, assumption that emergency paramedics are dispatched, the scenario-type training method that provide the situation of pre-hospital cardiac arrest and perform the CPR are applied.

Figure 2. Descending through the stairs using a long spine plate

In figure 2, each team deal with the same situation of total one time, and the required time is about between 10 minutes and 15 minutes each. The scenario is a situation of cardiac arrest that has not been observed in a four-story building, and it will be divided into a case where CPR is performed in the field for about 10 minutes and perform the manual chest compressions during transport and a case that perform the chest compression using the

mechanical CPR device. The transport was carried out using an ambulance stretcher for a distance about 50 meters to the ambulance after descending through the stairs using a long spine plate in a four-story building. All team evaluators consisted of the 6 members which are 3 first arrival team and 3 last arrival team, and each team's scenario have applied the same basic resuscitation scenario.

Figure 3. Descending through the stairs using a mechanical CPR device

In figure 3, three of the 13 teams are ordered to use a mechanical CPR device (hereinafter referred to as “LUCAS2”) at the transfer stage to descend the stairs, pass the corridor, and transfer to the ambulance.

The training was conducted by one scenario with the field and transport, and the 26 data values were extracted from total 13 groups by pausing and restarting at stage of the end of the site and beginning of the transport in order to separate the data for numerical comparison.

The equipment such as LUCAS2 (PHYSSIO CONTROL, USA) and Resusci Anne Simulator TM (Laerdal, Norway) were used.

Result and Discussion

Quality comparison of manual chest compression in the field/transport stage: In the field, the depth and compression rate were 58.7 mm and 118.8 per minute. However, the figure was slightly lower in complete chest recoil rate and the exact compressive rate, which can be interpreted as excessive compression exceeding 60 millimeters.

In the transport stage, the speed of the chest compressions did not decrease with 119 times per minute, but the mean compressive depth was reduced by approximately 25 mm from approximately 58.7 mm at the field to 33.43 mm in transit (p<0.05). In addition,

the exact compressive rate was also reduced from approximately 37.4% to 11.7% (p = 0.031).

This is consistent with the prior assumption that the quality of the chest compressions in the transport stage will be significantly lower than at the field stage.

In the transport stage, it is shown the significantly lower chest compressive depth than in the field. Fixing patients on mobile stretchers and transporting them to stairs or corridors has fundamental limitations in implementing quality chest compressions due to structural limitations, no matter how hard paramedics try. The resuscitation rate of the patient can be greatly reduced [12]. Therefore, if it needed to transport for a long time from the field to ambulance, the mechanical CPR device should be used or another tactical transport method should be considered.

Table 1. Quality of manual cardiopulmonary resuscitation in field and transport stage

Variable	Field		In transit		t	p
	M	SD	M	SD		
Mean chest compressive depth (mm)	58.7	2.8	33.4	5.6	10.597	0.000**
Complete chest recoil rate (%)	40.8	18.3	93.7	7.8	-7.001	0.000**
Exact chest compression rate (%)	37.4	26.2	11.7	9.1	2.451	0.031*
Chest compression (/min)	118.8	2.1	119.2	2.4	-0.352	0.731

*: p<0.05, **:p<0.001

Quality comparison of LUCAS chest compression in the field and transport stage: By recording mean 52.5 mm in field and also 53.0mm in transport, comparison results of chest compressions showed no statistically significant difference.

This is consistent with the prior hypothesis as a result from the mechanical characteristics of automatic cardiopulmonary resuscitation devices.

Table 2. Quality of mechanical cardiopulmonary resuscitation in field and transport stage

Variable	Field		In transit		t	p
	M	SD	M	SD		
Mean chest compressive depth (mm)	52.5	0.7	53.0	1.4	-0.447	0.698
Complete chest recoil rate (%)	89.0	2.8	95.0	1.4	-2.683	0.115
Exact chest compression rate (%)	86.5	4.9	96.0	1.4	-2.610	0.121
Chest compression (/min)	101.0	0.0	101.0	0.0	1.259	0.335

*: p<0.05, **: p<0.001

Quality comparison of chest compression of manual/LUCAS2 in transport stage: When comparing manual CPR and LUCAS2 in the transport stage, the mean chest compressive depth of LUCAS2 was 53.0mm and manual CPR was 33.4mm. The mean chest compressive depth of LUCAS2 in the transport stage is statistically significant difference compared to manual CPR ($p < 0.002$) by recording the pressure depth and the number of pressures. In addition, LUCAS2 had better figures than manual CPR in the section of complete chest compressive rate (M-CPR 11.71%, LUCAS2™ 96.00% $p < 0.005$). It can be seen that LUCAS2 provides significantly higher quality chest compression than manual chest compressions at the transport stage in side of chest compressive depth.

When comparing manual CPR and LUCAS2 in the transport stage, the mean chest compressive depth of LUCAS2 was 53.0mm compared that the mean chest compressive depth of manual CPR was 33.4mm. The mean chest compressive depth of LUCAS2 in the transport stage is statistically significant difference compared to manual CPR ($p < 0.002$) by recording the pressure depth and the number of pressures consistent with the guidelines. In addition, LUCAS2 had better figures than manual CPR in the section of complete chest compressive rate ($p < 0.005$). It can be seen that LUCAS2 provides significantly higher quality chest compression than manual chest compressions at the transport stage in side of chest compressive depth, complete chest recoil rate, exact chest compressive rate.

Table 3. Quality comparison of chest compression of manual/CPR device in transport stage

Variable	Field		In transit		t	p
	M	SD	M	SD		
Mean chest compressive depth (mm)	33.4	5.6	53.0	1.4	-4.664	0.002*
Complete chest recoil rate (%)	93.7	7.8	95.0	1.4	-0.221	0.832
Exact chest compression rate (%)	11.7	9.1	96.0	1.4	-12.421	0.000**
Chest compression (/min)	119.2	2.4	101.0	0.0	10.137	0.000**

*: $p < 0.05$, **: $p < 0.001$

The chest compressive depth of manual CPR at stable field was recorded to the mean 58.7 mm, and the chest compressive speed was recorded to 18 times per minute. This is in accordance with the standard “The depth of chest compression should be about 5 cm [13], and not more than 6 cm [14]. The speed is suggested 100 ~ 120 times per minute and this can be said that the chest compression of the appropriate quality is made. However, there were many cases of excessive pressure of more than 60 mm and the many trainees were generally tended to show incomplete relaxation. This is an area that needs to be improved by education. In the transport stage, it is shown the significantly lower chest compressive depth than in the field. This suggests that serious problems may occur with coronary artery blood flow rate and cerebral blood flow rate in patients [15]. Fixing patients on mobile stretchers and transporting them to stairs or corridors has fundamental limitations in implementing quality chest compressions due to structural limitations, no matter how hard paramedics try [7].

Conclusion

As a result of this study, the field stage recorded the depth and speed of meeting the 2015 guideline of Korean Association of Cardiopulmonary Resuscitation. In comparison, the transfer stage, which consists of stairs and corridors, had a quality deterioration in chest compressive depth of about 20 mm. This suggests that there is a structural limitation where high quality CPR is difficult to take in the transport stage, which becomes a factor to reduce blood flow pressure in patients with cardiac arrest and thus reduces survival rate. On the other hand, the mechanical CPR device provided a constant chest compressive speed and depth without any quality deterioration in the transport stage compared to manual CPR.

In conclusion to sum up, paramedics cannot maintain proper CPR quality through manual CPR in the transport stage, and in such situations, mechanical CPR device can help maintain the quality of CPR. This pattern is similarly

shown in precedent studies comparing manual CPR and mechanical CPR in structurally difficult situations such as latest stairs and corridors. Therefore, the results of this study have a same position as the conclusions and suggestions of precedent studies, and at least in order to maintain quality of CPR in the transport stage, mechanical CPR device should be actively considered.

Actual Pressure Ulcer Awareness of a Person in Charge of Pressure Ulcer Management

Ji-Hoon Choi¹, Cheong-Hwan Lim², Sung-Hun Jeong³

¹Doctor, ²Professor, Dept. of Health Care, Hanseo University, 46, Hanseo 1-ro, Haemi-myeon, Seosan-si, Chungcheongnam-do, Rep. of Korea, ³Doctor, Dept. of Radiology, Seosan Jungang General Hospital, Suseoksanupro, Chungcheongnam-do, Rep. of Korea

Abstract

Background/Objectives: The aging population due to increases of average life expectancy elderly population is perceived a serious problem in the medical sector. The objective of this study was to determine the degree of awareness of pressure ulcer in nurses in charge of pressure ulcer management in medical institutions and to provide basic data for setting guidelines.

Method/Statistical Analysis: A survey and analysis were conducted on 40 nurses in charge of nursing care at a nursing hospital. The survey tool was developed by quoting a pressure ulcer prevention management tool developed by Moore and Price. The survey was conducted in a face-to-face manner, explaining the purpose of the study directly. A total of five questions are recognized as pressure ulcer management, and the reliability is Cronbach's $\alpha = .785$ and consisted of a five-point Likert scale. The general characteristics are gender, age, work experience, Education, and hospital size of nursing hospital, with total five questions and reliability being Cronbach's $\alpha = .654$.

Findings: "How much do you know about the pressure ulcer?" showed the highest 'Yes' of 30%. In the pressure ulcer management knowledge section, "Do you know about changing your bed posture at least every two hours?" showed the highest 'very yes' of 82.5%. "Do you know the standard of management when a pressure ulcer occurs?" showed 45.0% of 'Yes' and "Do you know the factors involved in the pressure ulcer?" with 47.5%. "Do you know about the relationship between humidity and temperature among the factors involved in the pressure ulcer?" showed 57.5% (23).

Improvements/Applications: The results of this study show the degree of pressure ulcer management by nursing hospital nurses in charge of the pressure ulcer management. Knowledge of the pressure ulcers was high, but low awareness of the factors involved in the management standards emerged. It is expected that this data will be used as basic data for setting up education and management measures for the management of the pressure ulcers in the future.

Keywords: Pressure ulcer, pressure ulcer management awareness, nurse, nursing hospital, pressure ulcer prevention.

Introduction

With increase of the average life expectancy, the number of senior citizens in Korea is also increased. Currently, there are 7,684,919 senior citizens aged 65 years or older in Korea, accounting for 14.9% of the total population^[1]. Older adults are at higher risk of

developing pressure ulcer even under small external pressures^[2], with a high percentage of muscles, having chronic diseases, and physical conditions such as sensory disorders. Baths are defined as ulcers caused by chronic or repetitive pressure on bone projections or soft tissues, causing problems in blood circulation locally due to a reduction in oxygen supply and nutrient delivery to the area^[3]. With respect to the aging population, the number of elderly patients with various diseases in medical institutions is increasing and the number of high-risk patients with pressure ulcers is expected to increase. Among various health factors of the elderly admitted to the nursing home, pressure ulcer is a frequent condition. Proper treatment after the onset of pressure ulcer is important. Its prevention is very important^[4]. Older adults are often impaired by cognitive function and lack of mobility, resulting in lower self-power. In addition, their skin's sensory function is degraded, making them vulnerable to the development of pressure ulcer^[5].

In the study by Lee Min-jeong (2010), 45 percent of the hospitalized patients who had pressure ulcers, 10 percent of the elderly nursing homes, and 10 percent of the households in general hospitals were found to have pressure ulcers. In addition, the time of the menopause was 47% within four days of hospitalization^[6] and Lim Kyung-choon (1995) on average took 5.6 days after hospitalization^[7]. In order to prevent pressure ulcers, systematic and active nursing care should be implemented immediately after hospitalization. Although all medical personnel are required to participate in the management of the pressure ulcer, especially since the nurse plays a central role in the management of the pressure ulcer, keeping an eye on the risk factors of the pressure ulcer and performing the pressure ulcer care directly^[8,9].

Much of the care of patients is now managed by medical institutions, away from caregivers. Various pressure ulcer nursing method and their effects have been presented in various research or educational literature. However, in actual medical institutions, basic physical change method, number of times, dressing method according to the level of the pressure ulcer, and materials used vary by department. Sometimes nursing care is being performed without knowing the theoretically exact basis. Thus, it is important to understand the care knowledge of pressure ulcer management personnel so that their knowledge of the pressure ulcer management personnel can be improved and accurate management can be implemented.

Most of preceding studies have tried to verify the effectiveness of preventive interventions such as change of body position or massage. However, studies on nursing knowledge or mediating nursing by nurses in charge of pressure ulcer managements are insufficient^[10]. If the importance of pressure ulcer therapy is recognized by a clinical nurse, pressure ulcer care could be improved^[11]. However, even if nurses in nursing hospitals have low knowledge of it, their active attitude toward it is an important predictor in preventing pressure ulcer^[12]. To increase the performance for the prevention of pressure ulcer, knowledge of pressure ulcer prevention and management consciousness of pressure ulcer nursing are very important. Thus, it is important to increase the performance of pressure ulcer nursing.

Therefore, the objective of this study was to determine the degree of awareness of pressure ulcer in nurses in charge of pressure ulcer management in medical institutions and to provide basic data for setting guidelines.

Method

Subject: The research targets were selected three nursing hospitals in U-city, Korea and conducted a survey on the recognition of pressure ulcer management by a nursing care nurse who directly manages patients at a nursing home. A total of 60 copies of questionnaire were distributed and 45 (66.6%) were recovered. After excluding 5 with insufficient response, a total of 40 were finally analyzed.

Method: The questionnaire used in this study was approved by the Institutional Bioethics Committee (MJH 2019-03-003-006). It was a questionnaire developed by researchers with modifications to the pressure ulcer prevention performance tool developed by Moore and Price. After researchers directly explained survey questions to nursing care nurses at nursing homes, they received consent from study subjects and conducted the survey.

A total of five questions were recognized for the management of pressure ulcers in this study. Its reliability had Cronbach's α of .785. It was evaluated with a five-point Likert scale. General characteristics were gender, age, work experience, academic background, and the hospital bed size of the medical institution, with a total of five questions for reliability. Its Cronbach's α was .654.

Data analysis was performed using IBM SPSS Statistics, Version 23 to correlate with frequency analysis. Statistical significance was within the range of 95% ($p < 0.05$).

Result

Population and Social Characteristics of the Subjects: [Table 1] The subjects of this study were a total of 40 bedside nurses in three nursing hospitals in U city. Nurses in charge of bed sores were examined in 20 patients (50%) in hospital A, 10 patients (25%) in hospital B and 10 patients (25%) in hospital C. The most common age group was 45-54 years old with 16 patients (40%), and 35-44 years old with 14 patients (35%). In terms of educational background, university graduates had the most 32 students (80%). Work experience was 15 (37.5%) in 10-19 years and 20-29 years respectively.

Management awareness of bedsores: [Table 2] The management recognition level of the person in charge of the pressure ulcer management is analyzed.

In response to “How much do you know about the pressure ulcer?” showed 52.5% (21 person) say “very yes” and 30.0% (12 person) say “yes”.

“Do you know about changing your bed posture at least every two hours?” showed 82.5% (33 person) for “Very yes”, 17.5% (7 person) for “Yes”

“Do you know the standard of management when a pressure ulcer occurs?” showed 45 percent (18 person), 42.5% (17 person) for “Very yes” and 12.5 percent in “ordinary” (5 person).

“Do you know the factors involved in the pressure ulcer?” showed 47.5 percent of “very yes” (19 person), 35.0% of “yes” (14 person), and 17.5% of “ordinary” (7 person).

“Do you know about the relationship between humidity and temperature among the factors involved in the pressure ulcer?” showed 57.5% in “yes” (23 person), 17.5% in “very yes”(7 person), 22.5 percent in “ordinary” (9 person) and 2.5 percent in “no” (1 person).

Correlation between Demographic Sociology and Pressure Recognition: [Table 3] The correlation between demographic characteristics and pressure ulcer management awareness showed a static correlation of “Do you know about changing bed rest every two hours at least?” ($r = .348, p < .05$). “Do you know the

standard of management when a pressure ulcer occurs?” showed a static correlation ($r = .357, p < .05$). “How much do you know about the pressure ulcer?” showed a static correlation ($r = .406, p < .05$). “Do you know about the relationship between humidity and temperature among the factors involved in the pressure ulcer?” showed a static correlation ($r = .418, p < .05$).

Table 1. Demographic characteristics (N = 40)

Discussion

The purpose of this study was to improve the quality of patient care including bed sores prevention and ultimately improve the quality of nursing care by analyzing the pressure of bed sores in nursing hospital.

In demographic characteristics of study subjects, nurses in charge of patients with pressure sores graduated most from university which showed positive correlation with pressure management awareness. Nurses aged between 20 and 29 years had the most work experience. In this study, the total work experience of more than 10 years was 80.0%, and in the study of Kim Mi-young (2016), 36.2%^[13] were more than 10 years and 24.9%^[14] were found to be working experience. It is highly confident because of its experience and understanding of patient care, and it will be able to show self-efficacy and stable nursing as shown by Kim Yeon-jung's^[15]. The ages were 45-54 years old, and as the results of the

study by Roh Kyung-min and Myung-sook Lee (2016) showed that the higher the age, the more career, and the lower the turnover to other organizations^[16]. It is considered to be.

Demographic characteristics and bed sore management awareness showed a positive correlation. The higher the results and position of Song Sung Sook (2017), the higher the quality of nursing services and the analysis of bed sore nursing was high due to the nature of being dedicated to nursing work with attention and responsibility from the manager's position^[17].

In the management awareness of nurses with pressure sores, Kwon Eun-sook (2005) showed that there was a significant difference in the management awareness of nursing home care by the characteristics of the subjects depending on the place of work and interest in bedsores^[18]. There were significant differences according to the environment^[19]. The necessity of regular education was consistent with the results of the questionnaire according to the management guidelines and programs for patients with pressure sores in medical institutions. Therefore, it is necessary to develop qualitative efforts for nursing care by developing programs to increase education and nursing capacity.

Conclusion

In this study, the conclusions of the study on the condition of bed sore management awareness of bed sore management were as follows.

First. In terms of demographic characteristics, the age of nurses in charge of patients with pressure ulcers was the highest in 45 to 54 years, and the academic background was the highest in college. Nurses showed the most work experience between 20 and 29.

Second, the level of awareness of the pressure ulcer management was high, but low awareness of the factors involved in the management standards appeared.

Third, academic background showed awareness of pressure ulcer management and static correlation.

As such, the results of this study are expected to be used as basic data for the establishment of education and management guidelines, by analyzing the effects of the pressure ulcer management by the person in charge of the pressure ulcer management at the nursing home by identifying the degree of the pressure ulcer management.

The factors affecting on Turnover Intention of Nurses

Sung-Ja Yoon

Professor, Kyungdong University, Dept. of Nursing, Korea

Abstract

Background/Objectives: Many medical institutions are struggling with nurse turnover rate which is increasing. Therefore, in this study, factors that affect the turnover intention of nurses was attempted to identify.

Method/Statistical Analysis: The study was conducted to 250 nurses working at general hospitals with more than 500 sickbeds located in Seoul from Feb 1 to Feb 28, 2019. The general characteristics of the subjects and the reasons for turnover were calculated by frequency and percentage, and the factors affecting turnover were acquired from the mean and standard deviation. A logistic regression analysis was conducted to identify the factors affecting turnover.

Findings: In terms of the number of turnovers, 58.1% was 1 time, 29.0% was 2 times, 9.7% was 3 times, and 3.2% was 4 times. For the question of whether there is a turnover intention, 42.9% answered 'yes' and 57.1% answered 'no', and the side with the answer 'no' was higher. Reasons for turnover by logistic regression analysis showed a significant difference in the 20s, single, 4-6 years of career nurses, adequacy of pay, and shift work. This shows a desire that nurses who are free from family members, who have a basic career and can easily access despite turnover into any hospital organization, and can build their careers, hope to receive proper pay they expect, and hope to work in the day time on weekdays free of physical physiological difficulties caused by shift work.

Improvements/Applications: The factors affecting the turnover intention of hospital nurses need to be made at the level of the hospital organization as well as the efforts of the nursing department.

Keywords: Turnover, Job immersion, Job stress, Job satisfaction, Clinical Nurse, Korea.

Introduction

Organizations incessantly strive to achieve their goals, and individuals would like to attain their goals through the organization^[1]. Modern hospital organizations have diverse human resources for efficient treatment of subjects, which complicates the organization and there is a possibility of conflict caused by heterogeneity between occupations^[2]. As the

turnover intention is the act of voluntary departure or transfer of members of the organization, exploring other jobs, or thinking about turnover^[3], the high turnover rate of members of the organization are regarded as an important indicator of organizational and workforce management. As nurses are the most important human resources of the hospital and they can affect the competitiveness and efficiency of the hospital, it is very significant to have a sufficient number of nurses^[4,5]. With the characteristic of the organization that supports for providing high quality professional care to patients^[6], the nursing work environment means the degree of nurses' participation in hospital policy, the adequacy of workforce and resources for professional nursing practices, establishing a foundation for providing quality care, and an environment that forms a cooperative

Professor, Kyungdong University, Dept. of Nursing,
Korea

e-mail: soyang1129@kduniv.ac.kr

relationship for solving problems [7]. It was mentioned that this positive nursing work environment leads to an improvement in the quality of nursing, which causes to increase job satisfaction and decrease job burnout of nurses, which affects the turnover intention [8]. Moreover it was reported that job immersion and job satisfaction of nurses have an effect on the turnover intention [9]. Nurses' job immersion affects job satisfaction [10-13] and nurses who have low job satisfaction experience absence from work and turnover [9]. Verbal violence was also reported to lead to incline nurse turnover rate [14]. Nurse's pay, furthermore, was reported to affect the turnover intention [6,15-16]. However, in another study, it was found that low pay has no significant effect on turnover intention or turnover [17].

Many medical institutions are struggling with nurse turnover rate which is increasing [19]. The high turnover rate of nurses has been pointed out as a negative factor that inhibits good quality nursing care [20]. Previously, a study regarding job satisfaction, job stress, empowerment, organizational commitment and burnout has been progressed to identify the turnover and turnover intention of nurses [9-10,21]. However, in order to understand the turnover phenomenon of nurses, rather than concentrating on the process or cause of turnover, there is a need arises to consider the process and causes by which turnover does not occur [5,22-23]. Therefore, in this study, factors that affect the turnover intention of nurses was attempted to identify.

Method

For the study, after explaining the purpose of the study and requesting consent to a total of 250 nurses working at general hospitals with more than 500 sickbeds located in S city from Feb 1 to Feb 28, 2019, the questionnaires were distributed to them and answered in a self-filled method. 238 out of 250 questionnaires were collected and 210 questionnaires except for unsatisfactory responses were analyzed. The questionnaire consisted of 7 general questions, 2 questions for turnover intention, and 2 questions for factors related to turnover. The data collected in the study were analyzed using the SPSS/WIN 21.0 program as follows. The general characteristics of the subjects and the reasons for turnover were calculated by frequency and percentage, and the factors affecting turnover were acquired from the mean and standard deviation. A logistic regression analysis was conducted to identify the factors affecting turnover. The statistical significance level was set to .05.

Result and Discussion

Table 1 showed that the average age of nurses was 31.8 years old, with 55.7% in the 20s, and in terms of marital status, 67.6% was single. As for the educational background, associate degree was 40.5%, bachelor's degree was 53.3%. Regarding career, 34.8% was less than 2 years, and 34.3% was more than 9 years, and the average of career was 7.7 years. In terms of the type of residence, it was shown that 64.3% was a residence with family. Regarding position, general nurses were 73.3%. As for the working department, it was found that wards were the highest at 31.4%. Concerning turnover experience, 32.9% had turnover experience and 67.1% had no experience. In terms of the number of turnovers, 58.1% was 1 time, 29.0% was 2 times. For the question of whether there is a turnover intention, 57.1% answered 'no'.

Turnover reason	Working environment	67	31.9
	Shift work	60	28.6
	Workload	44	21.0
	Pay	24	11.4
	Welfare Benefits	12	5.7
	Nurse's status	3	1.4
Total		210	100.0

Table 2 showed that as for factors affecting turnover, in the case of age, it was shown that having turnover

intention was 29.8 ± 7.3 , no turnover intention 33.2 ± 9.9 . In the case of marital status, it was shown that when single, having turnover intention was 78.9%, no turnover intention was 59.2%, and when married, having turnover intention was 21.1%, no turnover intention was 40.8%. In the case of education background, it was shown that when associate degree and above having turnover intention was 36.7%, no turnover intention was 43.3%, and when bachelor's degree, having turnover intention was 61.1%, no turnover intention was 47.5%, and when master's degree and above, having turnover intention was 2.2%, no turnover intention was 9.2%. In the case of career, it was shown that having turnover intention 6.0 ± 6.5 , no turnover intention 9.0 ± 8.5 . According to the residence type, it was shown that when residence with family, having turnover intention was 55.6%, no turnover intention was 70.8%, and in other types, having turnover intention 44.4%, no turnover intention 29.2%.

Table 2. Factors affecting turnover

Variables		Yes	No	P
		N(%) or M±SD		
Age		29.8±7.3	33.2±9.9	.004
Marital status	Single	71(78.9)	71(59.2)	.000
	Married	19(21.1)	49(40.8)	
Education	Associate degree	33(36.7)	52(43.3)	.040
	Bachelor's degree	55(61.1)	57(47.5)	
	Master's degree	2(2.2)	11(9.2)	
Career		6.0±6.5	9.0±8.5	.004
Residence type	With family	50(55.6)	85(70.8)	.020
	Other types	40(44.4)	35(29.2)	
Department	Ward	31(34.4)	35(29.2)	.370
	Intensive care unit	26(28.9)	27(22.5)	
	Surgery recovery room	3(3.3)	9(7.5)	
	Emergency room	5(5.6)	11(9.2)	
	Outpatient	4(4.4)	11(9.2)	
	Other	21(23.3)	27(22.5)	
Position		1.9±0.6	2.0±0.6	.039
Turnover experience	Yes	30(33.3)	39(32.5)	.510
	No	60(66.7)	81(67.5)	
Turnover number		1.8±0.9	1.5±0.7	.149
Turnover reason	Pay	17(18.9)	7(5.8)	.020
	Workload	15(16.7)	29(24.2)	
	Welfare	7(7.8)	5(4.2)	
	Shift work	19(21.1)	41(34.2)	
	Work environment	31(34.4)	36(30.0)	
	Nurse's status	1(1.1)	2(1.7)	
Total		90(100.0)	120(100.0)	

As for the turnover reason, it was shown that in the workload, having turnover intention 16.7%, no turnover intention 24.2%, and in the shift work, having turnover intention 21.1%, no turnover intention 34.2%, and in the work environment, having turnover intention 34.4%, no turnover intention 30.0%, and in the nurse's status, having turnover intention 1.1%, no turnover intention 1.7%.

Table 3 showed that reasons for turnover by logistic regression analysis showed a significant difference in the 20s, single, 4-6 years of career nurses, adequacy of pay, and shift work. This shows a desire that nurses who are free from family members, who have a basic career and can easily access despite turnover into any hospital organization, and can build their careers, hope to receive proper pay they expect, and hope to work in the day time on weekdays free of physical physiological difficulties caused by shift work.

Discussion

Nurses are currently working in health and medical institutions are 45.5% as of 2014, and more than 86% of hospital-level medical institutions do not comply with the nursing workforce standards [23]. Despite the fact that more than 20,000 nurses graduate every year, the reason why there is a lack of nurses in the field may be due to the high turnover rate. In 2015, the turnover rate of nurses was 12.4% on average, which is considerably higher than 2.16%, the turnover rate of other health workers. As turnover intention is directly linked to turnover [9], it is necessary to pay attention to turnover intention and relevant factors in order to reduce the turnover rate of nurses.

In this study, as a factor affecting turnover intention, nurses in their 20s showed a significant difference of .006, which is considered to receive a lot of real shock between theory and clinical practice. In order to tackle this problem, it is believed that it is needed to deepen the student practice time into a direct experience rather than a simple observer.

Unmarried nurses showed a significant difference of .003, which means a personal environment free on the job turnover as a single person has not yet formed a family, and a trend of increased opportunities for building 2~3 years of career and turning over to hospitals that they want, as graduates and experienced workers. This shows the same result as marital status accelerates a higher turnover intention [24].

Nurses of the 4-6 years of hospital career showed a significant difference of .009 in the turnover intention, which is thought to reflect another self-improvement and the trend of changing to a stable position after the 30s when building more than 4 years of career in university hospital level.

There was a significant level of .005 that pay is the cause of turnover, which is analyzed as the intention to turn over to the hospital that provides more pay according to their position, career, and ability on the process that all the information is exchanged and recognized in real-time online. This showed the same result as the result of the study that factors such as pay are related to turnover intention, as the result that Chan and Morsion [25] investigated the factors related to turnover intention in the survey of nurses of hospitals with 1,028 sickbeds.

There was a significant difference of .04 that shift work is the cause of turnover, which is regarded as an attempt to break away from shift work by showing that 3 shifts work breaks biorhythm as women and working at night and sleeping during the day act as a barrier to daily social life outside hospital work. This is also consistent with the study of Lee and Kang's [24], indicating that work patterns are a factor in the turnover.

Conclusion

Therefore, the factors affecting the turnover intention of hospital nurses need to be made at the level of the hospital organization as well as the efforts of the nursing department, and it is necessary to recognize the turnover intention is shown in the 4~6th years of working with independent judgment and experience after working as a new nurse, and to have them receive proper pay by improving the institutional and economic aspects which enable them to keep working, and it is needed to supplement the system to escape from the work of 3 shifts by introducing the system such as the placement of a dedicated nurse on night duty.

Three-dimensional Evaluation of Maxillary Sinus Volume in Different Sex Groups Using Cone-beam Computed Tomography

Eun-Young Jeon¹, Jeong-Hyun Lee², Sa-Beom Park², Jong-Tae Park³

¹Professor, Dept. Dental Hygiene, Kyung-Bok University, ²Graduate School Student,

³Professor, Dept. Oral Anatomy, Dan-kook University College of Dentistry, Korea

Abstract

Background/Objectives: Determining the sex of corpses is the first step of identification in a forensic analysis. Accurate anatomical knowledge for the maxillary-sinus serves as an important mediator of forensic sex determination.

Method/Statistical Analysis: This study included 57 patients (27 males and 30 females) of Dan-kook university dental hospital. Cone-beam computed tomography data images were imported and reconstructed into Three-dimensional models by an interactive medical image control system, Mimics 17.0 software. This study was analyze at 95% significance level using SPSS Version 20.0. The independent t-test was performed to compare the measured values among the two experimental groups.

Findings: The volume of the maxillary sinus measured with traditional radiography may differ from its actual size. The maxillary sinus can be more accurately measured using a 3D model restructured using the CBCT data as the 2D base compared to simple linear measurement in 2D model. In the present study, sex-specific volumes of the maxillary sinus were measured using a 3D model, and there were no significant differences in the volumes between the left and right for both men and women. However, between sexes, the mean left sinus volume was significantly greater among men (23.25) than women (17.59) ($p < 0.05$). The mean right sinus volume was also significantly greater among men (22.46) than women (17.35) ($p < 0.05$).

Improvements/Applications: This study obtained more accurate sex-specific anatomical data for the maxillary sinus using a 3D model. The volume of the maxillary sinus is valuable in researching sex determination.

Keywords: Maxillary Sinus, Volume, Sex determine, 3D Measurement, Mimics.

Introduction

Determining the sex of damaged corpses is the first step of identification in a forensic analysis^[1]. Sex is determined based on various body parts, such as the

skull, pelvis, and maxillary sinus. The maxillary sinus not only plays an important role in the formation of facial contour but also is an area with little damage in a corpse. Particularly, severely mutilated corpses or deaths from a disaster show severe damages to most bones in the skull, but the maxilla is known to incur little injury^[2].

Sexual dimorphism refers to the differences of morphology and size between different sexes of the same species. The maxillary sinus is known to feature sexual dimorphism in various species^[3]. Chatterjee et al. reported that the volume of maxillary sinus differs according to sex and that this is a useful feature in

e-mail: jongta2@hanmail.net

determining sex^[4]. Take et al. measured the volume of the maxillary sinus for 94 adults and observed that men have larger volumes than women do^[2]. Thus, accurate anatomical knowledge for the maxillary sinus and its sexual dimorphism serves as an important mediator of forensic sex determination

Many studies measured the sex-specific volume of the maxillary sinus^[5]. However, two-dimensional (2D) computed tomography(CT) images cannot accurately reproduce the complex three-dimensional (3D) structure of the maxillary sinus, so the validity of its results is doubtful. The size of the maxillary sinus measured with traditional radiography may differ from its actual size. Furthermore, the exact margin of the maxillary sinus is blurred, as it is overlapped with surrounding soft tissues and structures. Because CT images are high resolution images, the boundaries of the maxillary sinus and surrounding soft tissues are clearly distinguished^[6]. Cone-beam computed tomography (CBCT) can provide resolutions of a unit smaller than millimeter in a shorter scanning time and higher quality. The maxillary sinus can be more accurately measured using a 3D model reconstructed using the CBCT data as the 2D base compared to simple linear measurement in 2D model^[7-8].

Based on this background, Based on this background, the present study used a 3D model to measure the sinus volume and assess the sex differences to provide basic data on sex determination using the maxillary sinus of Koreans.

Method

The CBCT data of 57(27 males and 30 females) patients who met the study criteria were obtained from the Department of Oral and Maxillofacial Radiology at Dan-Kook University Dental College Hospital. This study was approved by the Dentistry Hospital Clinical Examination Committee of Dan-Kook University (DUDH IRB 2015-12-022). Only patients with 28 teeth and with no missing teeth or systemic disease were selected. The mean age of all of the patients was 22.8 years.

The CBCT data of the subjects who satisfied the study criteria were obtained in Digital Imaging and

Communications in Medicine(DICOM) format from a CBCT scanner (Alphard 3030, Asahi, Kyoto, Japan). CT scanning was performed with the following image scaling parameters: slice increment, 0.39 mm; slice thickness, 0.39 mm; and matrix, 512 x 512 pixels. After the corresponding DICOM file was imported from MIMICS software (version 17, Materialise, Leuven, Belgium), a 3D model of the skull was created based on the uploaded CBCT image, and this model was used to visually confirm the presence of maxillary sinus [Figure 1].In this study, 2 investigators each used MIMICS to create 3D models and evaluate the volume of the maxillary sinus in 57 patients.

This study performed statistical analyses using SPSS (version 20.0, Statistical Package for the Social Sciences, IBM, USA), with differences considered significant at the 95% level. The general characteristics of the subjects were analyzed using frequency analysis. The independent-samples t-test was performed to detected sex-related differences in the measured values.

Figure 1. 3D reconstruction of the left and right maxillary sinus

Result and Discussion

In the present study, sex-specific volumes of the maxillary sinus were measured using a 3D model. There were no significant differences in the volumes between men and women [Table 1].

Table 1. Comparison of the maxillary sinus volume of sides

Parameters	Patients (n)	Sides	Average (cm ³)	STD. Deviation	p-value
Male	27	Left	23.25	6.94	0.678
		Right	22.47	6.95	
Female	30	Left	17.59	4.83	0.849
		Right	17.35	4.84	

However, between sexes, the mean left sinus volume was significantly greater among men (23.25) than women (17.59) ($p = 0.001$). The mean right sinus volume was also significantly greater among men (22.46) than women (17.35) ($p = 0.002$) [Table 2].

Table 2. Comparison of the maxillary sinus volume of sex

Parameters	Sex	Patients (n)	Average (cm ³)	STD. Deviation	p-value
Left	Male	27	23.25	6.94	0.001
	Female	30	17.59	4.83	
Right	Male	27	22.47	6.95	0.002
	Female	30	17.35	4.84	

Discussion

Forensic research is highly crucial for identifying the sex of a mutilated cadaver that had gone through death by physical injury due to a fire or strong chemicals. The maxillary sinus is denser and thus damaged less than other bones used in sex identification such as the pelvic bone, longitudinal bone or skull. Therefore, it can be used for the challenging task of determining sex using the human skeleton^[9-10]. Until now, sexual dimorphism has been studied using bones like the foramen magnum, occipital bone, frontal bone and maxillary sinus. Analysis of sexual dimorphism in the foramen magnum demonstrated the presence of dimorphism. Moreover, it was concluded as the major bone that can be used to understand sexual dimorphism^[10-11]. Since the maxillary sinus has the advantage of high density and resistance to damage, it is suitable for sex determination and thus more research on sexual dimorphism should be conducted in the maxillary sinus.

Saccucci revealed that the average sinus volume of male and female is similar and thus sex determination using such structure is impossible^[12]. In contrast, the present study found that sinus volume was greater in male than in female. The left sinus volume in male was 23.25mm³ and right 22.47mm³ which were both significantly larger than in female, 17.59mm³ and 17.35mm³ ($p = 0.001$, $p = 0.002$). Gomes et al. worked on the sex determination equation using sinus volume measurements and obtained results similar to our study,

male (19.54) and female (15.28). Fernandes also showed that the average sinus volume was greater in male than in female^[13]. For Egyptians, the size of the maxillary sinus is a useful feature for sex determination^[3]. Kanthem also found that the average sinus volume is significantly greater in male (39.93mm³) than in female (21.53mm³) although the values were significantly different from our male data^[14]. In Kanthem's data, the male sinus volume had a wide range with the minimum of 26.06mm³ and maximum 53.51mm³. These average values of the data make it difficult to trust the results of the research.

The present study measured the sinus volume using a 3D model and assessed the sex differences in order to provide a basic database of sex determination using the maxillary sinus of Koreans based on CBCT data. We used a software that can calculate the volume of the maxillary sinus. CBCT is an effective method for diagnosing maxillofacial structure^[15]. CBCT data has been shown to be a useful tool for maxillary sinus analysis and the accuracy of the results has been verified^[16-18]. The anatomy depicted by CBCT is helpful for volume measurements. In this study, the 3D data of the maxillary sinus obtained from CBCT enabled accurate assessment for sexual dimorphism research using the maxillary sinus.

Conclusion

Sex determination is important in forensic identification. This study obtained more accurate sex-

specific anatomical data for the maxillary sinus using a 3D model. CBCT is a significant development in radiology, enabling more accurate measurement. The three-dimensional information obtained from CBCT provides the opportunity to see beyond the plane and the spatial overlap of structures and to visualize the fine differences using a true 1:1 imaging. Such research is highly crucial for sex identification of an individual in estimation anthropology and criminal investigations and the volume of the maxillary sinus is valuable in researching sex determination.

Development of Personal Safety Education Program for Nursing Students Using Hybrid Application

Sang-Mee Koo¹, Rae-Eun Kim²

¹Professor, UI University, Dept of Nursing, Korea, ²Professor, UI University, Dept of Social Welfare & Counseling, Korea

Abstract

Background/Objectives: This study describes a method of developing a personal safety education program for nursing college students using a hybrid application. The purpose of this study is to ensure that nursing college students receive appropriate education, protect themselves from the elements, and make the best use of their nursing ability before conducting clinical training.

Method/Statistical Analysis: This study uses Orem's theory of self-nursing as the basis of the theory, and the program was developed according to the ADDIE model. In the literature review, we selected themes with high demands through interviews with experts and research subjects, and developed a personal safety education hybrid application.

Findings: The contents of the developed educational program were conducted in four chassis. When practicing at a hospital, when visiting a practicum in a local community, management of musculoskeletal diseases and stress management during clinical practice. The satisfaction level of education through the developed application was very high with $4.84 \pm .33$ points out of 5 points.

Improvements/Applications: Using the application developed through this research, pre-clinical education for health centers in hospitals and communities at nursing colleges could reduce safety accidents in the field. In the future, it will be necessary to verify the effectiveness of various nursing universities and grades.

Keywords: Mobile application, Hybrid application, Nursing student, Personal safety, Occupational hazards.

Introduction

The working environment of medical personnel is not safe. Many health care workers are at risk of being easily exposed to nosocomial infections, and the shift and long hours of work disrupt the circadian rhythm and reduce the quality of sleep. The degree of fatigue continues to increase^[1]. Long hours of work have also been found to increase the incidence of musculoskeletal injury and needle sticks^[2-3]. In the past, emphasis was placed on infectious diseases that occurred in patients, and recently, it has been expanded to include subjects who should be protected by health care practitioners

who carry out medical practices, and safety management in the overall medical environment. It is accessed as a department^[4]. For these reasons, nurses, especially nurses, are often in direct or indirect close contact with patients and are often exposed to various infectious diseases. Much of the time spent in clinical practice is spent on patient care, which increases the risk of infection exposure. A study of nursing students found that up to 61.5% of clinical trials had been exposed to infectious diseases, and had been exposed to needle stick injuries or blood of patients^[5-8].

Nursing students are more vulnerable to safety accidents than licensed nurses due to lack of experience, lack of expertise and skills, lack of knowledge, lack of tutorial, anxiety and lack of self-care^[9,10]. In addition, 85% of nursing college students did not report to the organization at the time of the occurrence of a safety accident related to infection and could not know the

Rae-Eun Kim

Professor, UI University, Dept of Social Welfare & Counseling, Korea

e-mail: versus486@u1.ac.kr

results of the patient’s serological test^[11]. Considering these points, before starting these exercises, standard precautions must be given to recognize and prevent risks and ensure that the agency in the event of a safety accident occurs. As shown in the current study of nurses working in hospitals, nurses who work in the infection control room or who do not specialize in infection control in graduate school lack knowledge of infection management and lack of self-confidence^[12].

^[13]Presents hazards that threaten the health of health professionals who provide family nursing care. It is being described, but the guideline is not provided in Korea yet. Home health care providers experience a variety of hazards in the United States, which can have a negative impact on job performance, job satisfaction and health. In addition, broader training is needed to identify hazards in the client homes they visit and to provide care in a safe environment ^[14]. Currently, when a job is found at a university hospital in Korea, new nurses are educated at the point of incidence, but this is also not structured for each hospital. In the case of

education, lecture-centered education is provided using manuals, pamphlets, and materials collected by the hospital nursing department^[15-17]. In Korea, there were a needlestick prevention program for nurses ^[15] and an education program for new infection control nurses^[16], but the development of educational programs for nursing college students has not been carried out. Although it is not well understood, only the investigation of blood and body fluid exposure during clinical training^[18] and the influence factors^[4,12] that affect the implementation of standard attention instructions for infection prevention have been advanced, and the structure before clinical training has been structured. It is time to find a plan that can be educated efficiently. In this study, Orem’s theory of self-care^[19] was applied as a theoretical framework. The purpose of this study is to define nursing students as beings with self-care needs that can protect themselves from risks and to comply with safety, and to contribute to the maximum performance of nursing students by developing and applying personal safety education programs. The theoretical framework of this study is shown in Figure 1.

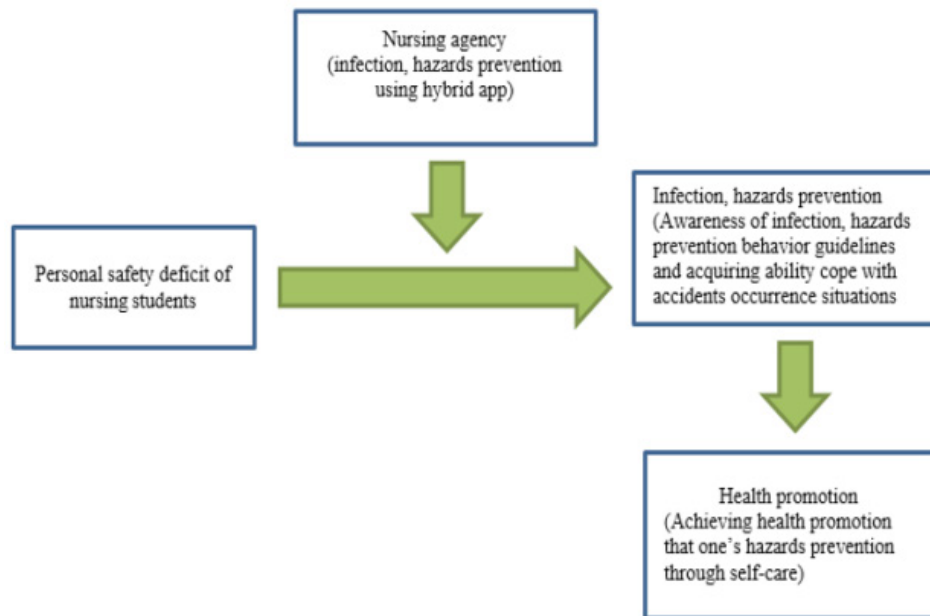

Figure 1. Framework of this study

Method

This study is a methodological study to improve the safety and health of nursing college students by developing a safety prevention program including the

infection of nursing college students using a hybrid app. The ADDIE model ^[20] was used to develop the program of this study. The ADDIE model has also been used as an evaluation rubric when developing new teaching strategies or media in instructional design^[21,22].

Result

1. Analysis: We referred to the guidelines proposed by [13]. In addition, we conducted a semi-structured interview survey on the necessity, content, method, and implementation period of safety education for nursing college students who completed clinical training for three or more semesters. As shown in Table 1 are composed of application contents.

Table 1. Contents of personal safety education program with hybrid app

Phase	Content
1	When practicing in the hospital <ul style="list-style-type: none"> • Concept of hospital infection, high risk of hospital infection, prevention of infection accidents, bloodborne pathogens including needlestick and sharp injuries, reporting method after infection exposure, necessary tests and vaccinations
2	When practicing home visit nursing at a health center or community care (in home health care) <ul style="list-style-type: none"> • The overall environment of the house (such as entering the house after confirming that the animal is bound, temperature in the house, house hygiene, places and things that only hurt)
3	Prevention of musculoskeletal diseases in all clinical practice (when changing patient position, assisting mobility)
4	Occupational Stress (verbal violence, sexual violence, sexual harassment, bullying, incivility)

2. Design: The program of this study was divided into the case of practicing in the hospital according to the practice place and the case of visiting nursing practice in the public health center and the community. Touch each table in the table view with the application then, it was designed to move to that area. When a nursing college student had a hospital infection accident during practical training, he was able to comprehend the situation in which the specific situation was embodied in video and accurately handled and reported.

3. Development: Development was based on the smartphone's general-purpose operating system Android. The screen was made using the photoshop CS4 program and using clear colors and text sizes. Each content has been developed so that it can be easily checked by turning it over, allowing nursing college students to play with videos that can happen in actual practical situations, and for confirmation learning, choose O, X quiz. Figure 2 shows part of the main screen. Two of the computer engineering

majors with extensive experience in developing educational smartphone applications and a professor who is currently teaching pedagogy at the university, participated in this development process.

Figure 2. Screenshot of the smartphone-based app

4. Implementation: After developing this educational program, the content validity was verified by using a group of experts and revised based on the results. QUIS^[24] was used to evaluate the validity of the hybrid app training program. It reflects overall satisfaction (method, impact, interest), screen drive(characters, sequence order), system information and capabilities (terminology, technology, speed, position on the screen), learner(requests), usefulness of confirmation learning, and can be evaluated on a 10-point scale. The supplemented assessment tool was validated with a CVI score of over 90% in all items in a content validation study of a specialist group including two professors in the nursing department and eight nurses working in hospitals and health centers verified.

5. Evaluation: As shown in Table 2, in the evaluation of the expert group after the development of the program. Table 3 was designed to evaluate the satisfaction after directly implementing the program for 12 nursing college students in 3rd grade.

Table 2. Expert's satisfaction of the application (N = 10)

Categories of Satisfaction	M±SD
Overall reaction the application <ul style="list-style-type: none"> • Level of enjoyment, power, stimulation, ease of use, satisfaction 	9.85±0.45
Screen <ul style="list-style-type: none"> • Character, sequence of order, organization of information, highlighting simplifies task 	9.33±0.36

Terminology and system information • Use of term, positioning message, operation speed, reflecting the needs of the users	9.56±0.71
Learning • User's needs, remembering, use of commands	9.78±0.26
Total	9.63±0.24

Table 3. Nursing students satisfaction of the personal safety program (N = 12)

Questions of Satisfaction	M±SD
Was it easy to understand personal safety?	4.89±.31
Was the content and composition appropriate?	4.89±.31
Do you think the teaching method is effective?	4.78±.26
Do you have any ideas to recommend to other students?	4.92±.45
Has the intention to protect personal safety increased?	4.81±.38
Total	4.84±.33

Discussion

This study is based on the contents that students should know before clinical training, especially in high-risk incidents that are likely to occur in nursing college students who practice a lot of time at hospitals and patients' homes. Was carried out to develop the application. Considering the lack of pre-training education, the program was developed. In addition, it can be said that the arbitration study on safety for nursing college students is meaningful in that it was implemented for the first time.

In this study, the ADDIE model was applied to develop a program, which was also used in a study developed by a sex education program for college students^[25] and elementary school students ^[26]. The ADDIE model allows the evaluation of the program process, and the teaching materials developed during the analysis, design and development process can be checked and changed. In this study, satisfaction levels were measured objectively for nursing college students and experts, and as a result, both groups were very satisfied. In addition, the quality of the program was improved by reflecting the modification requirements, and the safety of the research was ensured by actively reflecting the requirements of nursing college students who are users of the application.

In our study, we can find great significance in including the behavioral guidelines before and after home visit training for nursing college students for the first time

in Korea. It can be said that education is necessary at this point when the number of elderly people living alone and patients with disabilities are increasing and the demand for home-visit nursing services is also increasing. In our research, it was confirmed that university students majoring in nursing were able to increase their nursing ability by trying new method. Future social and national efforts for nursing college students are likely to be necessary, and sufficient time and preventive education should be provided before clinical practice.

Conclusion

In this study, it is considered that a wide range of viewpoints were presented to promote physical and mental health of nursing college students from the aspect of nursing research. Through this study, we will be able to grasp the overall hazards of nursing college students in clinical practice, and this will help them develop nursing skills and promote health. Also, in this study, by developing a personal safety prevention program using an application in nursing practice, a university nursing professor provided information on prevention of infection and information on safety accidents for nursing university students and resources available for education. The significance can be found in that it was provided.

Considering the increasing phenomenon of nursing college students in Korea and the current rate of occurrence of these safety accidents, the program developed by this researcher is an appropriate customization program that is very necessary in the future. We expect these jobs to contribute greatly to satisfaction and health promotion. This program was developed by reflecting the specificity of college students with high smartphone use rate, and the respondents' response was very high. Although the personal safety program of nursing students suggested a new point of view, this study was applied only to nursing students of one university. Therefore, we recommend effectiveness verification through continuous arbitration studies for a large number of nursing college students in various regions.

Development and Evaluation of Educational Program to Prevent Cervical Cancer among Vietnamese Immigrant Women

Tae-Im Kim¹, Sang-Mee Koo²

¹Professor, Daejeon University, Dept of Nursing, Korea, ²Professor, U1 University, Dept of Nursing, Korea

Abstract

Background/Objectives: This study was to develop and evaluate a cervical cancer prevention program for Vietnamese married immigrant women who show the high incidence of cervical cancer. In this regard, this study presents the grounds for the cervical cancer prevention program to be spread and adopted widely to promote Vietnamese married immigrant women's reproductive health.

Method/Statistical Analysis: Program was developed by the ADDIE model. The developed program was applied to Vietnamese immigrant women. Study design is random control group pre-test, post-test design. The effects of the program were assessed by health belief of Pap testing, knowledge of cervical cancer, and intention of preventive behavior. In the experimental group, four 120-minutes sessions of cervical cancer prevention education program intervention were provided once a week.

Findings: The results indicate that the educational program to prevent cervical cancer helps Vietnamese married immigrant women to lower the perceived barriers in cervical cancer prevention, to enhance the awareness about cervical cancer, and to raise the intention for cervical cancer prevention behavior, which proves the prevention program is very effective and useful.

Improvements/Applications: We expect that the devised program in this study be widely used in multicultural family support center to promote Vietnamese married immigrant women's reproductive health and quality of life.

Keywords: Vietnamese women, Cervix cancer, Prevention, Education program, Preventive behavior, Intention.

Introduction

Since the mid 1990s, the marriage between international women and Korean men has rapidly increased, and thus, multicultural families have also been rapidly increasing. In the Republic of Korea (ROK), a 'foreign' woman who married a Korean man is called a 'married immigrant woman'. The majority of their

nationalities are China, followed by Vietnam, Japan and Philippine^[1]. Most of them are women who have migrated from countries with a lower health-care level than ROK. It is difficult to comprehend their health status and preventive education regarding diseases^[2]. In recent years, Vietnamese immigrant women, who have a steady increase in the domestic (ROK) population, are known to have a higher risk of developing cervical cancer than women in other countries^[3,4].

In fact, Vietnamese married immigrant women living in the United States were twice as likely to develop cervical cancer as Caucasian women^[5]. The cervical cancer screening rate, one of the preventive health behaviors of cervical cancer, is significantly lower

Corresponding Author:

Sang-Mee Koo

Professor, U1 University, Dept of Nursing, Korea

e-mail: ksm@u1.ac.kr

than that of other Southeast Asian women migrating to the United States^[6-8]. It implies that the possibility of missing early detection/intervention of cervical cancer is increased. As a result, it is a cause of the health and life threat of Vietnamese migrant women. Since early detection can increase the cure rate, the practice of preventive health behavior is particularly emphasized. Papanicolaou test, condom use and vaccination against cervical cancer are recommended for prevention of cervical cancer^[9]. In the case of preventive behavior for cervical cancer practiced by domestic, married immigrant women, the cervical cancer screening rate of Vietnamese, married immigrant women, in some areas of ^[2]was 10.9%. Condom use among the spouse of the immigrant women was examined and 63.5% did not use condoms^[10]. The vaccination rate for cervical cancer vaccination was 7.2% ^[11]. Previous studies indicate that the overall practice of prevention of cervical cancer is very low. Therefore, in order to improve the reproductive health of Vietnamese women who are married immigrants, it is urgently necessary to develop and apply customized education programs to promote the practice of prevention of cervical cancer. Prophylactic health behaviors such as the practice of cervical cancer prevention are known to be linked with individuals' health beliefs^[12]. The higher the perceived sensitivity, the perceived severity, the perceived benefit, and the less perceived barriers of the disease, the better the practice of preventive health behavior for the disease^[13]. However, Vietnamese women are reported to have very low perceived sensitivity and severity to cervical cancer^[14,15]. This study is based on the ADDIE model^[16], a systematic approach to effective teaching design for Vietnamese women who are vulnerable to cervical cancer and developed a cervical cancer prevention education program using illustrations, based on the health belief model. This study attempted to provide an empirical basis for the use of this study as an intervention program for prevention of cervical cancer in Vietnamese married immigrant women.

The hypotheses of this study are as follows.

Hypothesis 1: There will be differences in cervical cancer screening health beliefs in the experimental group and the control group.

Hypothesis 2: The experimental group will have higher cervical cancer knowledge scores than the control group.

Hypothesis 3: The experimental group will have a higher prevalence of preventive behaviors (condom use, Pap testing, vaccination) than the control group.

Method

This study used a randomized control group pretest-posttest design to develop an educational program to improve the prevalence of cervical cancer prevention in Vietnamese married immigrant women.

Subjects: Based on the research report of^[17] that proved its effectiveness after mediating the reproductive health promotion program for married immigrant women, and the research report of^[18] that provided the cervical cancer prevention education program and verified its effect, the significance level, power, and effect size were set as $\alpha = 0.05$, $1 - \beta = 0.8$ and $d = 0.80$, respectively. The minimum number of samples per group required for the independent t-test was 26^[19], which was calculated using G-power 3.1 program^[20]. In this study, a total of 60 subjects were recruited for the experimental group and the control group. Two subjects dropped out in the course of this study and 58 participants participated in the study.

Program development process and contents: The practitioners asked to translate all the lecture materials into Vietnamese and provide them with a Vietnamese interpreter at the lecture. They also requested to look for the most understandable way to communicate with the Vietnamese women. Table 1 shows the educational programs based on the above analysis results. In order to increase the perceived sensitivity of cervical cancer, as a material to be used in the very first class, stories about the incidence of cervical cancer of Vietnamese women who moved to other countries were provided with illustrations to make it easier to sympathize with the subject of learning [Figure 1].

Figure 1. Illustrated material examples

Table 1. Contents of program

Phase	Contents
1	perceived sensibility (structure and function of female reproductive organs, incidence of cervix cancer among female Vietnamese living in the U.S.A)
2	perceived seriousness(definition and cause of cervix cancer, relationship between cervix cancer and HPV, symptom of cervix cancer in each phrase, diagnosis method, treatment and prognosis)
3	perceived barriers(necessaries for examination without any symptoms, pap smear and process and benefits, cultural barriers, recommendation for examination)
4	perceived benefits(prevention method of cervix cancer, benefits of cervix cancer vaccine, use of condom and its expected result)

Measures: RSBB-V (Revised Susceptibility, Benefits, and Barriers Scale–Vietnamese version) developed by [26] was used for Pap testing health beliefs. The cultural barrier for cervical cancer screening was assessed with the CBSI–V (Cultural Barriers Screening Inventory-Vietnamese version) developed by [26]. The knowledge of cervical cancer is a tool developed by [27]. For the intention of cervical cancer prevention, an instrument developed by [28] was used in this study. The reliability of all the instruments was above .70. All the research devices used in this study were approved by the authors through email correspondence.

Result

1. General characteristics of the subjects: There was no significant difference between the two groups in terms of the general characteristics of the subjects, and the two groups were determined to be homogeneous.

2. Hypothesis Test:

The effects of program were as follows:

1. The experimental group has decreased in perceived barriers score significantly than that of the control group ($t = -2.65, p = .011$).
2. The experimental group has a statistically significant higher score in the knowledge of cervical cancer, compared to the control group ($t = 8.22, p < .001$).
3. The experimental group showed statistically significant higher intention score of prevention behavior compared to control group ($t = 5.56, p < .001$). Also the experimental group significantly increased the preventive behavior intention like condom use ($t = 2.63, p < .001$), Pap testing ($t = 3.24, p = .002$), HPV vaccination ($t = 2.46, p = .017$).

Discussion

The purpose of this study is to develop and apply a cervical cancer prevention education program to Vietnamese married migrant women who are known to have high cervical cancer incidence and to verify its effectiveness. The cervical cancer prevention education program developed by this study is unique from the existing education program developed in previous studies on women’s health for married immigrant women.

First, the educational program developed by this study is the first customized cervical cancer prevention education program developed in ROK to reflect the situational specificity of Vietnamese immigrant women. Considering that the proportion of Vietnamese nationality among married immigrant women in ROK is on the constant rise, the cervical cancer prevention education program developed by this study is timely and necessary for the improvement of preventive health behavior of Vietnamese married immigrant Vietnamese women. In the future, it will serve as an intervention program that contributes to the improvement of their health and quality of life. Second, the cervical cancer prevention education program developed by this study is a customized education program based on the cultural specificity and needs of Vietnamese immigrant women using the ADDIE model. [18] developed a cervical cancer prevention education program for immigrant women. In the study by [18], the origins of the married immigrant women were diverse. Thus, the cultural characteristics of the origins of married migrant women were not fully reflected. In this study, the research subjects were restricted to Vietnamese married immigrant women. In order to accurately grasp their current status, educational needs, vulnerabilities, and situational specificity, the contents and method of the education program were developed through the results of focus group interviews and the review of previous studies, thereby improving the participants understanding of the education program. Third, this study created and used illustrations in electronic lecture materials to help participants understand the goal of the education and to increase their intention to participate in preventive actions, which is the ultimate goal of the program. This feature is different from the cervical cancer prevention education program attempted in previous studies.

In this study, the first lecture was provided with a short story, “Booty Tam, American Married Immigrant Woman.” In each lecture, the participants were

encouraged to express their thoughts and obstacles to Pap testing through the main character in the illustration.

As a result, particular, the awareness of cervical cancer and the intention to prevent cervical cancer in the experimental group increased significantly compared to the control group. It indirectly suggests that the illustrations have been effective in inducing understanding and cooperation among Vietnamese married immigrant women who are not used to expressing their thoughts and feelings.

As a result of examining Pap testing within 6 months after providing educational program, the screening rate in this study was significantly higher than that in previous studies, suggesting that the educational program using illustrations was effective. Regarding the practice rate of cervical cancer screening within 6 months after the educational program, the research conducted by [23], which provided Chinese immigrant women in the U. S. with educational programs using videos, pamphlets and screening kits has the practice rate of 39.0%. A study on immigrant women residing in the United States by [22,29] has the practice rate of 61.7%, 65.8%. Compared to these previous studies, this study has the practice rate of 75.8%, indirectly indicating that the educational program was effective. Fourth, the educational materials developed by this study were produced in Korean and Vietnamese to share these materials with their spouses. This study is meaningful in that the Vietnamese married immigrant women actively participated in the program that includes their spouses in the curriculum.

Conclusion

In this study, randomized control study design was used to validate this study's effect, to provide a basis for practical application and widespread use of the cervical cancer prevention education program developed by this study. As a result of hypothesis test, the experimental group who received the cervical cancer screening program compared to the control group, has statistically meaningful 1) increase of the perceived sensitivity and 2) decrease of the perceived barriers among cervical cancer screening health beliefs. Through this, it can be concluded that the cervical cancer prevention education program developed by this study is a highly effective customized education program for promoting cervical cancer prevention behavior of Vietnamese married immigrant women. In the future, we hope that this educational program will be actively deployed to

multicultural family support centers, health centers, and various community organizations to prevent cervical cancer and to promote preventive health behaviors for cervical cancer.

Abstract

Background/Objectives: External and mental stress from hair loss degrades the quality of life and affects the interpersonal relationship and daily social life of individuals. Lately, due to an increase in hair loss population, various chemically synthesized products for hair loss prevention or treatment have been commercialized in the market. However, these products have well-known adverse effects. In order to prevent such adverse effects, this study aimed to develop a natural substance and utilize a tool that aids its transdermal delivery. This study intended to elucidate the scalp health and hair loss prevention effects of Eclipta prostrata and microneedle therapy system (MTS) use on the scalp of office workers in their 20s and 30s who have suffered from hair loss, in addition, to present a potential product for improving scalp conditions and preventing hair loss.

Method/Statistical Analysis: In order to identify the effects of the MTS and the Eclipta prostrata extract on improvement of scalp condition and prevention of hair loss, this study conducted scalp treatments on 24 office workers in their 20s and 30s who have suffered from hair loss by dividing them into three groups: MTS group, Eclipta prostrata group, and MTS-Eclipta prostrata group. The scalp treatment was performed for 10 weeks with one 30-min turn per week, resulting in 10 turns in total. The same home care products including shampoo and conditioner were distributed to all participants for use during the entire period of experiment. Hair density, hair thickness, effect on scalp improvement, and hairline distance were measured using a scalp diagnostic device (Kong Scope, Korea) and a measuring tape before, 5 weeks after, and 10 weeks after the experiment. Participants were then surveyed for satisfaction level after the experiment.

Findings: In the results, all three groups showed increase in hair density and thickness and a decrease in frontal hairline distance at both hairlines, 10 weeks after the experiment. Only the MTS-Eclipta prostrata group showed a statistically significant increase in hair density from 18 ea at 0 week to 19.43 at 10 weeks, hair line thickness, and frontal hairline distance changes. The Eclipta prostrata group also showed a significant increase in hair thickness. Furthermore, majority of the participants showed clean scalps with new hair growths 10 weeks after the experiment.

Improvements/Applications: It was revealed that co-treatment with MTS and Eclipta prostrata extract had more effect on hair density, hair thickness and hairline distance change. Furthermore, the satisfaction survey

e-mail: whiteapple80@hanmail.net

result after the experiment showed a positive response for hair richness and reduction in itching and sebum amount, thereby building self-confidence. Accordingly, it was proved that the use of MTS and the *Eclipta prostrata* extract is effective in scalp health and hair loss improvement.

Keywords: *Eclipta prostrata* extract, MTS (Microneedle Therapy System), Hair care, Hair loss, Scalp health.

Introduction

The external and mental stress from hair loss negatively affect the quality of life, interpersonal relationship, and daily social life of individuals. An increase in the number of hair loss population leads to an increase in the population that have suffered from hair loss-related symptoms as well. Therefore, creating demands for hair and scalp health products and treatments such as hair transplantation.

For accurate investigation of hair loss population, the data of number of patients who had been hospitalized or had been outpatients due to hair loss from 2013 to 2017 were acquired from the Healthcare Bigdata Open System^[1] provided by the Health Insurance Review & Assessment Service (HIRA).

According to HIRA, the number of hair loss patients treated in 2013 was 205,659. Also, there was a slight decrease in number from 208,688 in 2014 to 208,534 in 2015 and a significant increase from 212,916 in 2016 to 215,025 in 2017^[1].

Recently, there have been several studies and clinical trials that evaluate the efficacy of natural extracts on hair growth, for instance, cultured wild ginseng roots which was proven to facilitate hair loss prevention, hair growth, dandruff control, and have antibacterial properties^[2].

MTS is a device that can approximately create 200,000 micro-holes with its 192 microneedles to facilitate effective transdermal transport of compounds and induce collagen synthesis^[3]. According to a study, use of MTS on human dermis showed improvement in pores, pigment reduction, hair density, and hair thickness. Moreover, the use of traditional medicinal herb extracts, green tea, biota seed and MTS resulted in increased hair density^[4].

Eclipta prostrata L. refers to an annual or biennial plant that belongs to the Asteraceae family and typically grows in moist areas and in central or southern regions of

Korea. A damage to its stem causes a leak of Chinese ink-like black liquid which can be used to dye beard or hair black and to grow hair, a method used by the ancients as stated in *Uibangyuchwi*, the biggest oriental medicine encyclopedia. It has various names such as *Yejangcho*, *Mukallyeon*, *Mukttucho*, *Mukcho*, *Mugyeoncho*, *Hallyeonpul*, and *Haryeoncho*. In *Sinsuboncho*, it is named as *Eopungjang* and in *Dogyengboncho* as *Hallyeonja*, which is its generic name. In oriental medicine, *Eclipta prostrata* is characterized to have a spicy and salty taste and a warm property^[5, 6]. The entire body of *Eclipta prostrata* plant contains active ingredients such as saponin, nicotine, tannin, vitamin A, ecliptine, and thiophene compounds while its leaves contain wedelolactone and desmethylwedelolactone-7-glucoside^[7]. Of these, nicotine and wedelolactone have been known to cause the dark coloring of the liquid.

One study stated that *Eclipta prostrata* can be used for management of inflammation^[8]. Recently, both desmethyl-wedelolactone and wedelolactone were isolated from the leaf extract^[9] and 2-[butadiin-(1,3)-yl]-5-[buten-(3)-in-(1)-yl]-thiophen, a thiophene derivative, was separated from the entire body of the *Eclipta prostrata* plant^[10]. Other studies have reported on the biological activities of the compounds found in *Eclipta prostrata* such as their effects on liver function in hepatic carbon tetrachloride poisoning^[11], as well as mechanism of their hypoglycemic effect^[12, 13], anticancer effect^[14], hair growth effect in albino rats^[15], healing effects of ethanol extracts^[16], and immune-boosting effects^[17, 18].

The traditional oriental medicine literature show that *Eclipta prostrata* can change gray hairs to black, can provide anti-aging function^[19], and can be used for prevention and treatment of inflammatory diseases^[20, 21]. This study aims to elucidate the effects of *Eclipta prostrata* and MTS on scalp and hair loss in normal office workers in their 20s and 30s who have suffered from hair loss, in addition, to present a potential product for improving scalp conditions and preventing hair loss.

Method

- Study Subjects:** The participants of this study were 24 normal office workers in their 20s and 30s from K call center in Yun deung po-gu, Seoul. Their patterns of hair loss, types of scalp, and general characteristics were examined.
- Study Materials:** Carefully screened Eclipta prostrata was cleanly washed and dried, then matured with ultrasound waves within the solvent (1,3- Butylene Glycol 30% and Glycerin 5%) for 96 hours at 60°C. Afterwards, filtration was performed for extraction. The extraction ratio of Eclipta prostrata was 1:15~20, containing 5~6% of the original juice from Eclipta prostrata.

Table 1. Ingredient analysis

Compounding Ingredient	Weight (%)
Purified Water	62
Butylene Glycol	30
Glycerin	5
Eclipta Prostrata Extract	3
Total	100

3. Study Procedure

The comparison of variables of before and after the care such as hair density, hair thickness, effect on scalp improvement, and frontal hairline distance change, of male and female adult office workers in their 20s and 30s who have suffered from scalp troubles and hair loss is shown in Figure 2.

Figure 2. Whole Experiment Flow Diagram

- Analysis Methodology:** The acquired results were statistically processed using SAS (Statistical Analysis System version 9.1.3) and Statistics Program R (version 2.13.0).

Result

- General Characteristics of Participants:** The general characteristics, hair loss patterns, scalp

types, time of initial hair loss, and stress of participants were examined. The average age of the 22 to 30-year-old participants was 28. In terms of hair loss, no family history accounted for 45.8%, 33.3% from father’s side and 20.8% from mother’s side. Furthermore, normal stress accounted for 66.7% and scalp type fell into two, oily or dry, both 33.3%.

2. Hair Density Change before and after Experiment for each Group: The measurements revealed non-significant increased tendency in hair density in both the MTS and the Eclipta prostrata groups

while the MTS-Eclipta prostrata group exhibited a statistically significant difference with 18.00 ea at week 0 to 19.43 at 10 weeks after the experiment as shown in table 2.

5. Scalp Improvement: The scalp status of most participants showed blurry and generally reddened scalps with excessive sebum and dead skin cell-clogged holes, predominantly thin and weak hairs and empty follicles. Ten weeks post-treatment

revealed a nearly normal scalp appearance of pellucid and clean scalp with decreased amount of excreted sebum, clean holes, and new hair growth as shown in Figure 3.

Figure 3. Scalp Status Change in MTS group before and after the Care

Discussion

This study was conducted by dividing the participants into a control group, which used a scalp improvement agent with the natural extracts and an experimental group, which added scalp scrubs. People with long-standing hair loss treatment failure had benefited from improvement thus, the Eclipta prostrata was observed to

have positive effects on the hairs and on the problematic scalps. The study demonstrated a notable effect on hair loss treatment in the control group which used scalp improvement agent with natural Eclipta prostrata extract and a significant improvement in hair growth and thickness in the experimental group that used scalp improvement agent, natural Eclipta prostrata extract, and

MTS. Furthermore, aside from improved problematic scalp, the latter had better improvement in the number and thickness of hairs compared to the control group that only used MTS.

Based on these results, it is deemed that the compounds of the *Eclipta prostrata* extract, such as saponin, tannin, amara, ecliptine (*Eclipta prostrata* with small leaves), vitamin A-like substances, and wedelolactone and demethylwedelolactone-7-glucosid that are compounds of nicotine and coumarin, have brought in antioxidative and antibacterial effects to human body, thereby improving blood circulation and preventing hair loss and dandruff formation. The study elucidated the effects of *Eclipta prostrata* and MTS only in participants who are office workers aged 20-30 years old, therefore, further studies by age groups and by scalp types are necessary.

Conclusion

This study compared the variables, which include hair density, hair thickness, scalp improvement effect and the frontal hairline distance change, of before and after the care in the male and female office workers in their 20s and 30s who have suffered from scalp troubles and hair loss. The results are as follows. Firstly, hair density of all three groups increased at 10 weeks after the experiment. Secondly, in terms of hair thickness, all three groups exhibited an increased tendency when comparing Week 0 and Week 10. Also, the *Eclipta prostrata* group showed a statistically significant difference. Thirdly, regarding frontal forehead hairline distance, the measurement results of the distance to a terminal hair revealed that a decreased tendency was observed at both hairlines at 10 weeks after the experiment in all three groups. The MTS-*Eclipta prostrata* groups had statistically significant difference in all variables. Lastly, most of the pre-treatment scalp status of the participants were overall red and blurry, had holes clogged with excessive sebum and dead skin cells, with predominantly thin and weak hairs, and had some empty follicles. Ten weeks later, however, it was observed that the status of most of the scalps were pellucid and clean, close to normal scalp appearance, and with presence of new hair growths, decreased amount of secreted sebum, and clean hole surroundings.

In summary, when co-treated with MTS and *Eclipta prostrata* for scalp care, a positive effect was observed in terms of hair density, hair thickness, and frontal

hairline distance compared to those of MTS or *Eclipta prostrata* alone, moreover, participants from all three groups showed satisfaction after scalp care.

Based on the findings of this study, *Eclipta prostrata* is expected to play the role of a safe anti-hair loss agent and scalp condition enhancer, and is thought to have a high potential as a cosmetic with an anti-hair loss function.

Abstract

Background/Objectives: The purpose of this study was to identify the highest activation in Vastus Medialis (VMO), Vastus Lateralis (VL) and Rectus Femoris (RF) while performing various squat exercises to create an effective exercising method.

Method/Statistical Analysis: 40 healthy subjects (males 23, females 17) from S University were recruited. Subjects performed four different types of squats; General Squats (GS), Instability Squats on an unstable surface (IS), Knee Adduction Squats (KAS), and Wall squats (WS). The difference in the activation of VMO, VLO and RF were recorded during the various exercises were analyzed and recorded with the EMG.

Findings: Measurements of all the experiments were analyzed using one-way ANOVA. Within these results, RF showed the most activation during (WS) and the least activation during (KAS). However, there were no significant differences found between (GS) and (IS). VLO showed the most activation during (GS). On the other hand, there were no significant differences found within (IS) and (WS). In addition to our results, VMO showed the least activation during (KAS). All three muscles displayed different activation patterns during each squat exercise.

Improvements/Applications: Considering these findings, this study may help to design a more effective exercise for specific muscles when strengthening the leg muscles.

Keywords: Weight bearing exercise, Various squat, Base of support, Muscle activity, Selective Quadriceps.

Introduction

Modern science has made life convenient, but it has caused a decrease of activities resulting in an increase of health problems^[1]. Squat is the most commonly used^[2] and the best exercise for the quadriceps because it requires more movement of the joint than weightless exercises. It also stimulates the senses, functional

pattern of muscle recruitment^[3] and it equally applies force to the buttocks, thighs, and calf muscles and the trunk muscles^[4]. Closed chain movement, such as squat, is less prone to shear force due to increased compression of the femoral joint and co-contraction of the quadriceps and hamstring^[5]. It is said that it is important to keep the tibia perpendicular to the floor in order to avoid sprains^[6] and certain amount of anterior displacement in the knee can prevent excessive stress and back pain^[7].

The quadriceps play the most important role in lifting body weight^[8] and exercises that activate the quadriceps help prevent injuries. When weakened, it reduces walking speed, balance and increases the risk of knee osteoarthritis^[9-11]. It is suggested that atherapeutic approach should be developed to optimize the function of the quadriceps before muscle reintegration^[12].

There are various method in performing the squatting exercise. Squatting on an unstable surface enhances postural orientation^[13], improve balance, and motor control while activating core muscles^[14-15]. It is also suitable for those who need to have low level training^[16-17].

Based on the anatomy that the VMO muscle reaches the distal part of Adductor Magnus^[18], it has been shown that VMO activation can be selectively obtained and strengthened through hip adduction^[19-20].

Muscle strengthening of the quadriceps through squat is considered functional because it promotes muscle mobilization, and stimulates the proprioceptive sensation^[21]. Squat has been extensively used in clinical practice but the effectiveness of the patient’s posture has not been clearly differentiated.^[22] In this study, we investigated which muscles were most active in various squats so we can design a more effective exercising method.

Method

1. Participants: [Table 1] 40 healthy adult men and women in Asan, South Chungcheong Province who did not have any musculoskeletal or any neurological diseases during the last 6 months were selected as the subjects for this study. Before participating in this study, subjects were sufficiently informed about the content and purpose of the study and filled out consent forms. This study was conducted with the approval of the Institutional Bioethics Committee of Sun Moon University (SM-201805-036-2). shows the general characteristics of the subjects. All values are mean±standard deviation

Table 1. General Characteristics (N = 40)

Types	Mean
Sex (M/F)	23/17
Age (Years)	20.8±1.43
Height (cm)	168.3±9.2

2. Procedures: [Table 2] The purpose of this study was to compare the muscle activity of RF, VLO, VMO of 40 healthy subjects according to the four types of squat exercises; General squat(GS), squats on an unstable surface(IS), squats with a ball between the knees(KAS), and wall squats with a swiss ball against their back(WS). The squat types differed between stable or unstable surfaces, knee adduction, knee abduction, and walls. Before exercise, the body

weight and height of the subjects were measured by a body composition analyzer then the subjects did warm up for 5 minutes. The squat experiment was performed after attaching the measuring pad to the location of the RF muscle, VLO muscle, and VMO muscle. During the squat, the legs were spread shoulder width with the subject facing forward. Each exercises were held in the respective order and was held for 10 seconds; GS, IS KAS, WS. The subjects took a 5-minute break upon completing each exercise. All of the squat types except the GS were guided multiple times and there was constant feedback in order to maintain the correct posture. All squat exercises were performed by bending the knee at 90° and the flexion angle was measured using a digital goniometer. [Figure 1, 2].

Figure 1. Types of Squats (A:General Squat, B: Instability Squat, C:Knee Adduction Squat, D: Wall Squat)

3. Measurement: In this study, EMG QUS100 (Zero wire EMG, Italy, 2009) was used to measure the muscle activity of the RF muscle, the VLO muscle, and the VMO muscle while the subjects were performing the experiment. Surface EMG, which evaluates the function of the bony muscle, can be used to electrophysiologically analyze the kinetic activity of each muscle.^[22] The pad of the VLO was attached laterally 55° and 10cm above the knee, and the VMO was attached medially 55° and 4 cm above the knee^[19]. In order to reduce the skin resistance of the electromyographic pads, the attachment site was depilated.

4. Statistical Analysis Result: [Figure 2] For data analysis, the SPSS/PC ver 22.0 for windows program was used. One-way ANOVA was used to compare the muscle activity of each exercise group. All study results were subjected to a post-test least significant difference (LSD) test, and all statistical significance levels were set at p <.05. The root mean square (RMS) value of the EMG was measured and the filtering bandwidth was 20 ~ 450Hz. And a 60Hz notch filter was used to reduce the static.

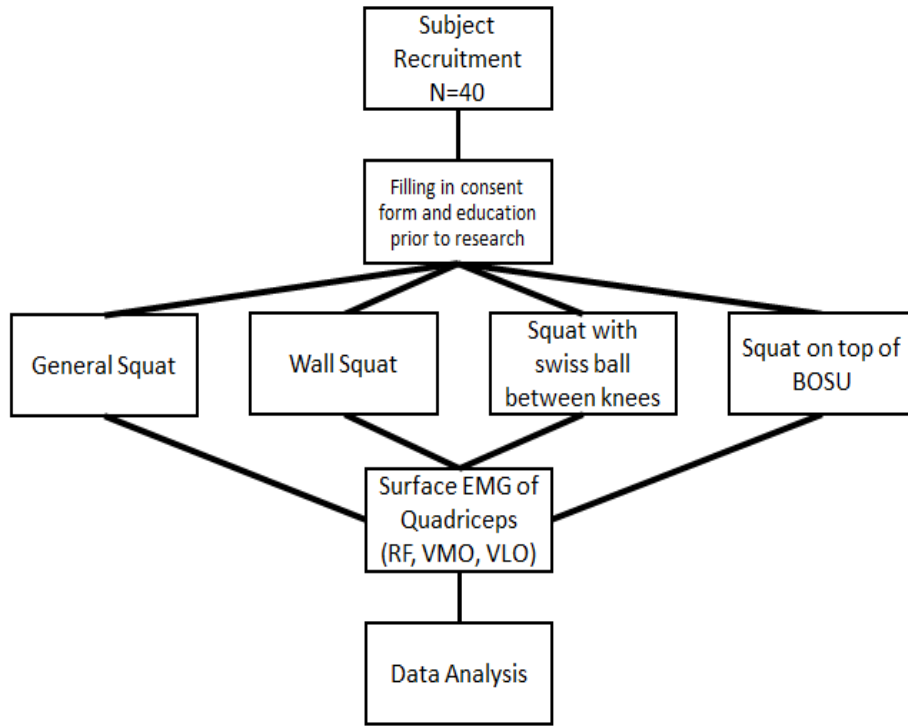

Figure 2. Flow diagram of experimental protocol

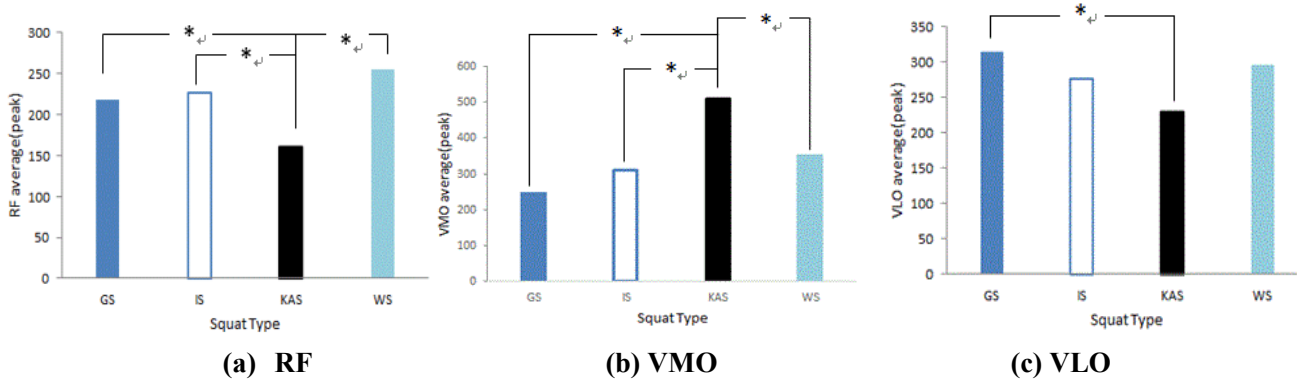

Figure 3. Muscle activation average according to type of squats for RF, VMO, VLO

Table 2. Types of Squat

Type	Squatting on a stable surface
GS	Squatting on an unstable surface
IS	Squatting on an unstable surface
KAS	Squatting while inducing knee adduction
WS	Wall squatting while leaning against a ball

GS: General Squats, IS: Instability Squats on an unstable surface, KAS: Knee Adduction Squats, WS: Wall squats.

Result

Changes in muscle activity according to the squat type were significantly different in some muscles.

- 1. RF activation average according to types of squat:** [Table 3] In the RF, when comparing the results of GS (133.92±21.18) and IS (93.54±14.79), GS and WS (183.24±28.97), IS and KAS (41.45±6.55), IS and WS, and finally, KAS and WS, there was no significant difference (p>.05). However, when comparing KAS to every squat there was a significant difference (p<.05). Considering these findings, GS, IS and WS produced the most activation within RF [Figure3 (a)].
- 2. VMO activation average according to types of squat:** [Table 3] In the VMO, when comparing the

results of GS (104.14±16.47) and IS (168.22±26.60), GS and WS (153.61±24.29), IS and WS, WS and GS, there was no significant difference (p>.05). However, when comparing KAS (70.68±11.18) and GS, and other squats, significant differences were found (p<.05). Due to these results, we have concluded that the KAS (70.68±11.18) showed the most activation in the VMO [Figure 3 (b)].

3. VLO activation average according to types of squat: [Table 3] In the VLO, when comparing the results of GS(88.67±14.02) and IS(160.01±25.30), GS and WS(195.90±30.97), IS and KAS(96.58±15.27), IS and WS, KAS and WS, there was no significant difference (p>.05). However, when comparing GS and KAS, there was a significant difference (p<.05).

Therefore, it was concluded that GS produced the most activation in the VLO [Figure 3 (c)].

Discussion

The purpose of this study was to investigate the differences in muscle activity of the RF, the VMO muscle, and the VLO muscle while performing GS, IS, KAS, and WS. Blanpied suggested that the quadriceps were required to assist the hip joint during squatting^[23]. The VMO is physiologically the weakest muscular muscle^[24] and is active during knee stabilization, knee extension and lateral movement^[25]. VMO is the first to exhibit atrophy; once weakened, it can cause an imbalance in the muscles and increase the lateral movement of the knee^[26-28] which results in various diseases^[29]. Therefore, for the purpose of this study, it was necessary to know the ratio of the muscle activity of the VMO, the VLO, and RF muscle.

There were significant differences in some muscles according to each squat type. For the RF. there was a significant difference in KAS with GS, IS, and WS. It can be seen that excluding KAS, the GS, IS, and WS approach are good exercise method for activating the RF muscle. When Shawn R (2010) performed GS body weight shifted to the tip of the toe, indicating that muscle activity was high in the RF^[30]. Nairn (2016) also supported these results by stating that squatting on an unstable support surface resulted in high muscle activity in the RF^[31]. In addition, Felipe (2011) reported that the wall squatting against a swiss ball was effective in producing muscle activity of RF.

In the VMO muscle, there was a significant difference between KAS and GS, KAS and IS, KAS and WS ($p > .05$). respectively. In HyoukHyong (2015) reported that a squat with isometric adduction using a ball was effective in selective activation of VMO^[32], which aligned with our results.

Shawn (2010) reported that there was a significant difference in muscle activity of the VLO muscles during a traditional squat^[30]. Likewise, there was significant difference in GS, IS, WS movement in the RF, and in the muscle of the VMO, the most significant difference was found in the KAS exercise.

This study has some limitations. First, it cannot be generalized to patients and all ages because it is conducted on adults in their 20's. Second, these results were done on a short-term therefore, the results of a long term test is unknown. Third, it was assumed that the signal from EMG was muscle activity. Finally, the subject's fatigue may affect the outcome by repeating the inter-experiment squat.

Conclusion

In order to investigate the muscle activity according to posture, each muscle was compared and analyzed. In the case of the RF muscle, a significant difference was found in all four squat method; GS, KAS, IS, and WS. The most significant difference in the VLO was found in the KAS. Finally, in VMO, there was a significant difference in the GS. Therefore, it was found that the squat type that is most effective for the selective strengthening of the RF is GS and IS WS, and for the VMO, the most effective exercise the KAS. In addition, we found that the maximum activation of the VLO was shown greatest during the GS.

Through the use of these results, we hope to suggest an effective exercise method for the selective muscle strengthening of the RF, VLO and VMO respectively.

Change of Serratus Anterior Muscle Thickness According to Knee Flexion Angle During Knee-Push Up Plus Exercise on Sling

Yun-Ji An¹, Ye-Ji An¹, Ji-Heon Hong², Jae-Ho Yu², Jin-Seop Kim², Dong-Yeop Lee²

¹Faculty Student, ²Professor, Department of Physical Therapy, Sun Moon University, Asan-si, Chungnam, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to compare the change of thickness of serratus anterior muscle to different angles of knee flexion when knee push up plus (KPP) exercise is conducting on an unstable surface (sling).

Method/Statistical Analysis: There were 30 healthy young male and female students randomly selected and divided into 3 different groups along different knee flexion angles on an unstable surface (sling). The three groups of ten did KPP exercises on the sling. The muscle was measured before and after the exercise.

Findings: All three groups showed some changes in the thickness of the muscle. The group with the biggest change was the 60° knee flexion, followed by 75° and 90° groups.

Improvements/Applications: Based on the results, all experimental groups showed some differences with KPP exercise conducted on an unstable surface (sling) and especially the group with the lowest angle had the most effect. Therefore, it is concerned that a lower knee flexion angle can be more effective on the KPP exercise.

Keywords: *Serratus anterior muscle, push up plus exercise, unstable support surface, knee flexion angle, thickness change, ultrasonography.*

Introduction

Neck pain is also very common following backache symptoms, and patients with neck pain can improve forehead posture. The posture gives some effects on the position of the shoulder joint and its kinematics^[1]. To treat the pain and the abnormal stance, it can be helpful to do stabilizing exercises for shoulder and retraining serratus anterior(SA) muscle to control muscle^[2].

SA is quite important to make shoulder muscle stable. Also, the proper function of SA muscle helps

to keep normal scapulohumeral rhythm while raising arms up. When the humerus is flexion and external rotation, SA muscle has the shoulder blade remain in a stable position. Moreover, SA muscle can stop winging scapular and help the shoulder blade stay in posterior tilt while practicing upward rotation. SA muscle has an important role for stabilizing the scapula and its settlement influence on shoulder stabilization. Thus, many treatments and exercise therapy protocols have been studied to activate SA muscle for prevention and rehabilitation of shoulder joint dysfunction^[3].

Recently PUP (Push-Up Plus) exercise has been widely used as a type of exercise to rotator cuff. PUP is the exercise to increase the function of SA muscle and decrease extremity muscle activity. Also it is highly recommended because it shows the highest average of muscular activation compared to other activation exercises for SA muscle^[4]. There are several ways of

e-mail: kan717@hanmail.net

PUP exercise such as Standard Push-up Plus (SPP), Knee Push-up (KPP) with kneeling SPP, Wall Push-up (WPP) with standing and putting hands against the wall, and other exercises with applying SPP. These alternative ways applied SPP are to help patients to put less or limitation on weight load when they cannot repeat SPP at the early stage of rehabilitating program^[5].

PUP exercise is an exercise through repetition of the scapula’s protraction and retraction with hands supporting either unstable or stable support sling. It is used as a therapy for the patients who have injured or damaged shoulders to improve the rehabilitation and various kinesitherapies have been developed with different flexural angles of the shoulder, many types of support surfaces and the positions of supporting hands.

According to previous studies, PUP exercise on an unstable support surface (sling) has more effective than that on a stable support surface (sling)^[6,7]. Additionally, there was another result showing that shoulder 110 flexion has more efficacious than other shoulder angles^[8]. However, there was no study to show us which knee flexion angle can be the most efficient to do PUP exercise. Therefore, the aim of this study was to find out the most effective way for stabilizing shoulder muscle comparing the thickness of SA when trying different knee flexion angles for KPP exercise on an sling.

Materials and Method

1. Subjects of Study: The subjects were healthy young adults who volunteered to participate in the study. The experiment was conducted with a short orientation about its purpose and its process. Thirty healthy young male and female adults in their 20’s, who do not have any pain on shoulder or knee joints for the past 6 months, musculoskeletal system disorder on shoulder or knee joints in the past or now, any experience of surgical procedure, physical damages or disorders on other parts of the body, were randomly selected. This study proceeded with

the bioethical approval of IRB. (Approval number: SM-2018-05-034-2)

2. Instrument and Method:

- (a) **Instrument:** eZono 3000 was used to measure the thickness of SA muscle in the study. Ultrasonography imaged the structural feature of muscle in the body^[9].
- (b) **Method:** The measurements were conducted by the tester who fully knew about the study and the tester measured the subjects 3 times to reduce errors and then measured the thickness of SA muscle on the clearest image [Figure 1.(a)].

Figure 1: (a) Ultrasonography by imaging of SA muscle (b) Measurement posture using ultrasonography

For the measuring process, the subjects lay down on their side and put one of their arms up. Then we put the ultrasonography horizontally around the fifth rib and measured the thickness of serratus anterior muscle which is located right above its rib shadow^[10] [Figure 1.(b)].

3. Analysis: In this study, 30 adult males and females who had no abnormality in their shoulders were randomly selected and divided into 3 groups. The first group, Group 1 for knee flexion 90°, the second group, Group 2 for 75°, and the third, Group 3 for 60° [Table 1], [Figure 3].

Table 1: General Characteristics of the subject (N = 30)

Characteristic	group 1 (n=10)	group 2 (n=10)	group 3 (n=10)
Age (y)	21.05±1.72	20.80±1.03	22.00±3.12
Height (cm)	168.78±10.69	170.12±9.06	165.42±9.38
Weight (kg)	71.56±11.37	69.35±12.09	73.13±10.98

group 1: knee flexion 90°, group 2: knee flexion 75°, group 3: knee flexion 60°

Figure 3. Posture by group. group 1: knee flexion 90°, group 2: knee flexion 75°, group 3: knee flexion 60°

The groups were divided by different angles of knee flexion and degrees of the lines between the distance of fibula lateral line and femur lateral epicondyle and the distance from femur lateral epicondyle to femur lateral line in crawling position. Each group had 10 people; 3 were female and the rest were male.

Before the experiment started, there was an orientation to explain about the study and teach the participants about the exercising postures. For PUP exercise, they put the knees down and bent shoulder in right angle with their hands on an unstable surface (sling). To make 90° of shoulder flexion, hands were put as wide as shoulders and posed in an external rotation which performs optimal muscle activation^[8,11,12]. In this position, the protraction and retraction of the shoulder blades were repeated in 10 times for 10 seconds per set. During 3 sets, there was a 30-second break between sets. The three groups had done the exercise with different settings of the knee flexion angles twice a week.

The results of the differences of the thickness of SA muscle before and after the PUP exercise were compared to study the change of the muscle along the different angles of knee flexion for PUP exercise on an unstable supporting surface (sling). The instrument, ultrasonography measured the thickness for three times then the clearest image was chosen to look [Figure 4] below shows the process of the experiment.

Figure 4. Experiment protocol flow chart

4. **Statistical Analysis:** All the values of the experiment were calculated with SPSS/PC ver. 20.0 for window program. Matching sample T-test was used to compare the groups before and after. For the comparison of the average of the groups, one-

way-layout analysis of variance was used and post verification method was used to show the difference between factors. Significant levels were set $p < .05$ to verify statistics.

Result

[Table 2] shows the different thickness of SA muscle of each group when the KPP exercise had done on an unstable supporting surface (sling) twice a week.

Table 2: Before and after each exercise group serratus anterior muscle thickness Average (N = 30)

	Before exercise	After exercise	Response difference	t	p
Group 1	5.27±1.96	5.64±1.99	.37	-12.33	.00***
Group 2	5.97±1.63	6.61±1.87	.64	-6.12	.00***
Group 3	5.66±1.57	6.55±1.62	.89	-11.40	.00***

group 1: knee flexion 90°, group 2: knee flexion 75°, group 3: knee flexion 60°, * $p < .05$, ** $p < .01$, *** $p < .001$

Before the exercise, Group 1 with right angle got the average of 5.27±1.96, Group 2 with 75° got 5.97±1.63 and Group 3 of 60° had 5.66±1.57 for the average value. After the exercise, the first group with 90° got 5.64±1.99 on the average of the muscle change, the second got 6.61±1.87 and the third had 6.55±1.62 average. Therefore, there was some difference in comparing the change of the thickness of SA muscle ($p < .05$).

Moreover, like [Figure 5] shows the increase on average before and after conducting the exercise, the changes between Group 1 and 2 and between Group 2 and 3 did not show enough compared to no difference between Group 1 and 3 on the thickness change of SA muscle.

Figure 5. The mean of the before and after difference of each group

Discussion

This experiment was done to show the difference of the SA muscle thickness before and after the exercise. The three groups all got some positive results after conducting KPP exercise on an unstable supporting surface (sling). The biggest difference was shown from the knee flexion 60°.

The SA muscle observed in the study can stabilize the shoulder muscle and its exercise can help to release the neckache and control and relax forward head posture pain^[1]. According to one study found that applied PUP exercise can be generally used to treat patients for shoulder rehabilitation and when doing the exercise in kneeling position, the shoulder blades protraction can more activate serratus anterior muscle^[4]. Additionally, based on another experiment by Ludewig, P. M. et al. SSP exercise has shown the highest level of SA muscle activity among Standard Push-Up Plus Exercise (SPP), Wall Push-Up Plus Exercise (WPP), Elbow Push-Up Plus Exercise (EPP), and Knee Push-Up Plus Exercise (KPP) had done on stable surface (sling), followed by KPP, EPP, and WPP. In addition, these exercises can be good alternatives for SPP exercise^[5]. Jeong, S. Y. et al. found that PUP exercise with a sling (as unstable supporting surface) increased SA muscle activation more than that on stable supporting surface. Also, this showed a sling can bring more positive activation on the shoulder muscles^[7].

Based on the studies above, the study we conducted focused on serratus anterior muscle which stabilizes muscles on the shoulders, doing PUP exercise to help muscle movement. Although Ludewig, P. M. et al. said that SPP exercise showed the most muscle activation in her study, upon consideration of female participants in this experiment, the study we conducted chose KPP exercise which is a little bit easier to do and has the second highest muscle activation results in her study. KPP exercise was conducted on unstable supporting condition (sling) because muscle activity of SA muscle is higher when PUP exercise is conducted on unstable surface.

Cho, S. B. et al. and his researchers found shoulder external rotation made the highest level of SA muscle activity compared to other shoulder angles, internal rotation and neutral position^[3]. In the current study, when the PUP exercise was performed at 10, 20, and 30% wider than shoulder width and 10%, 20%, and 30% narrower than the shoulder width and shoulder width,

The SA muscle activity was the highest at the shoulder width^[11]. There was another experiment by Lee, S. Y. et al. to find which shoulder flexion angle can have higher level of SA muscle activity. 110° of the flexion showed the most activation rate on the muscle followed by 90° and 70°^[8]. The experiment we did accepted the factors from the previous studies which could make the highest activation of SA muscle, shoulder external rotation and hand position as the shoulders apart. Also 90° of shoulder flexion could be one of the factors for this experiment. Even though they showed the result that 110° had the most activation when PUP exercise was done, we chose 90° which showed the second better activation on SA muscle considering the truth that all participants in the study by Lee, S. Y. et al. were healthy male adults. To check the factor about different weight load, we had an experiment on knee flexion angles. There was a significant difference on knee flexion 60°.

The result showed that unstable surface stimulates ones' proprioception to encourage SA muscle activation. The sense of proprioception and the stability of joints can be improved through weight load^[13]. This can bring 20% more of maximum voluntary contraction of SA muscle through gradual load and PUP exercise stimulating the proprioception^[14].

The limitation of this study is that it is not possible to generalize research to people of all ages because they have been experimented with healthy men and women in their 20s. Also, during the exercise, there are some difficulties to keep balance on unstable supporting surface (sling) and to have hard exercise intensity along narrower knee flexions. Lastly the experiment has been done with a fewer study subjects.

Later studies will increase the number of subjects to obtain more reliable research results. We propose additional studies that can maintain a constant posture such as fixing the position of the head by placing the bar on the head during KPP. Moreover, due to the exercise in unstable supporting surfaces (slings) when establishing treatment plans, continuous study will be required by a variety of subjects to consider musculoskeletal patients with knee or shoulder problems or a nervous system patient with a problem with balance.

Conclusion

For the study, healthy female and male adults in 20s participated in the exercise with each knee flexion option like 60°, 75°, and 90° on the unstable surface. Then it

showed that the group with 60° had the biggest change, .89mm, on the thickness of SA muscle comparing before and after the exercise. The second group performed on 75° flexion was following with the average .64mm change. Lastly, Group 3 had got the smallest change .37mm on the thickness of the muscle. Between the groups of 60° and 90° of knee flexion, there was a significant difference in the averages they got. Thus, the experiment showed that PUP (Push-up Plus) exercise was the most effective with the 60° of knee flexion which put the most weight load on.

A Study on the Recognition of Child Abuse and Countermeasures

Shinhong Min

Professor, Baekseok University, Department of Nursing, Korea

Abstract

Background/Objectives: With the recent emergence of child abuse as a social issue, national responsibility, not a family problem, is being emphasized. Child abuse is taking place in a private space of family. Abuse by biological parents is occurring continuously.

Method/Statistical Analysis: This study conducted a survey of 300 children's mother with elementary school students living in area C. Recognition of child abuse by type and awareness of how to deal with child abuse were investigated.

Findings: As a result, awareness of the seriousness of the occurrence of child abuse was high. However, parents' experience of finding abused children appeared relatively low. This is a result of parents' inability to clearly distinguish child abuse and a lack of information about it.

Improvements/Applications: Therefore, it is necessary to establish clear criteria for child abuse and provide correct knowledge through regular parental education and promotion. In addition, practical measures such as legal sanctions are needed to deal with child abuse cases.

Keywords: *Attitude, Child abuse, Countermeasure, Mother of a school-age child, Recognition.*

Introduction

Child abuse is a criminal act that negatively affects the physical, emotional, and social development of children and causes many problems. Therefore, not only is prevention of child abuse important, but it also needs to be made efforts to find the abuse before it gets worse. The nation has long taken it for granted that parents have the right to discipline and discipline children in a patriarchal large family culture. Childhood should not be ignored or abused just because it is a child, nor should abuse be justified just because it is a parent^[1]. However, compared to advanced countries, social awareness of the problem of child abuse in households was relatively low. It wasn't until recently that child abuse emerged

as a serious problem that related laws and systems were reorganized^[2]. The definition of child abuse varies. Child abuse is a comprehensive term that includes all forms of child abuse and neglect, generally meaning deliberate acts of delegation and neglect^[3]. This extends to not only physical abuse but also emotional, sexual and neglect. In our country, 7 of Article 3 of the Child Welfare Act, "Child abuse refers to adults, including caregivers, committing physical, mental and sexual violence or abuse that could harm the child's health or well-being, or hinder normal development, and child caregivers abandoning or neglect the child," which includes passive neglect as well as active abuse.

Physical abuse refers to the deliberate or accidental physical injury to a child. Objectively obvious traumatic bodily injury means that a child is subjected to severe or severe beating, unprovoked beating, and repeated beatings^[4]. Emotional abuse does not directly inflict physical damage on children, but it refers to the damage to a child's sense of self-respect by parents ignoring or hating them and discriminating against or verbally abusing other siblings. Sexual abuse refers to forcing

Corresponding Author:

Shinhong Min

Professor, Baekseok University, Department of Nursing, Korea

e-mail: shmin@bu.ac.kr

an immature child to damage a sexual body part or requiring a child to come into contact with a sexual body part, which he or she has been forced to do^[5].

Obligation refers to any act that can hinder the normal development of a child by the caregiver's deliberate and repeated neglect of child care and protection to the type of neglect is distinguished by physical neglect, educational neglect, medical neglect, emotional neglect, and sexual neglect. Physical neglect includes not providing basic shelter, not protecting children from injury and danger, and leaving the child in a dirty environment or in dangerous condition. Educational neglect includes the act of allowing child absenteeism, not caring for school supplies, and neglecting special educational needs. Medical neglect includes not taking the necessary medical treatment for children and not vaccinating children who need vaccinations. Emotional neglect refers to the inability of parents or dependent children to be encouraged to develop growth because they are not interested in or very interested in children. It can be said that children do not talk, or show affection by stroking or touching. Emotional neglect arises from parents' lack of affection or neglect. Sexual neglect means the same state of letting a child be exposed to sexual assault or sexual exploitation^[2].

In recent years, various types and ranges of abuse have occurred in Korea, ranging from simple physical abuse to serious overlapping abuse, and the number of cases of abuse has also been on the rise. The number of cases of child abuse reported in Korea increased by more than 16 times from 2,105 in 2001 to 34,169 in 2017. According to the 2017 National Child Abuse Status Report, overlapping cases accounted for 10,875 cases (48.6%), followed by 4,728 cases of emotional abuse, 2,728 cases (21.1%), physical abuse, 3,285 cases (14.7%), neglect (22.5%) and sexual abuse 692 cases (3.1%). In particular, 76.8% of the perpetrators of child abuse cases that occurred in 2017 were biological parents, while 80.4% of the abuse locations were homes^[6].

The serious reason for this problem is that the victim is physically and mentally immature and abused by a trusted and dependent guardian of a young child who lacks self-defense capabilities^[7]. Child abuse not only causes physical damage, such as simple bruises and fractures, but also leads to death in severe cases, psychologically damaging the development of self-function, which seriously affects the development and adaptation of children. Nevertheless, many parents and

adults in society are not aware that they are abusing their children. There needs to be a change in the idea that corporal punishment is necessary to discipline children. Also, the idea that parenting is a parental right and cannot be interfered should be changed^[8]. To prevent the occurrence of child abuse, we need to educate the negative aspects of corporal punishment in child rearing, and to educate the effective method of parenting. Parents who raise and protect children do not regard child abuse as abuse, but as discipline or not abuse, so it is necessary to improve awareness of it. An expanded awareness of child abuse is needed to first recognize the importance of parents' role in protecting abused children.

Therefore, it is necessary to ensure that education and promotion of child abuse can be done first to parents who are most closely related to the child as well as to the reporting officer. This was done because studies on parents' awareness and attitudes toward child abuse were necessary. The results of the study will help raise awareness of child abuse and help prevent and treat child abuse quickly.

Method

This study is a study on the perception and attitudes of child abuse among primary school children to find out their parents' perception of child abuse as a social problem. This study was conducted on 300 mothers of students attending two elementary schools located in area C. This study required that questionnaires be distributed and responded online from 2 March to 10 March 2019. First, they agreed to participate in the study on their own and stated that their responses should be kept secret in addition to the study.

In order to explore recognition by type of child abuse (physical abuse, emotional abuse, sexual abuse, neglect) based on the Child Welfare Act, this study used a measure of child abuse assessment developed by Hong and Lee^[9]. The tool consists of 29 questions, classified into 8 questions of physical abuse, 5 questions of emotional abuse, 7 questions of sexual abuse, and 9 questions of neglect. To identify the perception by type of child abuse, the survey was answered with a five-point equilibrium scale of "Not at all" (1 point) "I don't think it's abuse" (2 point) "I don't know if it's abuse" (3 point) "I think it's abuse," (4 point) and (5 point).

'Awareness of Finding and Countermeasures for Abuse Children' used a tool developed by Baek^[10]. The contents were composed of seven total questions,

including how to cope with abuse, how to report child abuse, whether to recognize child abuse, whether to recognize child abuse, whether to operate a reporting phone, whether to recognize a reporting obligation, and whether to recognize a reporting officer in Article 26 of the Child Abuse Act.

Result and Discussion

1. General Characteristics: The general characteristics consisted of items of respondents’ age, educational level, religion, income level and occupational status <Table 1>. The comparable figures were 62.2% in their 40’s, 31.8% in their 30’s and 6% in their 20’s. Fifty-eight. 3% of college graduates, 35.2% below high school graduates, and 6.5% above graduate school graduates. Religion was 45.8% without religion, 33.2% with Christianity, 13% with Catholicism and 8% with Buddhism. The income level was 61.5% below 3 million won to 5 million won, 30.2% over 5 million won and 8.3% below 3 million won. The employment status was 74.5% without a job and 25.5% with a job.

Table 1: General characteristics

Categorization		N	%
Age	20’s	18	6.0
	30’s	95	31.8
	40’s and above	187	62.2
Academic background	Below high school graduation	106	35.2
	A college graduate	175	58.3
	Graduate degree or higher	19	6.5
Religion	Christianity	100	33.2
	Catholic	39	13.0
	Buddhism	24	8.0
	No religion	137	45.8
Monthly income	Less than 3 million won	25	8.3
	3 million won - 5 million won	184	61.5
	5 million won or more	91	30.2
Occupation status	Yes	77	25.5
	No	223	74.5

2. Recognition of abuse by type of child abuse: Awareness of child abuse is shown in Table 2. Child abuse was the highest with 4.48 points, physical abuse with 4.46 points, emotional abuse with 4.33 points, sexual abuse with 4.88 points and neglect with 4.29 points, while parental awareness of child abuse was generally high.

Table 2: Recognition of abuse by type of child abuse

Categorization		M	SD
Child abuse		4.48	0.333
Type	Physical abuse	4.46	0.389
	Emotional abuse	4.33	0.456
	Sexual abuse	4.88	0.321
	Neglect of duty	4.29	0.435

- 3. Differences in the perception of child abuse according to general characteristics:** A look at the differences in type perception of child abuse showed that there were no differences in age, religion, income level and job status, and there were differences in education level. Those who answered that they were college graduates and those who graduated from graduate schools were higher than those who had less than a high school diploma.
- 4. Differences in the perception of physical abuse according to general characteristics:** A look at the differences in perception of physical abuse by type showed that there were no differences between age, education level, religion, and income level and job status.
- 5. Differences in the perception of emotional abuse according to general characteristics:** A look at the differences in the type of perception of emotional abuse showed that there were no differences between age, education level, religion, and income level and job status.
- 6. Differences in the perception of sexual abuse according to general characteristics:** A study of the differences in perceptions of different types of sexual abuse showed that there were no differences in age, education, religion or job status, and that there were differences in income levels. Those who answered more than 5 million won were higher than those who said less than 3 million won.
- 7. Differences in the perception of neglect of duty according to general characteristics:** A study of the differences in perceptions of types of neglect showed that there were no differences in age, religion, income level and job status, and there were differences in education level. Those who answered “more than graduate school” and those who answered “college graduate” were better aware of neglect than those who said they should graduate from high school.

Looking at the differences in perceptions of different types of child abuse depending on whether or not child abuse is discovered, respondents with experience in finding children are more aware of physical abuse, emotional abuse, sexual abuse, and neglect and child abuse as a whole than those with no experience of discovery.

A study of the degree of awareness by type of child abuse based on the recognition of child abuse obligations showed that respondents who were aware of the reporting obligation were all more aware of physical and emotional abuse, sexual abuse, neglect and child abuse than those who were not aware of it, but no statistical difference was made

Discussion

To summarize the results, the parents' awareness of child abuse was high, and the perception by type was shown in the order of sexual abuse, physical abuse, emotional abuse and neglect. A look at the differences according to general characteristics showed that there were no differences among age groups. Depending on the level of educational background, the higher the level of educational background, the more accurate it is to recognize child abuse and neglect. Religion has shown no difference. The higher the income level of households, the more accurately they perceive sexual abuse. Lastly, there is no difference depending on whether or not they are employed.

Second, awareness of how to deal with child abuse accounted for a high percentage of respondents who had no experience finding abused children. Respondents who had found that they did not take action because they were not serious enough to intervene or because the evidence was not clear. According to the method of reporting, most of the respondents who did not know about the obligation to report the report by phone showed a high percentage of the respondents who knew about the obligation to report the report.

The perception by type of child abuse by third-parent child abuse detection experience showed that respondents with experience in finding children are more likely to recognize physical abuse, emotional abuse, sexual abuse, and neglect and child abuse as a whole than those with no experience of discovery. There were also no significant differences in the recognition of different types of child abuse depending on whether the reporting obligation was recognized.

From the above findings, the perception of the seriousness of child abuse cases was high, but parents' experience of finding abusive children was relatively low. I think this is a result of a lack of clear distinction between child abuse and proper information about child abuse. Therefore, more publicity and regular education will be needed by developing practical programs on preventive parenting so that child abuse can be established with clear measures and criteria to be connected to actual behavior. In addition, it will be required to realize the importance of awareness of child abuse, make it legally mandatory for lectures and programs on parental education, and implement information education related to child protection services to cope with child abuse.

Conclusion

In this study, the awareness of the seriousness of the occurrence of child abuse was high, but parents' experience of finding abusive children was relatively low. This is a lack of proper information about child abuse that makes it hard to distinguish between child abuses. Therefore, it is necessary to establish clear measures and criteria for child abuse to be applicable in real life. Practical programs on preventive parenting should be developed for this purpose. It will also require more publicity and regular education. It should also realize the importance of awareness of child abuse and make it legally mandatory for parent education lectures and programs related to it. Information education related to child protection services shall be mandatory to cope with the occurrence of child abuse. In particular, public relations should be carried out on a national level so that there is no difficulty in coping with the role and function of the Center for Prevention of Child Abuse and simple report reception calls.

Also, the idea that corporal punishment is necessary to discipline should be changed. And the idea that parenting is a parental right should be changed. Therefore, in order to prevent the occurrence of child abuse, research is needed on the effects of programs that explain the negative aspects of corporal punishment in child care and educate more effective child care method.

Influencing Factors on Mid-Life Well-Being

Hae-Kyung Chang

Professor, Department of Nursing, Hanseo University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to identify the factors which may influence a mid-life well-being.

Method/Statistical Analysis: This study is a descriptive survey design using a convenience sampling. The data were analyzed using descriptive statistics, t-test, ANOVA, Pearson's correlation coefficient and stepwise multiple regression using the SPSS 22.0 program.

Findings: As a result of conducting the stepwise regression analysis, the explanatory power of above 4 variables was appeared to be 52.3% including positive thinking ($\beta = .416, p < .001$), depression ($\beta = -.266, p < .001$), meaning of life ($\beta = .196, p < .001$) and perceived health status ($\beta = .110, p = .027$).

Improvements/Applications: This study will be used as basic data for developing nursing intervention programs that can improve well-being of middle age by establishing factors that affect well-being of middle age using variables of multilateral aspects.

Keywords: *Mid-life, Meaning of life, Depression, Positive thinking, Self-efficacy, Social support.*

Introduction

Mid-life is a kind of transition period from adulthood to old age and is an important and meaningful stage in the life cycle. In recent years, people have shown lots of interests in life satisfaction, happiness and well-being which promote happiness and growth of individuals emphasizing the positive aspects of human beings.

Well-being is used in combination with many similar concepts such as quality of life, happiness, life satisfaction, positive emotions and morale^[1]. General well-being is divided into subjective well-being (life satisfaction, happiness) focusing on the 'pleasant' result and psychological well-being (purpose and meaning of life) that emphasizes 'self-fulfilling' results^[2]. Among

them, the subjective well-being is closely related to depression^[3] which can be considered as a variable that negatively affects well-being as a factor to reduce the life quality throughout the middle age. Meaning of life is an indicator of psychological health related to happiness, and the effort to find meaning of life is the power to lead the life well by discovering meaning of life in the adversity or suffering experienced in the life^[4].

Positive thinking is a factor that allows people to accept and cope positively with their life despite the negative side in the life. Having positive thinking is not only a means of gaining happiness, but also is reported to have a significant effect on the mental health as a factor that can promote health, life quality and well-being^[5]. Social support is an important factor influencing well-being^[2]. The greater the social support, the less likely they are to experience stress and the potential to develop mental symptoms therefrom^[6]. The concept of self-efficacy has been diversely applied in the nursing or health-related fields and acts as a determinant to create behavioral change and motivation for solving problems occurring in the middle age, such that it can be assumed as a factor affecting well-being^[7].

There have been few studies on well-being in the aspect of nursing. In particular, no integrated approach to the factors affecting well-being of middle age has been carried out. Therefore, this study aims to find a nursing intervention plan that can improve well-being of middle age by establishing variables that affect well-being of middle age.^[1]

Method

1. **Subjects:** In this study, middle-aged men and women from 40 to 59 years old living in three areas Seoul, Gyeonggi-do, and Chungcheongnam-do, were selected as subjects. To verify the fitness of the sample size, the G*Power 3.0 program was used and a significance level of .05, effect size of .15, verification power of .95 and 12 predictive factors were applied to the regression analysis to acquire the final number of 184 subjects. A total of 219 copies were used in the final analysis.
2. **Instruments:**
 1. **Well-being:** The scale developed by Dupuy^[8] and revised by this researcher. This tool consists of 5 points scale from 1 to 5 points with 18 items. The higher score, the higher score of well-being. Cronbach 's $\alpha = .83$ in this study.
 2. **Meaning of Life:** The scale used in Won et al.^[4] was used to measure the meaning of life. The higher the score on the 7-point scale of 10 questions, the more subjective meaning of life they have. Cronbach 's $\alpha = .93$ in this study.
 3. **Depression:** Korean version of Center for Epidemiologic Studies Depression Scale-Revised, K-CESD-R which Lee et al.^[9] validated the feasibility and reliability was used in this study. The tool consists of five scales ranging from 0 to 4 points in 20 questions. The higher score, the higher score of depression. Cronbach 's $\alpha = .96$ in this study.
 4. **Positive thinking:** The positive accident scale developed by Kim et al.^[5] was used to measure positive thinking. This tool consists of 18 questions, ranging from 1 point of 'not at all' to 5 points of 'very much'. The higher score, the more score of positive thinking. Cronbach 's $\alpha = .94$ in this study.
 5. **Self-efficacy:** In this study, Korean Version of General Self-Efficacy scale (GSE) developed by Schwarzer & Jerusalem^[10] was used to measure the Self-Efficacy. This tool consists of 10 questions from 1 point of 'not at all' to 4 points of 'very much'. The higherscore, the higher score of self-efficacy. Cronbach 's $\alpha = .90$ in this study.
 6. **Social support:** In this study, Korean version of the MSPSS scale (Multiple Dimensional Scale of Perceived Social Support) developed by Zimet et al.^[11] was used to measure the social support. This tool consists of 5-points scale with total 12 questions. The higher score, the higher score of social support. Cronbach 's $\alpha = .95$ in this study.
3. **Data collection:** Data collection period was from 1st May 2019 to 30th June 2019. Data were collected by sampling the middle-aged men and women who visited religious and service organizations and sports centers. In addition, after explaining the purpose of the study, the researcher asked subjects who voluntarily participated in the study to fill out the written consent form and then answer the questionnaire.
4. **Ethical Consideration:** The researcher explained to subjects the purpose of the study, promised anonymity and confidentiality, and explained in advance that the subject would not have to respond if they were reluctant to reveal personal information. The researcher also explained that subjects can stop or withdraw the answering at any time if they do not want to participate in the study.
5. **Data Analysis:** Using the SPSS/WIN 22.0 program, the subjects' general characteristics and variables were analyzed for frequency, percentage, mean, and standard deviation. The difference in well-being according to general characteristics was analyzed using ANOVA and Scheffé test. In addition, multiple regression analysis was conducted to establish the factors affecting well-being of subjects.

Result and Discussion

1. **General characteristics of subjects:** The average age of subjects was 46.51 years old. Among them, 40 to 49 years old was the most common with 154 persons (70.3%), and number of female subjects, 113 persons (51.6%) was greater than that of male subjects. For the degree of education, 182 persons (83.1%) graduated college or higher, 181 persons

(82.6%) had spouse, 110 persons (50.2%) who had a religion, and 178 persons (81.3%) had a job. 157 persons (71.7%) considered their economic status as ‘middle’, 91 persons (41.6%) considered

their perceived health status as moderate while 101 persons (46.2%) thought their sleep status as good [Table 1].

Table 1. General Characteristics and Difference of Well-being according to Characteristics (N = 219)

Characteristics	Categories	n (%)	Well-being		
			M±SD	t/F (P)	Scheffé
Age (Years)	40-49	154(70.3)	3.03±0.45	-0.37(.707)	
	50-59	65(29.7)	3.06±0.47		
Sex	Male	106(48.4)	3.08±0.46	1.28(.878)	
	Female	113(51.6)	3.00±0.45		
Education	Below high school	37(16.9)	3.11±0.51	1.03(.286)	
	Above college	182(83.1)	3.03±0.44		
Spouse	Yes	181(82.6)	3.04±0.47	-0.35(.730)	
	No	38(17.4)	3.06±0.39		
Religion	Yes	110(50.2)	3.01±0.47	-1.01(.313)	
	No	109(49.8)	3.07±0.44		
Occupation	Yes	178(81.3)	3.04±0.43	0.26(.795)	
	No	41(18.7)	3.02±0.55		
Economic status	Low	55(25.1)	3.06±0.56	0.52(.597)	
	Middle	157(71.7)	3.04±0.45		
	High	7(3.2)	3.20±0.54		
Perceived health status	Bad ^a	57(26.0)	2.71±0.37	47.96(<.001)	a<b<c
	Moderate ^b	91(41.6)	2.99±0.34		
	Good ^c	71(32.4)	3.37±0.44		
Sleep status	Bad ^a	66(30.1)	2.77±0.39	22.64(<.001)	a<b<c
	Moderate ^b	52(23.7)	3.04±0.34		
	Good ^c	101(46.2)	3.22±0.46		

2. Descriptive Statistics of the Variables: The mean of subjects’ meaning of life was 4.57 (±0.97), 0.65 (±0.78) for depression, 3.24 (±0.62) for positive

thinking, 2.64 (±0.44) for self-efficacy, 3.44 (±0.76) for social support and 4.57 (±0.97) for well-being [Table 2].

Table 2. Descriptive Statistics of the Variables

Variables	M±SD	Min	Max
Meaning of life	4.57±0.97	1.80	7.00
Depression	0.65±0.78	0.00	3.85
Positive thinking	3.24±0.62	1.17	4.94
Self-efficacy	2.64±0.44	1.30	4.00
Social support	3.44±0.76	1.42	5.00
Well-being	3.04±0.46	1.78	4.33

3. Difference of well-being according to general characteristics: The difference of well-being according to general characteristics showed significant difference according to perceived health status ($F = 47.96, p < .001$) and sleep status ($F = 22.64, p < .001$). In other words, the better the perceived health and sleep status, the higher well-being [Table 1].

4. Correlations Coefficient among the Variables: Well-being of subjects had negative correlation with depression ($r = -.53, p < .001$), but had positive correlation with meaning of life ($r = .50, p < .001$), positive thinking ($r = .64, p < .001$), self-efficacy ($r = .48, p < .001$) and social support ($r = .48, p < .001$). In other words, the lower the depression score, the higher the meaning of life, positive thinking, self-efficacy, social support and well-being score [Table 3].

Table 3. Correlations Coefficient among the Variables

Variables	Meaningof life r(p)	Depression r(p)	Positive thinking r(p)	Self-efficacy r(p)	Social support r(p)
Well-being	.50(<.001)	-.53(<.001)	.64(<.001)	.48(<.001)	.48(<.001)

5. Factors affecting well-being of subjects: As a result of stepwise regression analysis, positive thinking ($\beta = .416, p < .001$), depression ($\beta = -.266, p < .001$), meaning of life ($\beta = .196, p < .001$), perceived

health status ($\beta = .110, p = .027$) were shown, and the explanatory power of these four variables was 52.3%. Among them, the most influential variable was positive thinking [Table 4].

Table 4. Factors Affecting Well-being of Subjects

Variables	B	SE	β	t	p
Intercept	2.122	.140		15.214	<.001
Positive thinking	.306	.042	.416	7.318	<.001
Depression	-.155	.030	-.266	-5.130	<.001
Meaning of life	.190	.053	.196	3.592	<.001
Perceived health status	.107	.048	.110	2.134	.027
F = 60.65, p<.001, Adj R ² = .523					

Discussion

In this study, well-being of subjects ranged from 1 to 5 with a mean score of 3.04. The subjective well-being is the overall happiness experienced by the individual and includes emotional states such as perceived assessment for overall life satisfaction, positive and negative emotions while it is reported that men experience more positive emotion and women experience more negative emotion^[12].

Well-being according to general characteristics showed significant difference according to the perceived health status and sleep status. Especially for middle age women, the quality of menopausal life differed according to their sleep status. This can be inferred from the fact

that the life quality is a health indicator^[13] affected by not only general well-being but also disease degree, such that the degree of well-being is different by these variables. In addition, early studies on well-being also reported that demographic variables had a low effect on the subjective well-being. However, the contradictory result that the younger people have higher well-being scores than the middle aged and showed differences according to culture, age and gender^[14] requires a further study in the future therefrom.

As a result of examining the correlation between well-being of middle age and variables, the lower the depression score, the higher the meaning of life, positive thinking, self-efficacy, social support and well-being

score. These findings support the result of previous studies that the higher the meaning of life, the higher the positive emotion^[4], the lower the depression^[3] and meaning of life is closely related to the life quality and well-being^[4]. Positive thinking is highly correlated with positive variables such as life satisfaction and well-being^[5]. It is reported that the higher the self-efficacy, the higher well-being^[15], so it is similar to the result of this study. In addition, it is consistent with the research result^[2] that the higher the degree to perceive the social support system or resources by the individual in the social relation, the higher well-being.

In order to identify the factors affecting well-being of middle age, as a result of hierarchical regression using the perceived health status and sleep status cognized to be different in well-being of middle age according to general characteristics as control variables, positive thinking, depression, meaning of life and perceived health status were shown to be significant variables. The explanatory power of these four variables was 52.3%. The most influential variable was positive thinking and is reported to be a variable^[5] that has a significant effect to the life satisfaction and well-being of individuals and supports the results of this study. The second factor affecting well-being of middle age was depression. Depression is an important variable that negatively affects the whole life after middle age. Depression was reported to make people not feel the life satisfaction and give negative effect^[6] to well-being by looking the life with a critical attitude.

Next, meaning of life is the decisive constituent of well-being, which supports the results of this study as a variable that directly affect the health and well-being^[1]. Therefore, the perception of meaning of life as a developmental task in the middle age is related to well-being of the middle age.

Lastly, the perceived health status means the physiological adaptation, and it is reported that as the perceived health status gets worse, the life quality decreases^[13], such that it is predictable that the health status perceived through the relation between the perceived health status, life quality and psychological well-being is an influence variable for well-being.

In addition, self-efficacy and social support were not identified as variables affecting well-being of middle age. However, as a result of identifying the relative influence of factors that explain the meaning of life, the biggest

influential variable was social support for middle aged men and self-efficacy for middle aged women^[8]. This is contradictory to the results of this study, considering that meaning of life is an important constituent of well-being^[1]. These results are difficult to compare directly with other studies due to different measuring tools used and variables that were entered as predicting variables in well-being of middle age, so repetitive studies are required in the future.

Therefore, it is necessary to prepare a way to strengthen the ability to adapt well to negative emotions such as depression by giving new meaning to life through cognitive change through positive thinking.

Conclusion

Through the above results, an active process to experience well-being and reorganize and understand the integral life of old age, for example, positive thinking through cognitive change, enhancing the ability to manage the individualized depression, giving a meaning of life at a new viewpoint, and promoting the physical and mental health status of individuals to prepare for old age. This study is meaningful in that it is an integrated approach that considers variables in various domains to provide nursing interventions to promote well-being of middle age. However, this study is limited to generalize the results by conveniently selecting middle age men and women living in some regions only.

Effectiveness of Virtual Reality Based Cognitive Rehabilitation on Cognitive Function, Motivation and Depression in Stroke Patients

Chang-Hyung Lee¹, Ye-Soon Kim², Jin-Hwa Jung³

¹Professor, Department of Rehabilitation Medicine, Pusan National University, ²Research Scientific Officer, Department of Healthcare and Public Health Research, National Rehabilitation Research Institute, National Rehabilitation Center, ³Professor, Department of Occupational Therapy, Semyung University, Republic of Korea

Abstract

Background/Objectives: The aim of this study was to investigate the effects of virtual reality cognitive training on cognitive function, rehabilitation motivation, and depression in patients with sub-acute stroke.

Method/Statistical Analysis: Total 22 patients with sub-acute stroke were included in our study. All stroke patients were classified either into experimental group (n = 11) or control group (n = 11). The experimental group performed virtual reality cognitive training on each session during 30 min/day, and control group conducted conventional cognitive therapy on each session during 30 min/day. The outcome measures were the LOTCA (Lowenstein Occupational Therapy Cognitive Assessment), VQ (Volitional questionnaire), BDI (Beck Depression Inventory) before and after intervention.

Findings: The both groups showed significant improvements in cognitive function before and after intervention ($p < .05$). The experimental group showed significant reduction in depression before and after the intervention ($p < .05$), but there was no significant change in the control group ($p > .05$). In comparisons for change score between the two groups, the experimental group showed a significant greater improvements in cognitive function and rehabilitation motivation than control group ($p < .05$).

Improvements/Applications: These findings suggest that virtual reality cognitive training may have a effects of the improvements of cognitive function and rehabilitation motivation than conventional cognitive therapy in sub-acute stroke.

Keywords: *Virtual Reality, Stroke, Cognitive function, Rehabilitation Motivation, Depression.*

Introduction

Stroke reduces the efficiency of synaptic connections in the brain's nervous system due to damage in the brain's blood vessels^[1]. Cognitive impairment was reported to be between 12-56%^[2], and the slower the recovery in cognitive function, the slower the patient's depression,

the lower the motivation, and the lower the quality of life not only for the patient but for the family^[3].

Cognition as meaning encompassing attention, memory, problem-solving skills, judgment, and high-dimensional thinking has been found to be a major factor in predicting an independent daily life ability, related to depression levels or recidivism in stroke^[4]. Thus, various rehabilitation approaches for physical and functional recovery of people with post-stroke cognitive decline are essential^[5-6].

The therapeutic approach of cognitive rehabilitation can be divided into traditional cognitive rehabilitation and computerized cognitive rehabilitation^[7]. Computerized

Semyung University, Republic of Korea
e-mail: otsalt@nate.com

cognitive rehabilitation is applied by strengthening memory, attention, etc. by performing games or tasks in the software using digital programs^[8-9].

The advantages of computerized cognitive rehabilitation over traditional cognitive rehabilitation are objectively measuring the amount of cognitive training or the degree of improvement of cognitive function, providing immediate feedback to patients, interesting and easy to adjust difficulty to patient level^[10].

Virtual reality is defined as a human-computer interface in which users interact with the environment in real time within a computer-generated virtual environment. The term was first mentioned by Jarson Lanier in 1989 and has since been developed globally^[11]. While most studies of the effects of virtual reality cognitive training have been reported on stroke patients with unilateral spatial neglect, it is not well known how it affects cognitive functions, rehabilitation motivation and depression^[12-18].

Therefore, this study wanted to know the effects of virtual reality cognitive training on cognitive function, rehabilitation motivation, and depression in patients with subacute stroke.

Method

This study was conducted on 22 patients with sub-acute stroke who were admitted to a rehabilitation hospital. The inclusion criteria were: (1) those diagnosed with stroke by a doctor, (2) those who had one month or more of a stroke, those who were less than six months old, and (3) Korean Mini-Mental Status Examination (K-MMSE) scores of 18 or 23 points, those who were able to perform according to their instructions, and (4) those whose medical conditions were stable. The criteria for exclusion were: (1) persons with severe unilateral spatial neglect, (2) persons unable to maintain independent seating, (3) persons with speech and hearing impairments, and (4) persons with illiteracy. All subjects voluntarily agreed to participate in the study after hearing a full explanation of the research involved. And after written consent, research was conducted.

Lowenstein Occupational Therapy Cognitive Assessment (LOTCA) was used to measure cognitive function. The inter-inspection reliability of this assessment was reported as 0.82 to 0.97^[20]. The Voluntary Questionnaire (VQ) was used to quantify the rehabilitation motivation of stroke patients.

The confidence between the examiners in the will questionnaires is between .75 and .90, the intrinsic value of the 14 items^[21]. Beck Depression Inventory (BDI) was used to quantify the level of depression^[22]. The classification of the level of depression based on the score is 0 to 9 without depression, 10 to 15 without depression, 16 to 23 with serious depression, and 24 to 63 with severe depression. Cronbach's alpha the examiners in BDI is .942^[23].

All subjects were assigned to experimental group (n = 11) or control group (n = 11). The two militaries received usual occupational therapy for 30 minutes a day, five times a week and four weeks. The experimental group received 30 minutes more per session of virtual reality cognitive training, while the control group received 30 minutes of conventional cognitive therapy. The control group received traditional cognitive therapy. Traditional cognitive therapy was determined based on previous studies, where activities through pencils and paper were conducted in the occupational therapy room^[24-26].

The experimental group mediated the virtual reality programs using software from the cognitive rehabilitation training system (Moto Cog, Cybermedic, Korea). The system is a program developed to improve the cognitive function of patients who need rehabilitation. The cognitive rehabilitation training system consists of basic training, a game course, a mission course, and a cognitive training program. To carry out a cognitive training program, the game course and a cognitive training program were introduced for intervention. The subjects of the experiment were trained, defining the composition of the intervention time for each half-hour session as 10 minutes for the game course and 20 minutes for the cognitive training program.

All the data collected were analyzed as SPSS 21. The statistical significance level of the study was set to .05. The general characteristics of the subject were identified by frequency analysis. The comparison of general characteristics, cognitive function, reproducibility, and depression in the two groups was analyzed with either the Mann Whitney U test or the Chi-Square test, and the change before and after intervention was confirmed by the Wilcoxon-signed rank Test.

Result and Discussion

1. General Characteristics: There was no significant difference in the general characteristics of the

subject between the two groups ($p > .05$) [Table 1]. There was no significant difference in the cognitive function, rehabilitation motivation, and in depression between the two group before intervention ($p > .05$) [Table 2].

- 2. Changes of cognitive function, rehabilitation motivation, and depression within groups before and after intervention:** The total score of LOTCA before and after intervention in the experimental group, except for motor praxis, showed significant improvement in the orientation, visual perception, spatial perception, visuo-motor organization, and thinking operation among the sub-items ($p < .05$), indicating significant positive changes in rehabilitation motivation and depression ($p < .05$). The total score of LOTCA before and after intervention in the control group, except for motor praxis, showed significant improvement in orientation, visual perception, spatial perception,

visuo-motor organization, and thinking operation among the sub-items ($p < .05$), indicating a significant improvement in the rehabilitation motivation ($p < .05$) [Table 3].

- 3. Comparison of cognitive function, rehabilitation motivation, and depression between two groups after intervention:** Comparing the changes before and after the intervention of the two groups, the experimental group had significantly greater improvements in the LOTCA than in the control group, the visual perception, spatial perception, visuo-motor organization and rehabilitation motivation ($p < .05$) [Table 4].
- 4. Relationship between rehabilitation motivation and depression in subjects:** Before intervention, the correlation between the rehabilitation motivation of 22 subjects and the depression was significant ($r = -.521$, $p < .05$) [Table 5].

Discussion

Results of table 2 were similar to those of Kim et al.^[19], who reported improvements in cognitive function in both groups, which conducted virtual reality training and occupational therapy (cognitive training) in acute stroke patients. Kim^[18] had significant improvement in cognitive function through intervention three times a week and twice a day for chronic stroke patients, but the control group that received conventional rehabilitation did not show significant improvement.

While the experimental group showed a significant decrease in depression before and after intervention, the control group showed a decrease in the BDI score. First of all, in comparing the variation between the two groups, rehabilitation motivation is concerned with the significantly greater improvement in the experimental group than in the control group. The pre-intervention values indicate a relationship between the motivation and the depression, so authors think virtual reality training has had a positive effect on reducing depression. In studies such as Kim et al.^[28], the reproducibility of stroke patients also shows a significant association between depression and quality of life, supporting the results of this study.

The experimental group showed significantly greater improvement in cognitive function than the control group. Subtitles showing greater change were visual perception, spatial perception, and visuo-motor organization. The improvement in this area of cognitive function is a virtual reality-based repetitive cognitive training that combines the effects of eye-hand coordination, attention, categorization ability, memory, recognition, calculation ability, visual perception, and language applied for 20 minutes at each session, and the effects of eye-hand coordination required to perform a specific task that has been performed for 10 minutes per session.

Brain damage causes the efficient fall into the neural circuitry between cerebral cortex, brain stem, and cranial nerve, resulting in a decrease in automatic

eye-hand coordination function, which is thought to indicate meaningful improvement in visual and spatial perception through virtual reality cognitive training^[27].

The limitations of this study are as follows. First, sample size was small. Second, the intervention period was relatively short at one month, and did not measure how long the effect of virtual reality cognitive training would last.

Conclusion

These results suggest that virtual reality cognitive training is more positive for the cognitive function and rehabilitation motivation of sub-acute stroke patients than conventional cognitive therapy. In future studies, limitations such as small sample size and missing follow-up are thought to be supplemented to require randomized controlled study.

Development of a Phantom for Low Dose Mammography

Chang- Gyu Kim

Professor, Gimcheon University, Department of Radiological Science, South Korea

Abstract

Background/Objectives: Interest in regular mammography has grown as a way for early detection of breast cancer. In this study, we produced a phantom that allows for an evaluation of the image quality of images acquired at different phases using X-rays.

Method/Statistical Analysis: To measure the radiation generated during breast cancer diagnosis using X-rays, the X-ray tube system by Varian was used to measure and analyze at a distance of 40 cm under the conditions of 22kVp, 20 mA, and 710mAs. To reduce errors in measurement, imaging of the breasts was done repeatedly for 10 times.

Findings: In the absorption image, there were 5.0 ± 0.2 fibers, 4.5 specks and 4.5 masses, making the total 14 which is higher than the 10 required to be officially authorized. In the dispersion and phase differential images, there were 5.5 ± 0.0 fibers, 4.5 specks, and 4.5 masses, making the total 14.5 which is higher than the 10 required to be officially authorized. In addition the image quality was better than that of the absorption image. When a dosimeter was used, the radiation exposure was an average of 2425.85 ± 0.33 mR. When the absorbed radiation was measured using a glass dosimeter, it was $1,334\pm 1.82$ μ Gy. This was different from the value converted using the valid radiation.

Improvements/Applications: In particular, phase differential imaging is expected to be applied to breast cancer tests where most of the tissue is soft, verification tests for foreign objects and forecasting of the progress in the disease.

Introduction

With the increase in fat intake, contemporary people have seen an increase in obesity, a fall in birth rates and nursing rates, a fall in the age of women's first period and an increase in the age at which menopause arrives, leading to more potential to be exposed to the risk factors of breast cancer. As such, there is a clear increase in demand for breast cancer tests^[1-2].

In the forecast of cancer incidence and cancer-

related deaths in 2018 by the WHO IARC, the cancer burden has been increasing. Breast cancer is forecast to be the most frequently occurring cancer for women, while for Asian men lung cancer is forecast to be ranked first. In other areas, prostate cancer is expected to be ranked first for men. Regardless of a nation's income level, breast cancer has a significantly higher incidence than any other cancer in women^[3-7].

In 2003, ICRP presented a Diagnostic Reference Level for radiation by measuring the radiation amount during mammography in the U.S. and U.K and has been recommending that governments have it applied. In Korea, too, efforts to reduce radiation exposure have increased, by evaluating the radiation that patients are exposed to during mammography and having a study jointly conducted by the KFDA and Korea Medical Image Quality Management Center^[7-12].

Interest in regular mammography has grown as a way for early detection of breast cancer. Mammography is offered at many medical institutions across the country. The Ministry of Health and Welfare, too, recommends that women over age 40 undergo a mammography.

Many report that an imaging device for the breasts that has a high contrast and resolution offers the benefits of early detection of breast cancer and increasing the survival rate by over 30% even when cancer is found^[13-14]. But ill-managed devices or certain types of imaging devices for the breasts may actually increase the risk of breast cancer.

Despite the growth in demand for check-ups for breast cancer around the world, there is no cost-effective test method for the dense breast tissue, raising the need for a new test method. In recent years, devices that have significantly increased the accuracy in diagnosis of dense breast tissue have appeared. Digital Breast Tomosynthesis, Automated Breast Ultrasound, X-ray phase contrast imaging technology and imaging devices that bring all these together have earned a lot of interest in the market.

Hologic has led the market for diagnosis devices for breast imaging launched in 2011 Selenia Dimension, which is the world's first three dimensional imaging device for the breasts approved by the FDA and KFDA. In recent years, low dose technology has seen progress to produce several tens of slices with radiation exposure on par with existing mammography. In particular, the two dimensional mammography required by FDA is not taken in addition, but the synthesis technology using Tomosynthesis is applied to reduce radiation exposure while realizing a high contrast level for the lesion. The technology is called C-View.

X-ray phase differential imaging technology uses information on dispersion and difference in phases to dramatically show the borders between similar types of substances with similar density^[7-12]. In addition, it has the benefit of using less radiation to produce better quality images compared to existing imaging technologies that leverage the difference in absorption rate of X-rays. Because of this trait, the technology is being researched for its application to low dose diagnostic devices for breast cancer^[13-15].

In this study, we produced a phantom that allows for an evaluation of the image quality of images acquired

at different phases using X-rays. The image quality and practical value of the technology were analyzed to optimize the valid radiation amount in a breast cancer test that has a high sensibility to radiation. The radiation amount and absorption amount for X-ray phase differential imaging was measured to verify the accuracy of the theoretical valid radiation and provide basic data for further research on X-ray phase differential phantoms.

Study Subjects and Methodology

1. **Evaluation of the practical value of the phantom manufactured in the lab:** For the radiation generating device, Hologic LORAD selonia System was used. To acquire images during breast cancer tests and evaluation of such images, the posture used for breast cancer tests at clinical hospitals conducting health check-ups was used. In the postures, R – CC, L – CC. R – MLO, L- MLO, the phantom produced by the researcher was exposed to a radiation of 28kVp 100mAs.
2. **Measuring and analyzing the radiation generated and absorbed during an X-ray test for breast cancer:** To measure the radiation generated during breast cancer diagnosis using X-rays, the X-ray tube system by Varian was used to measure and analyze at a distance of 40cm under the conditions of 22kVp, 20mA, and 710mAs.

The radiation generated was measured using Radcal 2026C device with a 360cc detector equipped. To reduce errors in measurement, imaging of the breasts was done repeatedly for 10 times.

For the measurement of radiation absorbed, the glass dosimeter ACE 100GD model of the Japanese company Chiyoda was used. For the calibration of the glass dosimeter, ¹³⁷Cs standard radiation from the Japanese Radiation Standard Center was applied, using a glass device receiving 6mGy.

Given the characteristics of the glass device, the annealing process before the radiation consisted of one hour of heating at 400°C, then cooling and measuring of the background value to measure 10-20μGy. After a panorama scan, pre-heating was done at 70°C for one hour. After a cooling period, the radiation value that the glass device was exposed to was read 10 times using the reader to calculate the mean and standard deviation. Using the calculated value, the background value was deducted to conclude the exposure of radiation ^[9, 13].

Conclusion and Discussion

1. Evaluation of the image quality when using an in-house produced phantom for breast cancer diagnosis tests: Diagnostic tests for breast cancer consist of self-diagnosis, clinical diagnosis, imaging tests, ultrasound tests and biopsy. Early detection of breast cancer not only improves the full recovery rate and survival rate, but also helps preserves the breasts and improves the quality of life. Imaging tests of the breasts are essential to the diagnosis of breast cancer and plays an important role in detecting early lesions that cannot be picked up on by diagnosis by touch or by ultrasound tests, such as subtle calcification.

In this study, a phantom was manufactured in the lab to evaluate the image quality and the technology of the X-ray phase differential imaging, as well as verify the data provided by the image.

The phantom was manufactured using a material that is similar to the breast tissue, artificially creating an environment similar to a disease in the breasts. Under the clinical imaging conditions, the X-ray absorbed was as seen in Figure 1, 2. As seen in the figures, in both the phantom made of liquid substances and the phantom made of solid substances, resolution had relatively decreased.

Figure 1. Image acquired from the phantom made of liquid substances

Figure 2. Image acquired from the phantom made of solid substances

To evaluate the resolution of images, the phantom made of solid substances was used to review the absorption image, dispersion image and phase differential image, as seen in Figure 3.

A team consisting of a radiology doctor and five radiologists with more than 10 years of experience conducted qualitative evaluation of the images. In the absorption image, there were 5.0 ± 0.2 fibers, 4.5 specks and 4.5 masses in resolution. The total was 14, which is more than the cutoff rate of 10 for the image to meet the authorized standard. In the dispersed image and phase differential image, there were 5.5 ± 0.0 fibers, 4.5 specks, and 4.5 masses. The total was 14.5 which is more than the cutoff rate of 10 for the image to meet the authorized standard. It was also confirmed that the quality of the image was better than that of the absorption image [Table 1].

Based on these results, the absorption image, dispersion image and phase differential image were analyzed using a phantom made of solid powder. The results were as seen in Figure 4. As seen in the figure, the lead substance has a low valid atomic number, leading to the data decreasing in the absorption image compared to those of the dispersion image and phase differential image. In particular, it was confirmed that the data were superior in the phase differential image.

Figure 3. Absorption, dispersion and phase differential in phantoms made of solid substances

Table 1. Evaluation of absorption, dispersion and phase differential in breast cancer imaging tests

	Absorption Image	Dispersion Image	Phase Differential
Fiber	5.0 ± 0.2	5.5 ± 0.0	5.5 ± 0.0
Specks	4.5 ± 0.0	4.5 ± 0.0	4.5 ± 0.0
Mass	4.5 ± 0.2	4.5 ± 0.2	4.5 ± 0.2
Total	14.0 ± 0.2	14.5 ± 0.1	14.5 ± 0.1

Figure 4. Analysis of the data from the absorption, dispersion and phase differential images using the in-house phantom made of solid substances

2. Measurement and analysis of the radiation exposed and absorbed during an X-ray diagnostic test for breast cancer: The mammary tissue in the breasts is relatively sensitive to radiation. As such, it is reported that X-ray diagnostic tests can rather increase the chances of causing cancer rather than giving the benefit of early detecting of breast cancer. For this reason, the measurement of radiation in breast cancer tests and defenses against radiation are very important.

In this study, to measure the radiation during an X-ray diagnostic test for breast cancer, the X-ray tube

system by Varian was used to measure at a distance of 40cm under the condition of 22kVp, 20mA, 710mAs. The measurement of radiation amount generated was done using Radical 2026C. To reduce the margin of error in measurement, it was repeated 10 times.

The measurement of the radiation amount absorbed was done using the glass dosimeter ACE 100GD model of the Japanese company Chiyoda. se company Chiyoda was used. For the calibration of the glass dosimeter, ¹³⁷Cs standard radiation from the Japanese Radiation Standard Center was applied, using a glass device receiving 6mGy. The radiation applied to the glass device was

measured 10 times through the reader to calculate the mean and standard deviation.

Table 2. Evaluation of the radiation exposed and absorbed during a diagnostic test for breast cancer

Scan No.	Radiation Exposure [mR±SD]	Radiation Absorbed [μGy±SD]
1	2425.85±0.35	1,324±1.82
2	2425.35±0.33	1,330±1.82
3	2432.85±0.32	1,334±1.82
4	2426.15±0.35	1,335±1.62
5	2418.85±0.31	1,333±1.82
6	2420.35±0.33	1,344±0.82
7	2423.65±0.35	1,338±1.82
8	2425.85±0.43	1,324±1.01
9	2431.35±0.29	1,332±1.23
10	2428.05±0.35	1,336±2.30
Average	2425.85±0.33	1,334±1.82

[Table 2] shows the evaluation of radiation exposure during the phase differential imaging for breast cancer tests. When a radiation measuring device that is highly dependent on direction was used, the mean was 2425.85±0.33mR. From a conservative viewpoint assuming that the energy of the X and r-rays applied to the human body has an energy absorption coefficient ratio of approximately 1.11 when the energy of the X and r-rays are 0.1MeV or higher, the absorbed amount can be calculated as $0.974 \times X[R] =$ approximately $1.0 \times X[R]$ [rad]. When this is converted to an equivalent dose, 1 R becomes 10mSv. Therefore, it is converted into 24.25mSv. This result shows that when the breast tissue's weighted coefficient 0.2 is multiplied, the value becomes 4.85mSv, which is much higher than the average valid radiation of 0.3mSv in a breast cancer X-ray test.

When the radiation absorbed was measured using a glass dosimeter, it was 1,334±1.82 μGy. When this is converted to valid radiation, the radiation's weighted coefficient 1 and the breast tissue's weighted coefficient of 0.2 are multiplied to generate 0.2668 mSv. This is a lower value than the average valid radiation of 0.3 mSv during one breast cancer X-ray test.

The radiation exposure converted to valid radiation amount and the absorbed amount converted to valid radiation amount were different. This difference indicates that in low energy of below 0.1MeV with low radiation, it is difficult to convert the radiation exposure into valid radiation. As such, to evaluate the radiation

exposure in low energy, the absorption amount must be used as a base. Follow-up studies would be needed in this field.

From these findings, it was verified that during a diagnostic test for breast cancer, the X-ray dispersion image and phase differential image reduce radiation exposure and improve the image quality. In particular, phase differential imaging is expected to be applied to breast cancer tests where most of the tissue is soft, verification tests for foreign objects and forecasting of the progress in the disease.

Conclusion

In breast cancer tests where there is high sensibility to radiation, optimization of the valid radiation is needed to acquire optimal images. This study used an in-house manufactured phantom to analyze the quality of image resolutions and the practical value of the technology, as well as to compare the radiation exposure and radiation absorption during X-ray phase differential imaging to analyze theoretical valid radiation

In the absorption image, there were 5.0±0.2 fibers, 4.5 specks and 4.5 masses, making the total 14 which is higher than the 10 required to be officially authorized.

In the dispersion and phase differential images, there were 5.5±0.0 fibers, 4.5 specks, and 4.5 masses, making the total 14.5 which is higher than the 10 required to be officially authorized. In addition the image quality was better than that of the absorption image.

When a dosimeter was used, the radiation exposure was an average of 2425.85±0.33mR. When the absorbed radiation was measured using a glass dosimeter, it was 1,334±1.82 μGy. This was different from the value converted using the valid radiation.

To evaluate the low energy radiation exposure, the absorbed radiation must be used as a base. Follow-up studies would be needed on this topic.

Medication Supportive Behavior of Mothers with Children with ADHD: A Structural Equation Model

Myeong-hui Choe¹, Hyunju Park²

¹Professor, Department of Nursing, Uiduk University, ²Professor, College of Nursing, Kangwon National University, South Korea

Abstract

Background/Objectives: This study aimed to establish and validate a supportive behavior model for the medication of mothers with children with ADHD based on Theory of Planned Behavior (TPB) and empirical evidence.

Method/Statistical Analysis: Participants were 205 mothers with children in elementary school in grades 1 to 3 who had been diagnosed with ADHD and experienced medication treatment. A constructed Structural Equation Model (SEM) was analyzed using AMOS program.

Findings: The goodness-of-fit index of the final model was found to be appropriate. The model's explanatory power for mother's medication supportive behavior was 90.4%. The intention for medication supportive behavior ($\beta = .486, p < .001$), subjective norms ($\beta = .250, p < .001$), the perceived control for the medication supportive behavior ($\beta = .287, p < .001$) and psychological health of mothers ($\beta = -.074, p = .008$) had a direct effect on medication supportive behavior. Mothers' ADHD knowledge ($\beta = .060, p = .016$) was found to have an indirect effect on medication supportive behavior.

Improvements/Applications: The results of this study are expected to guide the development of interventions to improve the medication compliance rate of ADHD children in lower academic years in elementary school.

Keywords: ADHD, Medication, Mother, Supportive behavior, Children.

Introduction

Attention-deficit hyperactivity disorder (ADHD) is a condition that occurs mainly in early childhood before 7 years old^[1]. In most cases, ADHD in children is typically found after entrance into elementary school as children experience having problems with academic performance or classroom life, such as disruptive behavior during class or noncompliance of rules. In this case, if the symptoms are not treated, more behavior

problems may occur in their later academic years; in this regard, early treatment is critically important^[1].

The primary treatment for ADHD is medication for treating brain function problems^[1,2]. In Korea, however, the proportion of children with ADHD who showed consistent medication compliance was about 5% only^[3], which is very low. The lack of adequate treatment of ADHD at the time it is needed negatively impacts children's academic achievements and peer relationships, leading to misconduct and crime in adolescence and adulthood. Thus, starting medication for ADHD from early elementary years is important^[1].

Meanwhile, the role of mothers is crucial to ensure smoothness of ADHD medication treatment of elementary schoolchildren. Treatment decisions for children with ADHD are largely made by parents, especially children in lower grades who tend to take

Corresponding Author:

Hyunju Park

Professor, College of Nursing, Kangwon National University, South Korea

e-mail: hpark@kangwon.ac.kr

medication given by their mother rather than take care of medication themselves^[4,5]. Therefore, to improve the medication compliance rate of children with ADHD, understanding mothers' medication supportive behavior is the first priority.

In previous studies, several factors related to mothers' medication supportive behavior for ADHD children have been reported in parts. In fact, there is no study on a mothers' medication supportive behavior model for the comprehensive understanding of these relationships. Therefore, in this study, we developed a hypothetical model comprising TPB-based variables (attitudes, subjective norms, perceived control, intention)^[2,3,5-9], which are known to be effective in the explanation of health-related behavior, and variables that have been reported as factors affecting mothers' medication supportive behavior for children with ADHD (social stigma perception, knowledge of ADHD, degree of symptoms, and the psychological health of mothers)^[2,3,5-11]. This study investigated the validity of the model.

Method

The present study employed cross-sectional design. Participants were the mothers of lower-grade children with ADHD in a Korean elementary school. They were recruited by convenience sampling according to the following inclusion criteria: a mother a) who has a child of age between 6–9 years diagnosed with ADHD and experienced ADHD medication treatment; b) who had been understood the purpose of the study, and agreed to participate in the study. A total of 205 questionnaires, which was a sufficient number of the sample size,^[12] were collected and analyzed. For the contents and method of this study, approval from K University's IRB was received.

The theoretical framework (Figure 1) was based on TPB and established by adding relationships between influential factors and concepts identified in the literature review.

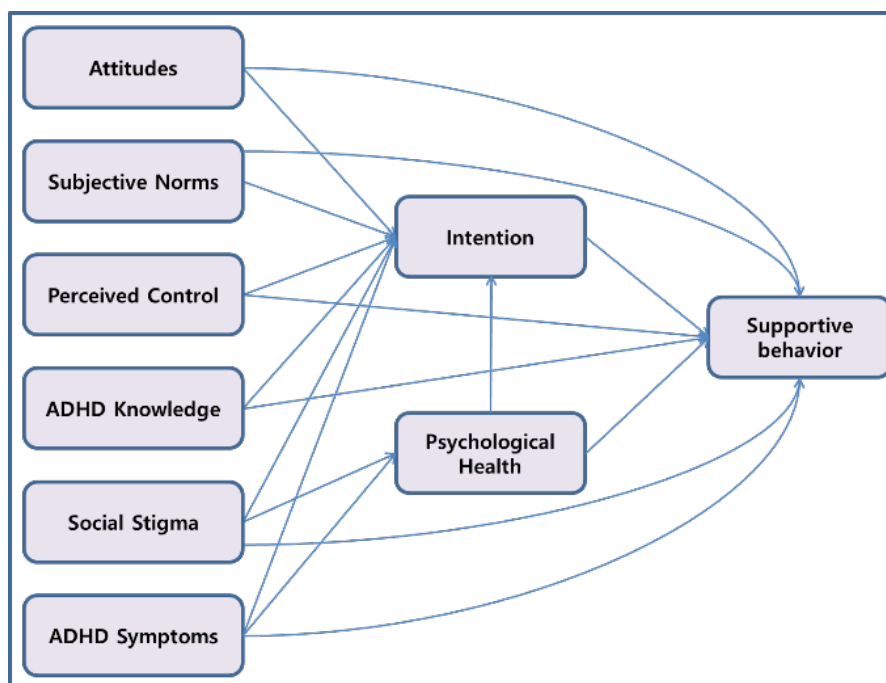

Figure 1. Theoretical framework

Ten observed variables for the hypothetical model were measured as follows. Attitudes referred to a mother's overall like or dislike of ADHD medication supportive behavior for their children^[13]. Measurement was carried out using Attitude Direct Questions from

the ADHD Medication Belief Report (AMBR)^[2], which consisted of five question measured on 7-point Likert scale. Higher scores mean positive attitudes. Cronbach's α was 0.93 in this study.

Subjective norms were measured by Subjective Norm Questions in the AMBR^[2]. Subjective norms referred to the extent to which significant others recognize a mother’s supportive behavior and to which a mother is willing to conform to expectations of significant others^[13]. This tool consisted of 11 questions measured on a 7-point Likert scale. The higher the score, the more positive the perception of subjective norms. Cronbach’s α was 0.95 in this study.

Perceived control referred to the perception that mothers perceive supportive behavior as easy or difficult^[13] and was measured by self-efficacy for the supportive behavior^[14]. The tool consisted of eight questions measured on a 5-point Likert scale. The higher the score, the higher a mother’s perceived control of a child’s ADHD medication supportive behavior. Cronbach’s α was 0.95 in this study.

Mothers’ knowledge of ADHD was measured by the questions associated with ADHD^[15], which consisted of 19 questions. Knowledge score was the sum of the number of questions answered correctly. Cronbach’s α was 0.62 in this study.

Social stigma is the degree to which mothers perceive social stigma for ADHD. It was measured on the social stigma scale^[16], which consisted of five items measured on a 4-point Likert scale. The higher the score, the more social stigma is perceived. Cronbach’s α 0.98 in this study.

ADHD symptoms referred to the degree of mothers’ perception of their child’s symptoms, measured using the ADHD Rating Scale(ARS)^[17], which consisted of 18 questions measured on a 4-point Likert scale; it had two subscales: attention deficit and hyperactivity symptoms^[17]. Higher scores indicate that symptoms are more severe. In this study, Cronbach’s α was 0.87 and 0.88 for each subscale.

Intention referred to the subjective possibility of mothers to perform supportive behavior^[13], which was measured by Intention Questions in the AMBR^[2]. The tool consisted of five questions measured on a 7-point Likert scale. Higher scores indicate strong intentions. Cronbach’s α was 0.99 in this study.

Psychological health referred to the depression of mothers, measured using the Beck Depression Inventory (BDI)^[18], which had 21 items measured on a 4-point Likert scale. Higher scores indicate severe depression. Cronbach’s α was 0.83 in this study.

Supportive behavior referred to a mother’s supportive behavior of the medication of a child. We measured the degree of supportive behavior of mothers for outpatient visits, drug doses, and time-to-dose compliance for their children^[3]. This tool was a three-item 10-point scale. The higher the score, the more likely a mother is well supporting her child. Cronbach’s α was 0.99 in this study.

From the collected data, participants’ general characteristics were analyzed by descriptive statistics using SPSS 22.0. For verification of the model, AMOS 22.0 were used. The normality of the observed variables was evaluated. Then, a confirmatory factor analysis (CFA) was conducted. Finally, the fitness of the hypothesis model was evaluated by goodness-of-fit indices, and the statistical significance of the direct, indirect, and total effects of the model was tested using Bootstrapping.

Result

1. Demographic Characteristics: Demographic characteristics of the subjects are shown in Table 1.

Table 1. General characteristics

Characteristics	Categories	N(%) or M±SD
Mothers		
Age		40.51±4.48
Marital status	Married	167(81.5)
	Divorced	38(18.5)
Economic status	Upper-middle	26(12.7)
	Middle	96(46.8)
	Lower-middle	61(29.8)
	Low	22(10.7)
Children		
Age		7.79±0.87
Gender	Boys	175(85.4)
	Girls	30(14.6)
Academic achievement	High	3(1.5)
	Upper-middle	14(6.8)
	Middle	51(24.9)
	Lower-middle	44(21.5)
	Low	93(45.4)
Age at ADHD diagnosis		6.17±0.75
Duration of ADHD treatment (month)		18.9±11.26
Current medication	Yes	180(87.8)
	No	25(12.2)
Experience of drug side effects	Yes	106(51.7)
	No	99(48.3)

M: Mean, SD: Standard deviation

2. Descriptive statistics and normality test of observed variables: All observed variables satisfied the condition of normal distribution^[12] (Table 2). VIF of each variable was distributed in the range of 1.77-5.91 and condition index was 49.785. The correlation coefficients between exogenous variables were in the range of 0.04–0.77, indicating no problems with multicollinearity^[12].

The results of the CFA showed that all goodness-of-fit indices were within the recommended range: $\chi^2(p) =$

.279, $\chi^2/df = 1.235$, RMSEA = .034, RMR = .013, GFI = .992, AGFI = .935, NFI = .995, RFI = .970, CFI = .999, and TLI = .994. Convergence validity was found with factor loading of observed variables between 0.50 and 0.99; average variance extracted (AVE) value was in the range of 0.71–0.98; and construct reliability was in the range of 0.91–0.99. The largest value of the correlation coefficients was 0.77 and the square of 0.77 was 0.59 (ϕ^2); as AVE value was larger than 0.59, the discriminant validity was also verified^[12].

Table 2. Descriptive statistics of observed variables

Variables	M±SD	Range	Skewness	Kurtosis	VIF	AVE	
Attitude	5.18±1.01	1~7	0.10	-0.84	3.34	0.71	
Subjective norms	4.83±1.33	1~7	-0.34	-0.43	5.53	0.87	
Perceived control	3.90±0.87	1~5	-0.54	-0.52	4.55	0.96	
Knowledge toward ADHD	0.66±0.15	0~1	-0.07	-1.06	2.17	-	
Social stigma	2.48±0.65	1~4	-0.08	0.30	2.81	0.97	
ADHD symp-toms	Attention deficit	1.44±0.52	0~3	0.32	0.02	2.34	0.94
	Hyperactivity	1.22±0.52	0~3	0.34	0.28	2.73	-
Intention	5.40±1.72	1~7	-1.05	0.35	5.91	0.98	
Psychological health	0.38±0.33	0~3	0.51	-0.51	1.77	0.94	
Behavior	7.10±2.87	1~10	-0.96	-0.12	1.77~5.91	0.98	

M: Mean, SD: Standard deviation, VIF: Variance inflation factor, AVE: Average variance extracted

3. Structural equation modeling: The goodness-of-fit indices of the hypothesis model are as follows: $\chi^2 = 34.716$, $df = 11$, $\chi^2(p) < .001$, $\chi^2/df = 3.156$, RMSEA = .103, RMR = .017, GFI = .968, AGFI = .839, NFI = .981, RFI = .924, CFI = .987, and TLI = .947. Of these, $\chi^2(p)$, χ^2/df , RMSEA and AGFI did not meet the criteria, so the model was modified^[12]. We added two paths to the hypothesis model. The goodness-of-fit indices of the modified model were all within the recommended range except for $\chi^2(p)$, so this model was confirmed as the final model^[12]: $\chi^2 = 18.358$, $df = 9$, $\chi^2(p) = .031$, $\chi^2/df = 2.040$, RMSEA = .071, RMR = .023, GFI = .982, AGFI = .892, NFI = .990, RFI = .951, CFI = .995, and TLI = .974.

4. Analysis of the effects of the final model: There are 10 significant paths of the final model (Figure 2). Variables with direct effects on supportive behavior were subjective norms ($\beta = .250$, $p < .001$), perceived control ($\beta = .287$, $p < .001$), intention ($\beta =$

.486, $p < .001$), and psychological health ($\beta = -.074$, $p = .008$). Direct ($\beta = .250$, $p = .002$), indirect ($\beta = .201$, $p = .018$), and total ($\beta = .451$, $p = .006$) effects were all significant in the path from subjective norms to supportive behavior. Direct ($\beta = .287$, $p = .006$), indirect ($\beta = .233$, $p = .023$), and total ($\beta = .520$, $p = .021$) effects were all significant in the path from perceived control to supportive behavior. Only indirect effects ($\beta = .060$, $p = .016$) were significant in the path from knowledge of ADHD to supportive behavior. Direct ($\beta = -.074$, $p = .008$) and total ($\beta = -.071$, $p = .011$) effects were significant in the path from psychological health to supportive behavior. Subjective norms, perceived control, knowledge of ADHD, intention, and psychological health explained 90.4% of supportive behavior.

The variables with significant direct effects on intention were subjective norms ($\beta = .413$, $p < .001$), perceived control ($\beta = .479$, $p < .001$), and knowledge of ADHD ($\beta = .100$, $p = .016$). These variables explained

83.0% of intention. The variables that directly affect psychological health were attitudes ($\beta = -.161, p = .049$), knowledge of ADHD ($\beta = -.163, p = .031$), and social

stigma ($\beta = .396, p < .001$), which explained 40.3% of psychological health.

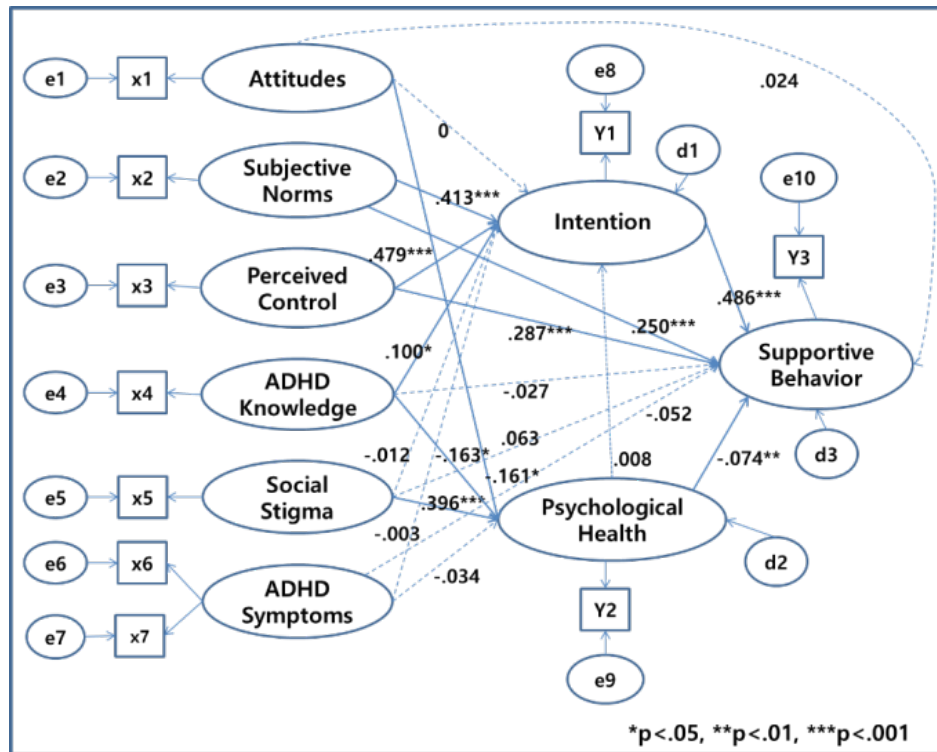

Figure 2. Path diagram for the final model

Discussion

In this study, the most influential variable on a mother’s supportive behavior was the intention for supportive behavior, and such intention was directly affected by subjective norms, perceived control, and knowledge of ADHD. These results are consistent with previous studies, which reported that the higher a mother’s supportive behavior intention for the medication of their child with ADHD, the better her child’s medication compliance and that the subjective norms perception affected the intention^[7]. It is also consistent with a previous study^[20] stating that subjective norms and perceived control had a significant effect on the intention of seeking help in women with incontinence. The results of knowledge of ADHD as a predictor of intention can also be found in a previous study^[10].

These findings indicate that interventions that increase the intention are effective in improving mothers’ supportive behavior in the medication of their children with ADHD. To enhance the intention, it is necessary to

provide mothers with nursing interventions that increase their subjective norms perception and perceived control of ADHD medication supportive behavior for children. In addition, supportive behavior increases along with mothers’ knowledge of their children’s condition and medication. Therefore, a program that helps mothers’ accurate understanding of their child’s condition and medication, such as active counseling by medical staff, are necessary.

Meanwhile, a mother’s psychological health negatively affected the direct path for supportive behavior and was influenced by attitudes and social stigma. These results imply that a child’s medication supportive behavior is less active when a mother’s depression is more severe. This finding is consistent with previous studies that reported negative correlations between a mother’s psychological health and supportive behavior [3,5,6,9]. It also supports a study that reported a positive correlation between a mother’s social stigma perception and her depression being related to her child with

ADHD^[9]. Therefore, these findings suggest that social biases and stigma of children with ADHD negatively affect a mother's psychological health and interfere with her supportive behavior to help her child's medication. Increasing medication compliance in children with ADHD requires a change in social perception of them. Therefore, more attention should be paid to the extent of depression of a mother taking care of children with ADHD.

The limitation of this study is that the generalization of study results is limited because participants were recruited by convenience sampling in limited areas. It is necessary to conduct a study with more representative samples later. Nevertheless, this study is the first to build and validate a model of medication supportive behavior of Korean mothers with children with ADHD. Its significance lies in its establishment of a theoretical framework for future intervention development.

Conclusion

In this study, intention for the medication supportive behavior, perceived control, subjective norms perception, psychological health, and knowledge of ADHD affected mothers' supportive behavior. Attitudes and social stigma perception directly affected psychological health of mothers. These results indicate that enhancing intention of a mother's supportive behavior, perceived control, and subjective norms perception; improving psychological health; and increasing knowledge of ADHD may improve mothers' medication supportive behavior.

Comparison of the Effects of Standardized Patient-based Simulation Education and Clinical Practice Education for Preoperative Nursing Care for High-risk Pregnant Women

Juhee Hwang¹, Hyunju Park²

¹Professor, Department of Nursing, Kyungdong University, South Korea

²Professor, College of Nursing, Kangwon National University, South Korea

Abstract

Background/Objectives: This study aimed to compare the effects of conventional clinical practice education and standardized patient-based simulation education on preoperative nursing care for high-risk pregnant women scheduled for a cesarean section, and, ultimately, to identify effective education method for nursing students.

Method/Statistical Analysis: This study used a non-equivalent control group, non-synchronized post-test design. The experimental group (34 subjects) received standardized patient-based simulation education, whereas the comparison group (32 subjects) participated in traditional clinical practice education. Descriptive statistics and ANCOVA was done to find the differences in the effects of the intervention between the two groups.

Findings: The results showed that clinical judgment ($F = 33.63, p < .001$), nursing performance competency ($F = 46.78, p < .001$), communication ability ($F = 13.90, p < .001$), and learning satisfaction ($F = 31.83, p < .001$), except for problem-solving ability, were significantly higher in the experimental group.

Improvements/Applications: Standardized patient-based simulation education can be effectively replaced with conventional clinical practice education when educating nursing students about preoperative nursing care for high-risk pregnant women.

Keywords: *Standardized patient program, Clinical practicum, Simulation education, Nursing students, Preoperative nursing care*

Introduction

As the primary goal of nursing education is to train, through theoretical and practical education, professional nurses who can provide qualitative nursing^[1]. However, with the recently increasing awareness of human rights among patients, there is a growing tendency for patients

to express that they do not want to be attended to by inexperienced and unskilled student nurses. Therefore, the conventional clinical practice education that provides nursing students with opportunities to perform direct nursing care in clinical settings is being reduced^[2]. In other words, there are limitations for nursing students to have sufficient nursing competence through clinical practice education, and it is thus necessary to seek alternatives to effective practice education for nursing students.

Recently, simulation education using standardized patients (SPs) has emerged as an effective practice education method. SPs are individuals trained to imitate realistic patients with respect to health condition,

Corresponding Author:

Hyunju Park

Professor, College of Nursing, Kangwon National University, South Korea

e-mail: hpark@kangwon.ac.kr

personality, and emotional reactions^[3]. Using scenarios that mimic clinical settings, SP-based simulation education aims to ensure that learning takes place in the process of allowing students to solve problems in situations similar to real-world situations^[4]. Therefore, SP-based simulation education has the advantage of allowing students to learn more realistic and empirical knowledge compared with other education method^[5].

In South Korea, there is growing awareness of the rights to privacy protection, especially among pregnant women who experience childbirth. In addition, owing to an extremely low birth rate, nursing students are having fewer learning opportunities to perform directly nursing care for pregnant women^[6]. Therefore, it is necessary to seek alternatives to practice education for nursing care for pregnant women.

No previous study has investigated the effects of SP-based education on preoperative nursing care for high-

risk pregnant women. In addition, studies comparing the effects of conventional clinical practice and SP-based education, even for other subjects of education, are scarce^[7]. Thus, the present study aimed to compare between the effects of SP-based simulation education and conventional clinical practice education, and to investigate whether clinical practice education can be replaced by SP-based simulation education.

Method

This was a study using a non-equivalent control group, non-synchronized post-test design [Figure 1]. The individuals of the study were the third-year students at a nursing college in C City, South Korea. The selection criteria were as follows: a) students who had already taken a women’s nursing theory course, and b) those who understood the purpose of this study and consented to join in this study.

Figure 1. Research Design

The number of sample was computed using G*Power (3.1.9.2). The number of sample required 30 individuals in each group with effect size of .65^[8], α of .05, and a power of .80. This study recruited 35 participants for

each group; 1 in the experimental group and 3 in the comparison group dropped out. Accordingly, a total of 66 individuals were used in the analysis. Approval from the IRB at K University was obtained.

Study procedure was as follows. Prior to the intervention, the SPs were trained and scenarios were developed. The SPs were trained to portray patients for six hours. The scenarios to be used for the intervention were reconstructed based on two medical records by the chief nurse at the ob-gyn ward and the researchers: one educational scenario for the intervention and one for evaluation. The scenarios were constructed of a topic related to preoperative nursing for high-risk pregnant women who were scheduled for a cesarean section owing to preterm premature rupture of membranes.

Subsequently, the baseline test was conducted to verify the homogeneity between the two groups [Figure 1]. Then, the comparison group received the intervention first. The comparison group was divided into five teams. On the first day, they received case study education about nursing care for pregnant women who were scheduled for a cesarean section, followed by conventional clinical practice for one week, through which the participants were allowed to experience preoperative nursing care for high-risk pregnant women who will undergo a caesarean section.

After a post-test was conducted with the comparison group, the experimental group received the intervention. They received two training sessions for one week. At the first session, the group was divided into six teams to receive the same case study education as done for the comparison group. Then, several students in each team practiced team nursing for one SP using an educational scenario. After completing the team-level practice, debriefing was carried out to analyze the nursing care performed by the students themselves. At the second education session, each student directly performed face-to-face nursing care for the SP for 10 minutes, and then debriefing was followed.

After completing the intervention, the post-test was conducted in both groups. During the post-test, the effects of the intervention were measured in the two groups using a scenario on preoperative nursing care for high-risk pregnant women, and SPs. The scenario used here was different from the one used for the students during the intervention.

In the post-test, clinical judgment and nursing performance competency were assessed by a third party who did not join in the education of students during the intervention to ensure that each student could not be identified as from either study group. Communication

ability was also assessed by SPs who did not participate during the intervention. These steps were intended to increase the validity of the measurement. Problem solving ability and learning satisfaction were self-evaluated by the students.

In the baseline test, general characteristics, trait anxiety, and self-efficacy were investigated. The general characteristics of the participants included gender, age, experience of simulation education, and academic grade. Trait anxiety was measured using a tool developed by Spielberger^[9]. The tool consists of 20 items rated on a 4-point Likert scale. A higher score means higher trait anxiety. Cronbach's α was .87 in this study. Self-efficacy was measured using a tool that was modified for the self-efficacy in preoperative nursing care for high-risk pregnant women from the Neuroscience Nursing Self-efficacy scale^[10]. This tool consists of 14 items rated on a 5-point Likert scale. A higher score means higher self-efficacy in preoperative nursing care for high-risk pregnant women. Cronbach's α was .87 in this study.

A post-test was conducted to compare the effects of the intervention in the experimental and comparison groups. The post-test measures included clinical judgment, nursing performance competency, communication ability, learning satisfaction and problem solving ability. Clinical judgment was investigated using the Lasater Clinical Judgment Rubric^[11], which consists of 11 items rated on a 4-point Likert scale. A higher score means higher clinical judgment. Cronbach's α was .88 in this study.

Nursing performance competency was measured using a tool that was modified by the researchers based on a checklist for evaluating preoperative patient nursing care presented by the Korean Accreditation Board of Nursing Education. This tool consists of 29 items rated on a 3-point Likert scale. A higher score means higher nursing competence. This tool was verified for content validity by two nursing professors, a chief delivery room nurse, and an ob-gyn physician. Cronbach's α was .87 in this study. Communication skills were measured with an instrument developed by Yoo^[12]. This tool consists of five items rated on a 5-point Likert scale. A higher score means higher communication competency. Cronbach's α was .85 in this study. Problem-solving ability was investigated with an instrument developed by Woo^[13] that consists of 25 items rated on a 5-point Likert scale. A higher score means higher problem-solving ability. Cronbach's α was .93 in this study. Learning satisfaction

was measured using a tool developed by Seong^[14]. This tool consisted of 20 items rated on a 5-point Likert scale. A higher score means higher learning satisfaction. Cronbach’s α was .94 in this study. Data analysis was done using SPSS (21.0). The homogeneity between the groups was examined using t-test and X²-test. As the results of the homogeneity test for the general characteristics of the two groups revealed that self-efficacy was not homogeneous, analysis of covariance (ANCOVA) was done to find a difference between the groups.

Result and Discussion

1. **Demographic Characteristics:** The characteristics of the individuals are presented in [Table 1]. The gender, age, experience of simulation education, academic grade, and trait anxiety were not significantly different between the groups. However, self-efficacy in preoperative nursing care for high-risk pregnant women was significantly higher in the comparison group ($p = .001$).

Table 1. General Characteristics of Individuals

Characteristics	Experimental (n = 34)	Comparison (n = 32)	χ^2 or t	p
	M(SD) or n(%)	M(SD) or n(%)

Discussion

The results showed that SP-based simulation education was more effective for training clinical judgment, nursing performance competency, and communication ability, and learning satisfaction compared with conventional clinical practice, except for problem-solving ability. A comparison of these results and the results of previous studies is as follows. First, owing to the scarcity of previous studies comparing the effects of SP-based simulation education and conventional practice education on clinical judgment, it is difficult to compare results directly. The results of a study of Chinese nursing students comparing the effects of conventional education (demonstrated by instructors) and SP-based simulation education showed that clinical judgment was significantly higher in students who received SP-based education^[15], which is similar to the results of our study. In addition, although self-efficacy of preoperative nursing care for high-risk pregnant women was found to be lower in the experimental group at baseline, clinical judgment was found to be improved more in the experimental group after the SP-based education, which implies that the effects of SP-based simulation education were greater.

Second, nursing performance competency, communication ability, and learning satisfaction were found to be significantly higher in the experimental group. This result is consistent with those of studies revealing that SP-based simulation education improved nursing students' nursing performance competency in ob-gyn pelvic examination education^[16], and end-of-life care education^[17], and of another study indicating that communication ability significantly improved after SP-based education on the topic of interactions with patients with depression^[18]. In addition, results of the present study are also consistent with those of a previous study indicating that learning satisfaction with SP-based simulation education on the topic of mental health was significantly higher^[19]. However, these previous studies were conducted without a control group, or were comparisons with a control group receiving no intervention. Therefore, as the present study compared between the effects of conventional clinical practice education and SP-based simulation education, our study is different from previous ones.

Third, no significant difference was seen in the problem-solving ability between the experimental and comparison groups. This result does not necessarily

mean that SP-based simulation education was not effective in increasing problem-solving ability but that both SP-based education and conventional clinical practice likely contributed similarly to problem solving ability. In addition, as self-efficacy was higher in the comparison group, the possibility that students with high self-confidence reported having high-problem solving ability could not be ruled out as well.

The limitations of the study are as follows. First, as the participants of this study were selected from a single nursing college, it is difficult to generalize the results of this study to other samples. Second, it was difficult to identify how much the students in the comparison group experienced in nursing care for high-risk pregnant women during their conventional clinical practice. Third, this study used a quasi-experimental design in which the individuals were not randomly assigned.

Nevertheless, the results of this study are significant as follows. First, although most previous studies used no control group, or used a control group without intervention, this study compared the effects of SP-based simulation education and conventional clinical practice using a comparison group receiving conventional clinical practice education. Second, previous studies often assessed the effects of education based on self-report measures. In the present study, clinical judgment, nursing performance competency, and communication ability were objectively assessed by third parties who were not aware of the participants' grouping. As such, this study has a high validity.

Conclusion

This study aimed to compare the effects of SP-based simulation education and conventional clinical practice education for nursing students on preoperative nursing care for high-risk pregnant women, and to seek effective practice education method for preoperative nursing care for high-risk pregnant women. The results showed that SP-based simulation education had higher effects on clinical judgment, nursing performance competency, communication ability, and learning satisfaction compared with the conventional clinical practice education. In addition, both education method showed similar effects on problem-solving ability. Therefore, conventional practice education can be effectively replaced by SP-based simulation education for preoperative nursing care in high-risk pregnant women.

Abstract

Background/Objectives: Many microorganisms reside in the oral cavity, and they are referred to as oral-resident bacteria. Oral microorganisms are an important cause of oral diseases, and as such, many studies have been conducted to control them. This study aimed to investigate the antimicrobial activity against *S. intermedius* and *S. gordonii* among the oral-resident bacteria using *Coptischinensis*, a natural extract.

Method/Statistical Analysis: To investigate the antimicrobial activity of *Coptischinensis*, the clear-zone confirmation method using filter paper and colony-forming unit (CFU) was used to check the bacterial proliferation. As the concentration of *Coptischinensis* increased, the size of the clear zone also increased. As a result of the CFU, bacterial proliferation was not observed in the experimental group as compared to the control group.

Findings: The results of this study proved the antimicrobial activity of *Coptischinensis* against the oral-resident bacteria *S. intermedius* and *S. gordonii*. The clear zone results showed that *S. intermedius* and *S. gordonii* were larger in size than the control group. CFU showed a large amount of colony in the control group but not exist colony in the experimental group. The result showed its potential as an antimicrobial agent applicable to oral-resident bacteria.

Improvements/Applications: *S. intermedius* and *S. gordonii* bacteria found in the oral cavity showed antimicrobial effect on the extracts. *Coptischinensis* was confirmed to be a preventative and therapeutic agent of tooth decay. In conclusion, the possibility that it can be applied to various intraoral antibacterial products in the future.

Keywords: Antibacterial activity, *Coptischinensis*, Dental caries, Dental pathogens, Microorganism.

Introduction

In the 21st century, with the Westernization of people's lifestyles, oral diseases have become

diverse and have emerged as a serious social problem. According to a recent WHO report on dental diseases, 60% of adults worldwide are suffering from dental caries and periodontal diseases^[1]. The most important factor causing oral diseases, as represented by dental caries and periodontal diseases, has been known to be dental plaque, composed of oral-resident bacteria that form a cluster on the tooth surface, or on and beneath the gingiva^[2]. It has been reported that more than 500 types of bacteria reside in the human oral cavity, and that 10⁸-10⁹ CFU/mg of bacteria are present in dental plaque^[3]. Dental caries is an oral and maxillofacial disease that

Corresponding Author:

e-mail: miss4228@naver.com

has plagued humanity since the ancient times, and its harmful effects have become a serious problem both economically and socially in both developing and developed countries^[4]. Dental caries occurs when the bacteria attached to the tooth surface form dental plaque, and then the bacteria of the dental plaque generate acids by fermenting the carbohydrates obtained from food^[5]. Among the many bacteria present in dental plaque, oral streptococci is considered a causative bacteria of dental caries^[6]. In particular, the *Streptococcus gordonii* (*S. gordonii*) in the oral cavity is known to play an important role in the adhesion of bacteria in the oral cavity by specifically binding to a specific glycoprotein of saliva^[7]. *Streptococcus intermedius* (*S. intermedius*) is an oral-resident bacterium clinically characterized by forming abscesses in the oral cavity^[8]. Moreover, it has been reported to form dental calculus like streptococci, and to cause endocarditis in vitro^[9].

Medicinal plant remedies have been attracting attention of late in South Korea for the prevention of oral infectious diseases and for the ongoing inhibition of oral pathogens. In particular, medicinal plants are expected to be able to overcome the problems of safety or tolerance, which the conventional natural therapeutic agents used from the olden times also had^[10]. Among the various medicinal plants, *Coptidisrhizoma* is a perennial vegetation belonging to *Coptis japonica* Makino (Japan), *Coptischinensis Franch* (China), or other wisteria (Ranunculaceae), and is a rootstock with almost no roots. *Coptidisrhizoma* is slightly odorous, with a very bitter taste, and has a persistently yellow color. It has strong antimicrobial activity against various pathogens as well as excellent anti-inflammation, antioxidant, hemostatic, blood pressure lowering, and anticancer effects^[11]. The studies on the antimicrobial activity of the natural extract of *Coptischinensis* against oral streptococci have been limited. Thus, this study was conducted to investigate the antimicrobial activity against dental caries of *Coptischinensis* extract, and to identify its potential for the prevention and treatment of oral diseases.

Method

Coptischinensis was purchased from Foodsynergy Co., Ltd. (Seoul, South Korea). After adding 80% ethanol to 100 g crushed *Coptischinensis*, extraction was done at 65°C for 12 hours. The extract was filtered using filter paper, and the *Coptischinensis* extract was concentrated using a rotary vacuum evaporator (N-1300E.V.S

EYELA Co., Japan). The concentrated *Coptischinensis* extract was again lyophilized using a freeze dryer (FD5508, Ilshin Lab, Yangju-kun, Kyunggi-do, South Korea). It was diluted in distilled water to form the 5, 10, 20, and 40 mg/mL concentrations, and as a control group, PBS (phosphate-buffered saline, Gibco™) was applied as a medium. *S. intermedius* (ATCC 9895) and *S. gordonii* (ATCC, 10558) were purchased from Korean Culture Center of Microorganisms (KCCM). Each microorganism was activated by brain heart infusion (BHI; Sigma-Aldrich, St. Louis, MO, USA) and was diluted at a 2x10⁶ ratio

100 µL (2x10⁶) of *S. intermedius* and *S. gordonii*, respectively, were applied on a solid medium; 100 µL of each experimental group was dropped onto a paper disc, and it was carefully placed on the solid medium inoculated with the bacteria. After keeping it at 37°C for 24 hours in each environment, the diameter of the clear zone was measured on a paper disc. The average value and standard deviation were obtained after three repeated experiments, to measure the diameter of the clear zone, where the growth was inhibited. Only the average value was recorded, however, because the degree of deviation was insignificant.

The media for each bacterium and bacteria (1X10⁵) were mixed at a ratio of 9 (medium):1 (bacteria). Mixed extracts were prepared at the 5, 10, 20, and 40 mg/mL concentrations, and 100 µL was inoculated into the solid medium. After keeping the extracts in a 37°C bacterial incubator for 24 hours, the number of CFUs present in the solid medium was checked.

Result

1. Clear zone results: As a result of the application of the *Coptischinensis* experimental group to *S. intermedius*, a slight bacterial concentration decrease of 1-2 mm around the filter paper was observed at the 5 mg concentration, but there was no definite zone. At the 10 mg concentration, a 10mm clear zone was observed, and at the 20 mg concentration, a 20 mm clear zone [Figure 1].

For the results of the application of the *Coptischinensis* experimental group to *S. gordonii*, a slight death of about 1 mm appeared around the 5 mg filter paper, and a 10mm clear zone was shown in the 10 mg group while a 15 mm clear zone was shown in the 20 mg group [Figure 2].

2. CFU Results: To examine the ability of the

Coptischinensis extract to inhibit bacterial proliferation, the group with only bacteria and the groups with 5, 10, and 20 mg of the extract with bacteria were incubated for 24 hours. As a result, it was confirmed that many bacteria survived in the control group with only bacteria, not mixed with the extract, and *S.intermedius* and *S.gordonii* were both killed in all the experimental groups (5, 10, and 20mg groups) overall [Figure 3].

As a result of the application of *Coptischinensis* extract to the opportunistic, infectious oral-resident bacteria, a definite clear zone appeared on the paper disc of *S. intermedius* when 10mg extract was applied, and became larger when 20mg extract was applied. Even in *S. gordoii*, a 10mm clear zone appeared in the 10mg extract, showing an antimicrobial activity almost similar to the one against *S. intermedius*, but a smaller clear zone was shown in the 20mg extract compared to the one in *S. intermedius*. In the comparison of CFUs, it was confirmed that bacteria were killed in all the 5, 10, and 20mg extracts [Figure 4].

Figure 1. Results of the clear zone of Coptischinensis extract against *S. intermedius*. (Saline: 0mm, base: 0 mm, 5mg: 1mm, 10mg: 10mm, 20mg: 20mm)

Figure 2. Results of the clear zone of Coptischinensis extract against *S.gordonii*. (Saline: 0mm, base: 0mm, 5mg: 1mm, 10mg: 10mm, 20mg: 15mm)

Discussion

Studies with the aim of finding new antimicrobial substances in natural resources like plants have been actively conducted of late. As such, this study was conducted to evaluate the antimicrobial activity against two kinds of oral-resident bacteria, using a substance isolated from *Coptischinensis* ethanol extract.

The environment in the oral cavity consists of various microorganisms linked together to form an ecosystem, in which biofilm is formed in various orders. The biofilm is usually present in the oral cavity, and if a trigger factor that causes opportunistic infection is involved, an oral disease may occur^[12-13]. In this study, *S. intermedius* and *S. gordonii*, which are normally residing in the oral cavity, were included in the experiment. *S. intermedius* in the root canal of the natural tooth is known to be present in the oral cavity, pharynx, and gastric juice, and is known to be capable of causing brain tumor and liver abscess through opportunistic infection^[14]. On the other hand, *S. gordonii* is not only associated with pulpitis but can also

cause systemic diseases like infective endocarditis and infectious arthritis^[15-17].

Looking at the previous studies on the antimicrobial activity of *Coptischinensis* extract against oral bacteria, Yoo et al. reported a 10-22 mg killing range on average as a result of the application of *Coptischinensis* to oral disease bacteria, including *S. sobrinus*, *A. viscosus*, and *S. mutans*^[18].

Cha et al. reported that *Coptischinensis* showed a strong antimicrobial activity against *Staphylococcus aureus* and *Candida albicans* in the study on the antimicrobial activity using various native cosmetic plants^[19]. In addition, various studies have shown the results of the excellent antimicrobial activity of *Coptischinensis*, which were similar to the results of this study^[18]. The excellent antimicrobial activity of *Coptischinensis* is attributed to a component called “berberin,” which is known to inhibit the metabolism of carbohydrates and the synthesis of the glycoproteins in the bacteria^[19]. Additionally, this component was found

to form a complex with the DNA of the bacterium, thereby affecting the DNA replication, inhibiting the growth and propagation of the bacterium, and exhibiting the antimicrobial activity^[20].

When evaluating the antimicrobial activity of *Coptischinensis* extract, the influence of the solvent used to make *Coptischinensis* extract should also be considered. In the case of *Coptischinensis*, it is known that its antimicrobial activity can be confirmed in all the extracts obtained from solvents like water, ethanol, and methanol, and its effect has been proven^[21]. Even native plants with excellent antimicrobial activity may have stronger antimicrobial activity in a wide range of bacteria, when mixed with other substances rather than when used alone. Thus, it is necessary to verify the antimicrobial activity in the future using this type of stable complex.

Conclusion

This study analyzed the antimicrobial activity of *Coptischinensis* ethanol extract as a natural plant by applying it to oral-resident bacteria. As a result of the analysis of the clear zone of *Coptischinensis* extract against two kinds of oral-resident bacteria, *S. intermedius* and *S. gordoi*, which may cause opportunistic infections, excellent antimicrobial activity was shown, and 20 and 15mm clear zones were observed at a high concentration of 20 mg, proving an excellent antibacterial activity. These results suggest that *Coptischinensis* extract can be used to efficiently control and manage oral-resident bacteria. Further studies using a combination of various extracts with similar antimicrobial activities and analyses of the component causing antimicrobial activity other than berberine of *Coptischinensis* need to be conducted.

Abstract

Background/Objectives: The purpose of this study is to identify the relations between the depression and the stress of the family with low income who are living with the patient with dementia and to utilize it as basic data to develop the health promotion program for the efficient management of the depression and stress in the family with low income.

Method/Statistical Analysis: The subjects of the study were the first analysis of 685,391 people over 45 years-old by requesting raw data from the Community Health Survey from 2015, 2016 and 2017. Trend analysis was conducted.

The statistical software R program was used for data analysis, and frequency analysis and chi-square analysis were conducted for the general characteristics, health behaviors, chronic diseases, depression, and stress according to the dementia patients and their living families. Performed linear to linear coupling were used for the yearly trend analysis. Logistic regression analysis was performed to analysis the factors related to depression as a dependent variable of family members living with dementia.

Findings: The yearly trend analysis showed an increase in hypertension with men over 75 years old, and housewives and smoking decreased ($p < 0.05$). Logistic regression analysis showed depression as a dependent variable, and the higher the educational background, the higher the level of education in agriculture, forestry, and fisheries compared to housewife or unemployed ($p < 0.05$).

Improvements/Applications: In conclusion, a systematic free counselling program for the management of chronic diseases, depression and stress for the elderly aged of 75 or older who are taking care of low-income and dementia patients is urgently needed.

Keywords: *Depress, Stress, Health behaviors, Dementia, Cohabitation family with dementia patients, Trend analysis.*

Introduction

In 2015, the dementia prevalence of the people having 65 years or older in our country is 9.8% and

the population of aged with dementia is estimated to be 648,000 and it is estimated to be increased to 2.71 million corresponded to 15% of entire population of aged in 2050^[1].

According to the announcement of Alzheimer's Disease International (2015), the worldwide dementia population is estimated as 46.8 million, it is expected to be increased to 135 million in 2050.^[2] The dementia prevalence of the people having 65 years or older in Korea is 9.8% and the dementia population is estimated
